**Table 9-160. OCP Address to LPDDR2/DDR3 Address Mapping for REG\_IBANK\_POS=0 and REG\_EBANK\_POS=1**

Logical Address			
Chip Select	Row Address	Bank Address	Column Address
# of bits defined by EBANK of SDRCR	# of bits defined by RSIZE of SDRCR	# of bits defined by IBANK of SDRCR	# of bits defined by PAGESIZE of SDRCR
EBANK=0 => 0 bits	RSIZE=0 => 9 bits	IBANK=0 => 0 bits	PAGESIZE=0 => 8 bits
EBANK=1 => 1 bit	RSIZE=1 => 10 bits	IBANK=1 => 1 bit	PAGESIZE=1 => 9 bits
	RSIZE=2 => 11 bits	IBANK=2 => 2 bits	PAGESIZE=2 => 10 bits
	RSIZE=3 => 12 bits	IBANK=3 => 3 bits	PAGESIZE=3 => 11 bits
	RSIZE=4 => 13 bits		
	RSIZE=5 => 14 bits		
	RSIZE=6 => 15 bits		
	RSIZE=7 => 16 bits		

### 9.3.3.3.6 Address Mapping when REG\_IBANK\_POS = 1 and REG\_EBANK\_POS = 1

For REG\_IBANK\_POS = 1 and REG\_EBANK\_POS = 1, the interleaving of banks within a device (per chip select) is limited to 4 banks. Also, the LPDDR2/DDR3 memory controller cannot interleave banks between the two chip selects. Thus, the LPDDR2/DDR3 memory controller can keep a maximum of 16 banks (8 internal banks across 2 chip selects) open at a time, but can only interleave among four of them.

**Table 9-161. OCP Address to LPDDR2/DDR3 Address Mapping for REG\_IBANK\_POS=1 and REG\_EBANK\_POS = 1**

Logical Address				
Chip Select	Bank Address[2]	Row Address	Bank Address[1:0]	Column Address
# of bits defined by EBANK of SDRCR	# of bits defined by IBANK of SDRCR	# of bits defined by RSIZE of SDRCR	# of bits defined by IBANK of SDRCR	# of bits defined by PAGESIZE of SDRCR
EBANK=0 => 0 bits	IBANK=0 => 0 bits	RSIZE=0 => 9 bits	IBANK=0 => 0 bits	PAGESIZE=0 => 8 bits
EBANK=1 => 1 bit	IBANK=1 => 0 bits	RSIZE=1 => 10 bits	IBANK=1 => 1 bit	PAGESIZE=1 => 9 bits
	IBANK=2 => 0 bits	RSIZE=2 => 11 bits	IBANK=2 => 2 bits	PAGESIZE=2 => 10 bits
	IBANK=3 => 1 bit	RSIZE=3 => 12 bits	IBANK=3 => 2 bits	PAGESIZE=3 => 11 bits
		RSIZE=4 => 13 bits		

**Table 9-161. OCP Address to LPDDR2/DDR3 Address Mapping for REG\_IBANK\_POS=1 and REG\_EBANK\_POS = 1 (continued)**

Logical Address				
Chip Select	Bank Address[2]	Row Address	Bank Address[1:0]	Column Address
		RSIZE=5 => 14 bits		
		RSIZE=6 => 15 bits		
		RSIZE=7 => 16 bits		

### 9.3.3.3.7 Address Mapping when REG\_IBANK\_POS = 2 and REG\_EBANK\_POS = 1

For REG\_IBANK\_POS = 2 and REG\_EBANK\_POS = 1, the interleaving of banks within a device (per chip select) is limited to 2 banks. Also, the LPDDR2/DDR3 memory controller cannot interleave banks between the two chip selects. Thus, the LPDDR2/DDR3 memory controller can keep a maximum of 16 banks (8 internal banks across 2 chip selects) open at a time, but can only interleave among two of them.

**Table 9-162. OCP Address to LPDDR2/DDR3 Address Mapping for REG\_IBANK\_POS=2 and REG\_EBANK\_POS = 1**

Logical Address				
Chip Select	Bank Address[2:1]	Row Address	Bank Address[0]	Column Address
# of bits defined by EBANK of SDRCR	# of bits defined by IBANK of SDRCR	# of bits defined by RSIZE of SDRCR	# of bits defined by IBANK of SDRCR	# of bits defined by PAGESIZE of SDRCR
EBANK=0 => 0 bits	IBANK=0 => 0 bits	RSIZE=0 => 9 bits	IBANK=0 => 0 bits	PAGESIZE=0 => 8 bits
EBANK=1 => 1 bit	IBANK=1 => 0 bits	RSIZE=1 => 10 bits	IBANK=1 => 1 bit	PAGESIZE=1 => 9 bits
	IBANK=2 => 1 bit	RSIZE=2 => 11 bits	IBANK=2 => 1 bit	PAGESIZE=2 => 10 bits
	IBANK=3 => 2 bits	RSIZE=3 => 12 bits	IBANK=3 => 1 bit	PAGESIZE=3 => 11 bits
		RSIZE=4 => 13 bits		
		RSIZE=5 => 14 bits		
		RSIZE=6 => 15 bits		
		RSIZE=7 => 16 bits		

### 9.3.3.3.8 Address Mapping when REG\_IBANK\_POS = 3 and REG\_EBANK\_POS = 1

For REG\_IBANK\_POS = 3 and REG\_EBANK\_POS = 1, the LPDDR2/DDR3 memory controller cannot interleave banks within a device (per chip select) or between the two chip selects. Thus, the LPDDR2/DDR3 memory controller can keep a maximum of 16 banks (8 internal banks across two chip selects) open at a time, but cannot interleave among of them.

**Table 9-163. OCP Address to LPDDR2/DDR3 Address Mapping for REG\_IBANK\_POS=3 and REG\_EBANK\_POS=1**

Logical Address			
Chip Select	Bank Address	Row Address	Column Address
# of bits defined by EBANK of SDRCR	# of bits defined by IBANK of SDRCR	# of bits defined by RSIZE of SDRCR	# of bits defined by PAGESIZE of SDRCR
EBANK=0 => 0 bits	IBANK=0 => 0 bits	RSIZE=0 => 9 bits	PAGESIZE=0 => 8 bits
EBANK=1 => 1 bit	IBANK=1 => 1 bit	RSIZE=1 => 10 bits	PAGESIZE=1 => 9 bits
	IBANK=2 => 2 bits	RSIZE=2 => 11 bits	PAGESIZE=2 => 10 bits
	IBANK=3 => 3 bits	RSIZE=3 => 12 bits	PAGESIZE=3 => 11 bits
		RSIZE=4 => 13 bits	
		RSIZE=5 => 14 bits	
		RSIZE=6 => 15 bits	
		RSIZE=7 => 16 bits	

Since the LPDDR2/DDR3 memory controller interleaves among less number of banks when IBANK\_POS!= 0 or EBANK\_POS= 1, these cases are lower in performance than the IBANK\_POS= 0 case. Thus these cases are only recommended to be used along with partial array self-refresh where performance can be traded off for power savings.

### 9.3.3.4 PHY DLL Calibration

When running in normal locked mode, the PHY DLL gets a reference clock (EMIFi\_DLL\_FCLK) from the PRCM, which is used by the DLL master to lock to the right frequency and provide the control code for a full period phase shift to the slave. The slave uses this code as a control for its internal delay line to produce the required delay for the signal considered.

When working in locked mode, the delay lines only get an updated control value from the master DLLs when an explicit dll\_calib command is issued by the EMIF controller. Failure to send such commands on a timely basis will result in inaccurate delay-line information if there is a significant voltage and temperature drift in the system. It is recommended to issue at least one command every 100  $\mu$ s. EMIF automatically sends ctrl\_update commands for:

- Refresh Exit
- Self Refresh Exit
- phy\_ready asserted during initialization

The PHY also internally generates a control value update upon completion of a leveling operation. Control is also added when leveling is not used and there are gradual voltage changes during frequency change. The EMIF4D\_DLL\_CALIB\_CTRL register can be programmed to generate a phy\_dll\_calib for a periodic interval based on EMIF\_FCLK cycles, so allow continued memory access as voltage is changing. A safe window of no activity will be guaranteed for this periodic generation of phy\_dll\_calib. In addition, a one shot generator for phy\_pll\_calib has also been added that will generate a single phy\_dll\_calib by setting the EMIF4D\_MISC\_REG[0] DLL\_CALIB\_OS bit to 1.

### DDR3 Output Impedance Calibration

The EMIF controller supports automatic output impedance (ZQ) calibration for LPDDR2 and DDR3 memories. The ZQ calibration can be enabled by setting to 0x1 the EMIF4D\_SDRAM\_OUTPUT\_IMPEDANCE\_CALIBRATION\_CONFIG[30] ZQ\_CS0EN bit. The EMIF supports three types of ZQ calibration commands:

- ZQINIT: ZQ calibration command during initialization
- ZQCL: ZQ calibration long command
- ZQCS: ZQ calibration short command

For DDR3, the EMIF will automatically issue a ZQINIT command during initialization. For LPDDR2, it is the software's responsibility for issuing a ZQINIT command (MRW to Mode Register 10). The EMIF will wait and block any other command for  $(reg\_zq\_zqinit\_mult+1)*(req\_zq\_zqcl\_mult+1)*(reg\_zq\_zqcs+1)$  number of clock DDR clock cycles every time a ZQINIT command is issued.

The EMIF periodically issues a ZQCS command every time reg\_zq\_refinterval expires. In other words, the reg\_zq\_refinterval defines the interval between ZQCS commands. The EMIF will wait and block any other command for  $(reg\_zq\_zqcs+1)$  number of DDR clock cycles every time a ZQCS command is issued.

If the reg\_zq\_sfexiten field is set to a 1, the EMIF will issue a ZQCL command every time it exits self-refresh, active power-down, and pre-charge power-down mode. The EMIF will wait and block any other command for  $(req\_zq\_zqcl\_mult+1)*(reg\_zq\_zqcs+1)$  number of DDR clock cycles every time a ZQCL command is issued.

If a separate calibration resistor is used per device, the ZQ calibration can be performed simultaneously over both chip selects. To enable ZQ calibration to be performed simultaneously over both chip selects, the reg\_zq\_dualcalen field must be set to a 1. If reg\_zq\_dualcalen is set to a 0, the EMIF will serially perform ZQ calibration per chip select.

### 9.3.3.5 Temperature Monitoring

The EMIF supports automatic temperature monitoring for LPDDR2 to facilitate the software to update the refresh rate according to the LPDDR2 device temperature changes. The temperature monitoring can be enabled per chip select by setting `reg_ta_cs0en` and `reg_ta_cs1en` fields in the SDRAM Temperature Alert Config register.

The EMIF periodically polls the temperature of LPDDR2 (by issuing an MRR command to Mode Register 4) every time `reg_ta_refinterval` expires. In other words, the `reg_ta_refinterval` defines the interval between temperature alert polls. If the EMIF sees a 1 on bit 7 of the read data value from MRR, indicating that the temperature has changed, it sends an interrupt both on the system and low-latency interrupt lines. After receiving the interrupt, the software will update the `reg_refresh_rate` field in the SDRAM Refresh Control register to the required value as per the temperature change.

If `reg_ta_sfexiten` field is set to a 1, the EMIF will poll for temperature change every time it exits self-refresh, active power-down, and pre-charge power-down modes.

Since the EMIF is performing a MRR, it needs information on how the LPDDR2 are connected. The `reg_ta_devwdt` and `reg_ta_devcnt` fields in the Temperature Alert Config register provides the necessary information to the EMIF for MRR data compare. For example, if `reg_ta_devwdt` is set to 0 indicating 8-bit devices used, and if `reg_ta_devcnt` is set to 2 indicating four devices used to form a 32-bit bus, the mask used for checking would be 4'b1111, that is, the EMIF would expect data on each lane of the bytes on a 32-bit DDR bus.

### Class of Service

The commands in the Command FIFO can be mapped to two classes of service namely 1 and 2. The mapping of commands to a particular class of service can be done based on the priority or the connection ID. The mapping based on priority can be done by setting the appropriate values in the `EMIF4D_PRIORITY_TO_CLASS_OF_SERVICE_MAPPING` register. The mapping based on connection ID can be done by setting the appropriate values of connection ID and the masks in the `EMIF4D_CONNECTION_ID_TO_CLASS_OF_SERVICE_1_MAPPING` and `EMIF4D_CONNECTION_ID_TO_CLASS_OF_SERVICE_2_MAPPING` registers. There are 3 connection ID and mask values that can be set for each class of service. In conjunction with the masks, each class of service can have a maximum of 144 connection IDs mapped to it. For example, a connection ID value of 0xFF along with a mask value of 0x3 will map all connection IDs from 0xF8 to 0xFF to that particular class of service.

Each class of service has an associated latency counter (`EMIF4D_COS_CONFIG[23:16] COS_COUNT_1` and `EMIF4D_COS_CONFIG[15:8] COS_COUNT_2`). When the latency counter for a command expires, that is, reaches the value programmed for the class of service that the command belongs to, that command is executed next. If there is more than one command that has expired latency counter, the command with the highest priority is executed first. One exception to this rule is, if the `EMIF4D_COS_CONFIG[7:0] PR_OLD_COUNT` value expires for the oldest command in the queue. That command is executed first irrespective of priority or class of service. This is done to prevent the continuous blocking effect.

The `EMIF4D_COS_CONFIG[7:0] PR_OLD_COUNT` value is used to identify when the oldest command in the command FIFO has timed out. At this point during the arbitration process, this oldest command is issued regardless of the priority of the other commands in the FIFO. This feature is disabled when writing 0x0 to the `EMIF4D_COS_CONFIG[7:0] PR_OLD_COUNT` bit field. After issuing the oldest command, the other remaining commands in the FIFO are reordered by age. The next oldest command in the FIFO is given highest priority again and issued after the `EMIF4D_COS_CONFIG[7:0] PR_OLD_COUNT` value expires. If a new value in the `PR_OLD_COUNT` bit field is written during counting, that is, before `PR_OLD_COUNT` expires, the counter keeps working but if this value is smaller the oldest command is issued sooner and if this value is larger the oldest command is issued later.

The connection ID mapping allows the same connection ID to be put in both class of service 1 and 2. Also, a transaction might belong to one class of service if viewed by connection ID and might belong to another class of service if viewed by priority. In these cases, the command will belong to both class of service. The EMIF will try executing the command as soon as possible, when the smaller of the two counters (`EMIF4D_COS_CONFIG[23:16] COS_COUNT_1` and `EMIF4D_COS_CONFIG[15:8] COS_COUNT_2`) expires.

### 9.3.3.6 Performance Counters

The EMIF4D\_PERFORMANCE\_CTR\_1 and EMIF4D\_PERFORMANCE\_CTR\_2 registers are used to monitor or calculate the EMIF Controller bandwidth and efficiency. These counters are able to count events such as total SDRAM accesses, SDRAM activates, reads, writes, and other events. Each counter counts independent of the other. In addition to the ability of events counting, the counters can also filter the events from a particular master or address space. The events counting and filter enabling are configured using the EMIF4D\_PERFORMANCE\_CTR\_CONFIG register. The filter value used is configured through the EMIF4D\_PERFORMANCE\_CTR\_MASTER\_REGION\_SELECT register. Each counter can be configured independently.

Table 9-164 lists all the events that can be counted and whether a filter can be applied to a particular event. A filter is applied to an event if the following bits are set to 0x1 for that event:

- For Performance Counter 1: EMIF4D\_PERFORMANCE\_CTR\_CONFIG[15] CNTR1\_MCONNID\_EN and EMIF4D\_PERFORMANCE\_CTR\_CONFIG[14] CNTR1\_REGION\_EN;
- For Performance Counter 2: EMIF4D\_PERFORMANCE\_CTR\_CONFIG[31] CNTR2\_MCONNID\_EN and EMIF4D\_PERFORMANCE\_CTR\_CONFIG[30] CNTR2\_REGION\_EN.

**Table 9-164. Performance Counter Filter Configuration**

CNTR <sub>n</sub> _CFG <sup>(1)</sup>	CNTR <sub>n</sub> _REGION_EN	CNTR <sub>n</sub> _MCONNID_EN	Description
0x0	0x0	0x0 or 0x1	Count total SDRAM accesses
0x1	0x0	0x0 or 0x1	Count total SDRAM activates
0x2	0x0 or 0x1	0x0 or 0x1	Count total reads
0x3	0x0 or 0x1	0x0 or 0x1	Count total writes
0x4	0x0	0x0	Count number of EMIF_FICLK clock cycles during which the local Command FIFO is full
0x5	0x0	0x0	Count number of EMIF_FICLK clock cycles during which the local Write Data FIFO is full
0x6	0x0	0x0	Count number of EMIF_FICLK clock cycles during which the local Read Data FIFO is full
0x7	0x0	0x0	Count number of EMIF_FICLK clock cycles during which the local Return Command FIFO is full
0x8	0x0 or 0x1	0x0 or 0x1	Count number of priority elevations
0x9	0x0	0x0	Count number of EMIF_FICLK clock cycles that a command was pending
0xA	0x0	0x0	Count number of EMIF_FICLK cycles used by the EMIF controller for reads and writes.
0xB - 0xF	0x0	0x0	Reserved for future use.

<sup>(1)</sup> n = 1 or 2

**NOTE:** When the MReqDebug qualifier is set to 0x1 for a particular local command, the performance counters are not incremented for that particular command if the CNTR<sub>n</sub>\_CONFIG values are equal to 0x0, 0x1, 0x2, 0x3, or 0xA.

### Performance Counters General Examples

#### • General Example for Counting All Write Accesses

If the EMIF4D\_PERFORMANCE\_CTR\_1 register is used to count all write accesses from master with connection ID equal to 0xA (this is the system MMU) the following steps should be performed:

- To enable the writes counting, the EMIF4D\_PERFORMANCE\_CTR\_CONFIG[3:0] CNTR1\_CFG bit field must be set to 0x3.
- The EMIF4D\_PERFORMANCE\_CTR\_MASTER\_REGION\_SELECT[15:8] MCONNID1 bit field must be set to 0xA.
- To enable filtering, the EMIF4D\_PERFORMANCE\_CTR\_CONFIG[15] CNTR1\_MCONNID\_EN bit must be set to 0x1.

With this configuration EMIF4D\_PERFORMANCE\_CTR\_1 counts every write made to the EMIF from master 0xA to any address space. This does not include accesses from other masters and commands other than writes.

- **General Example for Counting Total Access**

If the EMIF4D\_PERFORMANCE\_CTR\_2 register is used to count total accesses to the SDRAM regardless of the address space or master the following steps should be performed:

- To enable counting of all accesses to the SDRAM, the EMIF4D\_PERFORMANCE\_CTR\_CONFIG[19:16] CNTR2\_CFG bit field must be set to 0x0.
- To disable filtering, both the EMIF4D\_PERFORMANCE\_CTR\_CONFIG[31] CNTR2\_MCONNID\_EN and EMIF4D\_PERFORMANCE\_CTR\_CONFIG[30] CNTR2\_REGION\_EN bits must be set to 0x0.

With this configuration EMIF4D\_PERFORMANCE\_CTR\_2 counts every access made to the SDRAM. This includes all accesses from all masters and to any address space.

- **General Example for Counting All Read Accesses**

If the EMIF4D\_PERFORMANCE\_CTR\_1 register is used to count all read accesses from master with connection ID equal to 0xA (this is the system MMU) to address space 0x0 the following steps should be performed:

- To enable the reads counting, the EMIF4D\_PERFORMANCE\_CTR\_CONFIG[3:0] CNTR1\_CFG bit field must be set to 0x2.
- The EMIF4D\_PERFORMANCE\_CTR\_MASTER\_REGION\_SELECT[15:8] MCONNID1bit field must be set to 0xA
- The EMIF4D\_PERFORMANCE\_CTR\_MASTER\_REGION\_SELECT[1:0] REGION\_SEL1 bit field must be set to 0x0.
- To enable filtering, both the EMIF4D\_PERFORMANCE\_CTR\_CONFIG[15] CNTR1\_MCONNID\_EN and the EMIF4D\_PERFORMANCE\_CTR\_CONFIG[14] CNTR1\_REGION\_EN bits must be set to 0x1.

With this configuration, EMIF4D\_PERFORMANCE\_CTR\_1 counts every read made to the EMIF from master 0xA to address space 0x0. This does not include accesses from other masters or to other address spaces and does not include commands other than reads.

### 9.3.4 EMIF Registers

Table 9-165 lists the memory-mapped registers for the EMIF. All register offset addresses not listed in Table 9-165 should be considered as reserved locations and the register contents should not be modified.

**Table 9-167. EMIF4D\_STS Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	BE	R	0h	Big Endian. Reflects the value on the config_big_endian port that defines whether the EMIF is in big or little endian mode.
30	DUAL_CLK_MODE	R	0h	Dual Clock mode. Reflects the value on the config_dual_clk_mode port that defines whether the ocp_clk and m_clk are asynchronous.
29	FAST_INIT	R	0h	Fast Init. Reflects the value on the config_fast_init port that defines whether the EMIF fast initialization mode has been enabled.
28-7	RESERVED	Rreturns0s	0h	
6	RDLVLGATETO	R	0h	Read DQS Gate Training Timeout. Value of 1 indicates read DQS gate training has timed out because read DQS gate training done was not received from the PHY.
5	RDLVLTO	R	0h	Read Data Eye Training Timeout. Value of 1 indicates read data eye training has timed out because read data eye training done was not received from the PHY.
4	WRLVLTO	R	0h	Write Leveling Timeout. Value of 1 indicates write leveling has timed out because write leveling done was not received from the PHY.
3	RESERVED	Rreturns0s	0h	
2	PHY_DLL_READY	R	0h	DDR PHY Ready. Reflects the value on the phy_ready port (active high) that defines whether the DDR PHY is ready for normal operation.
1-0	RESERVED	Rreturns0s	0h	

### 9.3.4.3 EMIF4D\_SDRAM\_CONFIG Register (offset = 8h) [reset = 0h]

Register mask: FFFFFFFFh

EMIF4D\_SDRAM\_CONFIG is shown in [Figure 9-145](#) and described in [Table 9-168](#).

**Figure 9-145. EMIF4D\_SDRAM\_CONFIG Register**

ROWSIZE	IBANK			EBANK	PAGESIZE		
R/W-0h	R/W-0h			R/W-0h	R/W-0h		

**Table 9-168. EMIF4D\_SDRAM\_CONFIG Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-29	SDRAM_TYPE	R/W	0h	SDRAM Type selection. Set to 3 for DDR3. Set to 4 for LPDDR2. All other values are reserved.
28-27	IBANK_POS	R/W	0h	Internal bank position. Set to 0 to assign internal bank address bits from lower OCP address bits as shown in tables. Set to 1, 2, or 3 to assign internal bank address bits from higher OCP address bits as shown in tables.
26-24	DDR_TERM	R/W	0h	DDR3 termination resistor value. Set to 0 to disable termination. Set to 1 for RZQ/4. Set to 2 for RZQ/2. Set to 3 for RZQ/6. Set to 4 for RZQ/12. Set to 5 for RZQ/8. All other values are reserved.
23	LPDDR2_DDQS	R/W	0h	LPDDR2 differential DQS enable. Set to 0 for single ended DQS. Set to 1 for differential DQS.
22-21	DYN_ODT	R/W	0h	DDR3 Dynamic ODT. Set to 0 to turn off dynamic ODT. Set to 1 for RZQ/4 and set to 2 for RZQ/2. All other values are reserved.
20	DDR_DISABLE_DLL	R/W	0h	Disable DLL select. Set to 1 to disable DLL inside SDRAM.
19-18	SDRAM_DRIVE	R/W	0h	SDRAM drive strength. For DDR3, set to 0 for RZQ/6 and set to 1 for RZQ/7. All other values are reserved.
17-16	CWL	R/W	0h	DDR3 CAS Write latency. Value of 0, 1, 2, and 3 (CAS write latency of 5, 6, 7, and 8) are supported. Use the lowest value supported for best performance. All other values are reserved.
15-14	NARROW_MODE	R/W	0h	SDRAM data bus width. Set to 0 for 32 bit and set to 1 for 16 bit. All other values are reserved.

**Table 9-168. EMIF4D\_SDRAM\_CONFIG Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
13-10	CL	R/W	0h	CAS Latency. The value of this field defines the CAS latency to be used when accessing connected SDRAM devices. Value of 2, 4, 6, 8, 10, 12, and 14 (CAS latency of 5, 6, 7, 8, 9, 10, and 11) are supported for DDR3. Value of 3, 4, 5, 6, 7, and 8 (CAS latency of 3, 4, 5, 6, 7, and 8) are supported for LPDDR2 SDRAM. All other values are reserved.
9-7	ROWSIZE	R/W	0h	Row Size. Defines the number of row address bits of connected SDRAM devices. Set to 0 for 9 row bits, set to 1 for 10 row bits, set to 2 for 11 row bits, set to 3 for 12 row bits, set to 4 for 13 row bits, set to 5 for 14 row bits, set to 6 for 15 row bits, and set to 7 for 16 row bits. This field is only used when reg_ibank_pos field in SDRAM Config register is set to 1, 2, or 3, or reg_ebank_pos field in SDRAM Config 2 register is set to 1.
6-4	IBANK	R/W	0h	Internal Bank setup. Defines number of banks inside connected SDRAM devices. Set to 0 for 1 bank, set to 1 for 2 banks, set to 2 for 4 banks, and set to 3 for 8 banks. All other values are reserved.
3	EBANK	R/W	0h	External chip select setup. Defines whether SDRAM accesses will use 1 or 2 chip select lines. Set to 0 to use pad_cs_o_n[0] only. Set to 1 to use pad_cs_o_n [1:0]. This bit will automatically be set to 0 if reg_cs1nvmen field in the LPDDR2 NVM is set to 1.
2-0	PAGESIZE	R/W	0h	Page Size. Defines the internal page size of connected SDRAM devices. Set to 0 for 256-word page (8 column bits), set to 1 for 512-word page (9 column bits), set to 2 for 1024-word page (10 column bits), and set to 3 for 2048-word page (11 column bits). All other values are reserved.

### 9.3.4.4 EMIF4D\_SDRAM\_CONFIG\_2 Register (offset = Ch) [reset = 0h]

Register mask: FFFFFFFFh

EMIF4D\_SDRAM\_CONFIG\_2 is shown in [Figure 9-146](#) and described in [Table 9-169](#).

**Figure 9-146. EMIF4D\_SDRAM\_CONFIG\_2 Register**

R/W-0h							

**Table 9-170. EMIF4D\_SDRAM\_REFRESH\_CTRL Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	INITREF_DIS	R/W	0h	Initialization and Refresh disable. When set to 1, EMIF will disable SDRAM initialization and refreshes, but will carry out SDRAM write/read transactions.
30	RESERVED	Rreturns0s	0h	
29	SRT	R/W	0h	DDR3 Self Refresh temperature range. Set to 0 for normal operating temperature range and set to 1 for extended operating temperature range when the reg_asr field is set to 0. This bit must be set to 0 if the reg_asr field is set to 1. A write to this field will cause the EMIF to start the SDRAM initialization sequence.
28	ASR	R/W	0h	DDR3 Auto Self Refresh enable. Set to 1 for auto Self Refresh enable. Set to 0 for manual Self Refresh reference indicated by the reg_srt field. A write to this field will cause the EMIF to start the SDRAM initialization sequence.
27	RESERVED	Rreturns0s	0h	
26-24	PASR	R/W	0h	Partial Array Self Refresh. These bits get loaded into the Extended Mode Register of DDR3 during initialization. Set to 0 for full array, set to 1 or 5 for 1/2 array, set to 2 or 6 for 1/4 array, set to 3 or 7 for 1/8 array, and set to 4 for 3/4 array to be refreshed. All other values are reserved. A write to this field will cause the EMIF to start the SDRAM initialization sequence.
23-16	RESERVED	Rreturns0s	0h	
15-0	REFRESH_RATE	R/W	0h	Refresh Rate. Value in this field is used to define the rate at which connected SDRAM devices will be refreshed. SDRAM refresh rate = EMIF rate / reg_refresh_rate where EMIF rate is equal to m_clk rate. If reg_refresh_rate < (8*reg_t_rfc)+reg_t_rp+reg_t_rcd+20 then it will be loaded with (8*reg_t_rfc)+reg_t_rp+reg_t_rcd+20. This is done to avoid lock-up situations when illegal values are programmed.

### 9.3.4.6 EMIF4D\_SDRAM\_REFRESH\_CTRL\_SHADOW Register (offset = 14h) [reset = 0h]

Register mask: FFFFFFFFh

EMIF4D\_SDRAM\_REFRESH\_CTRL\_SHADOW is shown in [Figure 9-148](#) and described in [Table 9-171](#).

**Figure 9-148. EMIF4D\_SDRAM\_REFRESH\_CTRL\_SHADOW Register**

**Table 9-172. EMIF4D\_SDRAM\_TIMING\_1 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-29	T_RTW	R/W	0h	Minimum number of DDR clock cycles between Read to Write data phases, minus one.
28-25	T_RP	R/W	0h	Minimum number of DDR clock cycles from Precharge to Activate or Refresh, minus one.
24-21	T_RCD	R/W	0h	Minimum number of DDR clock cycles from Activate to Read or Write, minus one.
20-17	T_WR	R/W	0h	Minimum number of DDR clock cycles from last Write transfer to Pre-charge, minus one.
16-12	T_RAS	R/W	0h	Minimum number of DDR clock cycles from Activate to Pre-charge, minus one. reg_t_ras >= reg_t_rcd.
11-6	T_RC	R/W	0h	Minimum number of DDR clock cycles from Activate to Activate, minus one.
5-3	T_RRD	R/W	0h	Minimum number of DDR clock cycles from Activate to Activate for a different bank, minus one. For an 8-bank DDR3, this field must be equal to ((tFAW/(4*tCK))-1).
2-0	T_WTR	R/W	0h	Minimum number of DDR clock cycles from last Write to Read, minus one.

### 9.3.4.8 EMIF4D\_SDRAM\_TIMING\_1\_SHADOW Register (offset = 1Ch) [reset = 0h]

Register mask: FFFFFFFFh

EMIF4D\_SDRAM\_TIMING\_1\_SHADOW is shown in [Figure 9-150](#) and described in [Table 9-173](#).

Bit	Field	Type	Reset	Description
31-16	TLEC	R/W	0h	IODFT Test Logic Execution Counter. Contains the number of cycle that the MISR signature will be accumulated. Upon the expiration of the counter the MISR capture will be turned off.
15	RESERVED	Rreturns0s	0h	
14	MT	R/W	0h	MISR on/off trigger command. 0h = inactive/no affect. 1h = MISR capture start on the first write or read command to the memory and continues to update the signature until reg_tlec expires, when mc = 3h. 1h = pattern generator starts on the first write or read command to the memory and continues to update the signature until reg_tlec expires, when reg_pc = 1h, 2h, 3h, 5h, 6h, or 7h. These bits are cleared when reg_tlec expires.
13	ACT_CAP_EN	R/W	1h	Active cycles capture enable. If set to a 1 the MISRs and pattern generators will shift only during active cycles. If set to a 0 the MISRs and pattern generators will shift every clock cycle.
12	OPG_LD	R/W	0h	Load pattern generators' initial value. Set to 1 to load an initial value in the pattern generators from reg_tlec.
11	RESERVED	R	0h	
10	RESET_PHY	R/W	0h	Reset DDR PHY.
9	RESERVED	Rreturns0s	0h	
8	MMS	R/W	0h	Chooses the source of the MISR input. Set to 0 for output register, and set to 1 for input capture.
7-6	RESERVED	Rreturns0s	0h	
5-4	MC	R/W	1h	MISR state. Set to 0 to download results. Set to 1 to hold current value. Set to 2 to load initial value from reg_pc bits. Set to 3 to enable MISR to capture signature.

**Table 9-187. EMIF4D\_IODFT\_TEST\_LOGIC\_GLOBAL\_CTRL Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
3-1	PC	R/W	0h	Pattern code. Defines the type of pattern that is selected for the pattern generators. Set to 0 for functional mode and set to 4 to hold current register value. For output pattern generator, set to 1 for random XOR, set to 2 for random XNOR, and set to 3 for an 8 bit shifter. For input pattern generator, set to 5 for random XOR, set to 6 for random XNOR, and set to 7 for an 8 bit shifter.
0	TM	R/W	1h	Functional mode enable. Set to 1 for functional mode, and set to 0 for IODFT mode.

### 9.3.4.23 EMIF4D\_IODFT\_TEST\_LOGIC\_CTRL\_MISR\_RESULT Register (offset = 64h) [reset = 0h]

RESERVED								DLL_CALIB_INTERVAL							
Rreturns0s-0h								R/W-0h							

**Table 9-199. EMIF4D\_DLL\_CALIB\_CTRL Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-20	RESERVED	Rreturns0s	0h	
19-16	ACK_WAIT	R/W	9h	The ack_wait determines the required wait time after a phy_dll_calib is generated before another command can be sent
15-9	RESERVED	Rreturns0s	0h	
8-0	DLL_CALIB_INTERVAL	R/W	0h	The dll_calib_interval field determines the interval between phy_dll_calib generation. This value is multiplied by a precounter of 16 m_clk cycles. Program this field one less the value you are targeting program 1 to achieve interval of 2 (minimum interval supported). Programming zero turns off function. Note the final intervals between dll_calib generation is also a function of ACK_WAIT . Final periodic interval is calculated by: $((dll\_calib\_interval+1)*16)+ACK\_WAIT$

### 9.3.4.35 EMIF4D\_DLL\_CALIB\_CTRL\_SHADOW Register (offset = 9Ch) [reset = 90000h]

Register mask: FFFFFFFFh

EMIF4D\_DLL\_CALIB\_CTRL\_SHADOW is shown in [Figure 9-177](#) and described in [Table 9-200](#).

**Figure 9-177. EMIF4D\_DLL\_CALIB\_CTRL\_SHADOW Register**

**Table 9-210. EMIF4D\_SDRAM\_OUTPUT\_IMPEDANCE\_CALIBRATION\_CONFIG Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	ZQ_CS1EN	R/W	0h	Writing a 1 enables ZQ calibration for CS1.
30	ZQ_CS0EN	R/W	0h	Writing a 1 enables ZQ calibration for CS0.
29	ZQ_DUALCALEN	R/W	0h	ZQ Dual Calibration enable. Allows both ranks to be ZQ calibrated simultaneously. Setting this bit requires both chip selects to have a seerate calibration resistor per device.
28	ZQ_SFEXITEN	R/W	0h	ZQCL on Self Refresh, Active Power-Down, and Precharge Power-Down exit enable. Writing a 1 enables the issuing of ZQCL on Self-Refresh, Active Power-Down, and Precharge Power-Down exit.
27-20	RESERVED	Rreturns0s	0h	
19-18	ZQ_ZQINIT_MULT	R/W	0h	Indicates the number of ZQCL intervals that make up a ZQINIT interval, minus one.
17-16	ZQ_ZQCL_MULT	R/W	0h	Indicates the number of ZQCS intervals that make up a ZQCL interval, minus one. ZQCS interval is defined by reg_zq_zqcs in SDRAM Timing 3 Register.
15-0	ZQ_REFINTERVAL	R/W	0h	Number of refresh periods between ZQCS commands. This field supports between one refresh period to 256 ms between ZQCS calibration commands. Refresh period is defined by reg_refresh_rate in SDRAM Refresh Control register.

### 9.3.4.46 EMIF4D\_TEMPERATURE\_ALERT\_CONFIG Register (offset = CCh) [reset = 0h]

Register mask: FFFFFFFFh

EMIF4D\_TEMPERATURE\_ALERT\_CONFIG is shown in [Figure 9-188](#) and described in [Table 9-211](#).

**Figure 9-188. EMIF4D\_TEMPERATURE\_ALERT\_CONFIG Register**

31	30	29	28	27	26	25	24

TA_REFINTERVAL							
R/W-0h							

**Table 9-211. EMIF4D\_TEMPERATURE\_ALERT\_CONFIG Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	TA_CS1EN	R/W	0h	Writing a 1 enables temperature alert polling for CS1.
30	TA_CS0EN	R/W	0h	Writing a 1 enables temperature alert polling for CS0.
29	RESERVED	Rreturns0s	0h	
28	TA_SFEXITEN	R/W	0h	Temperature Alert Poll on Self-Refresh, Active Power-Down, and Precharge Power-Down exit enable. Writing a 1 enables the issuing of a temperature alert poll on Self-Refresh exit.
27-26	TA_DEVWDT	R/W	0h	This field indicates how wide a physical device is. It is used in conjunction with the reg_ta_devcnt register to determine which byte lanes contain the temperature alert info. A value of 0 = eight bit wide, 1 = sixteen bit wide, 2 = thirty two bit wide. All others are reserved. If this field is set to 1 and the reg_ta_devcnt field is set to one the byte mask for checking will be 4'b0101.
25-24	TA_DEVCNT	R/W	0h	This field indicates which external byte lanes contain a device for temperature monitoring. A value of 0 = one device, 1 = two devices, 2 = four devices. All other reserved.
23-22	RESERVED	Rreturns0s	0h	
21-0	TA_REFINTERVAL	R/W	0h	Number of refresh periods between temperature alert polls. This field supports one refresh period to 10 seconds between temperature alert polls. Refresh period is defined by reg_refresh_rate in SDRAM Refresh Control register.

### 9.3.4.47 EMIF4D\_OCP\_ERROR\_LOG Register (offset = D0h) [reset = 0h]

Register mask: FFFFFFFFh

EMIF4D\_OCP\_ERROR\_LOG is shown in [Figure 9-189](#) and described in [Table 9-212](#).

COS_COUNT_2								PR_OLD_COUNT							
R/W-FFh								R/W-FFh							

**Table 9-225. EMIF4D\_COS\_CONFIG Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-24	RESERVED	Rreturns0s	0h	
23-16	COS_COUNT_1	R/W	FFh	Priority Raise Counter for class of service 1. Number of m_clk cycles after which the EMIF momentarily raises the priority of the class of service 1 commands in the Command FIFO. A value of N will be equal to N x 16 clocks.
15-8	COS_COUNT_2	R/W	FFh	Priority Raise Counter for class of service 2. Number of m_clk cycles after which the EMIF momentarily raises the priority of the class of service 2 commands in the Command FIFO. A value of N will be equal to N x 16 clocks.
7-0	PR_OLD_COUNT	R/W	FFh	Priority Raise Old Counter. Number of m_clk cycles after which the EMIF momentarily raises the priority of the oldest command in the Command FIFO. A value of N will be equal to N x 16 clocks.

### 9.3.4.61 EMIF4D\_1B\_ECC\_ERR\_CNT Register (offset = 130h) [reset = 0h]

Register mask: FFFFFFFFh

EMIF4D\_1B\_ECC\_ERR\_CNT is shown in [Figure 9-203](#) and described in [Table 9-226](#).

**Figure 9-203. EMIF4D\_1B\_ECC\_ERR\_CNT Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
REG_1B_ECC_ERR_CNT																															
R/W-0h																															

**Table 9-226. EMIF4D\_1B\_ECC\_ERR\_CNT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	REG_1B_ECC_ERR_CNT	R/W	0h	32 bit counter that displays number of 1 bit ECC errors. Writing a value will decrement the count by that value. For example, if the count is 0x1234_AB3, writing 0x1234_AB3 to this register will clear it.

### 9.3.4.62 EMIF4D\_1B\_ECC\_ERR\_THRSH Register (offset = 134h) [reset = 0h]

Register mask: FFFFFFFFh

EMIF4D\_1B\_ECC\_ERR\_THRSH is shown in [Figure 9-204](#) and described in [Table 9-227](#).

**Figure 9-204. EMIF4D\_1B\_ECC\_ERR\_THRSH Register**

REG_1B_ECC_ERR_WIN															
R/W-0h															

**Table 9-227. EMIF4D\_1B\_ECC\_ERR\_THRSH Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-24	REG_1B_ECC_ERR_THRSH	R/W	0h	1 bit ECC error threshold. The EMIF will generate an interrupt when the 1 bit ECC error count is greater than or equal to this threshold. A value of 0 will disable the generation of the interrupt.
23-16	RESERVED	Rreturns0s	0h	
15-0	REG_1B_ECC_ERR_WIN	R/W	0h	1 bit ECC error window in number of refresh periods. The EMIF will generate an interrupt when the 1 bit ECC error count is equal to or greater than the threshold within this window. A value of 0 will disable the window. Refresh period is defined by reg_refresh_rate in SDRAM Refresh Control register. The software can set this bitfield to 0x0 to reset the internal counter.

### 9.3.4.63 EMIF4D\_1B\_ECC\_ERR\_DIST\_1 Register (offset = 138h) [reset = 0h]

Register mask: FFFFFFFFh

EMIF4D\_1B\_ECC\_ERR\_DIST\_1 is shown in [Figure 9-205](#) and described in [Table 9-228](#).

**Figure 9-205. EMIF4D\_1B\_ECC\_ERR\_DIST\_1 Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
REG_1B_ECC_ERR_DIST_1																															
R/W-0h																															

**Table 9-228. EMIF4D\_1B\_ECC\_ERR\_DIST\_1 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	REG_1B_ECC_ERR_DIST_1	R/W	0h	1 bit ECC error distribution over data bus bit 31:0. A value of 1 on a bit indicates 1 bit error on the corresponding bit on the data bus. Writing a 1 to any bit will clear that bit. Writing a 0 has no effect.

### 9.3.4.64 EMIF4D\_1B\_ECC\_ERR\_ADDR\_LOG Register (offset = 13Ch) [reset = 0h]

Register mask: FFFFFFFFh

EMIF4D\_1B\_ECC\_ERR\_ADDR\_LOG is shown in [Figure 9-206](#) and described in [Table 9-229](#).

**Figure 9-206. EMIF4D\_1B\_ECC\_ERR\_ADDR\_LOG Register**

## 9.4 ELM

### 9.4.1 Introduction

Non-managed NAND flash memories can be dense and nonvolatile in their own nature, but error-prone. When reading from NAND flash memories, some level of error-correction is required. In the case of NAND modules with no internal correction capability, sometimes referred to as bare NANDs, the correction process is delegated to the memory controller.

The general-purpose memory controller (GPMC) probes data read from an external NAND flash and uses this to compute checksum-like information, called syndrome polynomials, on a per-block basis. Each syndrome polynomial gives a status of the read operations for a full block, including 512 bytes of data, parity bits, and an optional spare-area data field, with a maximum block size of 1023 bytes. Computation is based on a Bose-Chaudhuri-Hocquenghem (BCH) algorithm. The error-location module (ELM) extracts error addresses from these syndrome polynomials.

Based on the syndrome polynomial value, the ELM can detect errors, compute the number of errors, and give the location of each error bit. The actual data is not required to complete the error-correction algorithm. Errors can be reported anywhere in the NAND flash block, including in the parity bits.

The maximum acceptable number of errors that can be corrected depends on a programmable configuration parameter. 4-, 8-, and 16-bit error-correction levels are supported. The ELM relies on a static and fixed definition of the generator polynomial for each error-correction level that corresponds to the generator polynomials defined in the GPMC (there are three fixed polynomial for the three correction error levels). A larger number of errors than the programmed error-correction level may be detected, but the ELM cannot correct them all. The offending block is then tagged as uncorrectable in the associated computation exit status register. If the computation is successful, that is, if the number of errors detected does not exceed the maximum value authorized for the chosen correction capability, the exit status register contains the information on the number of detected errors.

When the error-location process completes, an interrupt is triggered to inform the central processing unit (CPU) that its status can be checked. The number of detected errors and their locations in the NAND block can be retrieved from the module through register accesses.

#### 9.4.1.1 ELM Features

The ELM has the following features:

- 4, 8, and 16 bits per 512-byte block error-location based on BCH algorithms
- Eight simultaneous processing contexts
- Page-based and continuous modes
- Interrupt generation on error-location process completion:
  - When the full page has been processed in page mode
  - For each syndrome polynomial in continuous mode

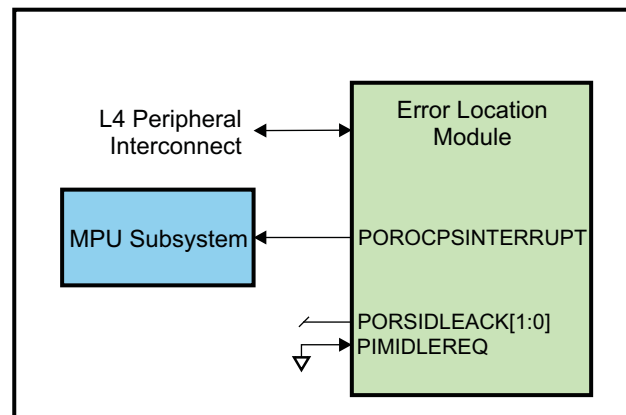

#### 9.4.1.2 Unsupported ELM Features

There are no unsupported ELM features in this device.

### 9.4.2 Integration

The error location module (ELM) is used to extract error addresses from syndrome polynomials generated using a BCH algorithm. Each of these polynomials gives a status of the read operations for a 512 bytes block from a NAND flash and its associated BCH parity bits, plus optionally some spare area information.

The ELM is intended to be used in conjunction with the GPMC. Syndrome polynomials generated on-the-fly when reading a NAND Flash page and stored in GPMC registers are passed to the ELM module. The MPU can then easily correct the data block by flipping the bits pointed to by the ELM error locations outputs.

**Figure 9-308. ELM Integration**

#### 9.4.2.1 ELM Connectivity Attributes

The general connectivity for the ELM module in this device is summarized in [Table 9-331](#).

**Table 9-331. ELM Connectivity Attributes**

Attributes	Type
Power Domain	Peripheral Domain
Clock Domain	L4PER_L4LS_GCLK
Reset Signals	PER_DOM_RST_N
Idle/Wakeup Signals	Smart Idle
Interrupt Requests	1 interrupt to MPU Subsystem
DMA Requests	None
Physical Address	L4 Peripheral slave port

#### 9.4.2.2 ELM Clock and Reset Management

The ELM operates from a single OCP interface clock.

**Table 9-332. ELM Clock Signals**

Clock Signal	Max Freq	Reference / Source	Comments
Functional/interface clock	100 MHz	CORE_CLKOUTM4 / 2	pd_per_l4ls_gclk From PRCM

#### 9.4.2.3 ELM Pin List

The ELM module does not include any external interface pins.

### 9.4.3 Functional Description

The ELM is designed around the error-location engine, which handles the computation based on the input syndrome polynomials.

The ELM maps the error-location engine to a standard interconnect interface by using a set of registers to control inputs and outputs.

#### 9.4.3.1 ELM Software Reset

To perform a software reset, write a 1 to the ELM\_SYSCONFIG[1] SOFTRESET bit. The ELM\_SYSSTS[0] RESETDONE bit indicates that the software reset is complete when its value is 1. When the software reset completes, the ELM\_SYSCONFIG[1] SOFTRESET bit is automatically reset.

#### 9.4.3.2 ELM Power Management

[Table 9-333](#) describes the power-management features available to the ELM module.

**Table 9-333. Local Power Management Features**

Feature	Registers	Description
Clock autogating	ELM_SYSCONFIG[0] AUTOGATING bit	This bit allows a local power optimization inside the module by gating the ELM_FCLK clock upon the interface activity.
Slave idle modes	ELM_SYSCONFIG[4:3] SIDLEMODE bit field	Force-idle, No-idle, and Smart-idle modes are available.
Clock activity	ELM_SYSCONFIG[8] CLOCKACTIVITY bit	The clock can be switched-off or maintained during the wake-up period.
Master Standby modes	N/A	
Global Wake-up Enable	N/A	
Wake-up Sources Enable	N/A	

#### CAUTION

The PRCM module has no hardware means of reading CLOCKACTIVITY settings. Thus, software must ensure consistent programming between the ELM CLOCKACTIVITY and ELM clock PRCM control bits.

#### 9.4.3.3 ELM Interrupt Requests

[Table 9-334](#) lists the event flags, and their masks, that can cause module interrupts.

**Table 9-334. Events**

Event Flag	Event Mask	Map to	Description
ELM_IRQSTS[8] PAGE_VALID	ELM_IRQEN[8] PAGE_MASK	ELM_IRQ	Page interrupt
ELM_IRQSTS[7] LOC_VALID_7	ELM_IRQEN[7] LOCATION_MASK_7	ELM_IRQ	Error-location interrupt for syndrome polynomial 7
ELM_IRQSTS[6] LOC_VALID_6	ELM_IRQEN[6] LOCATION_MASK_6	ELM_IRQ	Error-location interrupt for syndrome polynomial 6
ELM_IRQSTS[5] LOC_VALID_5	ELM_IRQEN[5] LOCATION_MASK_5	ELM_IRQ	Error-location interrupt for syndrome polynomial 5
ELM_IRQSTS[4] LOC_VALID_4	ELM_IRQEN[4] LOCATION_MASK_4	ELM_IRQ	Error-location interrupt for syndrome polynomial 4
ELM_IRQSTS[3] LOC_VALID_3	ELM_IRQEN[3] LOCATION_MASK_3	ELM_IRQ	Error-location interrupt for syndrome polynomial 3
ELM_IRQSTS[2] LOC_VALID_2	ELM_IRQEN[2] LOCATION_MASK_2	ELM_IRQ	Error-location interrupt for syndrome polynomial 2

**Table 9-334. Events (continued)**

Event Flag	Event Mask	Map to	Description
ELM_IRQSTS[1] LOC_VALID_1	ELM_IRQEN[1] LOCATION_MASK_1	ELM_IRQ	Error-location interrupt for syndrome polynomial 1
ELM_IRQSTS[0] LOC_VALID_0	ELM_IRQEN[0] LOCATION_MASK_0	ELM_IRQ	Error-location interrupt for syndrome polynomial 0

#### 9.4.3.4 Processing Initialization

ELM\_LOCATION\_CONFIG global setting parameters must be set before using the error-location engine. The ELM\_LOCATION\_CONFIG[1:0] ECC\_BCH\_LEVEL bit defines the error-correction level used (4-, 8-, or 16-bit error-correction). The ELM\_LOCATION\_CONFIG[26:16] ECC\_SIZE bit field defines the maximum buffer length beyond which the engine processing no longer looks for errors.

The CPU can choose to use the ELM in continuous mode or page mode. If all ELM\_PAGE\_CTRL[i] SECTOR\_i bits are reset (i is the syndrome polynomial number, i = 0 to 7), continuous mode is used. In any other case, page mode is implicitly selected.

- Continuous mode: Each syndrome polynomial is processed independently – results for a syndrome can be retrieved and acknowledged at any time, whatever the status of the other seven processing contexts.
- Page mode: Syndrome polynomials are grouped into atomic entities – only one page can be processed at any given time, even if all eight contexts are not used for this page. Unused contexts are lost and cannot be affected to any other processing. The full page must be acknowledged and cleared before moving to the next page.

For completion interrupts to be generated correctly, all ELM\_IRQEN[i] LOCATION\_MASK\_i bits (i = 0 to 7) must be forced to 0 when in page mode, and set to 1 in continuous mode. Additionally, the ELM\_IRQEN[8] PAGE\_MASK bit must be set to 1 when in page mode.

The CPU initiates error-location processing by writing a syndrome polynomial into one of the eight possible register sets. Each of these register sets includes seven registers: ELM\_SYNDROME\_FRAGMENT\_0\_i to ELM\_SYNDROME\_FRAGMENT\_6\_i. The first six registers can be written in any order, but ELM\_SYNDROME\_FRAGMENT\_6\_i must be written last because it includes the validity bit, which instructs the ELM that this syndrome polynomial must be processed (the ELM\_SYNDROME\_FRAGMENT\_6\_i[16] SYNDROME\_VALID bit).

As soon as one validity bit is asserted (ELM\_SYNDROME\_FRAGMENT\_6\_i[16] SYNDROME\_VALID = 0x1, with i = 0 to 7), error-location processing can start for the corresponding syndrome polynomial. The associated ELM\_LOCATION\_STS\_i and ELM\_ERROR\_LOCATION\_0\_i to ELM\_ERROR\_LOCATION\_15\_i registers are not reset (i = 0 to 7). The software must not consider them until the corresponding ELM\_IRQSTS[i] LOC\_VALID\_i bit is set.

#### 9.4.3.5 Processing Sequence

While the error-location engine is busy processing one syndrome polynomial, further syndrome polynomials can be written. They are processed when the current processing completes.

The engine completes early when:

- No error is detected; that is, when the ELM\_LOCATION\_STS\_i[8] ECC\_CORRECTABLE bit is set to 1 and the ELM\_LOCATION\_STS\_i[4:0] ECC\_NB\_ERRORS bit field is set to 0x0.
- Too many errors are detected; that is, when the ELM\_LOCATION\_STS\_i[8] ECC\_CORRECTABLE bit is set to 0 while the ELM\_LOCATION\_STS\_i[4:0] ECC\_NB\_ERRORS bit field is set with the value output by the error-location engine. The reported number of errors is not ensured if ECC\_CORRECTABLE is 0.

If the engine completes early, the associated error-location registers ELM\_ERROR\_LOCATION\_0\_i to ELM\_ERROR\_LOCATION\_15\_i are not updated (i = 0 to 7).

In all other cases, the engine goes through the entire error-location process. Each time an error-location is found, it is logged in the associated ECC\_ERROR\_LOCATION bit field. The first error detected is logged in the ELM\_ERROR\_LOCATION\_0\_i[12:0] ECC\_ERROR\_LOCATION bit field; the second in the ELM\_ERROR\_LOCATION\_1\_i[12:0] ECC\_ERROR\_LOCATION bit field, and so on.

**Table 9-335. ELM\_LOCATION\_STS\_i Value Decoding Table**

ECC_CORRECT ABLE Value	ECC_NB_ERRORS Value	Status	Number of Errors Detected	Action Required
1	0	OK	0	None
1	≠ 0	OK	ECC_NB_ERRORS	Correct the data buffer read based on the ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i results.
0	Any	Failed	Unknown	Software-dependant

#### 9.4.3.6 Processing Completion

When the processing for a given syndrome polynomial completes, its ELM\_SYNDROME\_FRAGMENT\_6\_i[16] SYNDROME\_VALID bit is reset. It must not be set again until the exit status registers, ELM\_LOCATION\_STS\_i (i = 0 to 7), for this processing are checked. Failure to comply with this rule leads to potential loss of the first polynomial process data output.

The error-location engine signals the process completion to the ELM. When this event is detected, the corresponding ELM\_IRQSTS[i] LOC\_VALID\_i bit is set (i = 0 to 7). The processing-exit status is available from the associated ELM\_LOCATION\_STS\_i register, and error locations are stored in order in the ECC\_ERROR\_LOCATION fields. The software must only read valid error-location registers based on the number of errors detected and located.

Immediately after the error-location engine completes, a new syndrome polynomial can be processed, if any is available, as reported by the ELM\_SYNDROME\_FRAGMENT\_6\_i[16] SYNDROME\_VALID validity bit, depending on the configured error-correction level. If several syndrome polynomials are available, a round-robin arbitration is used to select one for processing.

In continuous mode (that is, all bits in ELM\_PAGE\_CTRL are reset), an interrupt is triggered whenever a ELM\_IRQSTS[i] LOC\_VALID\_i bit is asserted. The CPU must read the ELM\_IRQSTS register to determine which polynomial is processed and retrieve the exit status and error locations (ELM\_LOCATION\_STS\_i and ELM\_ERROR\_LOCATION\_0\_i to ELM\_ERROR\_LOCATION\_15\_i). When done, the CPU must clear the corresponding ELM\_IRQSTS[i] LOC\_VALID\_i bit by writing it to 1. Other status bits must be written to 0 so that other interrupts are not unintentionally cleared. When using this mode, the ELM\_IRQSTS[8] PAGE\_VALID interrupt is never triggered.

In page mode, the module does not trigger interrupts for the processing completion of each polynomial because the ELM\_IRQEN[i] LOCATION\_MASK\_i bits are cleared. A page is defined using the ELM\_PAGE\_CTRL register. Each SECTOR\_i bit set means the corresponding polynomial i is part of the page processing. A page is fully processed when all tagged polynomials have been processed, as logged in the ELM\_IRQSTS[i] LOC\_VALID\_i bit fields. The module triggers an ELM\_IRQSTS[8] PAGE\_VALID interrupt whenever it detects that the full page has been processed. To make sure the next page can be correctly processed, all status bits in the ELM\_IRQSTS register must be cleared by using a single atomic-write access.

**NOTE:** Do not modify page setting parameters in the ELM\_PAGE\_CTRL register unless the engine is idle, no polynomial input is valid, and all interrupts have been cleared.

Because no polynomial-level interrupt is triggered in page mode, polynomials cleared in the ELM\_PAGE\_CTRL[i] SECTOR\_i bit fields (i = 0 to 7) are processed as usual, but are essentially ignored. The CPU must manually poll the ELM\_IRQSTS bits to check for their status.

## 9.4.4 Basic Programming Model

### 9.4.4.1 ELM Low Level Programming Model

#### 9.4.4.1.1 Processing Initialization

**Table 9-336. ELM Processing Initialization**

Step	Register/ Bit Field / Programming Model	Value
Resets the module	ELM_SYSCONFIG[1] SOFTRESET	0x1
Wait until reset is done.	ELM_SYSSTS[0] RESETDONE	0x1
Configure the slave interface power management.	ELM_SYSCONFIG[4:3] SIDLEMODE	Set value
Defines the error-correction level used	ELM_LOCATION_CONFIG[1:0] ECC_BCH_LEVEL	Set value
Defines the maximum buffer length	ELM_LOCATION_CONFIG[26:16] ECC_SIZE	Set value
Sets the ELM in continuous mode or page mode	ELM_PAGE_CTRL	Set value
<b>If</b> continuous mode is used	All ELM_PAGE_CTRL[i] SECTOR_i (i = 0 to 7)	0x0
Enables interrupt for syndrome polynomial i	ELM_IRQEN[i] LOCATION_MASK_i	0x1
<b>else</b> (page mode is used)	One syndrome polynomial i is set ELM_PAGE_CTRL[i] SECTOR_i (i = 0 to 7)	0x1
Disable all interrupts for syndrome polynomial and enable PAGE_MASK interrupt.	All ELM_IRQEN[i] LOCATION_MASK_i = 0x0 and ELM_IRQEN[8] PAGE_MASK = 0x1	Set value
<b>endif</b>		Set value
Set the input syndrome polynomial i.	ELM_SYNDROME_FRAGMENT_0_i	Set value
	ELM_SYNDROME_FRAGMENT_1_i	Set value
	ELM_SYNDROME_FRAGMENT_5_i	Set value
	ELM_SYNDROME_FRAGMENT_6_i	Set value
Initiates the computation process	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID	0x1

#### 9.4.4.1.2 Read Results

The engine goes through the entire error-location process and results can be read. [Table 9-337](#) and [Table 9-338](#) describe the processing completion for continuous and page modes, respectively.

**Table 9-337. ELM Processing Completion for Continuous Mode**

Step	Register/ Bit Field / Programming Model	Value
Wait until process is complete for syndrome polynomial i: Wait until the ELM_IRQ interrupt is generated, or poll the status register.		
Read for which i the error-location process is complete.	ELM_IRQSTS[i] LOC_VALID_i	0x1
<b>if</b> the process fails (too many errors)	ELM_LOCATION_STS_i[8] ECC_CORRECTABLE	0x0
It is software dependant.		
<b>else</b> (process successful, the engine completes)	ELM_LOCATION_STS_i[8] ECC_CORRECTABLE	0x1
Read the number of errors.	ELM_LOCATION_STS_i[4:0] ECC_NB_ERRORS	
Read the error-location bit addresses for syndrome polynomial i of the ECC_NB_ERRORS first registers. It is the software responsibility to correct errors in the data buffer.	ELM_ERROR_LOCATION_0_i[12:0] ECC_ERROR_LOCATION	
	ELM_ERROR_LOCATION_1_i[12:0] ECC_ERROR_LOCATION	
	...	
	ELM_ERROR_LOCATION_15_i[12:0] ECC_ERROR_LOCATION	

**Table 9-337. ELM Processing Completion for Continuous Mode (continued)**

Step	Register/ Bit Field / Programming Model	Value
<b>endif</b>		
Clear the corresponding i interrupt.	ELM_IRQSTS[i] LOC_VALID_i	0x1

A new syndrome polynomial can be processed after the end of processing (ELM\_SYNDROME\_FRAGMENT\_6\_i[16] SYNDROME\_VALID = 0x0) and after the exit status register check (ELM\_LOCATION\_STS\_i).

**Table 9-338. ELM Processing Completion for Page Mode**

Step	Register/ Bit Field / Programming Model	Value
Wait until process is complete for syndrome polynomial i: Wait until the ELM_IRQ interrupt is generated, or poll the status register.		
Wait for page completed interrupt: All error locations are valid.	ELM_IRQSTS[8] PAGE_VALID	0x1
<b>Repeat</b> the following actions the necessary number of times. That is, once for each valid defined block in the page.		
Read the process exit status.	ELM_LOCATION_STS_i[8] ECC_CORRECTABLE	
<b>if</b> the process fails (too many errors)	ELM_LOCATION_STS_i[8] ECC_CORRECTABLE	0x0
It is software dependant.		
<b>else</b> (process successful, the engine completes)	ELM_LOCATION_STS_i[8] ECC_CORRECTABLE	0x1
Read the number of errors.	ELM_LOCATION_STS_i[4:0] ECC_NB_ERRORS	
Read the error-location bit addresses for syndrome polynomial i of the ECC_NB_ERRORS first registers.	ELM_ERROR_LOCATION_0_i[12:0] ECC_ERROR_LOCATION	
	ELM_ERROR_LOCATION_1_i[12:0] ECC_ERROR_LOCATION	
	...	
	ELM_ERROR_LOCATION_15_i[12:0] ECC_ERROR_LOCATION	
<b>endif</b>		
<b>End Repeat</b>		
Clear the ELM_IRQSTS register.	ELM_IRQSTS	0x1FF

Next page can be correctly processed after a page is fully processed, when all tagged polynomials have been processed (ELM\_IRQSTS[i] LOC\_VALID\_i = 0x1 for all syndrome polynomials i used in the page).

#### 9.4.4.2 Use Case: ELM Used in Continuous Mode

In this example, the ELM module is programmed for an 8-bit error-correction capability in continuous mode. After reading a 528-byte NAND flash sector (512B data plus 16B spare area) with a 16-bit interface, a non-zero polynomial syndrome is reported from the GPMC (Polynomial syndrome 0 is used in the ELM):

- P = 0x0A16ABE115E44F767BFB0D0980

**Table 9-339. Use Case: Continuous Mode**

Step	Register/ Bit Field / Programming Model	Value
Resets the module	ELM_SYSCONFIG[1] SOFTRESET	0x1
Wait until reset is done.	ELM_SYSSTS[0] RESETDONE	0x1
Configure the slave interface power management: Smart idle is used.	ELM_SYSCONFIG[4:3] SIDLEMODE	0x2
Defines the error-correction level used: 8 bits	ELM_LOCATION_CONFIG[1:0] ECC_BCH_LEVEL	0x1

**Table 9-339. Use Case: Continuous Mode (continued)**

Step	Register/ Bit Field / Programming Model	Value
Defines the maximum buffer length: 528 bytes (2x528 = 1056)	ELM_LOCATION_CONFIG[26:16] ECC_SIZE	0x420
Sets the ELM in continuous mode	ELM_PAGE_CTRL	0
Enables interrupt for syndrome polynomial 0	ELM_IRQEN[0] LOCATION_MASK_0	0x1
Set the input syndrome polynomial 0.	ELM_SYNDROME_FRAGMENT_0_i (i=0)	0xFB0D0980
	ELM_SYNDROME_FRAGMENT_1_i (i=0)	0xE44F767B
	ELM_SYNDROME_FRAGMENT_2_i (i=0)	0x16ABE115
	ELM_SYNDROME_FRAGMENT_3_i (i=0)	0x0000000A
Initiates the computation process	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID (i=0)	0x1
Wait until process is complete for syndrome polynomial 0: IRQ_ELM is generated or poll the status register.		
Read that error-location process is complete for syndrome polynomial 0.	ELM_IRQSTS[0] LOC_VALID_0	0x1
Read the process exit status: All errors were successfully located.	ELM_LOCATION_STS_i[8] ECC_CORRECTABLE (i=0)	0x1
Read the number of errors: Four errors detected.	ELM_LOCATION_STS_i[4:0] ECC_NB_ERRORS (i=0)	0x4
Read the error-location bit addresses for syndrome polynomial 0 of the 4 first registers: Errors are located in the data buffer at decimal addresses 431, 1062, 1909, 3452.	ELM_ERROR_LOCATION_0_i (i=0)	0x1AF
	ELM_ERROR_LOCATION_1_i (i=0)	0x426
	ELM_ERROR_LOCATION_2_i (i=0)	0x775
	ELM_ERROR_LOCATION_3_i (i=0)	0xD7C
Clear the corresponding interrupt for polynomial 0.	ELM_IRQSTS[0] LOC_VALID_0	0x1

The NAND flash data in the sector are seen as a polynomial of degree 4223 (number of bits in a 528 byte buffer minus 1), with each data bit being a coefficient in the polynomial. When reading from a NAND flash using the GPMC module, computation of the polynomial syndrome assumes that the first NAND word read at address 0x0 contains the highest-order coefficient in the message. Furthermore, in the 16-bit NAND word, bits are ordered from bit 7 to bit 0, then from bit 15 to bit 8. Based on this convention, an address table of the data buffer can be built. NAND memory addresses in [Table 9-340](#) are given in decimal format.

**Table 9-340. 16-bit NAND Sector Buffer Address Map**

NAND Memory Address	Message bit addresses in the memory word															
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	4215	4214	4213	4212	4211	4210	4209	4208	4223	4222	4221	4220	4219	4218	4217	4216
1	4175	4174	4173	4172	4171	4170	4169	4168	4183	4182	4181	4180	4179	4178	4177	4176
...																
47	3463	3462	3461	3460	3459	3458	3457	3456	3471	3470	3469	3468	3467	3466	3465	3464
48	3447	3446	3445	3444	3443	3442	3441	3440	3455	3454	3453	3452	3451	3450	3449	3448
49	3431	3430	3429	3428	3427	3426	3425	3424	3439	3438	3437	3436	3435	3434	3433	3432
50	3415	3414	3413	3412	3411	3410	3409	3408	3423	3422	3421	3420	3419	3418	3417	3416
...																
255	135	134	133	132	131	130	129	128	143	142	141	140	139	138	137	136
256	119	118	117	116	115	114	113	112	127	126	125	124	123	122	121	120
257	103	102	101	100	99	98	97	96	111	110	109	108	107	106	105	104
258	87	86	85	84	83	82	81	80	95	94	93	92	91	90	89	88
259	71	70	69	68	67	66	65	64	79	78	77	76	75	74	73	72
260	55	54	53	52	51	50	49	48	63	62	61	60	59	58	57	56
261	39	38	37	36	35	34	33	32	47	46	45	44	43	42	41	40
262	23	22	21	20	19	18	17	16	31	30	29	28	27	26	25	24
263	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8

The table can now be used to determine which bits in the buffer were incorrect and must be flipped. In this example, the first bit to be flipped is bit 4 from the 49th byte read from memory. It is up to the processor to correctly map this word to the copied buffer and to flip this bit. The same process must be repeated for all detected errors.

#### 9.4.4.3 Use Case: ELM Used in Page Mode

In this example, the ELM module is programmed for an 16-bit error-correction capability in page mode. After reading a 528-byte NAND flash sector (512B data plus 16B spare area) with a 16-bit interface, four non-zero polynomial syndromes are reported from the GPMC (Polynomial syndrome 0, 1, 2, and 3 are used in the ELM):

- P0 = 0xE8B0 12ADDB5A318E05BE B0693DB28330B5CC A329AA05E0B718EF
- P1 = 0xBAD0 49A0D932C22E6669 0948DF08BE093336 79C6BA10E5F935EB
- P2 = 0x69D9 B86ABCD5EC3697FA A6498FEE54556EA0 1579EF7D60BA3189
- P3 = 0x0

**Table 9-341. Use Case: Page Mode**

Step	Register/ Bit Field / Programming Model	Value
Resets the module	ELM_SYSCONFIG[1] SOFTRESET	0x1
Wait until reset is done.	ELM_SYSSTS[0] RESETDONE	0x1
Configure the slave interface power management: Smart idle is used.	ELM_SYSCONFIG[4:3] SIDLEMODE	0x2
Defines the error-correction level used: 16 bits	ELM_LOCATION_CONFIG[1:0] ECC_BCH_LEVEL	0x2
Defines the maximum buffer length: 528 bytes	ELM_LOCATION_CONFIG[26:16] ECC_SIZE	0x420
Sets the ELM in page mode (4 blocks in a page)	ELM_PAGE_CTRL[0] SECTOR_0	0x1
	ELM_PAGE_CTRL[1] SECTOR_1	0x1
	ELM_PAGE_CTRL[2] SECTOR_2	0x1
	ELM_PAGE_CTRL[3] SECTOR_3	0x1

**Table 9-341. Use Case: Page Mode (continued)**

Step	Register/ Bit Field / Programming Model	Value
Disable all interrupts for syndrome polynomial and enable PAGE_MASK interrupt.	ELM_IRQEN	0x100
Set the input syndrome polynomial 0.	ELM_SYNDROME_FRAGMENT_0_i (i=0)	0xE0B718EF
	ELM_SYNDROME_FRAGMENT_1_i (i=0)	0xA329AA05

Initiates the computation process for syndrome polynomial 0	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID (i=0)	0x1
Initiates the computation process for syndrome polynomial 1	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID (i=1)	0x1
Initiates the computation process for syndrome polynomial 2	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID (i=2)	0x1
Initiates the computation process for syndrome polynomial 3	ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID (i=3)	0x1
Wait until process is complete for syndrome polynomial 0, 1, 2, and 3: Wait until the ELM_IRQ interrupt is generated or poll the status register.		
Wait for page completed interrupt: All error locations are valid.	ELM_IRQSTS[8] PAGE_VALID	0x1
Read the process exit status for syndrome polynomial 0: All errors were successfully located.	ELM_LOCATION_STS_i[8] ECC_CORRECTABLE (i=0)	0x1
Read the process exit status for syndrome polynomial 1: All errors were successfully located.	ELM_LOCATION_STS_i[8] ECC_CORRECTABLE (i=1)	0x1

**Table 9-341. Use Case: Page Mode (continued)**

Step	Register/ Bit Field / Programming Model	Value
Read the process exit status for syndrome polynomial 2: All errors were successfully located.	ELM_LOCATION_STS_i[8] ECC_CORRECTABLE (i=2)	0x1
Read the process exit status for syndrome polynomial 3: All errors were successfully located.	ELM_LOCATION_STS_i[8] ECC_CORRECTABLE (i=3)	0x1
Read the number of errors for syndrome polynomial 0: 4 errors detected.	ELM_LOCATION_STS_i[4:0] ECC_NB_ERRORS (i=0)	0x4
Read the number of errors for syndrome polynomial 1: 2 errors detected.	ELM_LOCATION_STS_i[4:0] ECC_NB_ERRORS (i=1)	0x2
Read the number of errors for syndrome polynomial 2: 1 error detected.	ELM_LOCATION_STS_i[4:0] ECC_NB_ERRORS (i=2)	0x1
Read the number of errors for syndrome polynomial 3: 0 errors detected.	ELM_LOCATION_STS_i[4:0] ECC_NB_ERRORS (i=3)	0x0
Read the error-location bit addresses for syndrome polynomial 0 of the 4 first registers:	ELM_ERROR_LOCATION_0_i (i=0)	0x1FE
	ELM_ERROR_LOCATION_1_i (i=0)	0x617
	ELM_ERROR_LOCATION_2_i (i=0)	0x650
	ELM_ERROR_LOCATION_3_i (i=0)	0xA83
Read the error-location bit addresses for syndrome polynomial 1 of the 2 first registers:	ELM_ERROR_LOCATION_0_i (i=1)	0x104E
	ELM_ERROR_LOCATION_1_i (i=1)	0x4
Read the errors location bit addresses for syndrome polynomial 2 of the first registers:	ELM_ERROR_LOCATION_0_i (i=1)	0x3E8
Clear the ELM_IRQSTS register.	ELM_IRQSTS	0x1FF

## 9.4.5 ELM Registers

Table 9-342 lists the memory-mapped registers for the ELM. All register offset addresses not listed in Table 9-342 should be considered as reserved locations and the register contents should not be modified.

**Table 9-342. ELM Registers**

Offset	Acronym	Register Name	Section
0h	ELM_REVISION	ELM Revision Register	<a href="#">Section 9.4.5.1</a>
10h	ELM_SYSCONFIG	ELM System Configuration Register	<a href="#">Section 9.4.5.2</a>
14h	ELM_SYSSTS	ELM System Status Register	<a href="#">Section 9.4.5.3</a>

#### 9.4.5.1 ELM\_REVISION Register (offset = 0h) [reset = 0h]

ELM\_REVISION is shown in [Figure 9-309](#) and described in [Table 9-343](#).

This register contains the IP revision code.

**Figure 9-309. ELM\_REVISION Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bit	Field	Type	Reset	Description
31-0	REVISION	R	0h	IP Revision, value 0 to FFFF FFFFh.

### 9.4.5.2 ELM\_SYSCONFIG Register (offset = 10h) [reset = 11h]

ELM\_SYSCONFIG is shown in [Figure 9-310](#) and described in [Table 9-344](#).

This register allows controlling various parameters of the OCP interface.

**Figure 9-310. ELM\_SYSCONFIG Register**

31	30	29	28	27	26	25	24
RESERVED							
R-0h							
23	22	21	20	19	18	17	16

R-0h			R/W-2h		R-0h	R/W-0h	R/W-1h

**Table 9-344. ELM\_SYSCONFIG Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-9	RESERVED	R	0h	
8	CLOCKACTIVITYOCPZ	R/W	0h	OCP Clock activity when module is in IDLE mode (during wake up mode period). 0h (R/W) = OCP Clock can be switch-off 1h (R/W) = OCP Clock is maintained during wake up period
7-5	RESERVED	R	0h	
4-3	SIDLEMODE	R/W	2h	Slave interface power management (IDLE req/ack control). 0h (R/W) = FORCE Idle. IDLE request is acknowledged unconditionally and immediately. (Default Dumb mode for safety) 1h (R/W) = NO idle. IDLE request is never acknowledged. 2h (R/W) = SMART Idle. The acknowledgment to an IDLE request is given based on the internal activity. 3h (R/W) = Reserved - do not use
2	RESERVED	R	0h	
1	SOFTRESET	R/W	0h	Module software reset. This bit is automatically reset by hardware (During reads, it always returns 0.). It has same effect as the OCP hardware reset. 0h (R/W) = Normal mode. 1h (R/W) = Start soft reset sequence.
0	AUTOGATING	R/W	1h	Internal OCP clock gating strategy. (No module visible impact other than saving power.) 0h (R/W) = OCP clock is free-running. 1h (R/W) = Automatic internal OCP clock gating strategy is applied based on the OCP interface activity.

### 9.4.5.3 ELM\_SYSSTS Register (offset = 14h) [reset = 0h]

ELM\_SYSSTS is shown in [Figure 9-311](#) and described in [Table 9-345](#).

**Figure 9-311. ELM\_SYSSTS Register**

**Table 9-345. ELM\_SYSSTS Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	RESERVED	R	0h	
0	RESETDONE	R	0h	Internal reset monitoring (OCP domain). Undefined since: From hardware perspective, the reset state is 0. From software user perspective, when the accessible module is 1. 0h (R/W) = Reset is on-going 1h (R/W) = Reset is done (completed)

#### 9.4.5.4 ELM\_IRQSTS Register (offset = 18h) [reset = 0h]

ELM\_IRQSTS is shown in [Figure 9-312](#) and described in [Table 9-346](#).

This register doubles as a status register for the error-location processes.

## ***Enhanced Direct Memory Access (EDMA)***

---

---

This chapter describes the EDMA of the device.

<b>Topic</b>	<b>Page</b>
<b>10.1 Introduction .....</b>	<b>1564</b>
<b>10.2 Integration .....</b>	<b>1567</b>
<b>10.3 Functional Description .....</b>	<b>1570</b>
<b>10.4 Registers .....</b>	<b>1633</b>
<b>10.5 Appendix A .....</b>	<b>1778</b>

## 10.1 Introduction

The enhanced direct memory access (EDMA3) controller's primary purpose is to service user-programmed data transfers between two memory-mapped slave endpoints on the device.

Typical usage includes, but is not limited to the following:

- Servicing software-driven paging transfers (e.g., transfers from external memory to internal device memory).
- Servicing event-driven peripherals, such as a serial port.
- Performing sorting or sub-frame extraction of various data structures.
- Offloading data transfers from the main device CPU(s).

The EDMA3 controller consists of two principal blocks:

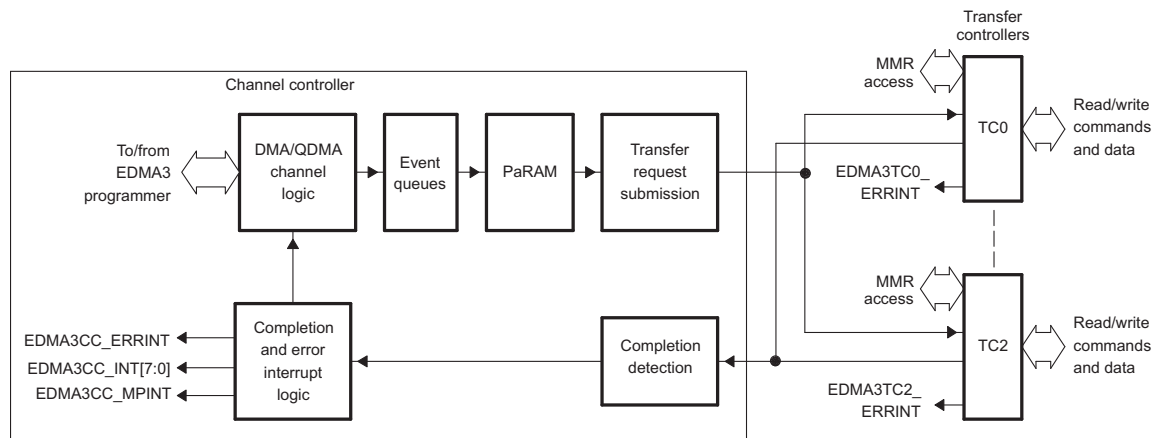

- EDMA3 channel controller (EDMA3CC).
- EDMA3 transfer controller(s) (EDMA3TC).

The EDMA3 channel controller serves as the user interface for the EDMA3 controller. The EDMA3CC includes parameter RAM (PaRAM), channel control registers, and interrupt control registers. The EDMA3CC serves to prioritize incoming software requests or events from peripherals and submits transfer requests (TRs) to the transfer controller.

The EDMA3 transfer controllers are slaves to the EDMA3 channel controller that is responsible for data movement. The transfer controller issues read/write commands to the source and destination addresses that are programmed for a given transfer. The operation is transparent to user.

### 10.1.1 EDMA3 Controller Block Diagram

Figure 10-1 shows a block diagram for the EDMA3 controller.

## 10.1.2 Third-Party Channel Controller (TPCC) Overview

### 10.1.2.1 TPCC Features

The general features of the TPCC module are:

- Up to 64 DMA Channels
  - Channels triggered by:
    - Event Synchronization
    - Manual Synchronization (CPU write to 'Event Set Register')
    - Chain Synchronization (completion of one transfer chains to the next)
  - Parameterizable support for programmable DMA Channel to PaRAM mapping
- Up to 8 QDMA Channels
  - QDMA Channels are triggered automatically upon writing to PaRAM
  - Support for programmable QDMA Channel to PaRAM mapping
- Up to 64 Event Inputs
- Up to 8 Interrupt outputs for multi-core support
- Up to 256 PaRAM entries
  - Each PaRAM entry can be used as DMA Entry (up to 64), QDMA Entry (up to 8), or Link Entry (remaining)
- 8 Priority Levels for mapping CC/TC priority relative to priority of other masters in the system.
- Up to 3 Event Queues
- 16 Event Entries per Event Queue
- Supports three-transfer dimensions
  - A-synchronized transfers—one dimension serviced per event
  - AB-synchronized transfers—two dimensions serviced per event
  - Independent Indexes on Source and Destination
  - Does not support direct submission of 3D transfer to TC
  - Chaining feature allows 3D transfer based on single event
- Increment and FIFO transfer addressing modes (TC feature)
- Linking mechanism allows automatic PaRAM Entry update
- Transfer Completion Signaling between TC and CC for Chaining and Interrupt generation.
- Programmable assignment of Priority to TC channel.
- Proxied Memory Protection for TR submission
- Parameterizable support for Active Memory Protection for accesses to PaRAM and registers.
- Queue Watermarking
- Missed Event Detection
- Error and status recording to facilitate debug
- Single Clock domain for all interfaces
- Parameterizable number of Write Completion interfaces (up to 8) (set to number of TC Channels)
- AET Event generation

### 10.1.2.2 Unsupported TPCC Features

This device does not support AET event generation because output is not connected.

### **10.1.3 Third-Party Transfer Controller (TPTC) Overview**

#### **10.1.3.1 TPTC Features**

The TPTC module includes the following features:

- Up to eight independent channels
- External event control use model (TPCC)
- Read and Write Master ports per Channel 64- or 128-bit configuration.
- Parameterizable FIFO size
- Up to four in-flight Transfer Requests
- Proxied Memory protection for data transfers
- Programmable Priority levels (up to 8)
- Background programming capability
- Supports 2-dimensional transfers with independent indexes on Source and Destination.
- Support for increment or FIFO-mode transfers
- Interrupt and error support
- Single clock domain for all interfaces

#### **10.1.3.2 Unsupported TPTC Features**

There are no unsupported TPTC features on this device.

## 10.2 Integration

### 10.2.1 Third-Party Channel Controller (TPCC) Integration

This device uses the TPCC peripheral to provide control over its third-party transfer channels (TPTCs). [Figure 10-2](#) shows the integration of the TPCC module.

**Figure 10-2. TPCC Integration**

#### 10.2.1.1 TPCC Connectivity Attributes

The general connectivity attributes of the TPCC are summarized in [Table 10-1](#).

**Table 10-1. TPCC Connectivity Attributes**

Attributes	Type
Power domain	Peripheral Domain
Clock domain	PD_PER_L3_GCLK
Reset signals	PER_DOM_RST_N
Idle/Wakeup signals	Smart Idle
Interrupt request	4 Regional Completion Interrupts: int_pend_po0 (EDMACOMPINT) – to MPU Subsystem int_pend_po1 (tpcc_int_pend_po1) – to PRU-ICSS Int_pend_po[3:2] - unused Error Interrupt: errint_po (EDMAERRINT) – to MPU Subsystem, PRU-ICSS Memory Protection Error Interrupt: mpint_p0 (EDMAMPERR) – to MPU Subsystem
DMA request	none
Physical address	L3 Fast slave port

#### 10.2.1.2 TPCC Clock and Reset Management

The TPCC operates from a single clock and runs at the L3\_Fast clock rate.

**Table 10-2. TPCC Clock Signals**

Clock Signal	Max Freq	Reference / Source	Comments
tpcc_clk_pi Interface / Functional clock	200 MHz	CORE_CLKOUTM4	pd_per_l3_gclk From PRCM

### 10.2.1.3 TPCC Pin List

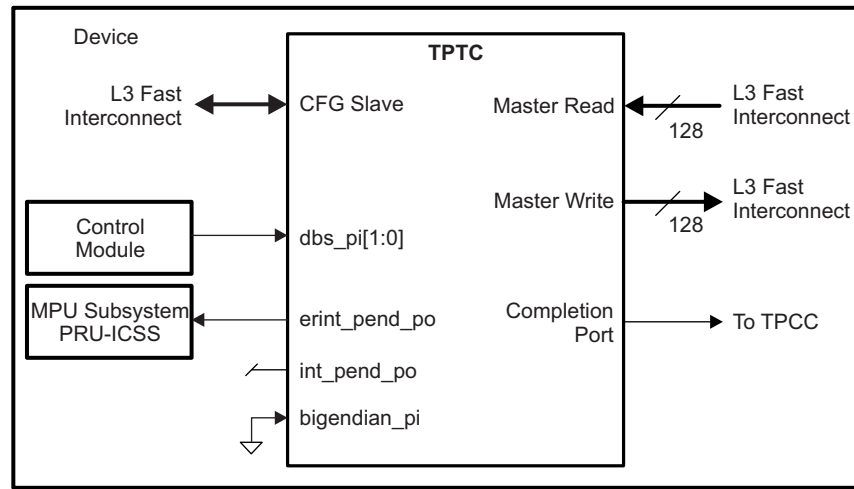

The TPCC module does not include any external interface pins.

## 10.2.2 Third-Party Transfer Controller (TPTC) Integration

This device uses three TPTC peripherals, TC0–TC2, to perform EDMA transfers between slave peripherals. TC3 is not supported.

The submission of transfer requests to the TPTCs is controlled by the TPCC. [Figure 10-3](#) shows the integration of the TPTC modules

**Figure 10-3. TPTC Integration**

### 10.2.2.1 TPTC Connectivity Attributes

The general connectivity attributes for the TPTCs are shown in [Table 10-3](#).

**Table 10-3. TPTC Connectivity Attributes**

Attributes	Type
Power domain	Peripheral Domain
Clock domain	PD_PER_L3_GCLK
Reset signals	PER_DOM_RST_N
Idle/Wakeup signals	Standby (2 ports) Smart Idle
Interrupt request	Error interrupt per instance erint_pend_po (TCERRINTx) – to MPU Subsystem and PRU-ICSS (tpc_erint_pend_po, TPTC0 only)
DMA request	none
Physical address	L3 Fast slave port

### 10.2.2.2 TPTC Clock and Reset Management

The TPTC operates from a single clock and runs at the L3\_Fast clock rate.

**Table 10-4. TPTC Clock Signals**

Clock Signal	Max Freq	Reference / Source	Comments
tpc_clk_pi Interface / Functional clock	200 MHz	CORE_CLKOUTM4	pd_per_l3_gclk From PRCM

### 10.2.2.3 TPTC Pin List

The TPTC module does not include any external interface pins.

## 10.3 Functional Description

This chapter discusses the architecture of the EDMA3 controller.

### 10.3.1 Functional Overview

#### 10.3.1.1 EDMA3 Channel Controller (EDMA3CC)

[Figure 10-4](#) shows a functional block diagram of the EDMA3 channel controller (EDMA3CC).

The main blocks of the EDMA3CC are as follows:

- **Parameter RAM (PaRAM):** The PaRAM maintains parameter sets for channel and reload parameter sets. You must write the PaRAM with the transfer context for the desired channels and link parameter sets. EDMA3CC processes sets based on a trigger event and submits a transfer request (TR) to the transfer controller.
- **EDMA3 event and interrupt processing registers:** Allows mapping of events to parameter sets, enable/disable events, enable/disable interrupt conditions, and clearing interrupts.
- **Completion detection:** The completion detect block detects completion of transfers by the EDMA3TC and/or slave peripherals. You can optionally use completion of transfers to chain trigger new transfers or to assert interrupts.
- **Event queues:** Event queues form the interface between the event detection logic and the transfer request submission logic.
- **Memory protection registers:** Memory protection registers define the accesses (privilege level and requestor(s)) that are allowed to access the DMA channel shadow region view(s) and regions of PaRAM.

Other functions include the following:

- **Region registers:** Region registers allow DMA resources (DMA channels and interrupts) to be assigned to unique regions that different EDMA3 programmers own (for example, ARM).
- **Debug registers:** Debug registers allow debug visibility by providing registers to read the queue status, controller status, and missed event status.

The EDMA3CC includes two channel types: DMA channels (64 channels) and QDMA channels (8 channels).

Each channel is associated with a given event queue/transfer controller and with a given PaRAM set. The main thing that differentiates a DMA channel from a QDMA channel is the method that the system uses to trigger transfers. See [Section 10.3.4](#).

**Figure 10-4. EDMA3 Channel Controller (EDMA3CC) Block Diagram**

A trigger event is needed to initiate a transfer. A trigger event may be due to an external event, manual write to the event set register, or chained event for DMA channels. QDMA channels auto-trigger when a write to the trigger word that you program occurs on the associated PaRAM set. All such trigger events are logged into appropriate registers upon recognition.

Once a trigger event is recognized, the appropriate event gets queued in the EDMA3CC event queue. The assignment of each DMA/QDMA channel to an event queue is programmable. Each queue is 16 events deep; therefore, you can queue up to 16 events (on a single queue) in the EDMA3CC at a time. Additional pending events that are mapped to a full queue are queued when the event queue space becomes available. See [Section 10.3.11](#).

If events on different channels are detected simultaneously, the events are queued based on a fixed priority arbitration scheme with the DMA channels being higher priority events than the QDMA channels. Among the two groups of channels, the lowest-numbered channel is the highest priority.

Each event in the event queue is processed in FIFO order. When the head of the queue is reached, the PaRAM associated with that channel is read to determine the transfer details. The TR submission logic evaluates the validity of the TR and is responsible for submitting a valid transfer request (TR) to the appropriate EDMA3TC (based on the event queue to the EDMA3TC association, Q0 goes to TC0, Q1 goes to TC1, Q2 goes to TC2, and Q3 goes to TC3). For more information, refer to [Section 10.3.3](#).

The EDMA3TC receives the request and is responsible for data movement, as specified in the transfer request packet (TRP), other necessary tasks like buffering, and ensuring transfers are carried out in an optimal fashion wherever possible. For more information on EDMA3TC, refer to [Section 10.3.1.2](#).

If you have decided to receive an interrupt or to chain to another channel on completion of the current transfer, the EDMA3TC signals completion to the EDMA3CC completion detection logic when the transfer is complete. You can alternately choose to trigger completion when a TR leaves the EDMA3CC boundary, rather than wait for all of the data transfers to complete. Based on the setting of the EDMA3CC interrupt registers, the completion interrupt generation logic is responsible for generating EDMA3CC completion interrupts to the CPU. For more information, refer to [Section 10.3.5](#).

Additionally, the EDMA3CC also has an error detection logic that causes an error interrupt generation on various error conditions (like missed events, exceeding event queue thresholds, etc.). For more information on error interrupts, refer to [Section 10.3.9.4](#).

### 10.3.1.2 EDMA3 Transfer Controller (EDMA3TC)

[Section 10.3.9.4](#) shows a functional block diagram of the EDMA3 transfer controller (EDMA3TC).

**Figure 10-5. EDMA3 Transfer Controller (EDMA3TC) Block Diagram**

The main blocks of the EDMA3TC are:

- **DMA program register set:** The DMA program register set stores the transfer requests received from the EDMA3 channel controller (EDMA3CC).
- **DMA source active register set:** The DMA source active register set stores the context for the DMA transfer request currently in progress in the read controller.
- **Read controller:** The read controller issues read commands to the source address.
- **Destination FIFO register set:** The destination (DST) FIFO register set stores the context for the DMA transfer request(s) currently in progress in the write controller.
- **Write controller:** The write controller issues write commands/write data to the destination slave.
- **Data FIFO:** The data FIFO exists for holding temporary in-flight data.
- **Completion interface:** The completion interface sends completion codes to the EDMA3CC when a transfer completes, and generates interrupts and chained events (also, see [Section 10.3.1.1](#) for more information on transfer completion reporting).

When the EDMA3TC is idle and receives its first TR, DMA program register set receives the TR, where it transitions to the DMA source active set and the destination FIFO register set immediately. The second TR (if pending from EDMA3CC) is loaded into the DMA program set, ensuring it can start as soon as possible when the active transfer completes. As soon as the current active set is exhausted, the TR is loaded from the DMA program register set into the DMA source active register set as well as to the appropriate entry in the destination FIFO register set.

The read controller issues read commands governed by the rules of command fragmentation and optimization. These are issued only when the data FIFO has space available for the data read. When sufficient data is in the data FIFO, the write controller starts issuing a write command again following the rules for command fragmentation and optimization. For more information on command fragmentation and optimization, refer to [Section 10.3.12.1.1](#).

Depending on the number of entries, the read controller can process up to two or four transfer requests ahead of the destination subject to the amount of free data FIFO.

### 10.3.2 Types of EDMA3 Transfers

An EDMA3 transfer is always defined in terms of three dimensions. [Figure 10-6](#) shows the three dimensions used by EDMA3 transfers. These three dimensions are defined as:

- 1st Dimension or Array (A): The 1st dimension in a transfer consists of ACNT contiguous bytes.
- 2nd Dimension or Frame (B): The 2nd dimension in a transfer consists of BCNT arrays of ACNT bytes. Each array transfer in the 2nd dimension is separated from each other by an index programmed using SRCBIDX or DSTBIDX.
- 3rd Dimension or Block (C): The 3rd dimension in a transfer consists of CCNT frames of BCNT arrays of ACNT bytes. Each transfer in the 3rd dimension is separated from the previous by an index programmed using SRCCIDX or DSTCIDX.

Note that the reference point for the index depends on the synchronization type. The amount of data transferred upon receipt of a trigger/synchronization event is controlled by the synchronization types (SYNCDIM bit in OPT). Of the three dimensions, only two synchronization types are supported: A-synchronized transfers and AB-synchronized transfers.

**Figure 10-6. Definition of ACNT, BCNT, and CCNT**

### 10.3.2.1 A-Synchronized Transfers

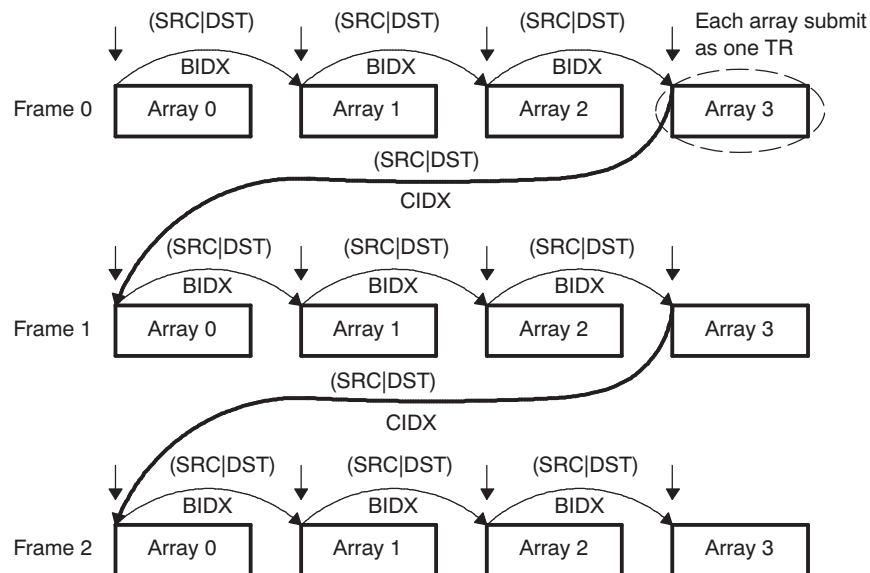

In an A-synchronized transfer, each EDMA3 sync event initiates the transfer of the 1st dimension of ACNT bytes, or one array of ACNT bytes. In other words, each event/TR packet conveys the transfer information for one array only. Thus, BCNT  $\times$  CCNT events are needed to completely service a PaRAM set.

Arrays are always separated by SRCBIDX and DSTBIDX, as shown in [Figure 10-7](#), where the start address of Array N is equal to the start address of Array N – 1 plus source (SRC) or destination (DST) BIDX.

Frames are always separated by SRCCIDX and DSTCIDX. For A-synchronized transfers, after the frame is exhausted, the address is updated by adding SRCCIDX/DSTCIDX to the beginning address of the last array in the frame. As in [Figure 10-7](#), SRCCIDX/DSTCIDX is the difference between the start of Frame 0 Array 3 to the start of Frame 1 Array 0.

[Figure 10-7](#) shows an A-synchronized transfer of 3 (CCNT) frames of 4 (BCNT) arrays of n (ACNT) bytes. In this example, a total of 12 sync events (BCNT  $\times$  CCNT) exhaust a PaRAM set. See [Section 10.3.3.6](#) for details on parameter set updates.

**Figure 10-7. A-Synchronized Transfers (ACNT = n, BCNT = 4, CCNT = 3)**

### 10.3.2.2 AB-Synchronized Transfers

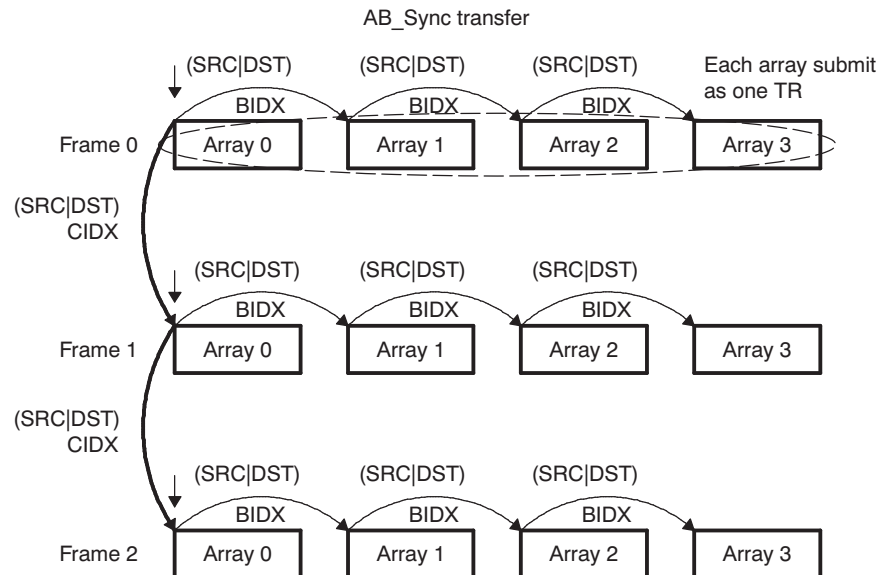

In a AB-synchronized transfer, each EDMA3 sync event initiates the transfer of 2 dimensions or one frame. In other words, each event/TR packet conveys information for one entire frame of BCNT arrays of ACNT bytes. Thus, CCNT events are needed to completely service a PaRAM set.

Arrays are always separated by SRCBIDX and DSTBIDX as shown in Figure 10-8. Frames are always separated by SRCCIDX and DSTCIDX.

Note that for AB-synchronized transfers, after a TR for the frame is submitted, the address update is to add SRCCIDX/DSTCIDX to the beginning address of the beginning array in the frame. This is different from A-synchronized transfers where the address is updated by adding SRCCIDX/DSTCIDX to the start address of the last array in the frame. See Section 10.3.3.6 for details on parameter set updates.

Figure 10-8 shows an AB-synchronized transfer of 3 (CCNT) frames of 4 (BCNT) arrays of  $n$  (ACNT) bytes. In this example, a total of 3 sync events (CCNT) exhaust a PaRAM set; that is, a total of 3 transfers of 4 arrays each completes the transfer.

**Figure 10-8. AB-Synchronized Transfers (ACNT =  $n$ , BCNT = 4, CCNT = 3)**

**NOTE:** ABC-synchronized transfers are not directly supported. But can be logically achieved by chaining between multiple AB-synchronized transfers.

### 10.3.3 Parameter RAM (PaRAM)

The EDMA3 controller is a RAM-based architecture. The transfer context (source/destination addresses, count, indexes, etc.) for DMA or QDMA channels is programmed in a parameter RAM table within EDMA3CC, referred to as PaRAM. The PaRAM table is segmented into multiple PaRAM sets. Each PaRAM set includes eight four-byte PaRAM set entries (32-bytes total per PaRAM set), which includes typical DMA transfer parameters such as source address, destination address, transfer counts, indexes, options, etc.

The PaRAM structure supports flexible ping-pong, circular buffering, channel chaining, and auto-reloading (linking).

The contents of the PaRAM include the following:

- 256 PaRAM sets
- 64 channels that are direct mapped and can be used as link or QDMA sets if not used for DMA channels
- 64 channels remain for link or QDMA sets

By default, all channels map to PaRAM set to 0. These should be remapped before use. For more information, see DCHMAP registers and QCHMAP registers.

**Table 10-5. EDMA3 Parameter RAM Contents**

PaRAM Set Number	Address	Parameters
0	EDMA Base Address + 4000h to EDMA Base Address + 401Fh	PaRAM set 0
1	EDMA Base Address + 4020h to EDMA Base Address + 403Fh	PaRAM set 1
2	EDMA Base Address + 4040h to EDMA Base Address + 405Fh	PaRAM set 2
3	EDMA Base Address + 4060h to EDMA Base Address + 407Fh	PaRAM set 3
4	EDMA Base Address + 4080h to EDMA Base Address + 409Fh	PaRAM set 4
5	EDMA Base Address + 40A0h to EDMA Base Address + 40BFh	PaRAM set 5
6	EDMA Base Address + 40C0h to EDMA Base Address + 40DFh	PaRAM set 6
7	EDMA Base Address + 40E0h to EDMA Base Address + 40FFh	PaRAM set 7
8	EDMA Base Address + 4100h to EDMA Base Address + 411Fh	PaRAM set 8
9	EDMA Base Address + 4120h to EDMA Base Address + 413Fh	PaRAM set 9
...	...	...
63	EDMA Base Address + 47E0h to EDMA Base Address + 47FFh	PaRAM set 63
64	EDMA Base Address + 4800h to EDMA Base Address + 481Fh	PaRAM set 64
65	EDMA Base Address + 4820h to EDMA Base Address + 483Fh	PaRAM set 65
...	...	...
254	EDMA Base Address + 5FC0h to EDMA Base Address + 5FDFh	PaRAM set 254
255	EDMA Base Address + 5FE0h to EDMA Base Address + 5FFFh	PaRAM set 255

### 10.3.3.1 PaRAM

Each parameter set of PaRAM is organized into eight 32-bit words or 32 bytes, as shown in [Figure 10-9](#) and described in [Table 10-6](#). Each PaRAM set consists of 16-bit and 32-bit parameters.

### Figure 10-9. PaRAM Set

Byte address	Set #	PaPARAM	PaPARAM set	Byte address offset
EDMA Base Address + 4000h	0	Parameter set 0	OPT	+0h
EDMA Base Address + 4020h	1	Parameter set 1	SRC	+4h
EDMA Base Address + 4040h	2	Parameter set 2	BCNT	+8h
EDMA Base Address + 4060h	3	Parameter set 3	ACNT	+8h
			DST	+Ch
			DSTBIDX	+10h
			BCNTRLD	+14h
			LINK	+14h
			DSTCIDX	+18h
			SRCCIDX	+18h
			Rsvd	+1Ch
			CCNT	+1Ch
EDMA Base Address + 5FC0	254	Parameter set 254		
EDMA Base Address + 5FE0	255	Parameter set 255		

**Table 10-6. EDMA3 Channel Parameter Description**

Offset Address (bytes)	Acronym	Parameter	Description
0h	OPT	Channel Options	Transfer configuration options
4h	SRC	Channel Source Address	The byte address from which data is transferred
8h <sup>(1)</sup>	ACNT	Count for 1st Dimension	Unsigned value specifying the number of contiguous bytes within an array (first dimension of the transfer). Valid values range from 1 to 65 535.
	BCNT	Count for 2nd Dimension	Unsigned value specifying the number of arrays in a frame, where an array is ACNT bytes. Valid values range from 1 to 65 535.
Ch	DST	Channel Destination Address	The byte address to which data is transferred
10h <sup>(1)</sup>	SRCBIDX	Source BCNT Index	Signed value specifying the byte address offset between source arrays within a frame (2nd dimension). Valid values range from –32 768 and 32 767.
	DSTBIDX	Destination BCNT Index	Signed value specifying the byte address offset between destination arrays within a frame (2nd dimension). Valid values range from –32 768 and 32 767.
14h <sup>(1)</sup>	LINK	Link Address	The PaRAM address containing the PaRAM set to be linked (copied from) when the current PaRAM set is exhausted. A value of FFFFh specifies a null link.
	BCNTRLD	BCNT Reload	The count value used to reload BCNT when BCNT decrements to 0 (TR is submitted for the last array in 2nd dimension). Only relevant in A-synchronized transfers.
18h <sup>(1)</sup>	SRCCIDX	Source CCNT Index	Signed value specifying the byte address offset between frames within a block (3rd dimension). Valid values range from –32 768 and 32 767.  A-synchronized transfers: The byte address offset from the beginning of the last source array in a frame to the beginning of the first source array in the next frame.  AB-synchronized transfers: The byte address offset from the beginning of the first source array in a frame to the beginning of the first source array in the next frame.
	DSTCIDX	Destination CCNT index	Signed value specifying the byte address offset between frames within a block (3rd dimension). Valid values range from –32 768 and 32 767.  A-synchronized transfers: The byte address offset from the beginning of the last destination array in a frame to the beginning of the first destination array in the next frame.  AB-synchronized transfers: The byte address offset from the beginning of the first destination array in a frame to the beginning of the first destination array in the next frame.
1Ch	CCNT	Count for 3rd Dimension	Unsigned value specifying the number of frames in a block, where a frame is BCNT arrays of ACNT bytes. Valid values range from 1 to 65 535.
	RSVD	Reserved	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.

<sup>(1)</sup> It is recommended to access the parameter set sets as 32-bit words whenever possible.

### 10.3.3.2 EDMA3 Channel PaRAM Set Entry Fields

#### 10.3.3.2.1 Channel Options Parameter (OPT)

The channel options parameter (OPT) is shown in [Figure 10-10](#) and described in [Table 10-7](#).

**Figure 10-10. Channel Options Parameter (OPT)**

31	30	28	27	24	23	22	21	20	19	18	17	16
PRIV	Reserved		PRIVID	ITCCHEN	TCCHEN	ITCINTEN	TCINTEN	Reserved				TCC
R-0	R-0		R-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0				R/W-0
15	12	11	10	8	7			4	3	2	1	0
TCC	TCCMODE	FWID				Reserved		STATIC	SYNCDIM	DAM	SAM	
R/W-0	R/W-0	R/W-0				R/W-0		R/W-0	R/W-0	R/W-0	R/W-0	R/W-0

**Table 10-7. Channel Options Parameters (OPT) Field Descriptions**

Bit	Field	Value	Description
31	PRIV	0 1	Privilege level (supervisor versus user) for the host/CPU/DMA that programmed this PaRAM set. This value is set with the EDMA3 master's privilege value when any part of the PaRAM set is written. User level privilege. Supervisor level privilege.
30-28	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
27-24	PRIVID	0-Fh	Privilege identification for the external host/CPU/DMA that programmed this PaRAM set. This value is set with the EDMA3 master's privilege identification value when any part of the PaRAM set is written.
23	ITCCHEN	0 1	Intermediate transfer completion chaining enable. Intermediate transfer complete chaining is disabled. Intermediate transfer complete chaining is enabled. When enabled, the chained event register (CER/CERH) bit is set on every intermediate chained transfer completion (upon completion of every intermediate TR in the PaRAM set, except the final TR in the PaRAM set). The bit (position) set in CER or CERH is the TCC value specified.
22	TCCHEN	0 1	Transfer complete chaining enable. Transfer complete chaining is disabled. Transfer complete chaining is enabled. When enabled, the chained event register (CER/CERH) bit is set on final chained transfer completion (upon completion of the final TR in the PaRAM set). The bit (position) set in CER or CERH is the TCC value specified.
21	ITCINTEN	0 1	Intermediate transfer completion interrupt enable. Intermediate transfer complete interrupt is disabled. Intermediate transfer complete interrupt is enabled. When enabled, the interrupt pending register (IPR / IPRH) bit is set on every intermediate transfer completion (upon completion of every intermediate TR in the PaRAM set, except the final TR in the PaRAM set). The bit (position) set in IPR or IPRH is the TCC value specified. To generate a completion interrupt to the CPU, the corresponding IER [TCC] / IERH [TCC] bit must be set.
20	TCINTEN	0 1	Transfer complete interrupt enable. Transfer complete interrupt is disabled. Transfer complete interrupt is enabled. When enabled, the interrupt pending register (IPR / IPRH) bit is set on transfer completion (upon completion of the final TR in the PaRAM set). The bit (position) set in IPR or IPRH is the TCC value specified. To generate a completion interrupt to the CPU, the corresponding IER [TCC] / IERH [TCC] bit must be set.
19-18	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.

**Table 10-7. Channel Options Parameters (OPT) Field Descriptions (continued)**

Bit	Field	Value	Description
17-12	TCC	0-3Fh	Transfer complete code. This 6-bit code sets the relevant bit in the chaining enable register (CER [TCC] / CERH [TCC]) for chaining or in the interrupt pending register (IPR [TCC] / IPRH [TCC]) for interrupts.
11	TCCMODE	0 1	Transfer complete code mode. Indicates the point at which a transfer is considered completed for chaining and interrupt generation. 0 Normal completion: A transfer is considered completed after the data has been transferred. 1 Early completion: A transfer is considered completed after the EDMA3CC submits a TR to the EDMA3TC. TC may still be transferring data when the interrupt/chain is triggered.
10-8	FWID	0-7h 0 1h 2h 3h 4h 5h 6h-7h	FIFO Width. Applies if either SAM or DAM is set to constant addressing mode. 0 FIFO width is 8-bit. 1h FIFO width is 16-bit. 2h FIFO width is 32-bit. 3h FIFO width is 64-bit. 4h FIFO width is 128-bit. 5h FIFO width is 256-bit. 6h-7h Reserved.
7-4	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
3	STATIC	0 1	Static set. 0 Set is not static. The PaRAM set is updated or linked after a TR is submitted. A value of 0 should be used for DMA channels and for non-final transfers in a linked list of QDMA transfers. 1 Set is static. The PaRAM set is not updated or linked after a TR is submitted. A value of 1 should be used for isolated QDMA transfers or for the final transfer in a linked list of QDMA transfers.
2	SYNCDIM	0 1	Transfer synchronization dimension. 0 A-synchronized. Each event triggers the transfer of a single array of ACNT bytes. 1 AB-synchronized. Each event triggers the transfer of BCNT arrays of ACNT bytes.
1	DAM	0 1	Destination address mode. 0 Increment (INCR) mode. Destination addressing within an array increments. Destination is not a FIFO. 1 Constant addressing (CONST) mode. Destination addressing within an array wraps around upon reaching FIFO width.
0	SAM	0 1	Source address mode. 0 Increment (INCR) mode. Source addressing within an array increments. Source is not a FIFO. 1 Constant addressing (CONST) mode. Source addressing within an array wraps around upon reaching FIFO width.

### 10.3.3.2.2 Channel Source Address (SRC)

The 32-bit source address parameter specifies the starting byte address of the source. For SAM in increment mode, there are no alignment restrictions imposed by EDMA3. For SAM in constant addressing mode, you must program the source address to be aligned to a 256-bit aligned address (5 LSBs of address must be 0). The EDMA3TC will signal an error, if this rule is violated. See [Section 10.3.12.3](#) for additional details.

### 10.3.3.2.3 Channel Destination Address (DST)

The 32-bit destination address parameter specifies the starting byte address of the destination. For DAM in increment mode, there are no alignment restrictions imposed by EDMA3. For DAM in constant addressing mode, you must program the destination address to be aligned to a 256-bit aligned address (5 LSBs of address must be 0). The EDMA3TC will signal an error, if this rule is violated. See [Section 10.3.12.3](#) for additional details.

#### 10.3.3.2.4 Count for 1st Dimension (ACNT)

ACNT represents the number of bytes within the 1st dimension of a transfer. ACNT is a 16-bit unsigned value with valid values between 0 and 65 535. Therefore, the maximum number of bytes in an array is 65 535 bytes (64K – 1 bytes). ACNT must be greater than or equal to 1 for a TR to be submitted to EDMA3TC. A transfer with ACNT equal to 0 is considered either a null or dummy transfer. A dummy or null transfer generates a completion code depending on the settings of the completion bit fields in OPT.

See [Section 10.3.3.5](#) and [Section 10.3.5.3](#) for details on dummy/null completion conditions.

#### 10.3.3.2.5 Count for 2nd Dimension (BCNT)

BCNT is a 16-bit unsigned value that specifies the number of arrays of length ACNT. For normal operation, valid values for BCNT are between 1 and 65 535. Therefore, the maximum number of arrays in a frame is 65 535 (64K – 1 arrays). A transfer with BCNT equal to 0 is considered either a null or dummy transfer. A dummy or null transfer generates a completion code depending on the settings of the completion bit fields in OPT.

See [Section 10.3.3.5](#) and [Section 10.3.5.3](#) for details on dummy/null completion conditions.

#### 10.3.3.2.6 Count for 3rd Dimension (CCNT)

CCNT is a 16-bit unsigned value that specifies the number of frames in a block. Valid values for CCNT are between 1 and 65 535. Therefore, the maximum number of frames in a block is 65 535 (64K – 1 frames). A transfer with CCNT equal to 0 is considered either a null or dummy transfer. A dummy or null transfer generates a completion code depending on the settings of the completion bit fields in OPT.

A CCNT value of 0 is considered either a null or dummy transfer. See [Section 10.3.3.5](#) and [Section 10.3.5.3](#) for details on dummy/null completion conditions.

#### 10.3.3.2.7 BCNT Reload (BCNTRLD)

BCNTRLD is a 16-bit unsigned value used to reload the BCNT field once the last array in the 2nd dimension is transferred. This field is only used for A-synchronized transfers. In this case, the EDMA3CC decrements the BCNT value by 1 on each TR submission. When BCNT reaches 0, the EDMA3CC decrements CCNT and uses the BCNTRLD value to reinitialize the BCNT value.

For AB-synchronized transfers, the EDMA3CC submits the BCNT in the TR and the EDMA3TC decrements BCNT appropriately. For AB-synchronized transfers, BCNTRLD is not used.

#### 10.3.3.2.8 Source B Index (SRCBIDX)

SRCBIDX is a 16-bit signed value (2s complement) used for source address modification between each array in the 2nd dimension. Valid values for SRCBIDX are between –32 768 and 32 767. It provides a byte address offset from the beginning of the source array to the beginning of the next source array. It applies to both A-synchronized and AB-synchronized transfers. Some examples:

- SRCBIDX = 0000h (0): no address offset from the beginning of an array to the beginning of the next array. All arrays are fixed to the same beginning address.
- SRCBIDX = 0003h (+3): the address offset from the beginning of an array to the beginning of the next array in a frame is 3 bytes. For example, if the current array begins at address 1000h, the next array begins at 1003h.
- SRCBIDX = FFFFh (–1): the address offset from the beginning of an array to the beginning of the next array in a frame is –1 byte. For example, if the current array begins at address 5054h, the next array begins at 5053h.

#### 10.3.3.2.9 Destination B Index (DSTBIDX)

DSTBIDX is a 16-bit signed value (2s complement) used for destination address modification between each array in the 2nd dimension. Valid values for DSTBIDX are between –32 768 and 32 767. It provides a byte address offset from the beginning of the destination array to the beginning of the next destination array within the current frame. It applies to both A-synchronized and AB-synchronized transfers. See SRCBIDX for examples.

### 10.3.3.2.10 Source C Index (SRCCIDX)

SRCCIDX is a 16-bit signed value (2s complement) used for source address modification in the 3rd dimension. Valid values for SRCCIDX are between –32 768 and 32 767. It provides a byte address offset from the beginning of the current array (pointed to by SRC address) to the beginning of the first source array in the next frame. It applies to both A-synchronized and AB-synchronized transfers. Note that when SRCCIDX is applied, the current array in an A-synchronized transfer is the last array in the frame (Figure 10-7), while the current array in an AB-synchronized transfer is the first array in the frame (Figure 10-8).

### 10.3.3.2.11 Destination C Index (DSTCIDX)

DSTCIDX is a 16-bit signed value (2s complement) used for destination address modification in the 3rd dimension. Valid values are between –32 768 and 32 767. It provides a byte address offset from the beginning of the current array (pointed to by DST address) to the beginning of the first destination array TR in the next frame. It applies to both A-synchronized and AB-synchronized transfers. Note that when DSTCIDX is applied, the current array in an A-synchronized transfer is the last array in the frame (Figure 10-7), while the current array in a AB-synchronized transfer is the first array in the frame (Figure 10-8).

### 10.3.3.2.12 Link Address (LINK)

The EDMA3CC provides a mechanism, called linking, to reload the current PaRAM set upon its natural termination (that is, after the count fields are decremented to 0) with a new PaRAM set. The 16-bit parameter LINK specifies the byte address offset in the PaRAM from which the EDMA3CC loads/reloads the next PaRAM set during linking.

You must program the link address to point to a valid aligned 32-byte PaRAM set. The 5 LSBs of the LINK field should be cleared to 0.

The EDMA3CC ignores the upper 2 bits of the LINK entry, allowing the programmer the flexibility of programming the link address as either an absolute/literal byte address or use the PaRAM-base-relative offset address. Therefore, if you make use of the literal address with a range from 4000h to 7FFFh, it will be treated as a PaRAM-base-relative value of 0000h to 3FFFh.

You should make sure to program the LINK field correctly, so that link update is requested from a PaRAM address that falls in the range of the available PaRAM addresses on the device.

A LINK value of FFFFh is referred to as a NULL link that should cause the EDMA3CC to perform an internal write of 0 to all entries of the current PaRAM set, except for the LINK field that is set to FFFFh. Also, see Section 10.3.5 for details on terminating a transfer.

### 10.3.3.3 Null PaRAM Set

A null PaRAM set is defined as a PaRAM set where all count fields (ACNT, BCNT, and CCNT) are cleared to 0. If a PaRAM set associated with a channel is a NULL set, then when serviced by the EDMA3CC, the bit corresponding to the channel is set in the associated event missed register (EMR, EMRH, or QEMR). This bit remains set in the associated secondary event register (SER, SERH, or QSER). *This implies that any future events on the same channel are ignored by the EDMA3CC and you are required to clear the bit in SER, SERH, or QSER for the channel.* This is considered an error condition, since events are not expected on a channel that is configured as a null transfer. For more information, see the SER and EMR registers.

### 10.3.3.4 Dummy PaRAM Set

A dummy PaRAM set is defined as a PaRAM set where at least one of the count fields (ACNT, BCNT, or CCNT) is cleared to 0 and at least one of the count fields is nonzero.

If a PaRAM set associated with a channel is a dummy set, then when serviced by the EDMA3CC, it will not set the bit corresponding to the channel (DMA/QDMA) in the event missed register (EMR, EMRH, or QEMR) and the secondary event register (SER, SERH, or QSER) bit gets cleared similar to a normal transfer. Future events on that channel are serviced. A dummy transfer is a legal transfer of 0 bytes. For more information, see the SER and EMR registers.

### 10.3.3.5 Dummy Versus Null Transfer Comparison

There are some differences in the way the EDMA3CC logic treats a dummy versus a null transfer request. A null transfer request is an error condition, but a dummy transfer is a legal transfer of 0 bytes. A null transfer causes an error bit ( $En$ ) in EMR to get set and the  $En$  bit in SER remains set, essentially preventing any further transfers on that channel without clearing the associated error registers.

[Table 10-8](#) summarizes the conditions and effects of null and dummy transfer requests.

**Table 10-8. Dummy and Null Transfer Request**

Feature	Null TR	Dummy TR
EMR/EMRH/QEMR is set	Yes	No
SER/SERH/QSER remains set	Yes	No
Link update (STATIC = 0 in OPT)	Yes	Yes
QER is set	Yes	Yes
IPR/IPRH CER/CERH is set using early completion	Yes	Yes

### 10.3.3.6 Parameter Set Updates

When a TR is submitted for a given DMA/QDMA channel and its corresponding PaRAM set, the EDMA3CC is responsible for updating the PaRAM set in anticipation of the next trigger event. For events that are not final, this includes address and count updates; for final events, this includes the link update.

The specific PaRAM set entries that are updated depend on the channel's synchronization type (A-synchronized or B-synchronized) and the current state of the PaRAM set. A B-update refers to the decrementing of BCNT in the case of A-synchronized transfers after the submission of successive TRs. A C-update refers to the decrementing of CCNT in the case of A-synchronized transfers after BCNT TRs for ACNT byte transfers have submitted. For AB-synchronized transfers, a C-update refers to the decrementing of CCNT after submission of every transfer request.

See [Table 10-9](#) for details and conditions on the parameter updates. A link update occurs when the PaRAM set is exhausted, as described in [Section 10.3.3.7](#).

After the TR is read from the PaRAM (and is in process of being submitted to EDMA3TC), the following fields are updated if needed:

- A-synchronized: BCNT, CCNT, SRC, DST.
- AB-synchronized: CCNT, SRC, DST.

The following fields are not updated (except for during linking, where all fields are overwritten by the link PaRAM set):

- A-synchronized: ACNT, BCNTRLD, SRCBIDX, DSTBIDX, SRCCIDX, DSTCIDX, OPT, LINK.
- AB-synchronized: ACNT, BCNT, BCNTRLD, SRCBIDX, DSTBIDX, SRCCIDX, DSTCIDX, OPT, LINK.

Note that PaRAM updates only pertain to the information that is needed to properly submit the next transfer request to the EDMA3TC. Updates that occur while data is moved within a transfer request are tracked within the transfer controller, and is detailed in [Section 10.3.12](#). For A-synchronized transfers, the EDMA3CC always submits a TRP for ACNT bytes (BCNT = 1 and CCNT = 1). For AB-synchronized transfers, the EDMA3CC always submits a TRP for ACNT bytes of BCNT arrays (CCNT = 1). The EDMA3TC is responsible for updating source and destination addresses within the array based on ACNT and FWID (in OPT). For AB-synchronized transfers, the EDMA3TC is also responsible to update source and destination addresses between arrays based on SRCBIDX and DSTBIDX.

[Table 10-9](#) shows the details of parameter updates that occur within EDMA3CC for A-synchronized and AB-synchronized transfers.

**Table 10-9. Parameter Updates in EDMA3CC (for Non-Null, Non-Dummy PaRAM Set)**

	A-Synchronized Transfer			AB-Synchronized Transfer		
	B-Update	C-Update	Link Update	B-Update	C-Update	Link Update
Condition:	BCNT > 1	BCNT == 1 && CCNT > 1	BCNT == 1 && CCNT == 1	N/A	CCNT > 1	CCNT == 1
SRC	+= SRCBIDX	+= SRCCIDX	= Link.SRC	in EDMA3TC	+= SRCCIDX	= Link.SRC
DST	+= DSTBIDX	+= DSTCIDX	= Link.DST	in EDMA3TC	+= DSTCIDX	= Link.DST
ACNT	None	None	= Link.ACNT	None	None	= Link.ACNT
BCNT	-= 1	= BCNTRLD	= Link.BCNT	in EDMA3TC	N/A	= Link.BCNT
CCNT	None	-= 1	= Link.CCNT	in EDMA3TC	-= 1	= Link.CCNT
SRCBIDX	None	None	= Link.SRCBIDX	in EDMA3TC	None	= Link.SRCBIDX
DSTBIDX	None	None	= Link.DSTBIDX	None	None	= Link.DSTBIDX
SRCCIDX	None	None	= Link.SRCBIDX	in EDMA3TC	None	= Link.SRCBIDX
DSTCIDX	None	None	= Link.DSTBIDX	None	None	= Link.DSTBIDX
LINK	None	None	= Link.LINK	None	None	= Link.LINK
BCNTRLD	None	None	= Link.BCNTRLD	None	None	= Link.BCNTRLD
OPT <sup>(1)</sup>	None	None	= LINK.OPT	None	None	= LINK.OPT

<sup>(1)</sup> In all cases, no updates occur if OPT.STATIC == 1 for the current PaRAM set.

**NOTE:** The EDMA3CC includes no special hardware to detect when an indexed address update calculation overflows/underflows. The address update will wrap across boundaries as programmed by the user. You should ensure that no transfer is allowed to cross internal port boundaries between peripherals. A single TR must target a single source/destination slave endpoint.

### 10.3.3.7 Linking Transfers

The EDMA3CC provides a mechanism known as linking, which allows the entire PaRAM set to be reloaded from a location within the PaRAM memory map (for both DMA and QDMA channels). Linking is especially useful for maintaining ping-pong buffers, circular buffering, and repetitive/continuous transfers with no CPU intervention. Upon completion of a transfer, the current transfer parameters are reloaded with the parameter set pointed to by the 16-bit link address field of the current parameter set. Linking only occurs when the STATIC bit in OPT is cleared.

---

**NOTE:** You should always link a transfer (EDMA3 or QDMA) to another useful transfer. If you must terminate a transfer, then you should link the transfer to a NULL parameter set. See [Section 10.3.3.3](#).

---

The link update occurs after the current PaRAM set event parameters have been exhausted. An event's parameters are exhausted when the EDMA3 channel controller has submitted all of the transfers that are associated with the PaRAM set.

A link update occurs for null and dummy transfers depending on the state of the STATIC bit in OPT and the LINK field. In both cases (null or dummy), if the value of LINK is FFFFh, then a null PaRAM set (with all 0s and LINK set to FFFFh) is written to the current PaRAM set. Similarly, if LINK is set to a value other than FFFFh, then the appropriate PaRAM location that LINK points to is copied to the current PaRAM set.

Once the channel completion conditions are met for an event, the transfer parameters that are located at the link address are loaded into the current DMA or QDMA channel's associated parameter set. This indicates that the EDMA3CC reads the entire set (eight words) from the PaRAM set specified by LINK and writes all eight words to the PaRAM set that is associated with the current channel. [Figure 10-11](#) shows an example of a linked transfer.

Any PaRAM set in the PaRAM can be used as a link/reload parameter set. The PaRAM sets associated with peripheral synchronization events (see [Section 10.3.6](#)) should only be used for linking if the corresponding events are disabled.

If a PaRAM set location is defined as a QDMA channel PaRAM set (by QCHMAP<sub>n</sub>), then copying the link PaRAM set into the current QDMA channel PaRAM set is recognized as a trigger event. It is latched in QER because a write to the trigger word was performed. You can use this feature to create a linked list of transfers using a single QDMA channel and multiple PaRAM sets. See [Section 10.3.4.2](#).

Linking to itself replicates the behavior of auto-initialization, thus facilitating the use of circular buffering and repetitive transfers. After an EDMA3 channel exhausts its current PaRAM set, it reloads all of the parameter set entries from another PaRAM set, which is initialized with values that are identical to the original PaRAM set. [Figure 10-11](#) shows an example of a linked to self transfer. Here, the PaRAM set 255 has the link field pointing to the address of parameter set 255 (linked to self).

---

**NOTE:** If the STATIC bit in OPT is set for a PaRAM set, then link updates are not performed.

---

### 10.3.3.8 Constant Addressing Mode Transfers/Alignment Issues

If either SAM or DAM is set (constant addressing mode), then the source or destination address must be aligned to a 256-bit aligned address, respectively, and the corresponding BIDX should be an even multiple of 32 bytes (256 bits). The EDMA3CC does not recognize errors here, but the EDMA3TC asserts an error if this is not true. See [Section 10.3.12.3](#).

---

**NOTE:** The constant addressing (CONST) mode has limited applicability. The EDMA3 should be configured for the constant addressing mode (SAM/DAM = 1) only if the transfer source or destination (on-chip memory, off-chip memory controllers, slave peripherals) support the constant addressing mode. See the device-specific data manual or chapter in this TRM to verify if the constant addressing mode is supported. If the constant addressing mode is not supported, the similar logical transfer can be achieved using the increment (INCR) mode (SAM/DAM = 0) by appropriately programming the count and indices values.

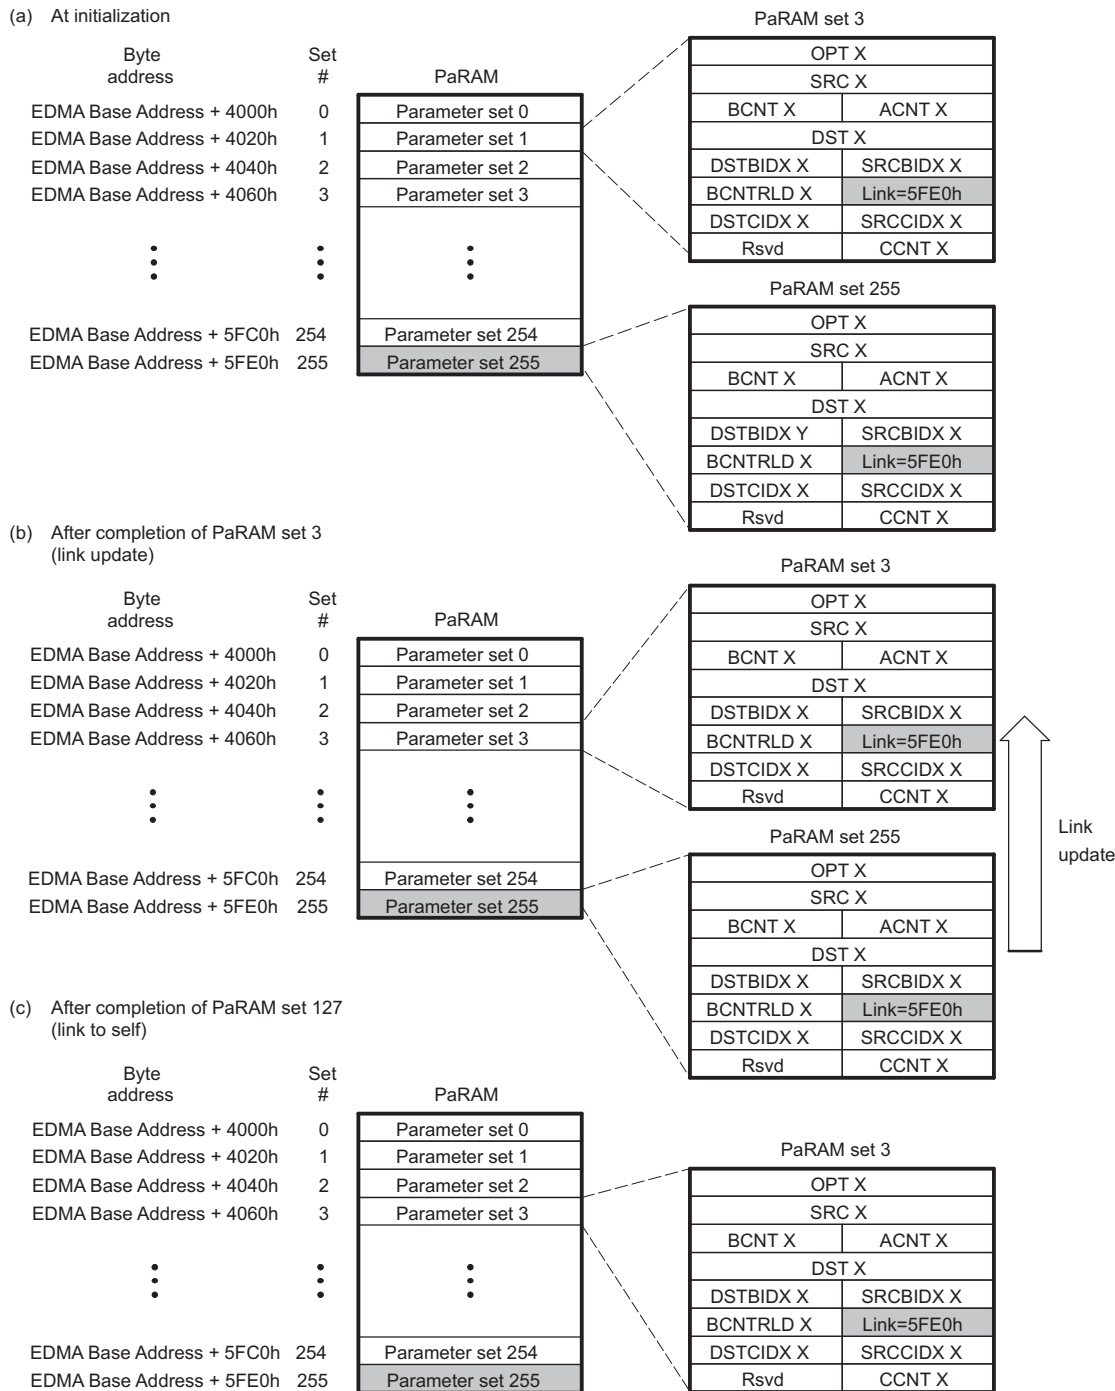

---

### 10.3.3.9 Element Size

The EDMA3 controller does not use element-size and element-indexing. Instead, all transfers are defined in terms of all three dimensions: ACNT, BCNT, and CCNT. An element-indexed transfer is logically achieved by programming ACNT to the size of the element and BCNT to the number of elements that need to be transferred. For example, if you have 16-bit audio data and 256 audio samples that must be transferred to a serial port, you can only do this by programming the ACNT = 2 (2 bytes) and BCNT = 256.

**Figure 10-11. Linked Transfer**

**Figure 10-12. Link-to-Self Transfer**

### 10.3.4 Initiating a DMA Transfer

There are multiple ways to initiate a programmed data transfer using the EDMA3 channel controller. Transfers on DMA channels are initiated by three sources.

They are listed as follows:

- **Event-triggered transfer request** (this is the more typical usage of EDMA3): A peripheral, system, or externally-generated event triggers a transfer request.
- **Manually-triggered transfer request:** The CPU to manually triggers a transfer by writing a 1 to the

corresponding bit in the event set register (ESR/ESRH).

- **Chain-triggered transfer request:** A transfer is triggered on the completion of another transfer or sub-transfer.

Transfers on QDMA channels are initiated by two sources. They are as follows:

- **Auto-triggered transfer request:** Writing to the programmed trigger word triggers a transfer.
- **Link-triggered transfer requests:** Writing to the trigger word triggers the transfer when linking occurs.

### 10.3.4.1 DMA Channel

#### 10.3.4.1.1 Event-Triggered Transfer Request

When an event is asserted from a peripheral or device pins, it gets latched in the corresponding bit of the event register ( $ER.En = 1$ ). If the corresponding event in the event enable register (EER) is enabled ( $EER.En = 1$ ), then the EDMA3CC prioritizes and queues the event in the appropriate event queue. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

If the PaPARAM set is valid (not a NULL set), then a transfer request packet (TRP) is submitted to the EDMA3TC and the  $En$  bit in ER is cleared. At this point, a new event can be safely received by the EDMA3CC.

If the PaPARAM set associated with the channel is a NULL set (see [Section 10.3.3.3](#)), then no transfer request (TR) is submitted and the corresponding  $En$  bit in ER is cleared and simultaneously the corresponding channel bit is set in the event miss register ( $EMR.En = 1$ ) to indicate that the event was discarded due to a null TR being serviced. Good programming practices should include cleaning the event missed error before re-triggering the DMA channel.

When an event is received, the corresponding event bit in the event register is set ( $ER.En = 1$ ), regardless of the state of  $EER.En$ . If the event is disabled when an external event is received ( $ER.En = 1$  and  $EER.En = 0$ ), the  $ER.En$  bit remains set. If the event is subsequently enabled ( $EER.En = 1$ ), then the pending event is processed by the EDMA3CC and the TR is processed/submitted, after which the  $ER.En$  bit is cleared.

If an event is being processed (prioritized or is in the event queue) and another sync event is received for the same channel prior to the original being cleared ( $ER.En \neq 0$ ), then the second event is registered as a missed event in the corresponding bit of the event missed register ( $EMR.En = 1$ ).

See [Section 7.2.2, EDMA Event Multiplexing](#), for a description of how DMA events map to the EDMA event crossbar. See [Section 10.3.20, EDMA Events](#), for a table of direct and crossbar mapped EDMA events.

#### 10.3.4.1.2 Manually Triggered Transfer Request

The CPU or any EDMA programmer initiates a DMA transfer by writing to the event set register (ESR). Writing a 1 to an event bit in the ESR results in the event being prioritized/queued in the appropriate event queue, regardless of the state of the  $EER.En$  bit. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

As in the event-triggered transfers, if the PaPARAM set associated with the channel is valid (it is not a null set) then the TR is submitted to the associated EDMA3TC and the channel can be triggered again.

If the PaPARAM set associated with the channel is a NULL set (see [Section 10.3.3.3](#)), then no transfer request (TR) is submitted and the corresponding  $En$  bit in ER is cleared and simultaneously the corresponding channel bit is set in the event miss register ( $EMR.En = 1$ ) to indicate that the event was discarded due to a null TR being serviced. Good programming practices should include clearing the event missed error before re-triggering the DMA channel.

If an event is being processed (prioritized or is in the event queue) and the same channel is manually set by a write to the corresponding channel bit of the event set register ( $ESR.En = 1$ ) prior to the original being cleared ( $ESR.En = 0$ ), then the second event is registered as a missed event in the corresponding bit of the event missed register ( $EMR.En = 1$ ).

### 10.3.4.1.3 Chain-Triggered Transfer Request

Chaining is a mechanism by which the completion of one transfer automatically sets the event for another channel. When a chained completion code is detected, the value of which is dictated by the transfer completion code (TCC[5:0] in OPT of the PaRAM set associated with the channel), it results in the corresponding bit in the chained event register (CER) to be set (CER.E[TCC] = 1).

Once a bit is set in CER, the EDMA3CC prioritizes and queues the event in the appropriate event queue. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

As in the event-triggered transfers, if the PaRAM set associated with the channel is valid (it is not a null set) then the TR is submitted to the associated EDMA3TC and the channel can be triggered again.

If the PaRAM set associated with the channel is a NULL set (see [Section 10.3.3.3](#)), then no transfer request (TR) is submitted and the corresponding  $En$  bit in CER is cleared and simultaneously the corresponding channel bit is set in the event miss register (EMR. $En$  = 1) to indicate that the event was discarded due to a null TR being serviced. In this case, the error condition must be cleared by you before the DMA channel can be re-triggered. Good programming practices might include clearing the event missed error before re-triggering the DMA channel.

If a chaining event is being processed (prioritized or queued) and another chained event is received for the same channel prior to the original being cleared (CER. $En$  != 0), then the second chained event is registered as a missed event in the corresponding channel bit of the event missed register (EMR. $En$  = 1).

---

**NOTE:** Chained event registers, event registers, and event set registers operate independently. An event ( $En$ ) can be triggered by any of the trigger sources (event-triggered, manually-triggered, or chain-triggered).

---

### 10.3.4.2 QDMA Channels

#### 10.3.4.2.1 Auto-triggered and Link-Triggered Transfer Request

QDMA-based transfer requests are issued when a QDMA event gets latched in the QDMA event register (QER. $En$  = 1). A bit corresponding to a QDMA channel is set in the QDMA event register (QER) when the following occurs:

- A CPU (or any EDMA3 programmer) write occurs to a PaRAM address that is defined as a QDMA channel trigger word (programmed in the QDMA channel mapping register (QCHMAP $n$ )) for the particular QDMA channel and the QDMA channel is enabled via the QDMA event enable register (QEER. $En$  = 1).
- EDMA3CC performs a link update on a PaRAM set address that is configured as a QDMA channel (matches QCHMAP $n$  settings) and the corresponding channel is enabled via the QDMA event enable register (QEER. $En$  = 1).

Once a bit is set in QER, the EDMA3CC prioritizes and queues the event in the appropriate event queue. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

As in the event-triggered transfers, if the PaRAM set associated with the channel is valid (it is not a null set) then the TR is submitted to the associated EDMA3TC and the channel can be triggered again.

If a bit is already set in QER (QER. $En$  = 1) and a second QDMA event for the same QDMA channel occurs prior to the original being cleared, the second QDMA event gets captured in the QDMA event miss register (QEMR. $En$  = 1).

### 10.3.4.3 Comparison Between DMA and QDMA Channels

The primary difference between DMA and QDMA channels is the event/channel synchronization. QDMA events are either auto-triggered or link triggered. auto-triggering allows QDMA channels to be triggered by CPUs with a minimum number of linear writes to PaRAM. Link triggering allows a linked list of transfers to be executed, using a single QDMA PaRAM set and multiple link PaRAM sets.

A QDMA transfer is triggered when a CPU (or other EDMA3 programmer) writes to the trigger word of the QDMA channel parameter set (auto-triggered) or when the EDMA3CC performs a link update on a PaRAM set that has been mapped to a QDMA channel (link triggered). Note that for CPU triggered (manually triggered) DMA channels, in addition to writing to the PaRAM set, it is required to write to the event set register (ESR) to kick-off the transfer.

QDMA channels are typically for cases where a single event will accomplish a complete transfer since the CPU (or EDMA3 programmer) must reprogram some portion of the QDMA PaRAM set in order to re-trigger the channel. In other words, QDMA transfers are programmed with BCNT = CCNT = 1 for A-synchronized transfers, and CCNT = 1 for AB-synchronized transfers.

Additionally, since linking is also supported (if STATIC = 0 in OPT) for QDMA transfers, it allows you to initiate a linked list of QDMAs, so when EDMA3CC copies over a link PaRAM set (including the write to the trigger word), the current PaRAM set mapped to the QDMA channel will automatically be recognized as a valid QDMA event and initiate another set of transfers as specified by the linked set.

### 10.3.5 Completion of a DMA Transfer

A parameter set for a given channel is complete when the required number of transfer requests is submitted (based on receiving the number of synchronization events). The expected number of TRs for a non-null/non-dummy transfer is shown in [Table 10-10](#) for both synchronization types along with state of the PaRAM set prior to the final TR being submitted. When the counts (BCNT and/or CCNT) are this value, the next TR results in a:

- Final chaining or interrupt codes to be sent by the transfer controllers (instead of intermediate).
- Link updates (linking to either null or another valid link set).

**Table 10-10. Expected Number of Transfers for Non-Null Transfer**

Sync Mode	Counts at time 0	Total # Transfers	Counts prior to final TR
A-synchronized	ACNT BCNT CCNT	(BCNT × CCNT ) TRs of ACNT bytes each	BCNT == 1 && CCNT == 1
AB-synchronized	ACNT BCNT CCNT	CCNT TRs for ACNT × BCNT bytes each	CCNT == 1

You must program the PaRAM OPT field with a specific transfer completion code (TCC) along with the other OPT fields (TCCHEN, TCINTEN, ITCCHEN, and ITCINTEN bits) to indicate whether the completion code is to be used for generating a chained event or/and for generating an interrupt upon completion of a transfer.

The specific TCC value (6-bit binary value) programmed dictates which of the 64-bits in the chain event register (CER[TCC]) and/or interrupt pending register (IPR[TCC]) is set.

You can also selectively program whether the transfer controller sends back completion codes on completion of the final transfer request (TR) of a parameter set (TCCHEN or TCINTEN), for all but the final transfer request (TR) of a parameter set (ITCCHEN or ITCINTEN), or for all TRs of a parameter set (both). See [Section 10.3.8](#) for details on chaining (intermediate/final chaining) and [Section 10.3.9](#) for details on intermediate/final interrupt completion.

A completion detection interface exists between the EDMA3 channel controller and transfer controllers. This interface sends back information from the transfer controller to the channel controller to indicate that a specific transfer is completed. Completion of a transfer is used for generating chained events and/or generating interrupts to the CPUs.

All DMA/QDMA PaRAM sets must also specify a link address value. For repetitive transfers such as ping-pong buffers, the link address value should point to another predefined PaRAM set. Alternatively, a non-repetitive transfer should set the link address value to the null link value. The null link value is defined as FFFFh. See [Section 10.3.3.7](#) for more details.

**NOTE:** Any incoming events that are mapped to a null PaRAM set results in an error condition. The error condition should be cleared before the corresponding channel is used again. See [Section 10.3.3.5](#).

There are three ways the EDMA3CC gets updated/informed about a transfer completion: normal completion, early completion, and dummy/null completion. This applies to both chained events and completion interrupt generation.

### 10.3.5.1 Normal Completion

In normal completion mode (TCCMODE = 0 in OPT), the transfer or sub-transfer is considered to be complete when the EDMA3 channel controller receives the completion codes from the EDMA3 transfer controller. In this mode, the completion code to the channel controller is posted by the transfer controller after it receives a signal from the destination peripheral. Normal completion is typically used to generate an interrupt to inform the CPU that a set of data is ready for processing.

### 10.3.5.2 Early Completion

In early completion mode (TCCMODE = 1 in OPT), the transfer is considered to be complete when the EDMA3 channel controller submits the transfer request (TR) to the EDMA3 transfer controller. In this mode, the channel controller generates the completion code internally. Early completion is typically useful for chaining, as it allows subsequent transfers to be chained-triggered while the previous transfer is still in progress within the transfer controller, maximizing the overall throughput of the set of the transfers.

### 10.3.5.3 Dummy or Null Completion

This is a variation of early completion. Dummy or null completion is associated with a dummy set ([Section 10.3.3.4](#)) or null set ([Section 10.3.3.3](#)). In both cases, the EDMA3 channel controller does not submit the associated transfer request to the EDMA3 transfer controllers. However, if the set (dummy/null) has the OPT field programmed to return completion code (intermediate/final interrupt/chaining completion), then it will set the appropriate bits in the interrupt pending registers (IPR/IPRH) or chained event register (CER/CERH). The internal early completion path is used by the channel controller to return the completion codes internally (that is, EDMA3CC generates the completion code).

## 10.3.6 Event, Channel, and PaRAM Mapping

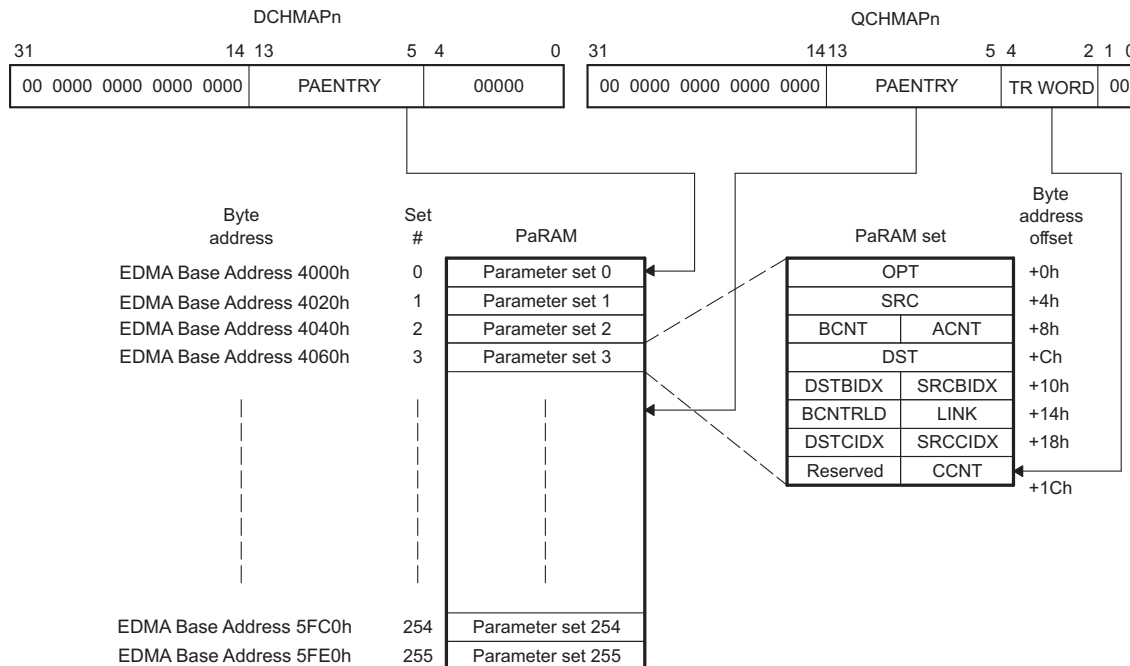

Several of the 64 DMA channels are tied to a specific hardware event, thus allowing events from device peripherals or external hardware to trigger transfers. A DMA channel typically requests a data transfer when it receives its event (apart from manually-triggered, chain-triggered, and other transfers). The amount of data transferred per synchronization event depends on the channel's configuration (ACNT, BCNT, CCNT, etc.) and the synchronization type (A-synchronized or AB-synchronized).

The association of an event to a channel is fixed, each DMA channel has one specific event associated with it. See [Section 7.2.2, EDMA Event Multiplexing](#), for a description of how DMA events map to the EDMA event crossbar. See [Section 10.3.20, EDMA Events](#), for a table of direct and crossbar mapped EDMA events.

In an application, if a channel does not use the associated synchronization event or if it does not have an associated synchronization event (unused), that channel can be used for manually-triggered or chained-triggered transfers, for linking/reloading, or as a QDMA channel.

### 10.3.6.1 DMA Channel to PaRAM Mapping

The mapping between the DMA channel numbers and the PaRAM sets is programmable (see [Table 10-5](#)). The DMA channel mapping registers (DCHMAPn) in the EDMA3CC provide programmability that allows the DMA channels to be mapped to any of the PaRAM sets in the PaRAM memory map. [Figure 10-13](#) illustrates the use of DCHMAP. There is one DCHMAP register per channel.

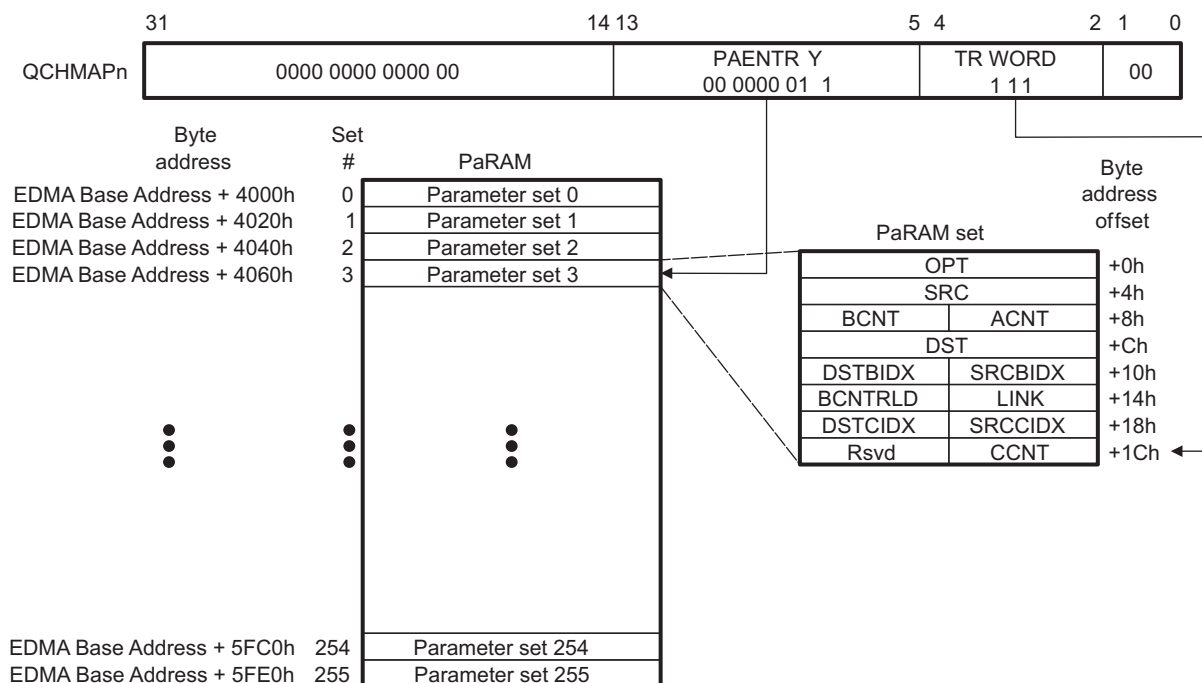

**Figure 10-13. DMA Channel and QDMA Channel to PaRAM Mapping**

### 10.3.6.2 QDMA Channel to PaRAM Mapping

The mapping between the QDMA channels and the PaRAM sets is programmable. The QDMA channel mapping register (QCHMAP) in the EDMA3CC allows you to map the QDMA channels to any of the PaRAM sets in the PaRAM memory map. [Figure 10-14](#) illustrates the use of QCHMAP.

Additionally, QCHMAP allows you to program the trigger word in the PaRAM set for the QDMA channel. A trigger word is one of the eight words in the PaRAM set. For a QDMA transfer to occur, a valid TR synchronization event for EDMA3CC is a write to the trigger word in the PaRAM set pointed to by QCHMAP for a particular QDMA channel. By default, QDMA channels are mapped to PaRAM set 0. You must appropriately re-map PaRAM set 0 before you use it.

### Figure 10-14. QDMA Channel to PaRAM Mapping

### 10.3.7 *EDMA3 Channel Controller Regions*

The EDMA3 channel controller divides its address space into eight regions. Individual channel resources are assigned to a specific region, where each region is typically assigned to a specific EDMA programmer.

You can design the application software to use regions or to ignore them altogether. You can use active memory protection in conjunction with regions so that only a specific EDMA programmer (for example, privilege identification) or privilege level (for example, user vs. supervisor) is allowed access to a given region, and thus to a given DMA or QDMA channel. This allows robust system-level DMA code where each EDMA programmer only modifies the state of the assigned resources. Memory protection is described in [Section 10.3.10](#).

### 10.3.7.1 Region Overview

The EDMA3 channel controller memory-mapped registers are divided in three main categories:

1. Global registers
2. Global region channel registers
3. Shadow region channel registers

The global registers are located at a single/fixed location in the EDMA3CC memory map. These registers control EDMA3 resource mapping and provide debug visibility and error tracking information.

The channel registers (including DMA, QDMA, and interrupt registers) are accessible via the global channel region address range, or in the shadow *n* channel region address ranges. For example, the event enable register (EER) is visible at the global address of EDMA Base Address + 1020h or region addresses of EDMA Base Address + 2020h for region 0, EDMA Base Address + 2220h for region 1, ... EDMA Base Address + 2E20h for region 7.

The DMA region access enable registers (DRAEm) and the QDMA region access enable registers (QRAEn) control the underlying control register bits that are accessible via the shadow region address space (except for IEVALn). [Table 10-11](#) lists the registers in the shadow region memory map. See the EDMA3CC memory map ([Section 10.4](#)) for the complete global memory maps. [Figure 10-15](#) illustrates the conceptual view of the regions.

**Table 10-11. Shadow Region Registers**

IEVAL		

**Figure 10-15. Shadow Region Registers**

### 10.3.7.2 Channel Controller Regions

There are eight EDMA3 shadow regions (and associated memory maps). Associated with each shadow region are a set of registers defining which channels and interrupt completion codes belong to that region. These registers are user-programmed per region to assign ownership of the DMA/QDMA channels to a region.

- **DRAEm and DRAEHm:** One register pair exists for each of the shadow regions. The number of bits in each register pair matches the number of DMA channels (64 DMA channels). These registers need to be programmed to assign ownership of DMA channels and interrupt (or TCC codes) to the respective region. Accesses to DMA and interrupt registers via the shadow region address view are filtered through the DRAE/DRAEH pair. A value of 1 in the corresponding DRAE(H) bit implies that the corresponding DMA/interrupt channel is accessible; a value of 0 in the corresponding DRAE(H) bit forces writes to be discarded and returns a value of 0 for reads.
- **QRAEn:** One register exists for every region. The number of bits in each register matches the number of QDMA channels (4 QDMA channels). These registers must be programmed to assign ownership of QDMA channels to the respective region. To enable a channel in a shadow region using shadow region 0 QEER, the respective bit in QRAE must be set or writing into QEESR will not have the desired effect.
- **MPPAn and MPPAG:** One register exists for every region. This register defines the privilege level, requestor, and types of accesses allowed to a region's memory-mapped registers.

It is typical for an application to have a unique assignment of QDMA/DMA channels (and, therefore, a given bit position) to a given region.

The use of shadow regions allows for restricted access to EDMA3 resources (DMA channels, QDMA channels, TCC, interrupts) by tasks in a system by setting or clearing bits in the DRAE/ORAE registers. If exclusive access to any given channel / TCC code is required for a region, then only that region's DRAE/ORAE should have the associated bit set.

#### Example 10-1. Resource Pool Division Across Two Regions

This example illustrates a judicious resource pool division across two regions, assuming region 0 must be allocated 16 DMA channels (0-15) and 1 QDMA channel (0) and 32 TCC codes (0-15 and 48-63). Region 1 needs to be allocated 16 DMA channels (16-32) and the remaining 7 QDMA channels (1-7) and TCC codes (16-47). DRAE should be equal to the OR of the bits that are required for the DMA channels and the TCC codes:

```
Region 0: DRAEH, DRAE = 0xFFFF0000, 0x0000FFFF QRAE = 0x00000001
Region 1: DRAEH, DRAE = 0x0000FFFF, 0xFFFF0000 QRAE = 0x000000FE
```

#### 10.3.7.3 Region Interrupts

In addition to the EDMA3CC global completion interrupt, there is an additional completion interrupt line that is associated with every shadow region. Along with the interrupt enable register (IER), DRAE acts as a secondary interrupt enable for the respective shadow region interrupts. See [Section 10.3.9](#) for more information.

#### 10.3.8 Chaining EDMA3 Channels

The channel chaining capability for the EDMA3 allows the completion of an EDMA3 channel transfer to trigger another EDMA3 channel transfer. The purpose is to allow you the ability to chain several events through one event occurrence.

Chaining is different from linking ([Section 10.3.3.7](#)). The EDMA3 link feature reloads the current channel parameter set with the linked parameter set. The EDMA3 chaining feature does not modify or update any channel parameter set; it provides a synchronization event to the chained channel (see [Section 10.3.4.1.3](#) for chain-triggered transfer requests).

Chaining is achieved at either final transfer completion or intermediate transfer completion, or both, of the current channel. Consider a channel *m* (DMA/QDMA) required to chain to channel *n*. Channel number *n* (0-63) needs to be programmed into the TCC bit of channel *m* channel options parameter (OPT) set.

- If final transfer completion chaining (TCCHEN = 1 in OPT) is enabled, the chain-triggered event occurs after the submission of the last transfer request of channel *m* is either submitted or completed (depending on early or normal completion).
- If intermediate transfer completion chaining (ITCCHEN = 1 in OPT) is enabled, the chain-triggered event occurs after every transfer request, except the last of channel *m* is either submitted or completed

(depending on early or normal completion).

- If both final and intermediate transfer completion chaining (TCCHEN = 1 and ITCCHEN = 1 in OPT) are enabled, then the chain-trigger event occurs after every transfer request is submitted or completed (depending on early or normal completion).

Table 10-12 illustrates the number of chain event triggers occurring in different synchronized scenarios. Consider channel 31 programmed with ACNT = 3, BCNT = 4, CCNT = 5, and TCC = 30.

**Table 10-12. Chain Event Triggers**

Options	(Number of chained event triggers on channel 30)	
	A-Synchronized	AB-Synchronized
TCCHEN = 1, ITCCHEN = 0	1 (Owing to the last TR)	1 (Owing to the last TR)
TCCHEN = 0, ITCCHEN = 1	19 (Owing to all but the last TR)	4 (Owing to all but the last TR)
TCCHEN = 1, ITCCHEN = 1	20 (Owing to a total of 20 TRs)	5 (Owing to a total of 5 TRs)

### 10.3.9 EDMA3 Interrupts

The EDMA3 interrupts are divided into 2 categories: transfer completion interrupts and error interrupts.

There are nine region interrupts, eight shadow regions and one global region. The transfer completion interrupts are listed in Table 10-13. The transfer completion interrupts and the error interrupts from the transfer controllers are all routed to the ARM interrupt controllers.

**Table 10-13. EDMA3 Transfer Completion Interrupts**

Name	Description
EDMA3CC_INT0	EDMA3CC Transfer Completion Interrupt Shadow Region 0
EDMA3CC_INT1	EDMA3CC Transfer Completion Interrupt Shadow Region 1
EDMA3CC_INT2	EDMA3CC Transfer Completion Interrupt Shadow Region 2
EDMA3CC_INT3	EDMA3CC Transfer Completion Interrupt Shadow Region 3
EDMA3CC_INT4	EDMA3CC Transfer Completion Interrupt Shadow Region 4
EDMA3CC_INT5	EDMA3CC Transfer Completion Interrupt Shadow Region 5
EDMA3CC_INT6	EDMA3CC Transfer Completion Interrupt Shadow Region 6
EDMA3CC_INT7	EDMA3CC Transfer Completion Interrupt Shadow Region 7

**Table 10-14. EDMA3 Error Interrupts**

Name	Description
EDMA3CC_ERRINT	EDMA3CC Error Interrupt
EDMA3CC_MPINT	EDMA3CC Memory Protection Interrupt
EDMA3TC0_ERRINT	TC0 Error Interrupt
EDMA3TC1_ERRINT	TC1 Error Interrupt
EDMA3TC2_ERRINT	TC2 Error Interrupt
EDMA3TC3_ERRINT	TC3 Error Interrupt

#### 10.3.9.1 Transfer Completion Interrupts

The EDMA3CC is responsible for generating transfer completion interrupts to the CPUs (and other EDMA3 masters). The EDMA3 generates a single completion interrupt per shadow region, as well as one for the global region on behalf of all 64 channels. The various control registers and bit fields facilitate EDMA3 interrupt generation.

The software architecture should either use the global interrupt or the shadow interrupts, but not both.

The transfer completion code (TCC) value is directly mapped to the bits of the interrupt pending register (IPR/IPRH). For example, if TCC = 10 0001b, IPRH[1] is set after transfer completion, and results in interrupt generation to the CPUs if the completion interrupt is enabled for the CPU. See [Section 10.3.9.1.1](#) for details on enabling EDMA3 transfer completion interrupts.

When a completion code is returned (as a result of early or normal completions), the corresponding bit in IPR/IPRH is set if transfer completion interrupt (final/intermediate) is enabled in the channel options parameter (OPT) for a PaRAM set associated with the transfer.

**Table 10-15. Transfer Complete Code (TCC) to EDMA3CC Interrupt Mapping**

TCC Bits in OPT (TCINTEN/ITCINTEN = 1)	IPR Bit Set	TCC Bits in OPT (TCINTEN/ITCINTEN = 1)	IPRH Bit Set <sup>(1)</sup>
0	IPR0	20h	IPR32/IPRH0
1	IPR1	21h	IPR33/IPRH1
2h	IPR2	22h	IPR34/IPRH2
3h	IPR3	23h	IPR35/IPRH3
4h	IPR4	24h	IPR36/IPRH4
...	...	...	...
1Eh	IPR30	3Eh	IPR62/IPRH30
1Fh	IPR31	3Fh	IPR63/IPRH31

<sup>(1)</sup> Bit fields IPR[32-63] correspond to bits 0 to 31 in IPRH, respectively.

You can program the transfer completion code (TCC) to any value for a DMA/QDMA channel. A direct relation between the channel number and the transfer completion code value does not need to exist. This allows multiple channels having the same transfer completion code value to cause a CPU to execute the same interrupt service routine (ISR) for different channels.

If the channel is used in the context of a shadow region and you intend for the shadow region interrupt to be asserted, then ensure that the bit corresponding to the TCC code is enabled in IER/IERH and in the corresponding shadow region's DMA region access registers (DRAE/DRAEH).

You can enable Interrupt generation at either final transfer completion or intermediate transfer completion, or both. Consider channel *m* as an example.

- If the final transfer interrupt (TCCINT = 1 in OPT) is enabled, the interrupt occurs after the last transfer request of channel *m* is either submitted or completed (depending on early or normal completion).
- If the intermediate transfer interrupt (ITCCINT = 1 in OPT) is enabled, the interrupt occurs after every transfer request, except the last TR of channel *m* is either submitted or completed (depending on early or normal completion).
- If both final and intermediate transfer completion interrupts (TCCINT = 1, and ITCCINT = 1 in OPT) are enabled, then the interrupt occurs after every transfer request is submitted or completed (depending on early or normal completion).

[Table 10-16](#) shows the number of interrupts that occur in different synchronized scenarios. Consider channel 31, programmed with ACNT = 3, BCNT = 4, CCNT = 5, and TCC = 30.

**Table 10-16. Number of Interrupts**

Options	A-Synchronized	AB-Synchronized
TCINTEN = 1, ITCINTEN = 0	1 (Last TR)	1 (Last TR)
TCINTEN = 0, ITCINTEN = 1	19 (All but the last TR)	4 (All but the last TR)
TCINTEN = 1, ITCINTEN = 1	20 (All TRs)	5 (All TRs)

### 10.3.9.1.1 Enabling Transfer Completion Interrupts

For the EDMA3 channel controller to assert a transfer completion to the external environment, the interrupts must be enabled in the EDMA3CC. This is in addition to setting up the TCINTEN and ITCINTEN bits in OPT of the associated PaRAM set.

The EDMA3 channel controller has interrupt enable registers (IER/IERH) and each bit location in IER/IERH serves as a primary enable for the corresponding interrupt pending registers (IPR/IPRH).

All of the interrupt registers (IER, IESR, IECR, and IPR) are either manipulated from the global DMA channel region, or by the DMA channel shadow regions. The shadow regions provide a view to the same set of physical registers that are in the global region.

The EDMA3 channel controller has a hierarchical completion interrupt scheme that uses a single set of interrupt pending registers (IPR/IPRH) and single set of interrupt enable registers (IER/IERH). The programmable DMA region access enable registers (DRAE/DRAEH) provides a second level of interrupt masking. The global region interrupt output is gated based on the enable mask that is provided by IER/IERH. see [Figure 10-16](#)

The region interrupt outputs are gated by IER and the specific DRAE/DRAEH associated with the region. See [Figure 10-16](#).

**Figure 10-16. Interrupt Diagram**

For the EDMA3CC to generate the transfer completion interrupts that are associated with each shadow region, the following conditions must be true:

- EDMA3CC\_INT0: (IPR.E0 & IER.E0 & DRAE0.E0) | (IPR.E1 & IER.E1 & DRAE0.E1) | ...|(IPRH.E63 & IERH.E63 & DRAHE0.E63)
- EDMA3CC\_INT1: (IPR.E0 & IER.E0 & DRAE1.E0) | (IPR.E1 & IER.E1 & DRAE1.E1) | ...| (IPRH.E63 & IERH.E63 & DRAHE1.E63)
- EDMA3CC\_INT2 : (IPR.E0 & IER.E0 & DRAE2.E0) | (IPR.E1 & IER.E1 & DRAE2.E1) | ...|(IPRH.E63 & IERH.E63 & DRAHE2.E63)....

- Up to EDMA3CC\_INT7 : (IPR.E0 & IER.E0 & DRAE7.E0) | (IPR.E1 & IER.E1 & DRAE7.E1) | ...|(IPRH.E63 & IERH.E63 & DRAEH7.E63)

**NOTE:** The DRAE/DRAEH for all regions are expected to be set up at system initialization and to remain static for an extended period of time. The interrupt enable registers should be used for dynamic enable/disable of individual interrupts.

Because there is no relation between the TCC value and the DMA/QDMA channel, it is possible, for example, for DMA channel 0 to have the OPT.TCC = 63 in its associated PaRAM set. This would mean that if a transfer completion interrupt is enabled (OPT.TCINTEN or OPT.ITCINTEN is set), then based on the TCC value, IPRH.E63 is set up on completion. For proper channel operations and interrupt generation using the shadow region map, you must program the DRAE/DRAEH that is associated with the shadow region to have read/write access to both bit 0 (corresponding to channel 0) and bit 63 (corresponding to IPRH bit that is set upon completion).

### 10.3.9.1.2 Clearing Transfer Completion Interrupts

Transfer completion interrupts that are latched to the interrupt pending registers (IPR/IPRH) are cleared by writing a 1 to the corresponding bit in the interrupt pending clear register (ICR/ICRH). For example, a write of 1 to ICR.E0 clears a pending interrupt in IPR.E0.

If an incoming transfer completion code (TCC) gets latched to a bit in IPR/IPRH, then additional bits that get set due to a subsequent transfer completion will not result in asserting the EDMA3CC completion interrupt. In order for the completion interrupt to be pulsed, the required transition is from a state where no enabled interrupts are set to a state where at least one enabled interrupt is set.

### 10.3.9.2 EDMA3 Interrupt Servicing

Upon completion of a transfer (early or normal completion), the EDMA3 channel controller sets the appropriate bit in the interrupt pending registers (IPR/IPRH), as the transfer completion codes specify. If the completion interrupts are appropriately enabled, then the CPU enters the interrupt service routine (ISR) when the completion interrupt is asserted.

After servicing the interrupt, the ISR should clear the corresponding bit in IPR/IPRH, thereby enabling recognition of future interrupts. The EDMA3CC will only assert additional completion interrupts when all IPR/IPRH bits clear.

When one interrupt is serviced many other transfer completions may result in additional bits being set in IPR/IPRH, thereby resulting in additional interrupts. Each of the bits in IPR/IPRH may need different types of service; therefore, the ISR may check all pending interrupts and continue until all of the posted interrupts are serviced appropriately.

Examples of pseudo code for a CPU interrupt service routine for an EDMA3CC completion interrupt are shown in [Example 10-2](#) and [Example 10-3](#).

The ISR routine in [Example 10-2](#) is more exhaustive and incurs a higher latency.

#### Example 10-2. Interrupt Servicing

The pseudo code:

1. Reads the interrupt pending register (IPR/IPRH).
2. Performs the operations needed.
3. Writes to the interrupt pending clear register (ICR/ICRH) to clear the corresponding IPR/IPRH bits.
4. Reads IPR/IPRH again:
  - (a) If IPR/IPRH is not equal to 0, repeat from step 2 (implies occurrence of new event between step 2 to step 4).
  - (b) If IPR/IPRH is equal to 0, this should assure you that all of the enabled interrupts are inactive.

### Example 10-2. Interrupt Servicing (continued)

**NOTE:** An event may occur during step 4 while the IPR/IPRH bits are read as 0 and the application is still in the interrupt service routine. If this happens, a new interrupt is recorded in the device interrupt controller and a new interrupt generates as soon as the application exits in the interrupt service routine.

[Example 10-3](#) is less rigorous, with less burden on the software in polling for set interrupt bits, but can occasionally cause a race condition as mentioned above.

### Example 10-3. Interrupt Servicing

If you want to leave any enabled and pending (possibly lower priority) interrupts; you must force the interrupt logic to reassert the interrupt pulse by setting the EVAL bit in the interrupt evaluation register (IEVAL).

The pseudo code is as follows:

1. Enters ISR.
2. Reads IPR/IPRH.
3. For the condition that is set in IPR/IPRH that you want to service, do the following:
  - (a) Service interrupt as the application requires.
  - (b) Clear the bit for serviced conditions (others may still be set, and other transfers may have resulted in returning the TCC to EDMA3CC after step 2).
4. Reads IPR/IPRH prior to exiting the ISR:
  - (a) If IPR/IPRH is equal to 0, then exit the ISR.
  - (b) If IPR/IPRH is not equal to 0, then set IEVAL so that upon exit of ISR, a new interrupt triggers if any enabled interrupts are still pending.

#### 10.3.9.3 Interrupt Evaluation Operations

The EDMA3CC has interrupt evaluate registers (IEVAL) that exist in the global region and in each shadow region. The registers in the shadow region are the only registers in the DMA channel shadow region memory map that are not affected by the settings for the DMA region access enable registers (DRAE/DRAEH). Writing a 1 to the EVAL bit in the registers that are associated with a particular shadow region results in pulsing the associated region interrupt (global or shadow), if any enabled interrupt (via IER/IERH) is still pending (IPR/IPRH). This register assures that the CPU does not miss the interrupts (or the EDMA3 master associated with the shadow region) if the software architecture chooses not to use all interrupts. See [Example 10-3](#) for the use of IEVAL in the EDMA3 interrupt service routine (ISR).

Similarly, an error evaluation register (EEVAL) exists in the global region. Writing a 1 to the EVAL bit in EEVAL causes the pulsing of the error interrupt if any pending errors are in EMR/EMRH, QEMR, or CCERR. The EVAL bit must be written with 1 to clear interrupts to the INTC, even when all error interrupt registers are cleared. See [Section 10.3.9.4, Error Interrupts](#), for additional information regarding error interrupts.

**NOTE:** While using IEVAL for shadow region completion interrupts, you should make sure that the IEVAL operated upon is from that particular shadow region memory map.

#### 10.3.9.4 Error Interrupts

The EDMA3CC error registers provide the capability to differentiate error conditions (event missed, threshold exceed, etc.). Additionally, setting the error bits in these registers results in asserting the EDMA3CC error interrupt. If the EDMA3CC error interrupt is enabled in the device interrupt controllers, then it allows the CPUs to handle the error conditions.

The EDMA3CC has a single error interrupt (EDMA3CC\_ERRINT) that is asserted for all EDMA3CC error conditions. There are four conditions that cause the error interrupt to pulse:

- DMA missed events: for all 64 DMA channels. DMA missed events are latched in the event missed registers (EMR/EMRH).
- QDMA missed events: for all 8 QDMA channels. QDMA missed events are latched in the QDMA event missed register (QEMR).
- Threshold exceed: for all event queues. These are latched in EDMA3CC error register (CCERR).
- TCC error: for outstanding transfer requests that are expected to return completion code (TCCHEN or TCINTEN bit in OPT is set to 1) exceeding the maximum limit of 63. This is also latched in the EDMA3CC error register (CCERR).

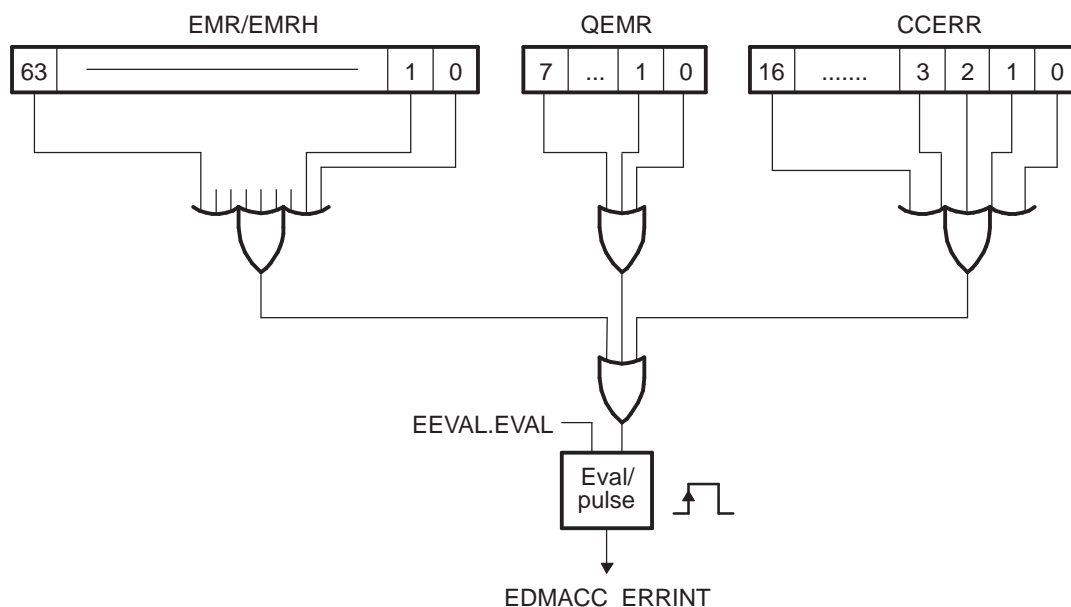

Figure 10-17 illustrates the EDMA3CC error interrupt generation operation.

If any of the bits are set in the error registers due to any error condition, the EDMA3CC\_ERRINT is always asserted, as there are no enables for masking these error events. Similar to transfer completion interrupts (EDMA3CC\_INT), the error interrupt also only pulses when the error interrupt condition transitions from no errors being set to at least one error being set. If additional error events are latched prior to the original error bits clearing, the EDMA3CC does not generate additional interrupt pulses.

To reduce the burden on the software, there is an error evaluate register (EEVAL) that allows re-evaluation of pending set error events/bits, similar to the interrupt evaluate register (IEVAL). You can use this so that the CPU does not miss any error events. You must write a 1 to the EEVAL.EVAL bit to clear interrupts to the INTC after all error registers have been cleared.

**NOTE:** It is good practice to enable the error interrupt in the device interrupt controller and to associate an interrupt service routine with it to address the various error conditions appropriately. Doing so puts less burden on the software (polling for error status); additionally, it provides a good debug mechanism for unexpected error conditions.

**Figure 10-17. Error Interrupt Operation**

### 10.3.10 Memory Protection

The EDMA3 channel controller supports two kinds of memory protection: active and proxy.

#### 10.3.10.1 Active Memory Protection

Active memory protection is a feature that allows or prevents read and write accesses (by any EDMA3 programmer) to the EDMA3CC registers (based on permission characteristics that you program). Active memory protection is achieved by a set of memory protection permissions attribute (MPPA) registers.

The EDMA3CC register map is divided into three categories:

- a global region.
- a global channel region.
- eight shadow regions.

Each shadow region consists of the respective shadow region registers and the associated PaRAM. For more detailed information regarding the contents of a shadow region, refer to section [Table 10-11](#).

Each of the eight shadow regions has an associated MPPA register (MPPA<sub>n</sub>) that defines the specific requestors and types of requests that are allowed to the regions resources.

The global channel region is also protected with a memory-mapped register (MPPAG). The MPPAG applies to the global region and to the global channel region, except the other MPPA registers themselves. For more detailed information on the list of the registers in each region, refer to the register memory-map in [Table 10-18](#).

The MPPA<sub>n</sub> have a certain set of access rules. For more information, see the bit field descriptions of MPPA<sub>n</sub>.

[Table 10-17](#) shows the accesses that are allowed or not allowed to the MPPAG and MPPA<sub>n</sub>. The active memory protection uses the PRIV and PRIVID attributes of the EDMA programmer. The PRIV is the privilege level (i.e., user vs. supervisor). The PRIVID refers to a privilege ID with a number that is associated with an EDMA3 programmer. See the device-specific data manual for the PRIVIDs that are associated with potential EDMA3 programmers.

**Table 10-17. Allowed Accesses**

Access	Supervisor	User
Read	Yes	Yes
Write	Yes	No

[Table 10-18](#) describes the MPPA register mapping for the shadow regions (which includes shadow region registers and PaRAM addresses).

The region-based MPPA registers are used to protect accesses to the DMA shadow regions and the associated region PaRAM. Because there are eight regions, there are eight MPPA region registers (MPPA[0-7]).

**Table 10-18. MPPA Registers to Region Assignment**

Register	Registers Protect	Address Range	PaRAM Protect <sup>(1)</sup>	Address Range
MPPAG	Global Range	0000h-1FFCh	N/A	N/A
MPPA0	DMA Shadow 0	2000h-21FCh	1st octant	4000h-47FCh
MPPA1	DMA Shadow 1	2200h-23FCh	2nd octant	4800h-4FFCh
MPPA2	DMA Shadow 2	2400h-25FCh	3rd octant	5000h-57FCh
MPPA3	DMA Shadow 3	2600h-27FCh	4th octant	5800h-5FFCh
MPPA4	DMA Shadow 4	2800h-29FCh	5th octant	6000h-67FCh
MPPA5	DMA Shadow 5	2A00h-2BFCh	6th octant	6800h-6FFCh
MPPA6	DMA Shadow 6	2C00h-2DFCh	7th octant	7000h-77FCh
MPPA7	DMA Shadow 7	2E00h-2FFCh	8th octant	7800h-7FFCh

<sup>(1)</sup> The PARAM region is divided into 8 regions referred to as an octant.

Example Access denied.

Write access to shadow region 7's event enable set register (EESR):

1. The original value of the event enable register (EER) at address offset 0x1020 is 0x0.
2. The MPPA[7] is set to prevent user level accesses (UW = 0, UR = 0), but it allows supervisor level accesses (SW = 1, SR = 1) with a privilege ID of 0. (AID0 = 1).
3. An EDMA3 programmer with a privilege ID of 0 attempts to perform a user-level write of a value of 0xFF00FF00 to shadow region 7's event enable set register (EESR) at address offset 0x2E30. Note that the EER is a read-only register and the only way that you can write to it is by writing to the EESR. Also remember that there is only one physical register for EER, EESR, etc. and that the shadow regions only provide to the same physical set.
4. Since the MPPA[7] has UW = 0, though the privilege ID of the write access is set to 0, the access is not allowed and the EER is not written to.

**Table 10-19. Example Access Denied**

Register	Value	Description
EER (offset 0x1020)	0x0000 0000	Value in EER to begin with.
EESR (offset 0x2E30)	0xFF00 FF00 ↓	Value attempted to be written to shadow region 7's EESR. This is done by an EDMA3 programmer with a privilege level of User and Privilege ID of 0.
MPPA[7] (offset 0x082C)	0x0000 04B0	Memory Protection Filter AID0 = 1, UW = 0, UR = 0, SW = 1, SR = 1.
	X	Access Denied
EER (offset 0x1020)	0x0000 0000	Final value of EER

Example Access Allowed

Write access to shadow region 7's event enable set register (EESR):

1. The original value of the event enable register (EER) at address offset 0x1020 is 0x0.
2. The MPPA[7] is set to allow user-level accesses (UW = 1, UR = 1) and supervisor-level accesses (SW = 1, SR = 1) with a privilege ID of 0. (AID0 = 1).
3. An EDMA3 programmer with a privilege ID of 0, attempts to perform a user-level write of a value of 0xABCD0123 to shadow region 7's event enable set register (EESR) at address offset 0x2E30. Note that the EER is a read-only register and the only way that you can write to it is by writing to the EESR. Also remember that there is only one physical register for EER, EESR, etc. and that the shadow regions only provide to the same physical set.
4. Since the MPPA[7] has UW = 1 and AID0 = 1, the user-level write access is allowed.
5. Remember that accesses to shadow region registers are masked by their respective DRAE register. In this example, the DRAE[7] is set of 0x9FF00FC2.
6. The value finally written to EER is 0x8BC00102.

**Table 10-20. Example Access Allowed**

Register	Value	Description
EER (offset 0x1020)	0x0000 0000	Value in EER to begin with.
EESR (offset 0x2E30)	0xFF00 FF00	Value attempted to be written to shadow region 7's EESR. This is done by an EDMA3 programmer with a privilege level of User and Privilege ID of 0.
MPPA[7] (offset 0x082C)	0x0000 04B3	Memory Protection Filter AID = 1, UW = 1, UR = 1, SW = 1, SR = 1.
	√ ↓	Access allowed.
DRAE[7] (offset 0x0378)	0x9FF0 0FC2 ↓	DMA Region Access Enable Filter
EESR (offset 0x2E30)	0x8BC0 0102 ↓	Value written to shadow region 7's EESR. This is done by an EDMA3 programmer with a privilege level of User and a Privilege ID of 0.
EER (offset 0x1020)	0xBC0 0102	Final value of EER.

### 10.3.10.2 Proxy Memory Protection

Proxy memory protection allows an EDMA3 transfer programmed by a given EDMA3 programmer to have its permissions travel with the transfer through the EDMA3TC. The permissions travel along with the read transactions to the source and the write transactions to the destination endpoints. The PRIV bit and PRIVID bit in the channel options parameter (OPT) is set with the EDMA3 programmer's PRIV value and PRIVID values, respectively, when any part of the PaRAM set is written.

The PRIV is the privilege level (i.e., user vs. supervisor). The PRIVID refers to a privilege ID with a number that is associated with an EDMA3 programmer.

See the data manual for the PRIVIDs that are associated with potential EDMA3 programmers.

These options are part of the TR that are submitted to the transfer controller. The transfer controller uses the above values on their respective read and write command bus so that the target endpoints can perform memory protection checks based on these values.

Consider a parameter set that is programmed by a CPU in user privilege level for a simple transfer with the source buffer on an L2 page and the destination buffer on an L1D page. The PRIV is 0 for user-level and the CPU has a PRIVID of 0.

The PaRAM set is shown in [Figure 10-18](#).

**Figure 10-18. PaRAM Set Content for Proxy Memory Protection Example**

(a) EDMA3 Parameters

Parameter Contents		Parameter	
0010 0007h		Channel Options Parameter (OPT)	
009F 0000h		Channel Source Address (SRC)	
0001h	0004h	Count for 2nd Dimension (BCNT)	Count for 1st Dimension (ACNT)
00F0 7800h		Channel Destination Address (DST)	
0001h	0001h	Destination BCNT Index (DSTBIDX)	Source BCNT Index (SRCBIDX)
0000h	FFFFh	BCNT Reload (BCNTRLD)	Link Address (LINK)
0001h	1000h	Destination CCNT Index (DSTCIDX)	Source CCNT Index (SRCCIDX)
0000h	0001h	Reserved	Count for 3rd Dimension (CCNT)

**Figure 10-19. Channel Options Parameter (OPT) Example**

(b) Channel Options Parameter (OPT) Content

31	30	29	28	27	24	23	22	21	20	19	18	17	16
0	0	00	0000		0	0	0	0	1	00	00		
PRIV Rsvd		Rsvd	PRIVID		ITCCHEN	TCCHEN	ITCINTEN	TCINTEN	Reserved		TCC		
15	12		11	10	8	7	4		3	2	1	0	
0000		0		000	0000		0		1	1	1		
TCC		TCCMOD		FWID	Reserved		STATIC		SYNCDIM	DAM	SAM		

The PRIV and PRIVID information travels along with the read and write requests that are issued to the source and destination memories.

For example, if the access attributes that are associated with the L2 page with the source buffer only allow supervisor read, write accesses (SR,SW), the user-level read request above is refused. Similarly, if the access attributes that are associated with the L1D page with the destination buffer only allow supervisor read and write accesses (SR, SW), the user-level write request above is refused. For the transfer to succeed, the source and destination pages should have user-read and user-write permissions, respectively, along with allowing accesses from a PRIVID 0.

Because the programmer's privilege level and privilege identification travel with the read and write requests, EDMA3 acts as a proxy.

Figure 10-20 illustrates the propagation of PRIV and PRIVID at the boundaries of all the interacting entities (CPU, EDMA3CC, EDMA3TC, and slave memories).

**Figure 10-20. Proxy Memory Protection Example**

### 10.3.11 Event Queues

Event queues are a part of the EDMA3 channel controller. Event queues form the interface between the event detection logic in the EDMA3CC and the transfer request (TR) submission logic of the EDMA3CC. Each queue is 16 entries deep; thus, each event queue can queue a maximum of 16 events. If there are more than 16 events, then the events that cannot find a place in the event queue remain set in the associated event register and the CPU does not stall.

There are four event queues for the device: Queue0, Queue1, Queue2, and Queue3. Events in Queue0 result in submission of its associated transfer requests (TRs) to TC0. Similarly, transfer requests that are associated with events in Queue3 are submitted to TC3.

An event that wins prioritization against other DMA and/or QDMA pending events is placed at the tail of the appropriate event queue. Each event queue is serviced in FIFO order. Once the event reaches the head of its queue and the corresponding transfer controller is ready to receive another TR, the event is de-queued and the PaRAM set corresponding to the de-queued event is processed and submitted as a transfer request packet (TRP) to the associated EDMA3 transfer controller.

Queue0 has highest priority and Queue3 has the lowest priority, if Queue0 and Queue1 both have at least one event entry and if both TC0 and TC1 can accept transfer requests, then the event in Queue0 is de-queued first and its associated PaRAM set is processed and submitted as a transfer request (TR) to TC0.

See [Section 10.3.11.4](#) for system-level performance considerations. All of the event entries in all of the event queues are software readable (not writeable) by accessing the event entry registers (Q0E0, Q0E1,...Q1E15, and so on). Each event entry register characterizes the queued event in terms of the type of event (manual, event, chained or auto-triggered) and the event number. For more information, see the bit fields in the queue event entry (QxEy) registers.

#### 10.3.11.1 DMA/QDMA Channel to Event Queue Mapping

Each of the 64 DMA channels and eight QDMA channels are programmed independently to map to a specific queue, using the DMA queue number register (DMAQNUM) and the QDMA queue number register (QDMANUM). The mapping of DMA/QDMA channels is critical to achieving the desired performance level for the EDMA and most importantly, in meeting real-time deadlines. See [Section 10.3.11.4](#).

**NOTE:** If an event is ready to be queued and both the event queue and the EDMA3 transfer controller that is associated to the event queue are empty, then the event bypasses the event queue, and moves the PaRAM processing logic, and eventually to the transfer request submission logic for submission to the EDMA3TC. In this case, the event is not logged in the event queue status registers.

### 10.3.11.2 Queue RAM Debug Visibility

There are four event queues and each queue has 16 entries. These 16 entries are managed in a circular FIFO manner. There is a queue status register (QSTAT) associated with each queue. These along with all of the 16 entries per queue can be read via registers QSTAT $n$  and QxEy, respectively.

These registers provide user visibility and may be helpful while debugging real-time issues (typically post-mortem), involving multiple events and event sources. The event queue entry register (QxEy) uniquely identifies the specific event type (event-triggered, manually-triggered, chain-triggered, and QDMA events) along with the event number (for all DMA/QDMA event channels) that are in the queue or have been de-queued (passed through the queue).

Each of the 16 entries in the event queue are read using the EDMA3CC memory-mapped register. By reading the event queue, you see the history of the last 16 TRs that have been processed by the EDMA3 on a given queue. This provides user/software visibility and is helpful for debugging real-time issues (typically post-mortem), involving multiple events and event sources.

The queue status register (QSTAT $n$ ) includes fields for the start pointer (STRTPTR) which provides the offset to the head entry of an event. It also includes a field called NUMVAL that provides the total number of valid entries residing in the event queue at a given instance of time. The STRTPTR may be used to index appropriately into the 16 event entries. NUMVAL number of entries starting from STRTPTR are indicative of events still queued in the respective queue. The remaining entry may be read to determine what's already de-queued and submitted to the associated transfer controller.

### 10.3.11.3 Queue Resource Tracking

The EDMA3CC event queue includes watermarking/threshold logic that allows you to keep track of maximum usage of all event queues. This is useful for debugging real-time deadline violations that may result from head-of-line blocking on a given EDMA3 event queue.

You can program the maximum number of events that can queue up in an event queue by programming the threshold value (between 0 to 15) in the queue watermark threshold A register (QWMTHRA). The maximum queue usage is recorded actively in the watermark (WM) field of the queue status register (QSTAT $n$ ) that keeps getting updated based on a comparison of number of valid entries, which is also visible in the NUMVAL bit in QSTAT $n$  and the maximum number of entries (WM bit in QSTAT $n$ ).

If the queue usage is exceeded, this status is visible in the EDMA3CC registers: the QTHRXCD $n$  bit in the channel controller error register (CCERR) and the THRXCD bit in QSTAT $n$ , where  $n$  stands for the event queue number. Any bits that are set in CCERR also generate an EDMA3CC error interrupt.

### 10.3.11.4 Performance Considerations

The main system bus infrastructure (L3) arbitrates bus requests from all of the masters (TCs, CPU(S), and other bus masters) to the shared slave resources (peripherals and memories).

The priorities of transfer requests (read and write commands) from the EDMA3 transfer controllers with respect to other masters within the system crossbar are programmed using the queue priority register (QUEPRI). QUEPRI programs the priority of the event queues (or indirectly, TC0-TC3, because Queue $N$  transfer requests are submitted to TCM).

Therefore, the priority of unloading queues has a secondary affect compared to the priority of the transfers as they are executed by the EDMA3TC (dictated by the priority set using QUEPRI).

### 10.3.12 EDMA3 Transfer Controller (EDMA3TC)

The EDMA3 channel controller is the user-interface of the EDMA3 and the EDMA3 transfer controller (EDMA3TC) is the data movement engine of the EDMA3. The EDMA3CC submits transfer requests (TR) to the EDMA3TC and the EDMA3TC performs the data transfers dictated by the TR; thus, the EDMA3TC is a slave to the EDMA3CC.

#### 10.3.12.1 Architecture Details

##### 10.3.12.1.1 Command Fragmentation

The TC read and write controllers in conjunction with the source and destination register sets are responsible for issuing optimally-sized reads and writes to the slave endpoints. An optimally-sized command is defined by the transfer controller default burst size (DBS), which is defined in [Section 10.3.12.5](#).

The EDMA3TC attempts to issue the largest possible command size as limited by the DBS value or the ACNT/BCNT value of the TR. EDMA3TC obeys the following rules:

- The read/write controllers always issue commands less than or equal to the DBS value.
- The first command of a 1D transfer command always aligns the address of subsequent commands to the DBS value.

[Table 10-21](#) lists the TR segmentation rules that are followed by the EDMA3TC. In summary, if the ACNT value is larger than the DBS value, then the EDMA3TC breaks the ACNT array into DBS-sized commands to the source/destination addresses. Each BCNT number of arrays are then serviced in succession.

For BCNT arrays of ACNT bytes (that is, a 2D transfer), if the ACNT value is less than or equal to the DBS value, then the TR may be optimized into a 1D-transfer in order to maximize efficiency. The optimization takes place if the EDMA3TC recognizes that the 2D-transfer is organized as a single dimension (ACNT == BIDX) and the ACNT value is a power of 2.

[Table 10-21](#) lists conditions in which the optimizations are performed.

**Table 10-21. Read/Write Command Optimization Rules**

ACNT ≤ DBS	ACNT is power of 2	BIDX = ACNT	BCNT ≤ 1023	SAM/DAM = Increment	Description
Yes	Yes	Yes	Yes	Yes	Optimized
No	x	x	x	x	Not Optimized
x	No	x	x	x	Not Optimized
x	x	No	x	x	Not Optimized
x	x	x	No	x	Not Optimized
x	x	x	x	No	Not Optimized

##### 10.3.12.1.2 TR Pipelining

TR pipelining refers to the ability of the source active set to proceed ahead of the destination active set. Essentially, the reads for a given TR may already be in progress while the writes of a previous TR may not have completed.

The number of outstanding TRs is limited by the number of destination FIFO register entries.

TR pipelining is useful for maintaining throughput on back-to-back small TRs. It minimizes the startup overhead because reads start in the background of a previous TR writes.

#### Example 10-4. Command Fragmentation (DBS = 64)

The pseudo code:

1. ACNT = 8, BCNT = 8, SRCBIDX = 8, DSTBIDX = 10, SRCADDR = 64, DSTADDR = 191

Read Controller: This is optimized from a 2D-transfer to a 1D-transfer such that the read side is equivalent to ACNT = 64, BCNT = 1.

Cmd0 = 64 byte

Write Controller: Because DSTBIDX != ACNT, it is not optimized.

Cmd0 = 8 byte, Cmd1 = 8 byte, Cmd2 = 8 byte, Cmd3 = 8 byte, Cmd4 = 8 byte, Cmd5 = 8 byte, Cmd6 = 8 byte, Cmd7 = 8 byte.

2. ACNT=128, BCNT = 1, SRCADDR = 63, DSTADDR = 513

Read Controller: Read address is not aligned.

Cmd0 = 1 byte, (now the SRCADDR is aligned to 64 for the next command)

Cmd1 = 64 bytes

Cmd2 = 63 bytes

Write Controller: The write address is also not aligned.

Cmd0 = 63 bytes, (now the DSTADDR is aligned to 64 for the next command)

Cmd1 = 64 bytes

Cmd2 = 1 byte

#### 10.3.12.1.3 Performance Tuning

By default, reads are as issued as fast as possible. In some cases, the reads issued by the EDMA3TC could fill the available command buffering for a slave, delaying other (potentially higher priority) masters from successfully submitting commands to that slave. The rate at which read commands are issued by the EDMA3TC is controlled by the RDRATE register. The RDRATE register defines the number of cycles that the EDMA3TC read controller waits before issuing subsequent commands for a given TR, thus minimizing the chance of the EDMA3TC consuming all available slave resources. The RDRATE value should be set to a relatively small value if the transfer controller is targeted for high priority transfers and to a higher value if the transfer controller is targeted for low priority transfers.

In contrast, the Write Interface does not have any performance turning knobs because writes always have an interval between commands as write commands are submitted along with the associated write data.

#### 10.3.12.2 Memory Protection

The transfer controller plays an important role in handling proxy memory protection. There are two access properties associated with a transfer: for instance, the privilege id (system-wide identification assigned to a master) of the master initiating the transfer, and the privilege level (user versus supervisor) used to program the transfer. This information is maintained in the PaRAM set when it is programmed in the channel controller. When a TR is submitted to the transfer controller, this information is made available to the EDMA3TC and used by the EDMA3TC while issuing read and write commands. The read or write commands have the same privilege identification, and privilege level as that programmed in the EDMA3 transfer in the channel controller.

#### 10.3.12.3 Error Generation

Errors are generated if enabled under three conditions:

- EDMA3TC detection of an error signaled by the source or destination address.
- Attempt to read or write to an invalid address in the configuration memory map.
- Detection of a constant addressing mode TR violating the constant addressing mode transfer rules (the source/destination addresses and source/destination indexes must be aligned to 32 bytes).

Either or all error types may be disabled. If an error bit is set and enabled, the error interrupt for the concerned transfer controller is pulsed.

#### 10.3.12.4 Debug Features

The DMA program register set, DMA source active register set, and the destination FIFO register set are used to derive a brief history of TRs serviced through the transfer controller.

Additionally, the EDMA3TC status register (TCSTAT) has dedicated bit fields to indicate the ongoing activity within different parts of the transfer controller:

- The SRCACTV bit indicates whether the source active set is active.
- The DSTACTV bit indicates the number of TRs resident in the destination register active set at a given instance.
- The PROGBUSY bit indicates whether a valid TR is present in the DMA program set.

If the TRs are in progression, caution must be used and you must realize that there is a chance that the values read from the EDMA3TC status registers will be inconsistent since the EDMA3TC may change the values of these registers due to ongoing activities.

It is recommended that you ensure no additional submission of TRs to the EDMA3TC in order to facilitate ease of debug.

##### 10.3.12.4.1 Destination FIFO Register Pointer

The destination FIFO register pointer is implemented as a circular buffer with the start pointer being DFSTRTPTR and a buffer depth of usually 2 or 4. The EDMA3TC maintains two important status details in TCSTAT that may be used during advanced debugging, if necessary. The DFSTRTPTR is a start pointer, that is, the index to the head of the destination FIFO register. The DSTACTV is a counter for the number of valid (occupied) entries. These registers may be used to get a brief history of transfers.

Examples of some register field values and their interpretation:

- DFSTRTPTR = 0 and DSTACTV = 0 implies that no TRs are stored in the destination FIFO register.
- DFSTRTPTR = 1 and DSTACTV = 2h implies that two TRs are present. The first pending TR is read from the destination FIFO register entry 1 and the second pending TR is read from the destination FIFO register entry 2.
- DFSTRTPTR = 3h and DSTACTV = 2h implies that two TRs are present. The first pending TR is read from the destination FIFO register entry 3 and the second pending TR is read from the destination FIFO register entry 0.

#### 10.3.12.5 EDMA3TC Configuration

[Table 10-22](#) provides the configuration of the individual EDMA3 transfer controllers present on the device. The default burst size (DBS) for each transfer controller is configurable using the TPTC\_CFG register in the control module.

**Table 10-22. EDMA3 Transfer Controller Configurations**

Name	TC0	TC1	TC2	TC3
FIFOSIZE	512 bytes	512 bytes	512 bytes	512 bytes
BUSWIDTH	16 bytes	16 bytes	16 bytes	16 bytes
DSTREGDEPTH	4 entries	4 entries	4 entries	4 entries
DBS	Configurable	Configurable	Configurable	Configurable

### 10.3.13 Event Dataflow

This section summarizes the data flow of a single event, from the time the event is latched to the channel controller to the time the transfer completion code is returned. The following steps list the sequence of EDMA3CC activity:

1. Event is asserted from an external source (peripheral or external interrupt). This also is similar for a manually-triggered, chained-triggered, or QDMA-triggered event. The event is latched into the `ER.En/ERH.En` (or `CER.En/CERH.En`, `ESR.En/ESRH.En`, `QER.En`) bit.
2. Once an event is prioritized and queued into the appropriate event queue, the `SER.En/SERH.En` (or `QSER.En`) bit is set to inform the event prioritization/processing logic to disregard this event since it is already in the queue. Alternatively, if the transfer controller and the event queue are empty, then the event bypasses the queue.
3. The EDMA3CC processing and the submission logic evaluates the appropriate PaRAM set and determines whether it is a non-null and non-dummy transfer request (TR).
4. The EDMA3CC clears the `ER.En/ERH.En` (or `CER.En/CERH.En`, `ESR.En/ESRH.En`, `QER.En`) bit and the `SER.En/SERH.En` bit as soon as it determines the TR is non-null. In the case of a null set, the `SER.En/SERH.En` bit remains set. It submits the non-null/non-dummy TR to the associated transfer controller. If the TR was programmed for early completion, the EDMA3CC immediately sets the interrupt pending register (`IPR.I[TCC]/IPRH.I[TCC]-32`).
5. If the TR was programmed for normal completion, the EDMA3CC sets the interrupt pending register (`IPR.I[TCC]/IPRH.I[TCC]`) when the EDMA3TC informs the EDMA3CC about completion of the transfer (returns transfer completion codes).
6. The EDMA3CC programs the associated EDMA3TC's Program Register Set with the TR.
7. The TR is then passed to the Source Active set and the DST FIFO Register Set, if both the register sets are available.
8. The Read Controller processes the TR by issuing read commands to the source slave endpoint. The Read Data lands in the Data FIFO of the EDMA3TC.
9. As soon as sufficient data is available, the Write Controller begins processing the TR by issuing write commands to the destination slave endpoint.
10. This continues until the TR completes and the EDMA3TC then signals completion status to the EDMA3CC.

### 10.3.14 EDMA3 Prioritization

The EDMA3 controller has many implementation rules to deal with concurrent events/channels, transfers, etc. The following subsections detail various arbitration details whenever there might be occurrence of concurrent activity. [Figure 10-21](#) shows the different places EDMA3 priorities come into play.

#### 10.3.14.1 Channel Priority

The DMA event registers (ER and ERH) capture up to 64 events; likewise, the QDMA event register (QER) captures QDMA events for all QDMA channels; therefore, it is possible for events to occur simultaneously on the DMA/QDMA event inputs. For events arriving simultaneously, the event associated with the lowest channel number is prioritized for submission to the event queues (for DMA events, channel 0 has the highest priority and channel 63 has the lowest priority; similarly, for QDMA events, channel 0 has the highest priority and channel 7 has the lowest priority). This mechanism only sorts simultaneous events for submission to the event queues.

If a DMA and QDMA event occurs simultaneously, the DMA event always has prioritization against the QDMA event for submission to the event queues.

#### 10.3.14.2 Trigger Source Priority

If a DMA channel is associated with more than one trigger source (event trigger, manual trigger, and chain trigger), and if multiple events are set simultaneously for the same channel ( $ER.En = 1$ ,  $ESR.En = 1$ ,  $CER.En = 1$ ), then the EDMA3CC always services these events in the following priority order: event trigger (via ER) is higher priority than chain trigger (via CER) and chain trigger is higher priority than manual trigger (via ESR).

This implies that if for channel 0, both  $ER.E0 = 1$  and  $CER.E0 = 1$  at the same time, then the  $ER.E0$  event is always queued before the  $CER.E0$  event.

#### 10.3.14.3 Dequeue Priority

The priority of the associated transfer request (TR) is further mitigated by which event queue is being used for event submission (dictated by DMAQNUM and QDMAQNUM). For submission of a TR to the transfer request, events need to be de-queued from the event queues. Queue 0 has the highest dequeue priority and queue 3 the lowest.

#### 10.3.14.4 System (Transfer Controller) Priority

INIT\_PRIORITY\_0 and INIT\_PRIORITY\_1 registers in the chip configuration module are used to configure the EDMA TC's priority through the system bus infrastructure. Additionally, the priority settings for DDR memory accesses are defined in the dynamic memory manager (DMM).

---

**NOTE:** The default priority for all TCs is the same, 0 or highest priority relative to other masters. It is recommended that this priority be changed based on system level considerations, such as real-time deadlines for all masters including the priority of the transfer controllers with respect to each other.

---

#### 10.3.15 EDMA3 Operating Frequency (Clock Control)

The EDMA3 channel controller and transfer controller are clocked from PLL\_L3 SYSCLK4. The EDMA3 system runs at the L3 clock frequency.

#### 10.3.16 Reset Considerations

A hardware reset resets the EDMA3 (EDMA3CC and EDMA3TC) and the EDMA3 configuration registers. The PaRAM memory contents are undefined after device reset and you should not rely on parameters to be reset to a known state. The PaRAM entry must be initialized to a desired value before it is used.

#### 10.3.17 Power Management

The EDMA3 (EDMA3CC and EDMA3TC) can be placed in reduced-power modes to conserve power during periods of low activity. The power management of the peripheral is controlled by the power reset clock management (PRCM). The PRCM acts as a master controller for power management for all peripherals on the device.

The EDMA3 controller can be idled on receiving a clock stop request from the PRCM. The requests to EDMA3CC and EDMA3TC are separate. In general, it should be verified that there are no pending activities in the EDMA3 controller

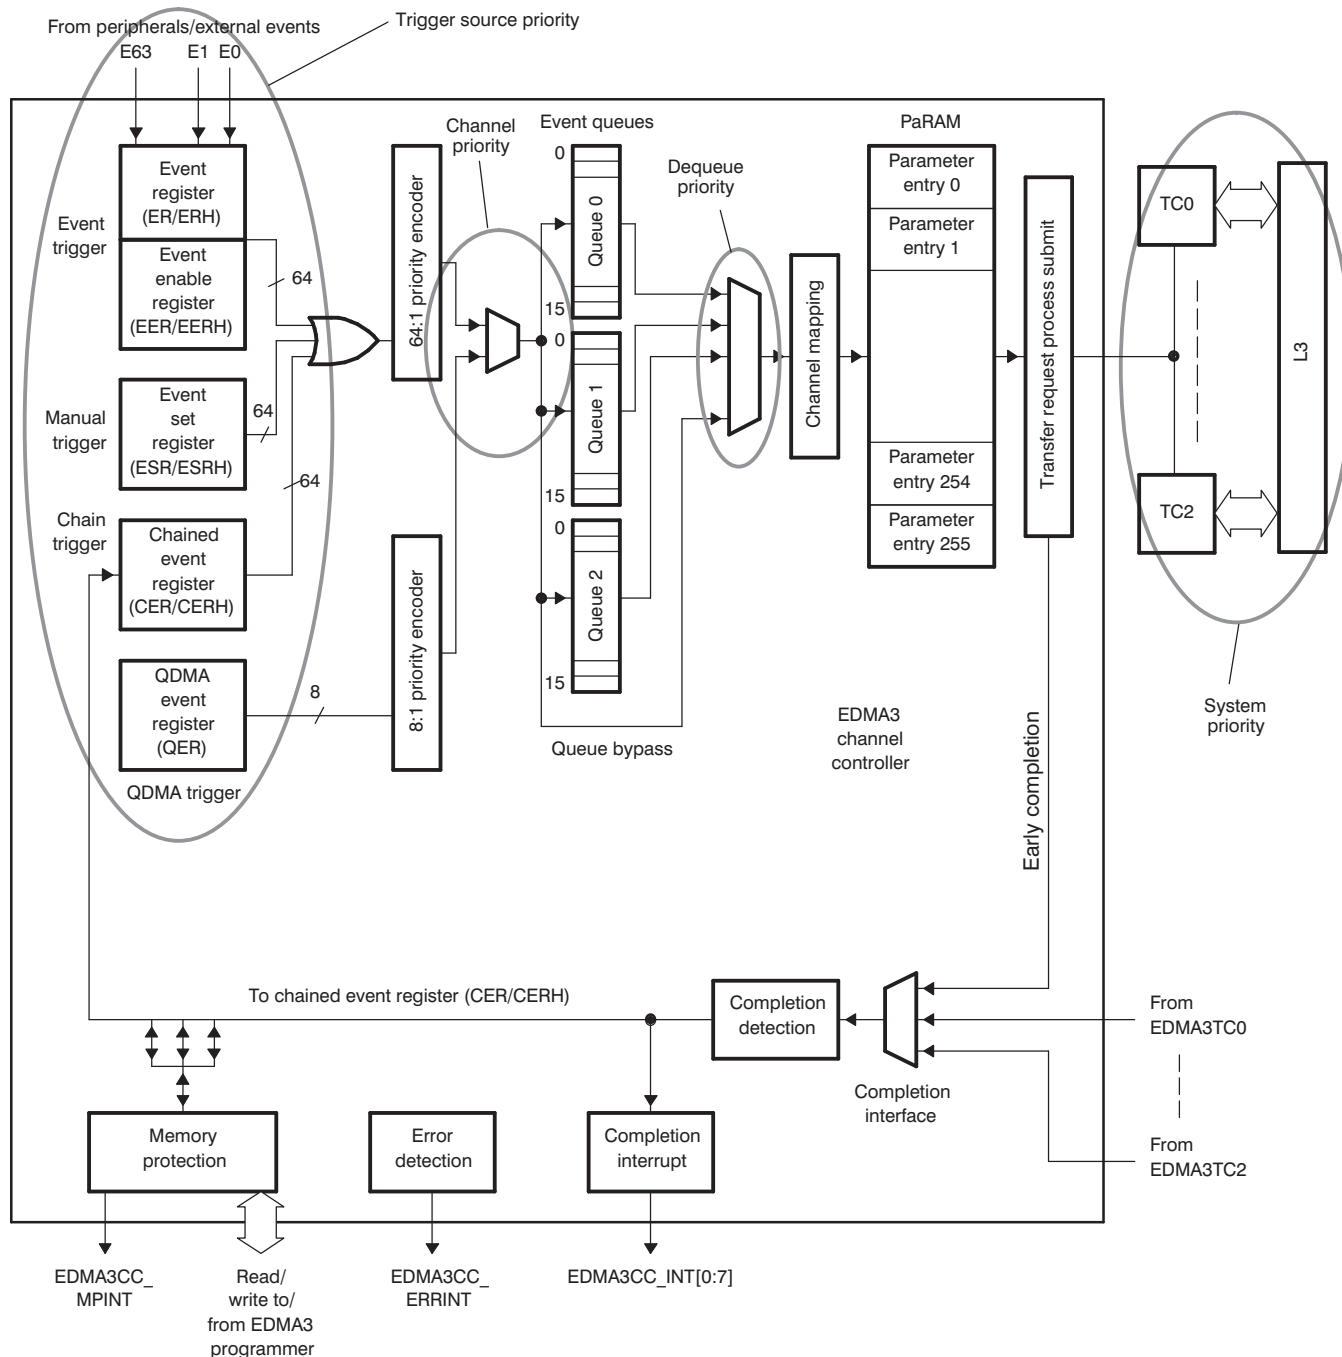

#### 10.3.18 Emulation Considerations

During debug when using the emulator, the CPU(s) may be halted on an execute packet boundary for single-stepping, benchmarking, profiling, or other debug purposes. During an emulation halt, the EDMA3 channel controller and transfer controller operations continue. Events continue to be latched and processed and transfer requests continue to be submitted and serviced.

Since EDMA3 is involved in servicing multiple master and slave peripherals, it is not feasible to have an independent behavior of the EDMA3 for emulation halts. EDMA3 functionality would be coupled with the peripherals it is servicing, which might have different behavior during emulation halts. For example, if a McASP is halted during an emulation access (FREE = 0 and SOFT = 0 or 1 in McASP registers), the McASP stops generating the McASP receive or transmit events (REVT or XEVT) to the EDMA. From the point of view of the McASP, the EDMA3 is suspended, but other peripherals (for example, a timer) still assert events and will be serviced by the EDMA.

**Figure 10-21. EDMA3 Prioritization**

### 10.3.19 EDMA Transfer Examples

The EDMA3 channel controller performs a variety of transfers depending on the parameter configuration. The following sections provide a description and PaRAM configuration for some typical use case scenarios.

#### 10.3.19.1 Block Move Example

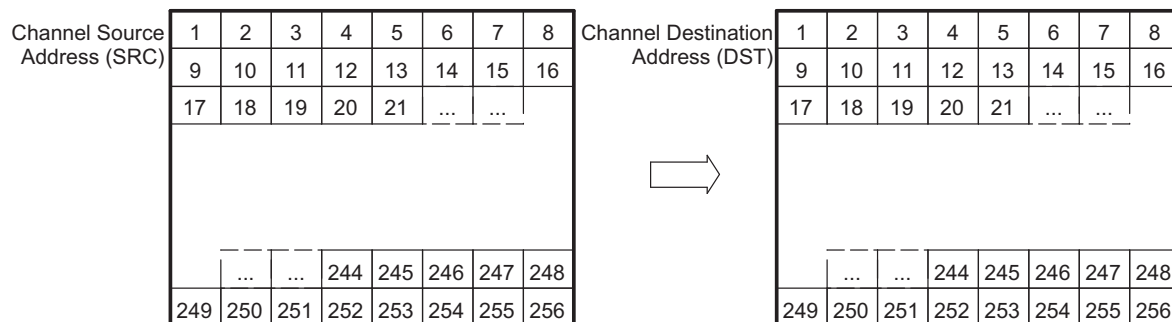

The most basic transfer performed by the EDMA3 is a block move. During device operation it is often necessary to transfer a block of data from one location to another, usually between on-chip and off-chip memory.

In this example, a section of data is to be copied from external memory to internal L2 SRAM as shown in Figure 10-22. Figure 10-23 shows the parameters for this transfer.

The source address for the transfer is set to the start of the data block in external memory, and the destination address is set to the start of the data block in L2. If the data block is less than 64K bytes, the PaRAM configuration shown in Figure 10-23 holds true with the synchronization type set to A-synchronized and indexes cleared to 0. If the amount of data is greater than 64K bytes, BCNT and the B-indexes need to be set appropriately with the synchronization type set to AB-synchronized. The STATIC bit in OPT is set to prevent linking.

This transfer example may also be set up using QDMA. For successive transfer submissions, of a similar nature, the number of cycles used to submit the transfer are fewer depending on the number of changing transfer parameters. You may program the QDMA trigger word to be the highest numbered offset in the PaRAM set that undergoes change.

**Figure 10-22. Block Move Example**

**Figure 10-23. Block Move Example PaRAM Configuration**

(a) EDMA Parameters

Parameter Contents		Parameter	
0010 0008h		Channel Options Parameter (OPT)	
Channel Source Address (SRC)		Channel Source Address (SRC)

### 10.3.19.2 Subframe Extraction Example

The EDMA3 can efficiently extract a small frame of data from a larger frame of data. By performing a 2D-to-1D transfer, the EDMA3 retrieves a portion of data for the CPU to process. In this example, a 640 × 480-pixel frame of video data is stored in external memory. Each pixel is represented by a 16-bit halfword. The CPU extracts a 16 × 12-pixel subframe of the image for processing. To facilitate more efficient processing time by the CPU, the EDMA3 places the subframe in internal L2 SRAM. Figure 10-24 shows the transfer of a subframe from external memory to L2. Figure 10-25 shows the parameters for this transfer.

The same PaPARAM entry options are used for QDMA channels, as well as DMA channels. The STATIC bit in OPT is set to prevent linking. For successive transfers, only changed parameters need to be programmed before triggering the channel.

Figure 10-24. Subframe Extraction Example

Figure 10-25. Subframe Extraction Example PaPARAM Configuration

(a) EDMA Parameters

Parameter Contents		Parameter	
0010 000Ch		Channel Options Parameter (OPT)

### 10.3.19.3 Data Sorting Example

Many applications require the use of multiple data arrays; it is often desirable to have the arrays arranged such that the first elements of each array are adjacent, the second elements are adjacent, and so on. Often this is not how the data is presented to the device. Either data is transferred via a peripheral with the data arrays arriving one after the other or the arrays are located in memory with each array occupying a portion of contiguous memory spaces. For these instances, the EDMA3 can reorganize the data into the desired format. [Figure 10-26](#) shows the data sorting.

To determine the parameter set values, the following need to be considered:

- ACNT - Program this to be the size in bytes of an element.
- BCNT - Program this to be the number of elements in a frame.
- CCNT - Program this to be the number of frames.
- SRCBIDX - Program this to be the size of the element or ACNT.
- DSTBIDX - CCNT × ACNT
- SRCCDX - ACNT × BCNT
- DSTCIDX - ACNT

The synchronization type needs to be AB-synchronized and the STATIC bit is 0 to allow updates to the parameter set. It is advised to use normal EDMA3 channels for sorting.

It is not possible to sort this with a single trigger event. Instead, the channel can be programmed to be chained to itself. After BCNT elements get sorted, intermediate chaining could be used to trigger the channel again causing the transfer of the next BCNT elements and so on. [Figure 10-27](#) shows the parameter set programming for this transfer, assuming channel 0 and an element size of 4 bytes.

**Figure 10-26. Data Sorting Example**

**Figure 10-27. Data Sorting Example PaRAM Configuration**

(a) EDMA Parameters

Parameter Contents		Parameter	
0090 0004h		Channel Options Parameter (OPT)	
Channel Source Address (SRC)		Channel Source Address (SRC)	
0400h	0004h	Count for 2nd Dimension (BCNT)	Count for 1st Dimension (ACNT)
Channel Destination Address (DST)		Channel Destination Address (DST)	
0010h	0001h	Destination BCNT Index (DSTBIDX)	Source BCNT Index (SRCBIDX)
0000h	FFFFh	BCNT Reload (BCNTRLD)	Link Address (LINK)

TCC	TCCMOD	FWID	Reserved	STATIC	SYNCDIM	DAM	SAM					

### 10.3.19.4 Peripheral Servicing Example

The EDMA3 channel controller also services peripherals in the background of CPU operation, without requiring any CPU intervention. Through proper initialization of the EDMA3 channels, they can be configured to continuously service on-chip and off-chip peripherals throughout the device operation. Each event available to the EDMA3 has its own dedicated channel, and all channels operate simultaneously. The only requirements are to use the proper channel for a particular transfer and to enable the channel event in the event enable register (EER). When programming an EDMA3 channel to service a peripheral, it is necessary to know how data is to be presented to the processor. Data is always provided with some kind of synchronization event as either one element per event (non-bursting) or multiple elements per event (bursting).

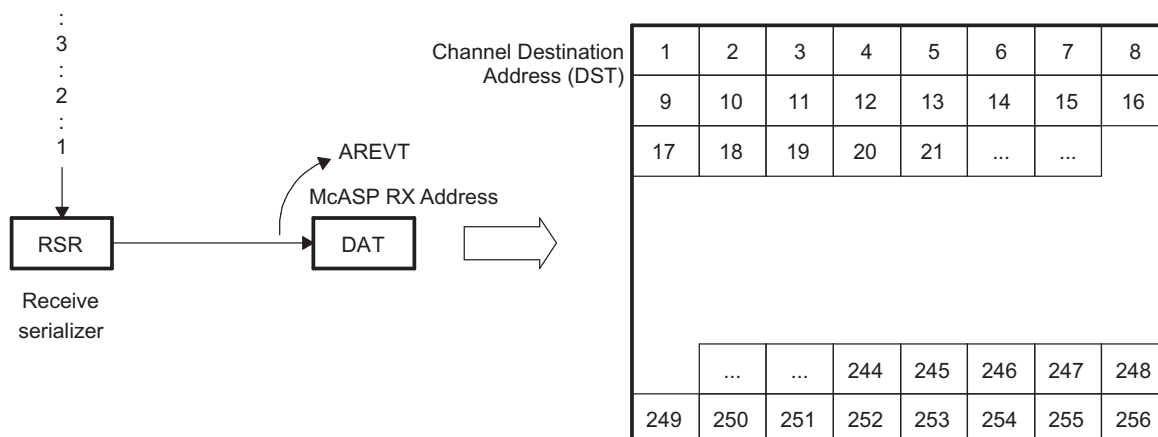

#### 10.3.19.4.1 Non-bursting Peripherals

Non-bursting peripherals include the on-chip multichannel audio serial port (McASP) and many external devices, such as codecs. Regardless of the peripheral, the EDMA3 channel configuration is the same.

The McASP transmit and receive data streams are treated independently by the EDMA3. The transmit and receive data streams can have completely different counts, data sizes, and formats. [Figure 10-28](#) shows servicing incoming McASP data.

To transfer the incoming data stream to its proper location in DDR memory, the EDMA3 channel must be set up for a 1D-to-1D transfer with A-synchronization. Because an event (AREVT) is generated for every word as it arrives, it is necessary to have the EDMA3 issue the transfer request for each element individually. [Figure 10-29](#) shows the parameters for this transfer. The source address of the EDMA3 channel is set to the data port address (DAT) for McASP, and the destination address is set to the start of the data block in DDR. Because the address of serializer buffer is fixed, the source B index is cleared to 0 (no modification) and the destination B index is set to 01b (increment).

Based on the premise that serial data is typically a high priority, the EDMA3 channel should be programmed to be on queue 0.

**Figure 10-28. Servicing Incoming McASP Data Example**

**Figure 10-29. Servicing Incoming McASP Data Example PaRAM Configuration**

(a) EDMA Parameters

Parameter Contents		Parameter	
0010 0000h		Channel Options Parameter (OPT)	
McASP RX Address		Channel Source Address (SRC)	
0100h	0001h	Count for 2nd Dimension (BCNT)	Count for 1st Dimension (ACNT)
Channel Destination Address (DST)		Channel Destination Address (DST)	
0001h	0000h	Destination BCNT Index (DSTBIDX)	Source BCNT Index (SRCBIDX)

#### 10.3.19.4.2 Bursting Peripherals

Higher bandwidth applications require that multiple data elements be presented to the processor core for every synchronization event. This frame of data can either be from multiple sources that are working simultaneously or from a single high-throughput peripheral that streams data to/from the processor.

In this example, a port is receiving a video frame from a camera and presenting it to the processor one array at a time. The video image is 640 × 480 pixels, with each pixel represented by a 16-bit element. The image is to be stored in external memory. [Figure 10-30](#) shows this example.

To transfer data from an external peripheral to an external buffer one array at a time based on  $EVT_n$ , channel  $n$  must be configured. Due to the nature of the data (a video frame made up of arrays of pixels) the destination is essentially a 2D entity. [Figure 10-31](#) shows the parameters to service the incoming data with a 1D-to-2D transfer using AB-synchronization. The source address is set to the location of the video framer peripheral, and the destination address is set to the start of the data buffer. Because the input address is static, the SRCBIDX is 0 (no modification to the source address). The destination is made up of arrays of contiguous, linear elements; therefore, the DSTBIDX is set to pixel size, 2 bytes. ANCT is equal to the pixel size, 2 bytes. BCNT is set to the number of pixels in an array, 640. CCNT is equal to the total number of arrays in the block, 480. SRCCIDX is 0 because the source address undergoes no increment. The DSTCIDX is equal to the difference between the starting addresses of each array. Because a pixel is 16 bits (2 bytes), DSTCIDX is equal to  $640 \times 2$ .

### 10.3.19.4.3 Continuous Operation

Configuring an EDMA3 channel to receive a single frame of data is useful, and is applicable to some systems. A majority of the time, however, data is going to be continuously transmitted and received throughout the entire operation of the processor. In this case, it is necessary to implement some form of linking such that the EDMA3 channels continuously reload the necessary parameter sets. In this example, McASP is configured to transmit and receive data on a T1 array. To simplify the example, only two channels are active for both transmit and receive data streams. Each channel receives packets of 128 elements. The packets are transferred from the serial port to internal memory and from internal memory to the serial port, as shown Figure 10-32.

The McASP generates AREVT for every element received and generates AXEVT for every element transmitted. To service the data streams, the DMA channels associated with the McASP must be setup for 1D-to-1D transfers with A-synchronization.

Figure 10-33 shows the parameter entries for the channel for these transfers. To service the McASP continuously, the channels must be linked to a duplicate PaRAM set in the PaRAM. After all frames have been transferred, the EDMA3 channels reload and continue. Figure 10-34 shows the reload parameters for the channel.

#### 10.3.19.4.3.1 Receive Channel

EDMA3 channel 15 services the incoming data stream of McASP. The source address is set to that of the receive serializer buffer, and the destination address is set to the first element of the data block. Because there are two data channels being serviced, A and B, they are to be located separately within the L2 SRAM.

To facilitate continuous operation, a copy of the PaRAM set for the channel is placed in PaRAM set 64. The LINK option is set and the link address is provided in the PaRAM set. Upon exhausting the channel 15 parameter set, the parameters located at the link address are loaded into the channel 15 parameter set and operation continues. This function continues throughout device operation until halted by the CPU.

#### 10.3.19.4.3.2 Transmit Channel

EDMA3 channel 12 services the outgoing data stream of McASP. In this case the destination address needs no update, hence, the parameter set changes accordingly. Linking is also used to allow continuous operation by the EDMA3 channel, with duplicate PaRAM set entries at PaRAM set 65.

#### 10.3.19.4.4 Ping-Pong Buffering

Although the previous configuration allows the EDMA3 to service a peripheral continuously, it presents a number of restrictions to the CPU. Because the input and output buffers are continuously being filled/emptied, the CPU must match the pace of the EDMA3 very closely to process the data. The EDMA3 receive data must always be placed in memory before the CPU accesses it, and the CPU must provide the output data before the EDMA3 transfers it. Though not impossible, this is an unnecessary challenge. It is particularly difficult in a 2-level cache scheme.

Ping-pong buffering is a simple technique that allows the CPU activity to be distanced from the EDMA3 activity. This means that there are multiple (usually two) sets of data buffers for all incoming and outgoing data streams. While the EDMA3 transfers the data into and out of the ping buffers, the CPU manipulates the data in the pong buffers. When both CPU and EDMA3 activity completes, they switch. The EDMA3 then writes over the old input data and transfers the new output data. [Figure 10-35](#) shows the ping-pong scheme for this example.

To change the continuous operation example, such that a ping-pong buffering scheme is used, the EDMA3 channels need only a moderate change. Instead of one parameter set, there are two; one for transferring data to/from the ping buffers and one for transferring data to/from the pong buffers. As soon as one transfer completes, the channel loads the PaRAM set for the other and the data transfers continue. [Figure 10-36](#) shows the EDMA3 channel configuration required.

Each channel has two parameter sets, ping and pong. The EDMA3 channel is initially loaded with the ping parameters ([Figure 10-36](#)). The link address for the ping set is set to the PaRAM offset of the pong parameter set ([Figure 10-37](#)). The link address for the pong set is set to the PaRAM offset of the ping parameter set ([Figure 10-38](#)). The channel options, count values, and index values are all identical between the ping and pong parameters for each channel. The only differences are the link address provided and the address of the data buffer.

##### 10.3.19.4.4.1 Synchronization with the CPU

To utilize the ping-pong buffering technique, the system must signal the CPU when to begin to access the new data set. After the CPU finishes processing an input buffer (ping), it waits for the EDMA3 to complete before switching to the alternate (pong) buffer. In this example, both channels provide their channel numbers as their report word and set the TCINTEN bit to generate an interrupt after completion. When channel 15 fills an input buffer, the E15 bit in the interrupt pending register (IPR) is set; when channel 12 empties an output buffer, the E12 bit in IPR is set. The CPU must manually clear these bits. With the channel parameters set, the CPU polls IPR to determine when to switch. The EDMA3 and CPU could alternatively be configured such that the channel completion interrupts the CPU. By doing this, the CPU could service a background task while waiting for the EDMA3 to complete.

#### 10.3.19.4.5 Transfer Chaining Examples

The following examples explain the intermediate transfer complete chaining function.

##### 10.3.19.4.5.1 Servicing Input/Output FIFOs with a Single Event

Many systems require the use of a pair of external FIFOs that must be serviced at the same rate. One FIFO buffers data input, and the other buffers data output. The EDMA3 channels that service these FIFOs can be set up for AB-synchronized transfers. While each FIFO is serviced with a different set of parameters, both can be signaled from a single event. For example, an external interrupt pin can be tied to the status flags of one of the FIFOs. When this event arrives, the EDMA3 needs to perform servicing for both the input and output streams. Without the intermediate transfer complete chaining feature this would require two events, and thus two external interrupt pins. The intermediate transfer complete chaining feature allows the use of a single external event (for example, a GPIO event). [Figure 10-39](#) shows the EDMA3 setup and illustration for this example.

A GPIO event (in this case, GPINT0) triggers an array transfer. Upon completion of each intermediate array transfer of channel 48, intermediate transfer complete chaining sets the E8 bit (specified by TCC of 8) in the chained event register (CER) and provides a synchronization event to channel 8. Upon completion of the last array transfer of channel 48, transfer complete chaining—not intermediate transfer complete chaining—sets the E8 bit in CER (specified by TCCMODE:TCC) and provides a synchronization event to channel 8. The completion of channel 8 sets the I8 bit (specified by TCCMODE:TCC) in the interrupt pending register (IPR), which can generate an interrupt to the CPU, if the I8 bit in the interrupt enable register (IER) is set.

**Figure 10-39. Intermediate Transfer Completion Chaining Example**

#### 10.3.19.4.5.2 Breaking Up Large Transfers with Intermediate Chaining

Another feature of intermediate transfer chaining (ITCCHEN) is for breaking up large transfers. A large transfer may lock out other transfers of the same priority level for the duration of the transfer. For example, a large transfer on queue 0 from the internal memory to the external memory using the EMIF may starve other EDMA3 transfers on the same queue. In addition, this large high-priority transfer may prevent the EMIF for a long duration to service other lower priority transfers. When a large transfer is considered to be high priority, it should be split into multiple smaller transfers. [Figure 10-40](#) shows the EDMA3 setup and illustration of an example single large block transfer.

**Figure 10-40. Single Large Block Transfer Example**

The intermediate transfer chaining enable (ITCCHEN) provides a method to break up a large transfer into smaller transfers. For example, to move a single large block of memory (16K bytes), the EDMA3 performs an A-synchronized transfer. The element count is set to a reasonable value, where reasonable derives from the amount of time it would take to move this smaller amount of data. Assume 1 Kbyte is a reasonable small transfer in this example. The EDMA3 is set up to transfer 16 arrays of 1 Kbyte elements, for a total of 16K byte elements. The TCC field in the channel options parameter (OPT) is set to the same value as the channel number and ITCCHEN are set. In this example, EDMA3 channel 25 is used and TCC is also set to 25. The TCINTEN may also be set to trigger interrupt 25 when the last 1 Kbyte array is transferred. The CPU starts the EDMA3 transfer by writing to the appropriate bit of the event set register (ESR.E25). The EDMA3 transfers the first 1 Kbyte array. Upon completion of the first array, intermediate transfer complete code chaining generates a synchronization event to channel 25, a value specified by the TCC field. This intermediate transfer completion chaining event causes EDMA3 channel 25 to transfer the next 1 Kbyte array. This process continues until the transfer parameters are exhausted, at which point the EDMA3 has completed the 16K byte transfer. This method breaks up a large transfer into smaller packets, thus providing natural time slices in the transfer such that other events may be processed. [Figure 10-41](#) shows the EDMA3 setup and illustration of the broken up smaller packet transfers.

## 10.4 Registers

**NOTE:** The EDMA3CC register descriptions in [Section 10.4.1](#) do not describe shadow registers. For a description of shadow registers, see [Section 10.3.7](#), *EDMA3 Channel Controller Regions*.

### 10.4.1 EDMA3CC Registers

[Table 10-25](#) lists the memory-mapped registers for the EDMA3CC. All register offset addresses not listed in [Table 10-25](#) should be considered as reserved locations and the register contents should not be modified.

**Table 10-25. EDMA3CC REGISTERS**

Offset	Acronym	Register Name	Section
0h	PID	Peripheral Identification Register	<a href="#">Section 10.4.2.1</a>
4h	CCCFG	EDMA3CC Configuration Register	<a href="#">Section 10.4.1.2</a>
10h	SYSCONFIG	EDMA3CC System Configuration Register	<a href="#">Section 20.1.2.2</a>
100h to 1FCh	DCHMAP0 to DCHMAP63	DMA Channel Mapping Registers 0-63	<a href="#">Section 10.4.1.4</a>
200h to 21Ch	QCHMAP0 to QCHMAP7	QDMA Channel Mapping Registers 0-7	<a href="#">Section 10.4.1.5</a>
240h to 25Ch	DMAQNUM0 to DMAQNUM7	DMA Queue Number Registers 0-7	<a href="#">Section 10.4.1.6</a>
260h	QDMAQNUM	QDMA Queue Number Register	<a href="#">Section 10.4.1.7</a>
284h	QUEPRI	Queue Priority Register	<a href="#">Section 10.4.1.8</a>
300h	EMR	Event Missed Register	<a href="#">Section 10.4.1.9</a>
304h	EMRH	Event Missed Register High	<a href="#">Section 10.4.1.10</a>
308h	EMCR	Event Missed Clear Register	<a href="#">Section 10.4.1.11</a>
30Ch	EMCRH	Event Missed Clear Register High	<a href="#">Section 10.4.1.12</a>
310h	QEMR	QDMA Event Missed Register	<a href="#">Section 10.4.1.13</a>
314h	QEMCR	QDMA Event Missed Clear Register	<a href="#">Section 10.4.1.14</a>
318h	CCERR	EDMA3CC Error Register	<a href="#">Section 10.4.1.15</a>
31Ch	CCERRCLR	EDMA3CC Error Clear Register	<a href="#">Section 10.4.1.16</a>

1090h	QSER	QDMA Secondary Event Register	<a href="#">Section 10.4.1.79</a>
1094h	QSECR	QDMA Secondary Event Clear Register	<a href="#">Section 10.4.1.80</a>

### 10.4.1.1 PID Register (offset = 0h) [reset = 0h]

PID is shown in [Figure 10-122](#) and described in [Table 10-107](#).

The peripheral identification register (PID) uniquely identifies the EDMA3CC and the specific revision of the EDMA3CC.

**Figure 10-42. PID Register**

**Table 10-26. PID Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-0	PID	R	0h	Peripheral identifier uniquely identifies the EDMA3CC and the specific revision of the EDMA3CC. Value 0 to FFFF FFFFh. Reset value for PID[31] to PID[16] is 4001h. Peripheral identifier uniquely identifies the EDMA3CC and the specific revision of the EDMA3CC. Value 0 to FFFF FFFFh. Reset value for PID[15] to PID[0] is 4C00h.

### 10.4.1.2 CCCFG Register (offset = 4h) [reset = 3224445h]

CCCFG is shown in [Figure 10-43](#) and described in [Table 10-27](#).

The EDMA3CC configuration register (CCCFG) provides the features/resources for the EDMA3CC in a particular device.

**Figure 10-43. CCCFG Register**

31	30	29	28	27	26	25	24

24	CHMAP_EXIST	R	1h	Channel mapping existence. 0h (R/W) = Reserved. 1h (R/W) = Channel mapping logic included.
23-22	RESERVED	R	0h	
21-20	NUM_REGN	R	2h	Number of MP and shadow regions. 0h (R/W) = Reserved. 1h (R/W) = Reserved 2h (R/W) = 4 regions. 3h (R/W) = Reserved.
19	RESERVED	R	0h	
18-16	NUM_EVQUE	R	2h	Number of queues/number of TCs. 0h (R/W) = Reserved. 1h (R/W) = Reserved. 2h (R/W) = 3 EDMA3TCs/Event Queues 3h (R/W) = Reserved from 3h to 7h. 7h (R/W) = Reserved.
15	RESERVED	R	0h	
14-12	NUM_PAENTRY	R	4h	Number of PaPARAM sets. 0h (R/W) = Reserved from 0h to 3h. 3h (R/W) = Reserved 4h (R/W) = 256 PaPARAM sets. 5h (R/W) = Reserved from 5h to 7h. 7h (R/W) = Reserved.
11	RESERVED	R	0h	

**Table 10-27. CCCFG Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
10-8	NUM_INTCH	R	4h	Number of interrupt channels. 0h (R/W) = Reserved from 0h to 3h. 3h (R/W) = Reserved. 4h (R/W) = 64 interrupt channels. 5h (R/W) = Reserved from 5h to 7. 7h (R/W) = Reserved.
7	RESERVED	R	0h	
6-4	NUM_QDMACH	R	4h	Number of QDMA channels. 0h (R/W) = Reserved from 0h to 3h. 3h (R/W) = Reserved. 4h (R/W) = 8 QDMA channels. 5h (R/W) = Reserved from 5h to 7. 7h (R/W) = Reserved.
3	RESERVED	R	0h	
2-0	NUM_DMACH	R	5h	Number of DMA channels. 0h (R/W) = Reserved from 0h to 4h. 4h (R/W) = Reserved. 5h (R/W) = 64 DMA channels. 6h (R/W) = Reserved. 7h (R/W) = Reserved.

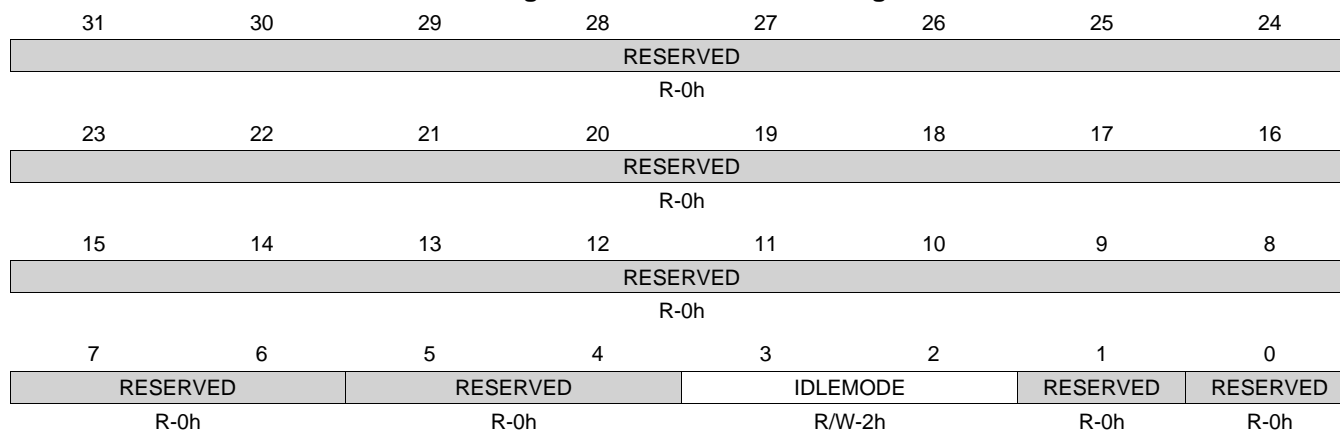

### 10.4.1.3 SYSCONFIG Register (offset = 10h) [reset = 8h]

SYSCONFIG is shown in [Figure 20-4](#) and described in [Table 20-6](#).

The EDMA3CC system configuration register is used for clock management configuration.

**Figure 10-44. SYSCONFIG Register**

**Table 10-28. SYSCONFIG Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-6	RESERVED	R	0h	
5-4	RESERVED	R	0h	
3-2	IDLEMODE	R/W	2h	Configuration of the local target state management mode. By definition, target can handle read/write transaction as long as it is out of IDLE state. 0h (R/W) = Force-idle mode: local target's idle state follows (acknowledges) the system's idle requests unconditionally, i.e. regardless of the IP module's internal requirements. Backup mode, for debug only. 1h (R/W) = No-idle mode: local target never enters idle state. Backup mode, for debug only. 2h (R/W) = Smart-idle mode: local target's idle state eventually follows (acknowledges) the system's idle requests, depending on the IP module's internal requirements. IP module shall not generate (IRQ- or DMA-request-related) wakeup events. 3h (R/W) = Smart-idle wakeup-capable mode: local target's idle state eventually follows (acknowledges) the system's idle requests, depending on the IP module's internal requirements. IP module may generate (IRQ- or DMA-request-related) wakeup events when in idle state. Mode is only relevant if the appropriate IP module "swakeup" output(s) is (are) implemented.
1	RESERVED	R	0h	
0	RESERVED	R	0h	

#### 10.4.1.4 DCHMAP0 to DCHMAP63 Register (offset = 100h to 1FCh) [reset = 0h]

DCHMAP0 to DCHMAP63 is shown in [Figure 10-45](#) and described in [Table 10-29](#).

**Figure 10-45. DCHMAP0 to DCHMAP63 Register**

**Table 10-29. DCHMAP0 to DCHMAP63 Register Field Descriptions**

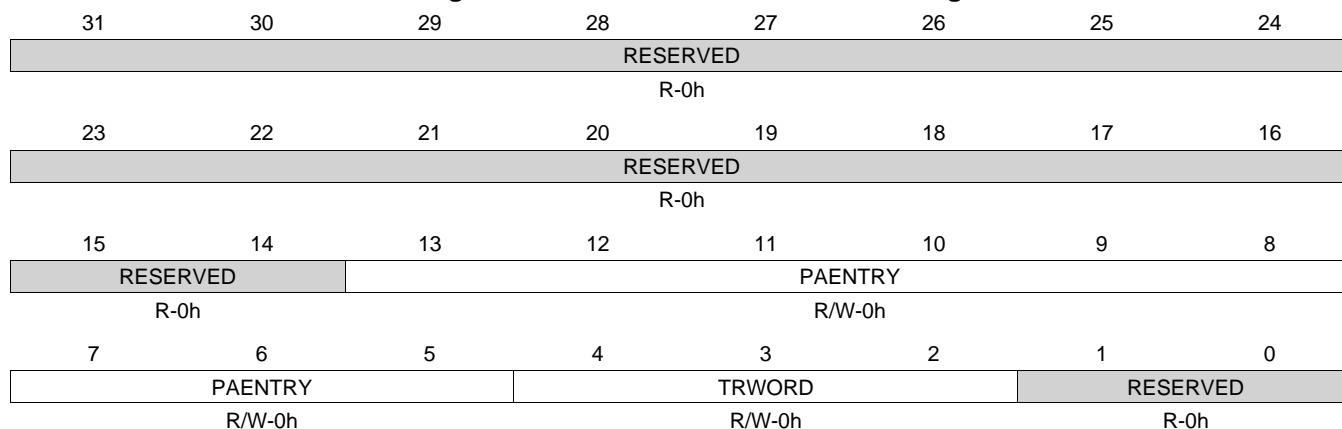

Bit	Field	Type	Reset	Description
31-14	RESERVED	R	0h	
13-5	PAENTRY	R/W	0h	Points to the PaRAM set number for DMA channel n. Value 0 to FFh.
4-0	RESERVED	R	0h	

### 10.4.1.5 QCHMAP0 to QCHMAP7 Register (offset = 200h to 21Ch) [reset = 0h]

QCHMAP0 to QCHMAP7 is shown in [Figure 10-46](#) and described in [Table 10-30](#).

Each QDMA channel in EDMA3CC can be associated with any PaRAM set available on the device. Furthermore, the specific trigger word (0-7) of the PaRAM set can be programmed. The PaRAM set association and trigger word for every QDMA channel register is configurable using the QDMA channel map register (QCHMAPn). At reset the QDMA channel map registers for all QDMA channels point to PaRAM set 0. If an application makes use of both a DMA channel that points to PaRAM set 0 and any QDMA channels, ensure that QCHMAP is programmed appropriately to point to a different PaRAM entry.

**Figure 10-46. QCHMAP0 to QCHMAP7 Register**

**Table 10-30. QCHMAP0 to QCHMAP7 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-14	RESERVED	R	0h	
13-5	PAENTRY	R/W	0h	PAENTRY points to the PaRAM set number for QDMA channel . 0h (R/W) = Parameter entry 0 through 255, from 0 to FFh. 1h (R/W) = Reserved, from 100h to 1FFh. Always write 0 to this bit. Writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
4-2	TRWORD	R/W	0h	Points to the specific trigger word of the PaRAM set defined by PAENTRY. A write to the trigger word results in a QDMA event being recognized.
1-0	RESERVED	R	0h	

#### 10.4.1.6 DMAQNUM0 to DMAQNUM7 Register (offset = 240h to 25Ch) [reset = 0h]

DMAQNUM0 to DMAQNUM7 is shown in [Figure 10-47](#) and described in [Table 10-31](#).

The DMA channel queue number register (DMAQNUMn) allows programmability of each of the 64 DMA channels in the EDMA3CC to submit its associated synchronization event to any event queue in the EDMA3CC. At reset, all channels point to event queue 0. Because the event queues in EDMA3CC have a fixed association to the transfer controllers, that is, Q0 TRs are submitted to TC0, Q1 TRs are submitted to TC1, etc., by programming DMAQNUM for a particular DMA channel also dictates which transfer controller is utilized for the data movement (or which EDMA3TC receives the TR request).

**Figure 10-47. DMAQNUM0 to DMAQNUM7 Register**

### 10.4.1.7 QDMAQNUM Register (offset = 260h) [reset = 0h]

QDMAQNUM is shown in [Figure 10-48](#) and described in [Table 10-32](#).

The QDMA channel queue number register (QDMAQNUMn) is used to program all the QDMA channels in the EDMA3CC to submit the associated QDMA event to any of the event queues in the EDMA3CC.

### 10.4.1.8 QUEPRI Register (offset = 284h) [reset = 777h]

QUEPRI is shown in [Figure 10-49](#) and described in [Table 10-33](#).

The queue priority register (QUEPRI) allows you to change the priority of the individual queues and the priority of the transfer request (TR) associated with the events queued in the queue. Because the queue to EDMA3TC mapping is fixed, programming QUEPRI essentially governs the priority of the associated transfer controller(s) read/write commands with respect to the other bus masters in the device. You can modify the EDMA3TC priority to obtain the desired system performance.

**Figure 10-49. QUEPRI Register**

**Table 10-33. QUEPRI Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-11	RESERVED	R	0h	
10-8	PRIQ2	R/W	7h	Priority level for queue 2. Dictates the priority level used by TC2 relative to other masters in the device. A value of 0 means highest priority and a value of 7 means lowest priority.
7	RESERVED	R	0h	
6-4	PRIQ1	R/W	7h	Priority level for queue 1. Dictates the priority level used by TC1 relative to other masters in the device. A value of 0 means highest priority and a value of 7 means lowest priority.
3	RESERVED	R	0h	
2-0	PRIQ0	R/W	7h	Priority level for queue 0. Dictates the priority level used by TC0 relative to other masters in the device. A value of 0 means highest priority and a value of 7 means lowest priority.

### 10.4.1.9 EMR Register (offset = 300h) [reset = 0h]

EMR is shown in [Figure 10-50](#) and described in [Table 10-34](#).

For a particular DMA channel, if a second event is received prior to the first event getting cleared/serviced, the bit corresponding to that channel is set/asserted in the event missed registers (EMR/EMRH). All trigger types are treated individually, that is, manual triggered (ESR/ESRH), chain triggered (CER/CERH), and event triggered (ER/ERH) are all treated separately. The EMR/EMRH bits for a channel are also set if an event on that channel encounters a NULL entry (or a NULL TR is serviced). If any EMR/EMRH bit is set (and all errors, including bits in other error registers (QEMR, CCERR) were previously cleared), the EDMA3CC generates an error interrupt. For details on EDMA3CC error interrupt generation, see Error Interrupts. This register is part of a set of registers that provide information on missed DMA and/or QDMA events, and instances when event queue thresholds are exceeded. If any of the bits in these registers is set, it results in the EDMA3CC generating an error interrupt.

**Figure 10-50. EMR Register**

**Table 10-34. EMR Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	En	R	0h	Channel 0 to 31 event missed. En is cleared by writing a 1 to the corresponding bit in the event missed clear register (EMCR). 0h (R/W) = No missed event. 1h (R/W) = Missed event occurred.

### 10.4.1.10 EMRH Register (offset = 304h) [reset = 0h]

EMRH is shown in [Figure 10-51](#) and described in [Table 10-35](#).

For a particular DMA channel, if a second event is received prior to the first event getting cleared/serviced, the bit corresponding to that channel is set/asserted in the event missed registers (EMR/EMRH). All trigger types are treated individually, that is, manual triggered (ESR/ESRH), chain triggered (CER/CERH), and event triggered (ER/ERH) are all treated separately. The EMR/EMRH bits for a channel are also set if an event on that channel encounters a NULL entry (or a NULL TR is serviced). If any EMR/EMRH bit is set (and all errors, including bits in other error registers (QEMR, CCERR) were previously cleared), the EDMA3CC generates an error interrupt. For details on EDMA3CC error interrupt generation, see Error Interrupts. This register is part of a set of registers that provide information on missed DMA and/or QDMA events, and instances when event queue thresholds are exceeded. If any of the bits in these registers is set, it results in the EDMA3CC generating an error interrupt.

**Figure 10-51. EMRH Register**

**Table 10-35. EMRH Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	En	R	0h	Channel 32 to 63 event missed. En is cleared by writing a 1 to the corresponding bit in the event missed clear register high (EMCRH). 0h (R/W) = No missed event. 1h (R/W) = Missed event occurred.

### 10.4.1.11 EMCR Register (offset = 308h) [reset = 0h]

EMCR is shown in [Figure 10-52](#) and described in [Table 10-36](#).

Once a missed event is posted in the event missed registers (EMR/EMRH), the bit remains set and you need to clear the set bit(s). This is done by way of CPU writes to the event missed clear registers (EMCR/EMCRH). Writing a 1 to any of the bits clears the corresponding missed event (bit) in EMR/EMRH; writing a 0 has no effect. This register is part of a set of registers that provide information on missed DMA and/or QDMA events, and instances when event queue thresholds are exceeded. If any of the bits in these registers is set, it results in the EDMA3CC generating an error interrupt.

**Figure 10-52. EMCR Register**

**Table 10-36. EMCR Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	En	W	0h	Event missed 0 to 31 clear. All error bits must be cleared before additional error interrupts will be asserted by the EDMA3CC. 0h (R/W) = No effect. 1h (R/W) = Corresponding missed event bit in the event missed register (EMR) is cleared (En = 0).

### 10.4.1.12 EMCRH Register (offset = 30Ch) [reset = 0h]

EMCRH is shown in [Figure 10-53](#) and described in [Table 10-37](#).

Once a missed event is posted in the event missed registers (EMR/EMRH), the bit remains set and you need to clear the set bit(s). This is done by way of CPU writes to the event missed clear registers (EMCR/EMCRH). Writing a 1 to any of the bits clears the corresponding missed event (bit) in EMR/EMRH; writing a 0 has no effect. This register is part of a set of registers that provide information on missed DMA and/or QDMA events, and instances when event queue thresholds are exceeded. If any of the bits in these registers is set, it results in the EDMA3CC generating an error interrupt.

**Figure 10-53. EMCRH Register**

**Table 10-37. EMCRH Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	En	W	0h	Event missed 32 to 63 clear. All error bits must be cleared before additional error interrupts will be asserted by the EDMA3CC. 0h (R/W) = No effect. 1h (R/W) = Corresponding missed event bit in the event missed register high (EMRH) is cleared (En = 0).

### 10.4.1.13 QEMR Register (offset = 310h) [reset = 0h]

QEMR is shown in [Figure 10-54](#) and described in [Table 10-38](#).

For a particular QDMA channel, if two QDMA events are detected without the first event getting cleared/serviced, the bit corresponding to that channel is set/asserted in the QDMA event missed register (QEMR). The QEMR bits for a channel are also set if a QDMA event on the channel encounters a NULL entry (or a NULL TR is serviced). If any QEMR bit is set (and all errors, including bits in other error registers (EMR/EMRH, CCERR) were previously cleared), the EDMA3CC generates an error interrupt. For details on EDMA3CC error interrupt generation, see Error Interrupts. This register is part of a set of registers that provide information on missed DMA and/or QDMA events, and instances when event queue thresholds are exceeded. If any of the bits in these registers is set, it results in the EDMA3CC generating an error interrupt.

**Figure 10-54. QEMR Register**

7-0	En	R	0h	Channel 0 to 7 QDMA event missed. En is cleared by writing a 1 to the corresponding bit in the QDMA event missed clear register (QEMCR). 0h (R/W) = No missed event. 1h (R/W) = Missed event occurred.

### 10.4.1.14 QEMCR Register (offset = 314h) [reset = 0h]

QEMCR is shown in [Figure 10-55](#) and described in [Table 10-39](#).

Once a missed event is posted in the QDMA event missed registers (QEMR), the bit remains set and you need to clear the set bit(s). This is done by way of CPU writes to the QDMA event missed clear registers (QEMCR). Writing a 1 to any of the bits clears the corresponding missed event (bit) in QEMR; writing a 0 has no effect. This register is part of a set of registers that provide information on missed DMA and/or QDMA events, and instances when event queue thresholds are exceeded. If any of the bits in these registers is set, it results in the EDMA3CC generating an error interrupt.

**Figure 10-55. QEMCR Register**

**Table 10-39. QEMCR Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-8	RESERVED	R	0h	
7-0	En	W	0h	QDMA event missed clear. All error bits must be cleared before additional error interrupts will be asserted by the EDMA3CC. 0h (R/W) = No effect. 1h (R/W) = Corresponding missed event bit in the QDMA event missed register (QEMR) is cleared (En= 0).

### 10.4.1.15 CCERR Register (offset = 318h) [reset = 0h]

CCERR is shown in [Figure 10-56](#) and described in [Table 10-40](#).

The EDMA3CC error register (CCERR) indicates whether or not at any instant of time the number of events queued up in any of the event queues exceeds or equals the threshold/watermark value that is set in the queue watermark threshold register (QWMTHRA). Additionally, CCERR also indicates if when the number of outstanding TRs that have been programmed to return transfer completion code (TRs which have the TCINTEN or TCCHEN bit in OPT set) to the EDMA3CC has exceeded the maximum allowed value of 63. If any bit in CCERR is set (and all errors, including bits in other error registers (EMR/EMRH, QEMR) were previously cleared), the EDMA3CC generates an error interrupt. For details on EDMA3CC error interrupt generation, see Error Interrupts. Once the error bits are set in CCERR, they can only be cleared by writing to the corresponding bits in the EDMA3CC error clear register (CCERRCLR). This register is part of a set of registers that provide information on missed DMA and/or QDMA events, and instances when event queue thresholds are exceeded. If any of the bits in these registers is set, it results in the EDMA3CC generating an error interrupt.

Bit	Field	Type	Reset	Description
31-17	RESERVED	R	0h	
16	TCCERR	R	0h	Transfer completion code error. TCCERR is cleared by writing a 1 to the corresponding bit in the EDMA3CC error clear register (CCERRCLR). 0h (R/W) = Total number of allowed TCCs outstanding has not been reached. 1h (R/W) = Total number of allowed TCCs has been reached.
15-3	RESERVED	R	0h	
2	QTHRXCD2	R	0h	Queue threshold error for queue 2. QTHRXCD2 is cleared by writing a 1 to the corresponding bit in the EDMA3CC error clear register (CCERRCLR). 0h (R/W) = Watermark/threshold has not been exceeded. 1h (R/W) = Watermark/threshold has been exceeded.
1	QTHRXCD1	R	0h	Queue threshold error for queue 1. QTHRXCD1 is cleared by writing a 1 to the corresponding bit in the EDMA3CC error clear register (CCERRCLR). 0h (R/W) = Watermark/threshold has not been exceeded. 1h (R/W) = Watermark/threshold has been exceeded.
0	QTHRXCD0	R	0h	Queue threshold error for queue 0. QTHRXCD0 is cleared by writing a 1 to the corresponding bit in the EDMA3CC error clear register (CCERRCLR). 0h (R/W) = Watermark/threshold has not been exceeded. 1h (R/W) = Watermark/threshold has been exceeded.

#### 10.4.1.16 CCERRCLR Register (offset = 31Ch) [reset = 0h]

CCERRCLR is shown in [Figure 10-57](#) and described in [Table 10-41](#).

The EDMA3CC error clear register (CCERRCLR) is used to clear any error bits that are set in the EDMA3CC error register (CCERR). In addition, CCERRCLR also clears the values of some bit fields in the queue status registers (QSTATn) associated with a particular event queue. Writing a 1 to any of the bits clears the corresponding bit in CCERR; writing a 0 has no effect. This register is part of a set of registers that provide information on missed DMA and/or QDMA events, and instances when event queue thresholds are exceeded. If any of the bits in these registers is set, it results in the EDMA3CC generating an error interrupt.

### 10.4.1.17 EEVAL Register (offset = 320h) [reset = 0h]

EEVAL is shown in [Figure 10-58](#) and described in [Table 10-42](#).

The EDMA3CC error interrupt is asserted whenever an error bit is set in any of the error registers (EMR/EMRH, QEMR, and CCERR). For subsequent error bits that get set, the EDMA3CC error interrupt is reasserted only when transitioning from an all the error bits cleared to at least one error bit is set. Alternatively, a CPU write of 1 to the EVAL bit in the error evaluation register (EEVAL) results in reasserting the EDMA3CC error interrupt, if there are any outstanding error bits set due to subsequent error conditions. Writes of 0 have no effect. This register is part of a set of registers that provide information on missed DMA and/or QDMA events, and instances when event queue thresholds are exceeded. If any of the bits in these registers is set, it results in the EDMA3CC generating an error interrupt.

**Figure 10-58. EEVAL Register**

Bit	Field	Type	Reset	Description
31-2	RESERVED	R	0h	
1	RESERVED	R	0h	
0	EVAL	W	0h	Error interrupt evaluate. 0h (R/W) = No effect. 1h (R/W) = Write 1 to clear interrupts when all error registers have been cleared. EDMA3CC error interrupt will remain if any errors have not been cleared in any of the error registers (EMR/EMRH, CCERR, QEMR)

### 10.4.1.18 DRAE0 Register (offset = 340h) [reset = 0h]

DRAE0 is shown in [Figure 10-59](#) and described in [Table 10-43](#).

The DMA region access enable register for shadow region 0 is programmed to allow or disallow read/write accesses on a bit-by-bit bases for all DMA registers in the shadow region 0 view of the DMA channel registers. Additionally, the DRAE0 configuration determines completion of which DMA channels will result in assertion of the shadow region 0 DMA completion interrupt. The DRAE registers are part of the group of the region access enable registers, which includes DRAEm and QRAEm. Where m is the number of shadow regions in the EDMA3CC memory map for a device. You can configure these registers to assign ownership of DMA/QDMA channels to a particular shadow region.

**Figure 10-59. DRAE0 Register**

**Table 10-43. DRAE0 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	En	R/W	0h	<p>DMA region access enable for bit 31 to 0 in region 0.</p> <p>0h (R/W) = Accesses via region 0 address space to bit 31 to 0 in any DMA channel register are not allowed. Reads return 0 on bit n and writes do not modify the state of bit 31 to 0. Enabled interrupt bits for bit n do not contribute to the generation of a transfer completion interrupt for shadow region 0.</p> <p>1h (R/W) = Accesses via region 0 address space to bit 31 to 0 in any DMA channel register are allowed. Reads return the value from bit n and writes modify the state of bit 31 to 0. Enabled interrupt bits for bit n contribute to the generation of a transfer completion interrupt for shadow region 0.</p>

### 10.4.1.19 DRAEH0 Register (offset = 344h) [reset = 0h]

DRAEH0 is shown in [Figure 10-60](#) and described in [Table 10-44](#).

The DMA region access enable register for shadow region 0 is programmed to allow or disallow read/write accesses on a bit-by-bit bases for all DMA registers in the shadow region 0 view of the DMA channel registers. Additionally, the DRAE0 configuration determines completion of which DMA channels will result in assertion of the shadow region 0 DMA completion interrupt. The DRAE registers are part of the group of the region access enable registers, which includes DRAEm and QRAEm. Where m is the number of shadow regions in the EDMA3CC memory map for a device. You can configure these registers to assign ownership of DMA/QDMA channels to a particular shadow region.

**Figure 10-60. DRAEH0 Register**

Reads return 0 on bit n and writes do not modify the state of bit 63 to 32. Enabled interrupt bits for bit 31 to 0 do not contribute to the generation of a transfer completion interrupt for shadow region 0.</p> <p>1h (R/W) = Accesses via region 0 address space to bit 63 to 32 in any DMA channel register are allowed. Reads return the value from bit n and writes modify the state of bit 63 to 32. Enabled interrupt bits for bit 31 to 0 contribute to the generation of a transfer completion interrupt for shadow region 0.</p>

### 10.4.1.20 DRAE1 Register (offset = 348h) [reset = 0h]

DRAE1 is shown in [Figure 10-61](#) and described in [Table 10-45](#).

The DMA region access enable register for shadow region 1 is programmed to allow or disallow read/write accesses on a bit-by-bit bases for all DMA registers in the shadow region 1 view of the DMA channel registers. Additionally, the DRAE1 configuration determines completion of which DMA channels will result in assertion of the shadow region 1 DMA completion interrupt. The DRAE registers are part of the group of the region access enable registers, which includes DRAEm and QRAEm. Where m is the number of shadow regions in the EDMA3CC memory map for a device. You can configure these registers to assign ownership of DMA/QDMA channels to a particular shadow region.

**Figure 10-61. DRAE1 Register**

Bit	Field	Type	Reset	Description
31-0	En	R/W	0h	<p>DMA region access enable for bit 63 to 32 in region 1.</p> <p>0h (R/W) = Accesses via region 1 address space to bit 63 to 32 in any DMA channel register are not allowed. Reads return 0 on bit n and writes do not modify the state of bit 63 to 32. Enabled interrupt bits for bit 31 to 0 do not contribute to the generation of a transfer completion interrupt for shadow region 1.</p> <p>1h (R/W) = Accesses via region 1 address space to bit 63 to 32 in any DMA channel register are allowed. Reads return the value from bit n and writes modify the state of bit 63 to 32. Enabled interrupt bits for bit 31 to 0 contribute to the generation of a transfer completion interrupt for shadow region 1.</p>

### 10.4.1.22 DRAE2 Register (offset = 350h) [reset = 0h]

DRAE2 is shown in [Figure 10-63](#) and described in [Table 10-47](#).

The DMA region access enable register for shadow region 2 is programmed to allow or disallow read/write accesses on a bit-by-bit bases for all DMA registers in the shadow region 2 view of the DMA channel registers. Additionally, the DRAE2 configuration determines completion of which DMA channels will result in assertion of the shadow region 2 DMA completion interrupt. The DRAE registers are part of the group of the region access enable registers, which includes DRAEm and QRAEm. Where m is the number of shadow regions in the EDMA3CC memory map for a device. You can configure these registers to assign ownership of DMA/QDMA channels to a particular shadow region.

**Figure 10-63. DRAE2 Register**

**Table 10-47. DRAE2 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	En	R/W	0h	<p>DMA region access enable for bit 31 to 0 in region 2.</p> <p>0h (R/W) = Accesses via region 2 address space to bit 31 to 0 in any DMA channel register are not allowed. Reads return 0 on bit n and writes do not modify the state of bit 31 to 0. Enabled interrupt bits for bit n do not contribute to the generation of a transfer completion interrupt for shadow region 2.</p> <p>1h (R/W) = Accesses via region 2 address space to bit 31 to 0 in any DMA channel register are allowed. Reads return the value from bit n and writes modify the state of bit 31 to 0. Enabled interrupt bits for bit n contribute to the generation of a transfer completion interrupt for shadow region 2.</p>

### 10.4.1.23 DRAEH2 Register (offset = 354h) [reset = 0h]

DRAEH2 is shown in [Figure 10-64](#) and described in [Table 10-48](#).

The DMA region access enable register for shadow region 2 is programmed to allow or disallow read/write accesses on a bit-by-bit bases for all DMA registers in the shadow region 2 view of the DMA channel registers. Additionally, the DRAE2 configuration determines completion of which DMA channels will result in assertion of the shadow region 2 DMA completion interrupt. The DRAE registers are part of the group of the region access enable registers, which includes DRAEm and QRAEm. Where m is the number of shadow regions in the EDMA3CC memory map for a device. You can configure these registers to assign ownership of DMA/QDMA channels to a particular shadow region.

**Figure 10-64. DRAEH2 Register**

**Table 10-48. DRAEH2 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	En	R/W	0h	<p>DMA region access enable for bit 63 to 32 in region 2.</p> <p>0h (R/W) = Accesses via region 2 address space to bit 63 to 32 in any DMA channel register are not allowed. Reads return 0 on bit n and writes do not modify the state of bit 63 to 32. Enabled interrupt bits for bit 31 to 0 do not contribute to the generation of a transfer completion interrupt for shadow region 2.</p> <p>1h (R/W) = Accesses via region 2 address space to bit 63 to 32 in any DMA channel register are allowed. Reads return the value from bit n and writes modify the state of bit 63 to 32. Enabled interrupt bits for bit 31 to 0 contribute to the generation of a transfer completion interrupt for shadow region 2.</p>

#### 10.4.1.24 DRAE3 Register (offset = 358h) [reset = 0h]

DRAE3 is shown in [Figure 10-65](#) and described in [Table 10-49](#).

The DMA region access enable register for shadow region 3 is programmed to allow or disallow read/write accesses on a bit-by-bit bases for all DMA registers in the shadow region 3 view of the DMA channel registers. Additionally, the DRAE3 configuration determines completion of which DMA channels will result in assertion of the shadow region 3 DMA completion interrupt. The DRAE registers are part of the group of the region access enable registers, which includes DRAEm and QRAEm. Where m is the number of shadow regions in the EDMA3CC memory map for a device. You can configure these registers to assign ownership of DMA/QDMA channels to a particular shadow region.

**Figure 10-65. DRAE3 Register**

**Table 10-49. DRAE3 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	En	R/W	0h	<p>DMA region access enable for bit 31 to 0 in region 3.</p> <p>0h (R/W) = Accesses via region 3 address space to bit 31 to 0 in any DMA channel register are not allowed. Reads return 0 on bit n and writes do not modify the state of bit 31 to 0. Enabled interrupt bits for bit n do not contribute to the generation of a transfer completion interrupt for shadow region 3.</p> <p>1h (R/W) = Accesses via region 3 address space to bit 31 to 0 in any DMA channel register are allowed. Reads return the value from bit n and writes modify the state of bit 31 to 0. Enabled interrupt bits for bit n contribute to the generation of a transfer completion interrupt for shadow region 3.</p>

### 10.4.1.25 DRAEH3 Register (offset = 35Ch) [reset = 0h]

DRAEH3 is shown in [Figure 10-66](#) and described in [Table 10-50](#).

The DMA region access enable register for shadow region 3 is programmed to allow or disallow read/write accesses on a bit-by-bit bases for all DMA registers in the shadow region 3 view of the DMA channel registers. Additionally, the DRAE3 configuration determines completion of which DMA channels will result in assertion of the shadow region 3 DMA completion interrupt. The DRAE registers are part of the group of the region access enable registers, which includes DRAEm and QRAEm. Where m is the number of shadow regions in the EDMA3CC memory map for a device. You can configure these registers to assign ownership of DMA/QDMA channels to a particular shadow region.

**Figure 10-66. DRAEH3 Register**

**Table 10-50. DRAEH3 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	En	R/W	0h	<p>DMA region access enable for bit 63 to 32 in region 3.</p> <p>0h (R/W) = Accesses via region 3 address space to bit 63 to 32 in any DMA channel register are not allowed. Reads return 0 on bit n and writes do not modify the state of bit 63 to 32. Enabled interrupt bits for bit 31 to 0 do not contribute to the generation of a transfer completion interrupt for shadow region 3.</p> <p>1h (R/W) = Accesses via region 3 address space to bit 63 to 32 in any DMA channel register are allowed. Reads return the value from bit n and writes modify the state of bit 63 to 32. Enabled interrupt bits for bit 31 to 0 contribute to the generation of a transfer completion interrupt for shadow region 3.</p>

### 10.4.1.26 DRAE4 Register (offset = 360h) [reset = 0h]

DRAE4 is shown in [Figure 10-67](#) and described in [Table 10-51](#).

The DMA region access enable register for shadow region 4 is programmed to allow or disallow read/write accesses on a bit-by-bit bases for all DMA registers in the shadow region 4 view of the DMA channel registers. Additionally, the DRAE4 configuration determines completion of which DMA channels will result in assertion of the shadow region 4 DMA completion interrupt. The DRAE registers are part of the group of the region access enable registers, which includes DRAEm and QRAEm. Where m is the number of shadow regions in the EDMA3CC memory map for a device. You can configure these registers to assign ownership of DMA/QDMA channels to a particular shadow region.

**Figure 10-67. DRAE4 Register**

**Table 10-51. DRAE4 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	En	R/W	0h	<p>DMA region access enable for bit 31 to 0 in region 4.</p> <p>0h (R/W) = Accesses via region 4 address space to bit 31 to 0 in any DMA channel register are not allowed. Reads return 0 on bit n and writes do not modify the state of bit 31 to 0. Enabled interrupt bits for bit n do not contribute to the generation of a transfer completion interrupt for shadow region 4.</p> <p>1h (R/W) = Accesses via region 4 address space to bit 31 to 0 in any DMA channel register are allowed. Reads return the value from bit n and writes modify the state of bit 31 to 0. Enabled interrupt bits for bit n contribute to the generation of a transfer completion interrupt for shadow region 4.</p>

### 10.4.1.27 DRAEH4 Register (offset = 364h) [reset = 0h]

DRAEH4 is shown in [Figure 10-68](#) and described in [Table 10-52](#).

The DMA region access enable register for shadow region 4 is programmed to allow or disallow read/write accesses on a bit-by-bit bases for all DMA registers in the shadow region 4 view of the DMA channel registers. Additionally, the DRAE4 configuration determines completion of which DMA channels will result in assertion of the shadow region 4 DMA completion interrupt. The DRAE registers are part of the group of the region access enable registers, which includes DRAEm and QRAEm. Where m is the number of shadow regions in the EDMA3CC memory map for a device. You can configure these registers to assign ownership of DMA/QDMA channels to a particular shadow region.

**Figure 10-68. DRAEH4 Register**

**Table 10-52. DRAEH4 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	En	R/W	0h	<p>DMA region access enable for bit 63 to 32 in region 4.</p> <p>0h (R/W) = Accesses via region 4 address space to bit 63 to 32 in any DMA channel register are not allowed. Reads return 0 on bit n and writes do not modify the state of bit 63 to 32. Enabled interrupt bits for bit 31 to 0 do not contribute to the generation of a transfer completion interrupt for shadow region 4.</p> <p>1h (R/W) = Accesses via region 4 address space to bit 63 to 32 in any DMA channel register are allowed. Reads return the value from bit n and writes modify the state of bit 63 to 32. Enabled interrupt bits for bit 31 to 0 contribute to the generation of a transfer completion interrupt for shadow region 4.</p>

#### 10.4.1.28 DRAE5 Register (offset = 368h) [reset = 0h]

DRAE5 is shown in [Figure 10-69](#) and described in [Table 10-53](#).

The DMA region access enable register for shadow region 5 is programmed to allow or disallow read/write accesses on a bit-by-bit bases for all DMA registers in the shadow region 5 view of the DMA channel registers. Additionally, the DRAE5 configuration determines completion of which DMA channels will result in assertion of the shadow region 5 DMA completion interrupt. The DRAE registers are part of the group of the region access enable registers, which includes DRAEm and QRAEm. Where m is the number of shadow regions in the EDMA3CC memory map for a device. You can configure these registers to assign ownership of DMA/QDMA channels to a particular shadow region.

**Figure 10-69. DRAE5 Register**

**Table 10-53. DRAE5 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	En	R/W	0h	<p>DMA region access enable for bit 31 to 0 in region 5.</p> <p>0h (R/W) = Accesses via region 5 address space to bit 31 to 0 in any DMA channel register are not allowed. Reads return 0 on bit n and writes do not modify the state of bit 31 to 0. Enabled interrupt bits for bit n do not contribute to the generation of a transfer completion interrupt for shadow region 5.</p> <p>1h (R/W) = Accesses via region 5 address space to bit 31 to 0 in any DMA channel register are allowed. Reads return the value from bit n and writes modify the state of bit 31 to 0. Enabled interrupt bits for bit n contribute to the generation of a transfer completion interrupt for shadow region 5.</p>

### 10.4.1.29 DRAEH5 Register (offset = 36Ch) [reset = 0h]

DRAEH5 is shown in [Figure 10-70](#) and described in [Table 10-54](#).

The DMA region access enable register for shadow region 5 is programmed to allow or disallow read/write accesses on a bit-by-bit bases for all DMA registers in the shadow region 5 view of the DMA channel registers. Additionally, the DRAE5 configuration determines completion of which DMA channels will result in assertion of the shadow region 5 DMA completion interrupt. The DRAE registers are part of the group of the region access enable registers, which includes DRAEm and QRAEm. Where m is the number of shadow regions in the EDMA3CC memory map for a device. You can configure these registers to assign ownership of DMA/QDMA channels to a particular shadow region.

**Figure 10-70. DRAEH5 Register**

**Table 10-54. DRAEH5 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	En	R/W	0h	<p>DMA region access enable for bit 63 to 32 in region 5.</p> <p>0h (R/W) = Accesses via region 5 address space to bit 63 to 32 in any DMA channel register are not allowed. Reads return 0 on bit n and writes do not modify the state of bit 63 to 32. Enabled interrupt bits for bit 31 to 0 do not contribute to the generation of a transfer completion interrupt for shadow region 5.</p> <p>1h (R/W) = Accesses via region 5 address space to bit 63 to 32 in any DMA channel register are allowed. Reads return the value from bit n and writes modify the state of bit 63 to 32. Enabled interrupt bits for bit 31 to 0 contribute to the generation of a transfer completion interrupt for shadow region 5.</p>

### 10.4.1.30 DRAE6 Register (offset = 370h) [reset = 0h]

DRAE6 is shown in [Figure 10-71](#) and described in [Table 10-55](#).

The DMA region access enable register for shadow region 6 is programmed to allow or disallow read/write accesses on a bit-by-bit bases for all DMA registers in the shadow region 6 view of the DMA channel registers. Additionally, the DRAE6 configuration determines completion of which DMA channels will result in assertion of the shadow region 6 DMA completion interrupt. The DRAE registers are part of the group of the region access enable registers, which includes DRAEm and QRAEm. Where m is the number of shadow regions in the EDMA3CC memory map for a device. You can configure these registers to assign ownership of DMA/QDMA channels to a particular shadow region.

**Figure 10-71. DRAE6 Register**

**Table 10-55. DRAE6 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	En	R/W	0h	<p>DMA region access enable for bit 31 to 0 in region 6.</p> <p>0h (R/W) = Accesses via region 6 address space to bit 31 to 0 in any DMA channel register are not allowed. Reads return 0 on bit n and writes do not modify the state of bit 31 to 0. Enabled interrupt bits for bit n do not contribute to the generation of a transfer completion interrupt for shadow region 6.</p> <p>1h (R/W) = Accesses via region 6 address space to bit 31 to 0 in any DMA channel register are allowed. Reads return the value from bit n and writes modify the state of bit 31 to 0. Enabled interrupt bits for bit n contribute to the generation of a transfer completion interrupt for shadow region 6.</p>

### 10.4.1.31 DRAEH6 Register (offset = 374h) [reset = 0h]

DRAEH6 is shown in [Figure 10-72](#) and described in [Table 10-56](#).

The DMA region access enable register for shadow region 6 is programmed to allow or disallow read/write accesses on a bit-by-bit bases for all DMA registers in the shadow region 6 view of the DMA channel registers. Additionally, the DRAE6 configuration determines completion of which DMA channels will result in assertion of the shadow region 6 DMA completion interrupt. The DRAE registers are part of the group of the region access enable registers, which includes DRAEm and QRAEm. Where m is the number of shadow regions in the EDMA3CC memory map for a device. You can configure these registers to assign ownership of DMA/QDMA channels to a particular shadow region.

**Figure 10-72. DRAEH6 Register**

**Table 10-56. DRAEH6 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	En	R/W	0h	<p>DMA region access enable for bit 63 to 32 in region 6.</p> <p>0h (R/W) = Accesses via region 6 address space to bit 63 to 32 in any DMA channel register are not allowed. Reads return 0 on bit n and writes do not modify the state of bit 63 to 32. Enabled interrupt bits for bit 31 to 0 do not contribute to the generation of a transfer completion interrupt for shadow region 6.</p> <p>1h (R/W) = Accesses via region 6 address space to bit 63 to 32 in any DMA channel register are allowed. Reads return the value from bit n and writes modify the state of bit 63 to 32. Enabled interrupt bits for bit 31 to 0 contribute to the generation of a transfer completion interrupt for shadow region 6.</p>

### 10.4.1.32 DRAE7 Register (offset = 378h) [reset = 0h]

DRAE7 is shown in [Figure 10-73](#) and described in [Table 10-57](#).

The DMA region access enable register for shadow region 7 is programmed to allow or disallow read/write accesses on a bit-by-bit bases for all DMA registers in the shadow region 7 view of the DMA channel registers. Additionally, the DRAE7 configuration determines completion of which DMA channels will result in assertion of the shadow region 7 DMA completion interrupt. The DRAE registers are part of the group of the region access enable registers, which includes DRAEm and QRAEm. Where m is the number of shadow regions in the EDMA3CC memory map for a device. You can configure these registers to assign ownership of DMA/QDMA channels to a particular shadow region.

**Figure 10-73. DRAE7 Register**

**Table 10-57. DRAE7 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	En	R/W	0h	<p>DMA region access enable for bit 31 to 0 in region 7.</p> <p>0h (R/W) = Accesses via region 7 address space to bit 31 to 0 in any DMA channel register are not allowed. Reads return 0 on bit n and writes do not modify the state of bit 31 to 0. Enabled interrupt bits for bit n do not contribute to the generation of a transfer completion interrupt for shadow region 7.</p> <p>1h (R/W) = Accesses via region 7 address space to bit 31 to 0 in any DMA channel register are allowed. Reads return the value from bit n and writes modify the state of bit 31 to 0. Enabled interrupt bits for bit n contribute to the generation of a transfer completion interrupt for shadow region 7.</p>

### 10.4.1.33 DRAEH7 Register (offset = 37Ch) [reset = 0h]

DRAEH7 is shown in [Figure 10-74](#) and described in [Table 10-58](#).

The DMA region access enable register for shadow region 7 is programmed to allow or disallow read/write accesses on a bit-by-bit bases for all DMA registers in the shadow region 7 view of the DMA channel registers. Additionally, the DRAE7 configuration determines completion of which DMA channels will result in assertion of the shadow region 7 DMA completion interrupt. The DRAE registers are part of the group of the region access enable registers, which includes DRAEm and QRAEm. Where m is the number of shadow regions in the EDMA3CC memory map for a device. You can configure these registers to assign ownership of DMA/QDMA channels to a particular shadow region.

**Figure 10-74. DRAEH7 Register**

**Table 10-58. DRAEH7 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	En	R/W	0h	<p>DMA region access enable for bit 63 to 32 in region 7.</p> <p>0h (R/W) = Accesses via region 7 address space to bit 63 to 32 in any DMA channel register are not allowed. Reads return 0 on bit n and writes do not modify the state of bit 63 to 32. Enabled interrupt bits for bit 31 to 0 do not contribute to the generation of a transfer completion interrupt for shadow region 7.</p> <p>1h (R/W) = Accesses via region 7 address space to bit 63 to 32 in any DMA channel register are allowed. Reads return the value from bit n and writes modify the state of bit 63 to 32. Enabled interrupt bits for bit 31 to 0 contribute to the generation of a transfer completion interrupt for shadow region 7.</p>

#### 10.4.1.34 QRAE0 to QRAE7 Register (offset = 380h to 39Ch) [reset = 0h]

QRAE0 to QRAE7 is shown in [Figure 10-75](#) and described in [Table 10-59](#).

The QDMA region access enable register for shadow region m (QRAEm) is programmed to allow or disallow read/write accesses on a bit-by-bit bases for all QDMA registers in the shadow region m view of the QDMA registers. This includes all 4-bit QDMA registers. The QRAE register is part of the group of the region access enable registers, which includes DRAEm and QRAEm. Where m is the number of shadow regions in the EDMA3CC memory map for a device. You can configure these registers to assign ownership of DMA/QDMA channels to a particular shadow region.

**Figure 10-75. QRAE0 to QRAE7 Register**

**Table 10-59. QRAE0 to QRAE7 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-8	RESERVED	R	0h	
7-0	En	R/W	0h	<p>QDMA region access enable for bit n/QDMA channel n in region m.</p> <p>0h (R/W) = Accesses via region m address space to bit n in any QDMA channel register are not allowed. Reads return 0 on bit n and writes do not modify the state of bit n.</p> <p>1h (R/W) = Accesses via region m address space to bit n in any QDMA channel register are allowed. Reads return the value from bit n and writes modify the state of bit n.</p>

### 10.4.1.35 Q0E0 to Q0E15 Register (offset = 400h to 43Ch) [reset = 0h]

Q0E0 to Q0E15 is shown in [Figure 10-76](#) and described in [Table 10-60](#).

The event queue entry registers (QxEy) exist for all 16 queue entries (the maximum allowed queue entries) for all event queues in the EDMA3CC. The event queue entry registers range from Q0E0 to Q0E15, Q1E0 to Q1E15, and Q2E0 to Q2E15. Each register details the event number (ENUM) and the event type (ETYPE). For example, if the value in Q1E4 is read as 000 004Fh, this means the 4th entry in queue 1 is a manually-triggered event on DMA channel 15. The Q0E0 register provides visibility into the event queues and a TR life cycle. These are useful for system debug as they provide in-depth visibility for the events queued up in the event queue and also provide information on what parts of the EDMA3CC logic are active once the event has been received by the EDMA3CC.

**Figure 10-76. Q0E0 to Q0E15 Register**

**Table 10-60. Q0E0 to Q0E15 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-8	RESERVED	R	0h	
7-6	ETYPE	R	0h	Event entry y in queue 0. Specifies the specific event type for the given entry in the event queue. 0h (R/W) = Event triggered via ER. 1h (R/W) = Auto-triggered via QER.
5-0	ENUM	R	0h	Event entry y in queue 0. Event number: QDMA channel number (0 to 3). DMA channel/event number (0 to 63).

#### 10.4.1.36 Q1E0 to Q1E15 Register (offset = 440h to 47Ch) [reset = 0h]

Q1E0 to Q1E15 is shown in [Figure 10-77](#) and described in [Table 10-61](#).

The event queue entry registers (QxEy) exist for all 16 queue entries (the maximum allowed queue entries) for all event queues in the EDMA3CC. The event queue entry registers range from Q0E0 to Q0E15, Q1E0 to Q1E15, and Q2E0 to Q2E15. Each register details the event number (ENUM) and the event type (ETYPE). For example, if the value in Q1E4 is read as 000 004Fh, this means the 4th entry in queue 1 is a manually-triggered event on DMA channel 15. The Q1E0 register provides visibility into the event queues and a TR life cycle. These are useful for system debug as they provide in-depth visibility for the events queued up in the event queue and also provide information on what parts of the EDMA3CC logic are active once the event has been received by the EDMA3CC.

**Figure 10-77. Q1E0 to Q1E15 Register**

**Table 10-61. Q1E0 to Q1E15 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-8	RESERVED	R	0h	
7-6	ETYPE	R	0h	Event entry y in queue 1. Specifies the specific event type for the given entry in the event queue. 0h (R/W) = Event triggered via ER. 1h (R/W) = Auto-triggered via QER.
5-0	ENUM	R	0h	Event entry y in queue 1. Event number: QDMA channel number (0 to 3). DMA channel/event number (0 to 63).

### 10.4.1.37 Q2E0 to Q2E15 Register (offset = 480h to 4BCh) [reset = 0h]

Q2E0 to Q2E15 is shown in [Figure 10-78](#) and described in [Table 10-62](#).

The event queue entry registers (QxEy) exist for all 16 queue entries (the maximum allowed queue entries) for all event queues in the EDMA3CC. The event queue entry registers range from Q0E0 to Q0E15, Q1E0 to Q1E15, and Q2E0 to Q2E15. Each register details the event number (ENUM) and the event type (ETYPE). For example, if the value in Q1E4 is read as 000 004Fh, this means the 4th entry in queue 1 is a manually-triggered event on DMA channel 15. The Q2E0 register provides visibility into the event queues and a TR life cycle. These are useful for system debug as they provide in-depth visibility for the events queued up in the event queue and also provide information on what parts of the EDMA3CC logic are active once the event has been received by the EDMA3CC.

**Figure 10-78. Q2E0 to Q2E15 Register**

**Table 10-62. Q2E0 to Q2E15 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-8	RESERVED	R	0h	
7-6	ETYPE	R	0h	Event entry y in queue 2. Specifies the specific event type for the given entry in the event queue. 0h (R/W) = Event triggered via ER. 1h (R/W) = Auto-triggered via QER.
5-0	ENUM	R	0h	Event entry y in queue 2. Event number: QDMA channel number (0 to 3). DMA channel/event number (0 to 63).

### 10.4.1.38 QSTAT0 to QSTAT2 Register (offset = 600h to 608h) [reset = Fh]

QSTAT0 to QSTAT2 is shown in [Figure 10-79](#) and described in [Table 10-63](#).

The queue status register (QSTAT) provides visibility into the event queues and a TR life cycle. These are useful for system debug as they provide in-depth visibility for the events queued up in the event queue and also provide information on what parts of the EDMA3CC logic are active once the event has been received by the EDMA3CC.

**Figure 10-79. QSTAT0 to QSTAT2 Register**

**Table 10-63. QSTAT0 to QSTAT2 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-25	RESERVED	R	0h	
24	THRCD	R	0h	Threshold exceeded. THRCD is cleared by writing a 1 to the corresponding QTHRCDn bit in the EDMA3CC error clear register (CCERRCLR). 0h (R/W) = Threshold specified by the Qn bit in the queue watermark threshold A register (QWMTHRA) has not been exceeded. 1h (R/W) = Threshold specified by the Qn bit in the queue watermark threshold A register (QWMTHRA) has been exceeded.
23-21	RESERVED	R	0h	
20-16	WM	R	0h	Watermark for maximum queue usage. Watermark tracks the most entries that have been in queue n since reset or since the last time that the watermark (WM) bit was cleared. WM is cleared by writing a 1 to the corresponding QTHRCDn bit in the EDMA3CC error clear register (CCERRCLR). 0h (R/W) = Legal values are 0 (empty) to 10h (full). 1h (R/W) = Reserved, from 11h to 1Fh. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
15-13	RESERVED	R	0h	
12-8	NUMVAL	R	0h	Number of valid entries in queue n. The total number of entries residing in the queue manager FIFO at a given instant. Always enabled. 0h (R/W) = Legal values are 0 (empty) to 10h (full). 1h (R/W) = Reserved, from 11h to 1Fh. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
7-4	RESERVED	R	0h	
3-0	STRTPTR	R	Fh	Start pointer. The offset to the head entry of queue n, in units of entries. Always enabled. Legal values are 0 (0th entry) to Fh (15th entry).

### 10.4.1.39 QWMTHRA Register (offset = 620h) [reset = A0A0Ah]

QWMTHRA is shown in [Figure 10-80](#) and described in [Table 10-64](#).

The queue watermark threshold A register (QWMTHRA) provides visibility into the event queues and a TR life cycle. These are useful for system debug as they provide in-depth visibility for the events queued up in the event queue and also provide information on what parts of the EDMA3CC logic are active once the event has been received by the EDMA3CC.

**Figure 10-80. QWMTHRA Register**

**Table 10-64. QWMTHRA Register Field Descriptions**

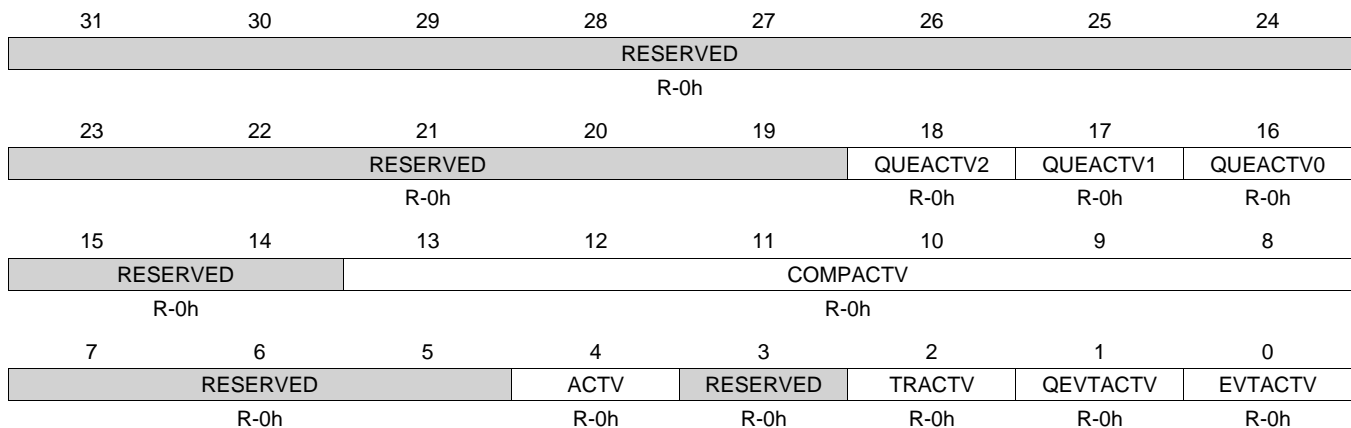

Bit	Field	Type	Reset	Description
31-21	RESERVED	R	0h	
20-16	Q2	R/W	Ah	Queue threshold for queue 2 value. The QTHRCD2 bit in the EDMA3CC error register (CCERR) and the THRXCD bit in the queue status register 2 (QSTAT2) are set when the number of events in queue 2 at an instant in time (visible via the NUMVAL bit in QSTAT2) equals or exceeds the value specified by Q2. 0h (R/W) = From 0h to 10h, The default is 16 (maximum allowed). 11h (R/W) = Disables the threshold errors. 12h (R/W) = From 12h to 1Fh, Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
15-13	RESERVED	R	0h	
12-8	Q1	R/W	Ah	Queue threshold for queue 1 value. The QTHRCD1 bit in the EDMA3CC error register (CCERR) and the THRXCD bit in the queue status register 1 (QSTAT1) are set when the number of events in queue 1 at an instant in time (visible via the NUMVAL bit in QSTAT1) equals or exceeds the value specified by Q1. 0h (R/W) = From 0h to 10h, The default is 16 (maximum allowed). 11h (R/W) = Disables the threshold errors. 12h (R/W) = From 12h to 1Fh, Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
7-5	RESERVED	R	0h	
4-0	Q0	R/W	Ah	Queue threshold for queue 0 value. The QTHRCD0 bit in the EDMA3CC error register (CCERR) and the THRXCD bit in the queue status register 0 (QSTAT0) are set when the number of events in queue 0 at an instant in time (visible via the NUMVAL bit in QSTAT0) equals or exceeds the value specified by Q0. 0h (R/W) = From 0h to 10h, The default is 16 (maximum allowed). 11h (R/W) = Disables the threshold errors. 12h (R/W) = From 12h to 1Fh, Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.

#### 10.4.1.40 CCSTAT Register (offset = 640h) [reset = 0h]

CCSTAT is shown in [Figure 10-81](#) and described in [Table 10-65](#).

The EDMA3CC status register (CCSTAT) has a number of status bits that reflect which parts of the EDMA3CC logic is active at any given instant of time. CCSTAT provides visibility into the event queues and a TR life cycle. These are useful for system debug as they provide in-depth visibility for the events queued up in the event queue and also provide information on what parts of the EDMA3CC logic are active once the event has been received by the EDMA3CC.

**Figure 10-81. CCSTAT Register**

**Table 10-65. CCSTAT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-19	RESERVED	R	0h	
18	QUEACTV2	R	0h	Queue 2 active. 0h (R/W) = No events are queued in queue 2. 1h (R/W) = At least one TR is queued in queue 2.
17	QUEACTV1	R	0h	Queue 1 active. 0h (R/W) = No events are queued in queue 1. 1h (R/W) = At least one TR is queued in queue 1.
16	QUEACTV0	R	0h	Queue 0 active. 0h (R/W) = No events are queued in queue 0. 1h (R/W) = At least one TR is queued in queue 0.
15-14	RESERVED	R	0h	
13-8	COMPACTV	R	0h	Completion request active. The COMPACTV field reflects the count for the number of completion requests submitted to the transfer controllers. This count increments every time a TR is submitted and is programmed to report completion (the TCINTEN or TCCCHEN bits in OPT in the parameter entry associated with the TR are set). The counter decrements for every valid TCC received back from the transfer controllers. If at any time the count reaches a value of 63, the EDMA3CC will not service any new TRs until the count is less than 63 (or return a transfer completion code from a transfer controller, which would decrement the count). 0h (R/W) = No completion requests outstanding. 1h (R/W) = Total of 1 completion request to 63 completion requests are outstanding, from 1h to 3Fh.
7-5	RESERVED	R	0h	

**Table 10-65. CCSTAT Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
4	ACTV	R	0h	Channel controller active. Channel controller active is a logical-OR of each of the *ACTV bits. The ACTV bit remains high through the life of a TR. 0h (R/W) = Channel is idle.. 1h (R/W) = Channel is busy.
3	RESERVED	R	0h	
2	TRACTV	R	0h	Transfer request active. 0h (R/W) = Transfer request processing/submission logic is inactive. 1h (R/W) = Transfer request processing/submission logic is active.
1	QEVTACTV	R	0h	QDMA event active. 0h (R/W) = No enabled QDMA events are active within the EDMA3CC. 1h (R/W) = At least one enabled QDMA event (QER) is active within the EDMA3CC.
0	EVTACTV	R	0h	DMA event active. 0h (R/W) = No enabled DMA events are active within the EDMA3CC. 1h (R/W) = At least one enabled DMA event (ER and EER, ESR, CER) is active within the EDMA3CC.

#### 10.4.1.41 MPFAR Register (offset = 800h) [reset = 0h]

MPFAR is shown in [Figure 10-82](#) and described in [Table 10-66](#).

A CPU write of 1 to the MPFCLR bit in the memory protection fault command register (MPFCR) causes any error conditions stored in MPFAR to be cleared.

**Figure 10-82. MPFAR Register**

**Table 10-66. MPFAR Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	FADDR	R	0h	Fault address. This 32 bit read-only status register contains the fault address when a memory protection violation is detected. This register can only be cleared via the memory protection fault command register (MPFCR). Value 0 to FFFF FFFFh.

### 10.4.1.42 MPFSR Register (offset = 804h) [reset = 0h]

MPFSR is shown in [Figure 10-83](#) and described in [Table 10-67](#).

A CPU write of 1 to the MPFCLR bit in the memory protection fault command register (MPFCR) causes any error conditions stored in MPFSR to be cleared.

**Figure 10-83. MPFSR Register**

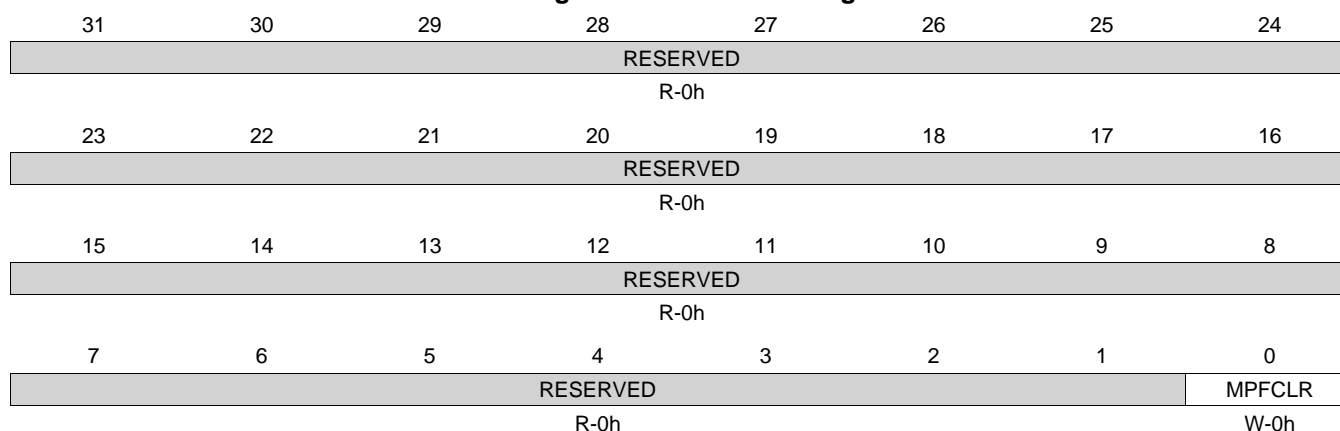

**Table 10-67. MPFSR Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-13	RESERVED	R	0h	
12-9	FID	R	0h	Faulted identification. FID contains valid information if any of the MP error bits (UXE, UWE, URE, SXE, SWE, SRE) are nonzero (that is, if an error has been detected.) The FID field contains the privilege ID for the specific request/requestor that resulted in an MP error. Value 0 to Fh.
8-6	RESERVED	R	0h	
5	SRE	R	0h	Supervisor read error. 0h (R/W) = No error detected. 1h (R/W) = Supervisor level task attempted to read from a MP page without SR permissions.
4	SWE	R	0h	Supervisor write error. 0h (R/W) = No error detected. 1h (R/W) = Supervisor level task attempted to write to a MP page without SW permissions.
3	SXE	R	0h	Supervisor execute error. 0h (R/W) = No error detected. 1h (R/W) = Supervisor level task attempted to execute from a MP page without SX permissions.
2	URE	R	0h	User read error. 0h (R/W) = No error detected. 1h (R/W) = User level task attempted to read from a MP page without UR permissions.
1	UWE	R	0h	User write error. 0h (R/W) = No error detected. 1h (R/W) = User level task attempted to write to a MP page without UW permissions.
0	UXE	R	0h	User execute error. 0h (R/W) = No error detected. 1h (R/W) = User level task attempted to execute from a MP page without UX permissions.

### 10.4.1.43 MPFCR Register (offset = 808h) [reset = 0h]

MPFCR is shown in [Figure 10-84](#) and described in [Table 10-68](#).

**Figure 10-84. MPFCR Register**

**Table 10-68. MPFCR Register Field Descriptions**

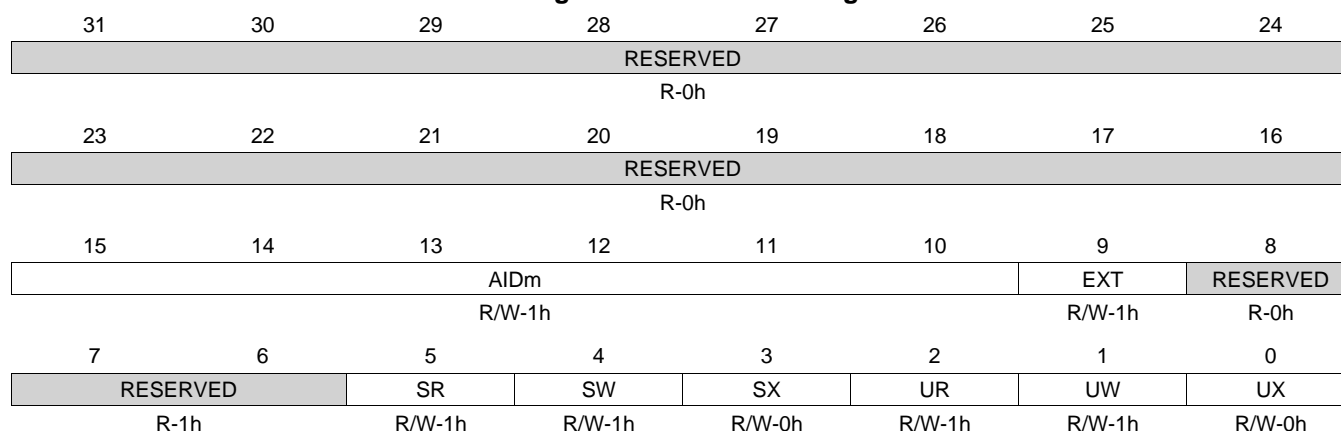

Bit	Field	Type	Reset	Description
31-1	RESERVED	R	0h	
0	MPFCLR	W	0h	Fault clear register. 0h (R/W) = CPU write of 0 has no effect. 1h (R/W) = CPU write of 1 to the MPFCLR bit causes any error conditions stored in the memory protection fault address register (MPFAR) and the memory protection fault status register (MPFSR) to be cleared.

#### 10.4.1.44 MPPAG Register (offset = 80Ch) [reset = 676h]

MPPAG is shown in [Figure 10-85](#) and described in [Table 10-69](#).

**Figure 10-85. MPPAG Register**

**Table 10-69. MPPAG Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	
15-10	AIDm	R/W	1h	Allowed ID 'N' 0h (R/W) = Requests with Privilege ID == N are not allowed to region M, regardless of permission settings (UW, UR, SW, SR). 1h (R/W) = Requests with Privilege ID == N are permitted, if access type is allowed as defined by permission settings (UW, UR, SW, SR).
9	EXT	R/W	1h	External Allowed ID. 0h (R/W) = Requests with Privilege ID >= 6 are not allowed to region M, regardless of permission settings (UW, UR, SW, SR). 1h (R/W) = Requests with Privilege ID >= 6 are permitted, if access type is allowed as defined by permission settings (UW, UR, SW, SR).
8	RESERVED	R	0h	
7-6	RESERVED	R	1h	
5	SR	R/W	1h	Supervisor read permission. 0h (R/W) = Supervisor read accesses are not allowed from region M. 1h (R/W) = Supervisor write accesses are allowed from region M addresses.
4	SW	R/W	1h	Supervisor write permission. 0h (R/W) = Supervisor write accesses are not allowed to region M. 1h (R/W) = Supervisor write accesses are allowed to region N addresses.
3	SX	R/W	0h	Supervisor execute permission. 0h (R/W) = Supervisor execute accesses are not allowed from region M. 1h (R/W) = Supervisor execute accesses are allowed from region M addresses.
2	UR	R/W	1h	User read permission. 0h (R/W) = User read accesses are not allowed from region M. 1h (R/W) = User read accesses are allowed from region N addresses.

**Table 10-69. MPPAG Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
1	UW	R/W	1h	User write permission. 0h (R/W) = User write accesses are not allowed to region M. 1h (R/W) = User write accesses are allowed to region M addresses.
0	UX	R/W	0h	User execute permission. 0h (R/W) = User execute accesses are not allowed from region M. 1h (R/W) = User execute accesses are allowed from region M addresses.

#### 10.4.1.45 MPPA0 to MPPA7 Register (offset = 810h to 82Ch) [reset = 676h]

MPPA0 to MPPA7 is shown in [Figure 10-86](#) and described in [Table 10-70](#).

**Figure 10-86. MPPA0 to MPPA7 Register**

**Table 10-70. MPPA0 to MPPA7 Register Field Descriptions**

### 10.4.1.46 ER Register (offset = 1000h) [reset = 0h]

ER is shown in [Figure 10-87](#) and described in [Table 10-71](#).

All external events are captured in the event register (ER/ERH). The events are latched even when the events are not enabled. If the event bit corresponding to the latched event is enabled (EER.En/EERH.En = 1), then the event is evaluated by the EDMA3CC logic for an associated transfer request submission to the transfer controllers. The event register bits are automatically cleared (ER.En/ERH.En = 0) once the corresponding events are prioritized and serviced. If ER.En/ERH.En are already set and another event is received on the same channel/event, then the corresponding event is latched in the event miss register (EMR.En/EMRH.En), provided that the event was enabled (EER.En/EERH.En = 1). Event n can be cleared by the CPU writing a 1 to corresponding event bit in the event clear register (ECR/ECRH). The setting of an event is a higher priority relative to clear operations (via hardware or software). If set and clear conditions occur concurrently, the set condition wins. If the event was previously set, then EMR/EMRH would be set because an event is lost. If the event was previously clear, then the event remains set and is prioritized for submission to the event queues. The Debug List table provides the type of synchronization events and the EDMA3CC channels associated to each of these external events. This register is part of a set of registers that pertain to the 64 DMA channels. The 64 DMA channels consist of a set of registers (with exception of DMAQNUMn) that each have 64 bits and the bit position of each register matches the DMA channel number. Each register is named with the format reg\_name that corresponds to DMA channels 0 through 31 and reg\_name\_High that corresponds to DMA channels 32 through 64. For example, the event register (ER) corresponds to DMA channel 0 through 31 and the event register high register (ERH) corresponds to DMA channel 32 through 63. The register is typically called the event register. The DMA channel registers are accessible via read/writes to the global address range. They are also accessible via read/writes to the shadow address range. The read/write ability to the registers in the shadow region are controlled by the DMA region access registers (DRAEm/DRAEHm).

**Figure 10-87. ER Register**

**Table 10-71. ER Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	En	R	0h	<p>Event 0 to 31. Events 0 to 31 are captured by the EDMA3CC and are latched into ER. The events are set (En = 1) even when events are disabled (En = 0 in the event enable register, EER). 0h (R/W) = EDMA3CC event is not asserted. 1h (R/W) = EDMA3CC event is asserted. Corresponding DMA event is prioritized versus other pending DMA/QDMA events for submission to the EDMA3TC.</p>

### 10.4.1.47 ERH Register (offset = 1004h) [reset = 0h]

ERH is shown in [Figure 10-88](#) and described in [Table 10-72](#).

All external events are captured in the event register (ER/ERH). The events are latched even when the events are not enabled. If the event bit corresponding to the latched event is enabled (EER.En/EERH.En = 1), then the event is evaluated by the EDMA3CC logic for an associated transfer request submission to the transfer controllers. The event register bits are automatically cleared (ER.En/ERH.En = 0) once the corresponding events are prioritized and serviced. If ER.En/ERH.En are already set and another event is received on the same channel/event, then the corresponding event is latched in the event miss register (EMR.En/EMRH.En), provided that the event was enabled (EER.En/EERH.En = 1). Event n can be cleared by the CPU writing a 1 to corresponding event bit in the event clear register (ECR/ECRH). The setting of an event is a higher priority relative to clear operations (via hardware or software). If set and clear conditions occur concurrently, the set condition wins. If the event was previously set, then EMR/EMRH would be set because an event is lost. If the event was previously clear, then the event remains set and is prioritized for submission to the event queues. The Debug List table provides the type of synchronization events and the EDMA3CC channels associated to each of these external events. This register is part of a set of registers that pertain to the 64 DMA channels. The 64 DMA channels consist of a set of registers (with exception of DMAQNUMn) that each have 64 bits and the bit position of each register matches the DMA channel number. Each register is named with the format reg\_name that corresponds to DMA channels 0 through 31 and reg\_name\_High that corresponds to DMA channels 32 through 64. For example, the event register (ER) corresponds to DMA channel 0 through 31 and the event register high register (ERH) corresponds to DMA channel 32 through 63. The register is typically called the event register. The DMA channel registers are accessible via read/writes to the global address range. They are also accessible via read/writes to the shadow address range. The read/write ability to the registers in the shadow region are controlled by the DMA region access registers (DRAEm/DRAEHm).

**Figure 10-88. ERH Register**

**Table 10-72. ERH Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	En	R	0h	<p>Event 32 to 63. Events 32 to 63 are captured by the EDMA3CC and are latched into ERH. The events are set (En = 1) even when events are disabled (En = 0 in the event enable register high, EERH). 0h (R/W) = EDMA3CC event is not asserted. 1h (R/W) = EDMA3CC event is asserted. Corresponding DMA event is prioritized versus other pending DMA/QDMA events for submission to the EDMA3TC.</p>

### 10.4.1.48 ECR Register (offset = 1008h) [reset = 0h]

ECR is shown in [Figure 10-89](#) and described in [Table 10-73](#).

Once an event has been posted in the event registers (ER/ERH), the event is cleared in two ways. If the event is enabled in the event enable register (EER/EERH) and the EDMA3CC submits a transfer request for the event to the EDMA3TC, it clears the corresponding event bit in the event register. If the event is disabled in the event enable register (EER/EERH), the CPU can clear the event by way of the event clear registers (ECR/ECRH). Writing a 1 to any of the bits clears the corresponding event; writing a 0 has no effect. Once an event bit is set in the event register, it remains set until EDMA3CC submits a transfer request for that event or the CPU clears the event by setting the corresponding bit in ECR/ECRH. This register is part of a set of registers that pertain to the 64 DMA channels. The 64 DMA channels consist of a set of registers (with exception of DMAQNUMn) that each have 64 bits and the bit position of each register matches the DMA channel number. Each register is named with the format reg\_name that corresponds to DMA channels 0 through 31 and reg\_name\_High that corresponds to DMA channels 32 through 64. For example, the event register (ER) corresponds to DMA channel 0 through 31 and the event register high register (ERH) corresponds to DMA channel 32 through 63. The register is typically called the event register. The DMA channel registers are accessible via read/writes to the global address range. They are also accessible via read/writes to the shadow address range. The read/write ability to the registers in the shadow region are controlled by the DMA region access registers (DRAEm/DRAEHm).

**Figure 10-89. ECR Register**

**Table 10-73. ECR Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	En	W	0h	Event clear for event 0 to 31. Any of the event bits in ECR is set to clear the event (En) in the event register (ER). A write of 0 has no effect. 0h (R/W) = No effect. 1h (R/W) = EDMA3CC event is cleared in the event register (ER).

#### 10.4.1.49 ECRH Register (offset = 100Ch) [reset = 0h]

ECRH is shown in [Figure 10-90](#) and described in [Table 10-74](#).

Once an event has been posted in the event registers (ER/ERH), the event is cleared in two ways. If the event is enabled in the event enable register (EER/EERH) and the EDMA3CC submits a transfer request for the event to the EDMA3TC, it clears the corresponding event bit in the event register. If the event is disabled in the event enable register (EER/EERH), the CPU can clear the event by way of the event clear registers (ECR/ECRH). Writing a 1 to any of the bits clears the corresponding event; writing a 0 has no effect. Once an event bit is set in the event register, it remains set until EDMA3CC submits a transfer request for that event or the CPU clears the event by setting the corresponding bit in ECR/ECRH. This register is part of a set of registers that pertain to the 64 DMA channels. The 64 DMA channels consist of a set of registers (with exception of DMAQNUMn) that each have 64 bits and the bit position of each register matches the DMA channel number. Each register is named with the format reg\_name that corresponds to DMA channels 0 through 31 and reg\_name\_High that corresponds to DMA channels 32 through 64. For example, the event register (ER) corresponds to DMA channel 0 through 31 and the event register high register (ERH) corresponds to DMA channel 32 through 63. The register is typically called the event register. The DMA channel registers are accessible via read/writes to the global address range. They are also accessible via read/writes to the shadow address range. The read/write ability to the registers in the shadow region are controlled by the DMA region access registers (DRAEm/DRAEHm).

**Figure 10-90. ECRH Register**

**Table 10-74. ECRH Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	En	W	0h	Event clear for event 32 to 63. Any of the event bits in ECRH are set to clear the event (En) in the event register high (ERH). A write of 0 has no effect. 0h (R/W) = No effect. 1h (R/W) = EDMA3CC event is cleared in the event register high (ERH).

### 10.4.1.50 ESR Register (offset = 1010h) [reset = 0h]

ESR is shown in [Figure 10-91](#) and described in [Table 10-75](#).

The event set registers (ESR/ESRH) allow the CPU (EDMA3 programmers) to manually set events to initiate DMA transfer requests. CPU writes of 1 to any event set register (En) bits set the corresponding bits in the registers. The set event is evaluated by the EDMA3CC logic for an associated transfer request submission to the transfer controllers. Writing a 0 has no effect. The event set registers operate independent of the event registers (ER/ERH), and a write of 1 is always considered a valid event regardless of whether the event is enabled (the corresponding event bits are set or cleared in EER.En/EERH.En). Once the event is set in the event set registers, it cannot be cleared by CPU writes, in other words, the event clear registers (ECR/ECRH) have no effect on the state of ESR/ESRH. The bits will only be cleared once the transfer request corresponding to the event has been submitted to the transfer controller. The setting of an event is a higher priority relative to clear operations (via hardware). If set and clear conditions occur concurrently, the set condition wins. If the event was previously set, then EMR/EMRH would be set because an event is lost. If the event was previously clear, then the event remains set and is prioritized for submission to the event queues. Manually-triggered transfers via writes to ESR/ESRH allow the CPU to submit DMA requests in the system, these are relevant for memory-to-memory transfer scenarios. If the ESR.En/ESRH.En bit is already set and another CPU write of 1 is attempted to the same bit, then the corresponding event is latched in the event missed registers (EMR.En/EMRH.En = 1). This register is part of a set of registers that pertain to the 64 DMA channels. The 64 DMA channels consist of a set of registers (with exception of DMAQNUMn) that each have 64 bits and the bit position of each register matches the DMA channel number. Each register is named with the format reg\_name that corresponds to DMA channels 0 through 31 and reg\_name\_High that corresponds to DMA channels 32 through 64. For example, the event register (ER) corresponds to DMA channel 0 through 31 and the event register high register (ERH) corresponds to DMA channel 32 through 63. The register is typically called the event register. The DMA channel registers are accessible via read/writes to the global address range. They are also accessible via read/writes to the shadow address range. The read/write ability to the registers in the shadow region are controlled by the DMA region access registers (DRAEm/DRAEHm).

**Figure 10-91. ESR Register**

**Table 10-75. ESR Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	En	R/W	0h	Event set for event 0 to 31. 0h (R/W) = No effect. 1h (R/W) = Corresponding DMA event is prioritized versus other pending DMA/QDMA events for submission to the EDMA3TC.

### 10.4.1.51 ESRH Register (offset = 1014h) [reset = 0h]

ESRH is shown in [Figure 10-92](#) and described in [Table 10-76](#).

The event set registers (ESR/ESRH) allow the CPU (EDMA3 programmers) to manually set events to initiate DMA transfer requests. CPU writes of 1 to any event set register (En) bits set the corresponding bits in the registers. The set event is evaluated by the EDMA3CC logic for an associated transfer request submission to the transfer controllers. Writing a 0 has no effect. The event set registers operate independent of the event registers (ER/ERH), and a write of 1 is always considered a valid event regardless of whether the event is enabled (the corresponding event bits are set or cleared in EER.En/EERH.En). Once the event is set in the event set registers, it cannot be cleared by CPU writes, in other words, the event clear registers (ECR/ECRH) have no effect on the state of ESR/ESRH. The bits will only be cleared once the transfer request corresponding to the event has been submitted to the transfer controller. The setting of an event is a higher priority relative to clear operations (via hardware). If set and clear conditions occur concurrently, the set condition wins. If the event was previously set, then EMR/EMRH would be set because an event is lost. If the event was previously clear, then the event remains set and is prioritized for submission to the event queues. Manually-triggered transfers via writes to ESR/ESRH allow the CPU to submit DMA requests in the system, these are relevant for memory-to-memory transfer scenarios. If the ESR.En/ESRH.En bit is already set and another CPU write of 1 is attempted to the same bit, then the corresponding event is latched in the event missed registers (EMR.En/EMRH.En = 1). This register is part of a set of registers that pertain to the 64 DMA channels. The 64 DMA channels consist of a set of registers (with exception of DMAQNUMn) that each have 64 bits and the bit position of each register matches the DMA channel number. Each register is named with the format reg\_name that corresponds to DMA channels 0 through 31 and reg\_name\_High that corresponds to DMA channels 32 through 64. For example, the event register (ER) corresponds to DMA channel 0 through 31 and the event register high register (ERH) corresponds to DMA channel 32 through 63. The register is typically called the event register. The DMA channel registers are accessible via read/writes to the global address range. They are also accessible via read/writes to the shadow address range. The read/write ability to the registers in the shadow region are controlled by the DMA region access registers (DRAEm/DRAEHm).

**Figure 10-92. ESRH Register**

**Table 10-76. ESRH Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	En	R/W	0h	Event set for event 32 to 63. 0h (R/W) = No effect. 1h (R/W) = Corresponding DMA event is prioritized versus other pending DMA/QDMA events for submission to the EDMA3TC.

### 10.4.1.52 CER Register (offset = 1018h) [reset = 0h]

CER is shown in [Figure 10-93](#) and described in [Table 10-77](#).

When the OPTIONS parameter for a PaRAM entry is programmed to returned a chained completion code (ITCCHEN = 1 and/or TCCHEN = 1), then the value dictated by the TCC[5:0] (also programmed in OPT) forces the corresponding event bit to be set in the chained event registers (CER/CERH). The set chained event is evaluated by the EDMA3CC logic for an associated transfer request submission to the transfer controllers. This results in a chained-triggered transfer. The chained event registers do not have any enables. The generation of a chained event is essentially enabled by the PaRAM entry that has been configured for intermediate and/or final chaining on transfer completion. The En bit is set (regardless of the state of EER.En/EERH.En) when a chained completion code is returned from one of the transfer controllers or is generated by the EDMA3CC via the early completion path. The bits in the chained event register are cleared when the corresponding events are prioritized and serviced. If the En bit is already set and another chaining completion code is return for the same event, then the corresponding event is latched in the event missed registers (EMR.En/EMRH.En= 1). The setting of an event is a higher priority relative to clear operations (via hardware). If set and clear conditions occur concurrently, the set condition wins. If the event was previously set, then EMR/EMRH would be set because an event is lost. If the event was previously clear, then the event remains set and is prioritized for submission to the event queues. This register is part of a set of registers that pertain to the 64 DMA channels. The 64 DMA channels consist of a set of registers (with exception of DMAQNUMn) that each have 64 bits and the bit position of each register matches the DMA channel number. Each register is named with the format reg\_name that corresponds to DMA channels 0 through 31 and reg\_name\_High that corresponds to DMA channels 32 through 64. For example, the event register (ER) corresponds to DMA channel 0 through 31 and the event register high register (ERH) corresponds to DMA channel 32 through 63. The register is typically called the event register. The DMA channel registers are accessible via read/writes to the global address range. They are also accessible via read/writes to the shadow address range. The read/write ability to the registers in the shadow region are controlled by the DMA region access registers (DRAEm/DRAEHm).

**Figure 10-93. CER Register**

**Table 10-77. CER Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	En	R	0h	Chained event for event 0 to 31. 0h (R/W) = No effect. 1h (R/W) = Corresponding DMA event is prioritized versus other pending DMA/QDMA events for submission to the EDMA3TC.

### 10.4.1.53 CERH Register (offset = 101Ch) [reset = 0h]

CERH is shown in [Figure 10-94](#) and described in [Table 10-78](#).

When the OPTIONS parameter for a PaRAM entry is programmed to returned a chained completion code (ITCCHEN = 1 and/or TCCHEN = 1), then the value dictated by the TCC[5:0] (also programmed in OPT) forces the corresponding event bit to be set in the chained event registers (CER/CERH). The set chained event is evaluated by the EDMA3CC logic for an associated transfer request submission to the transfer controllers. This results in a chained-triggered transfer. The chained event registers do not have any enables. The generation of a chained event is essentially enabled by the PaRAM entry that has been configured for intermediate and/or final chaining on transfer completion. The En bit is set (regardless of the state of EER.En/EERH.En) when a chained completion code is returned from one of the transfer controllers or is generated by the EDMA3CC via the early completion path. The bits in the chained event register are cleared when the corresponding events are prioritized and serviced. If the En bit is already set and another chaining completion code is return for the same event, then the corresponding event is latched in the event missed registers (EMR.En/EMRH.En= 1). The setting of an event is a higher priority relative to clear operations (via hardware). If set and clear conditions occur concurrently, the set condition wins. If the event was previously set, then EMR/EMRH would be set because an event is lost. If the event was previously clear, then the event remains set and is prioritized for submission to the event queues. This register is part of a set of registers that pertain to the 64 DMA channels. The 64 DMA channels consist of a set of registers (with exception of DMAQNUMn) that each have 64 bits and the bit position of each register matches the DMA channel number. Each register is named with the format reg\_name that corresponds to DMA channels 0 through 31 and reg\_name\_High that corresponds to DMA channels 32 through 64. For example, the event register (ER) corresponds to DMA channel 0 through 31 and the event register high register (ERH) corresponds to DMA channel 32 through 63. The register is typically called the event register. The DMA channel registers are accessible via read/writes to the global address range. They are also accessible via read/writes to the shadow address range. The read/write ability to the registers in the shadow region are controlled by the DMA region access registers (DRAEm/DRAEHm).

**Figure 10-94. CERH Register**

**Table 10-78. CERH Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	En	R	0h	Chained event set for event 32 to 63. 0h (R/W) = No effect. 1h (R/W) = Corresponding DMA event is prioritized versus other pending DMA/QDMA events for submission to the EDMA3TC.

### 10.4.1.54 EER Register (offset = 1020h) [reset = 0h]

EER is shown in [Figure 10-95](#) and described in [Table 10-79](#).

The EDMA3CC provides the option of selectively enabling/disabling each event in the event registers (ER/ERH) by using the event enable registers (EER/EERH). If an event bit in EER/EERH is set (using the event enable set registers, EESR/EESRH), it will enable that corresponding event. Alternatively, if an event bit in EER/EERH is cleared (using the event enable clear registers, EECR/EECRH), it will disable the corresponding event. The event registers latch all events that are captured by EDMA3CC, even if the events are disabled (although EDMA3CC does not process it). Enabling an event with a pending event already set in the event registers enables the EDMA3CC to process the already set event like any other new event. The EER/EERH settings do not have any effect on chained events (CER.En/CERH.En= 1) and manually set events (ESR.En/ESRH.En= 1). This register is part of a set of registers that pertain to the 64 DMA channels. The 64 DMA channels consist of a set of registers (with exception of DMAQNUMn) that each have 64 bits and the bit position of each register matches the DMA channel number. Each register is named with the format reg\_name that corresponds to DMA channels 0 through 31 and reg\_name\_High that corresponds to DMA channels 32 through 64. For example, the event register (ER) corresponds to DMA channel 0 through 31 and the event register high register (ERH) corresponds to DMA channel 32 through 63. The register is typically called the event register. The DMA channel registers are accessible via read/writes to the global address range. They are also accessible via read/writes to the shadow address range. The read/write ability to the registers in the shadow region are controlled by the DMA region access registers (DRAEm/DRAEHm).

**Figure 10-95. EER Register**

**Table 10-79. EER Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	En	R	0h	Event enable for events 0 to 31. 0h (R/W) = Event is not enabled. An external event latched in the event register (ER) is not evaluated by the EDMA3CC. 1h (R/W) = Event is enabled. An external event latched in the event register (ER) is evaluated by the EDMA3CC.

#### 10.4.1.55 EERH Register (offset = 1024h) [reset = 0h]

EERH is shown in [Figure 10-96](#) and described in [Table 10-80](#).

The EDMA3CC provides the option of selectively enabling/disabling each event in the event registers (ER/ERH) by using the event enable registers (EER/EERH). If an event bit in EER/EERH is set (using the event enable set registers, EESR/EESRH), it will enable that corresponding event. Alternatively, if an event bit in EER/EERH is cleared (using the event enable clear registers, EECR/EECRH), it will disable the corresponding event. The event registers latch all events that are captured by EDMA3CC, even if the events are disabled (although EDMA3CC does not process it). Enabling an event with a pending event already set in the event registers enables the EDMA3CC to process the already set event like any other new event. The EER/EERH settings do not have any effect on chained events (CER.En/CERH.En= 1) and manually set events (ESR.En/ESRH.En= 1). This register is part of a set of registers that pertain to the 64 DMA channels. The 64 DMA channels consist of a set of registers (with exception of DMAQNUMn) that each have 64 bits and the bit position of each register matches the DMA channel number. Each register is named with the format reg\_name that corresponds to DMA channels 0 through 31 and reg\_name\_High that corresponds to DMA channels 32 through 64. For example, the event register (ER) corresponds to DMA channel 0 through 31 and the event register high register (ERH) corresponds to DMA channel 32 through 63. The register is typically called the event register. The DMA channel registers are accessible via read/writes to the global address range. They are also accessible via read/writes to the shadow address range. The read/write ability to the registers in the shadow region are controlled by the DMA region access registers (DRAEm/DRAEHm).

**Figure 10-96. EERH Register**

**Table 10-80. EERH Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	En	R	0h	Event enable for events 32 to 63. 0h (R/W) = Event is not enabled. An external event latched in the event register high (ERH) is not evaluated by the EDMA3CC. 1h (R/W) = Event is enabled. An external event latched in the event register high (ERH) is evaluated by the EDMA3CC.

### 10.4.1.56 EECR Register (offset = 1028h) [reset = 0h]

EECR is shown in [Figure 10-97](#) and described in [Table 10-81](#).

The event enable registers (EER/EERH) cannot be modified by directly writing to them. The intent is to ease the software burden for the case where multiple tasks are attempting to simultaneously modify these registers. The event enable clear registers (EECR/EECRH) are used to disable events. Writes of 1 to the bits in EECR/EECRH clear the corresponding event bits in EER/EERH; writes of 0 have no effect. This register is part of a set of registers that pertain to the 64 DMA channels. The 64 DMA channels consist of a set of registers (with exception of DMAQNUMn) that each have 64 bits and the bit position of each register matches the DMA channel number. Each register is named with the format reg\_name that corresponds to DMA channels 0 through 31 and reg\_name\_High that corresponds to DMA channels 32 through 64. For example, the event register (ER) corresponds to DMA channel 0 through 31 and the event register high register (ERH) corresponds to DMA channel 32 through 63. The register is typically called the event register. The DMA channel registers are accessible via read/writes to the global address range. They are also accessible via read/writes to the shadow address range. The read/write ability to the registers in the shadow region are controlled by the DMA region access registers (DRAEm/DRAEHm).

**Figure 10-97. EECR Register**

**Table 10-81. EECR Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	En	W	0h	Event enable clear for events 0 to 31. 0h (R/W) = No effect. 1h (R/W) = Event is disabled. Corresponding bit in the event enable register (EER) is cleared (En = 0).

### 10.4.1.57 EECRH Register (offset = 102Ch) [reset = 0h]

EECRH is shown in [Figure 10-98](#) and described in [Table 10-82](#).

The event enable registers (EER/EERH) cannot be modified by directly writing to them. The intent is to ease the software burden for the case where multiple tasks are attempting to simultaneously modify these registers. The event enable clear registers (EECR/EECRH) are used to disable events. Writes of 1 to the bits in EECR/EECRH clear the corresponding event bits in EER/EERH; writes of 0 have no effect. This register is part of a set of registers that pertain to the 64 DMA channels. The 64 DMA channels consist of a set of registers (with exception of DMAQNUMn) that each have 64 bits and the bit position of each register matches the DMA channel number. Each register is named with the format reg\_name that corresponds to DMA channels 0 through 31 and reg\_name\_High that corresponds to DMA channels 32 through 64. For example, the event register (ER) corresponds to DMA channel 0 through 31 and the event register high register (ERH) corresponds to DMA channel 32 through 63. The register is typically called the event register. The DMA channel registers are accessible via read/writes to the global address range. They are also accessible via read/writes to the shadow address range. The read/write ability to the registers in the shadow region are controlled by the DMA region access registers (DRAEm/DRAEHm).

**Figure 10-98. EECRH Register**

**Table 10-82. EECRH Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	En	W	0h	Event enable clear for events 32 to 63. 0h (R/W) = No effect. 1h (R/W) = Event is disabled. Corresponding bit in the event enable register high (EERH) is cleared (En = 0).

### 10.4.1.58 EESR Register (offset = 1030h) [reset = 0h]

EESR is shown in [Figure 10-99](#) and described in [Table 10-83](#).

The event enable registers (EER/EERH) cannot be modified by directly writing to them. The intent is to ease the software burden for the case where multiple tasks are attempting to simultaneously modify these registers. The event enable set registers (EESR/EESRH) are used to enable events. Writes of 1 to the bits in EESR/EESRH set the corresponding event bits in EER/EERH; writes of 0 have no effect. This register is part of a set of registers that pertain to the 64 DMA channels. The 64 DMA channels consist of a set of registers (with exception of DMAQNUMn) that each have 64 bits and the bit position of each register matches the DMA channel number. Each register is named with the format reg\_name that corresponds to DMA channels 0 through 31 and reg\_name\_High that corresponds to DMA channels 32 through 64. For example, the event register (ER) corresponds to DMA channel 0 through 31 and the event register high register (ERH) corresponds to DMA channel 32 through 63. The register is typically called the event register. The DMA channel registers are accessible via read/writes to the global address range. They are also accessible via read/writes to the shadow address range. The read/write ability to the registers in the shadow region are controlled by the DMA region access registers (DRAEm/DRAEHm).

**Figure 10-99. EESR Register**

**Table 10-83. EESR Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	En	W	0h	Event enable set for events 0 to 31. 0h (R/W) = No effect. 1h (R/W) = Event is enabled. Corresponding bit in the event enable register (EER) is set (En = 1).

### 10.4.1.59 EESRH Register (offset = 1034h) [reset = 0h]

EESRH is shown in [Figure 10-100](#) and described in [Table 10-84](#).

The event enable registers (EER/EERH) cannot be modified by directly writing to them. The intent is to ease the software burden for the case where multiple tasks are attempting to simultaneously modify these registers. The event enable set registers (EESR/EESRH) are used to enable events. Writes of 1 to the bits in EESR/EESRH set the corresponding event bits in EER/EERH; writes of 0 have no effect. This register is part of a set of registers that pertain to the 64 DMA channels. The 64 DMA channels consist of a set of registers (with exception of DMAQNUMn) that each have 64 bits and the bit position of each register matches the DMA channel number. Each register is named with the format reg\_name that corresponds to DMA channels 0 through 31 and reg\_name\_High that corresponds to DMA channels 32 through 64. For example, the event register (ER) corresponds to DMA channel 0 through 31 and the event register high register (ERH) corresponds to DMA channel 32 through 63. The register is typically called the event register. The DMA channel registers are accessible via read/writes to the global address range. They are also accessible via read/writes to the shadow address range. The read/write ability to the registers in the shadow region are controlled by the DMA region access registers (DRAEm/DRAEHm).

**Figure 10-100. EESRH Register**

**Table 10-84. EESRH Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	En	W	0h	Event enable set for events 32 to 63. 0h (R/W) = No effect. 1h (R/W) = Event is enabled. Corresponding bit in the event enable register high (EERH) is set (En= 1).

### 10.4.1.60 SER Register (offset = 1038h) [reset = 0h]

SER is shown in [Figure 10-101](#) and described in [Table 10-85](#).

The secondary event registers (SER/SERH) provide information on the state of a DMA channel or event (0 through 63). If the EDMA3CC receives a TR synchronization due to a manual-trigger, event-trigger, or chained-trigger source (ESR.En/ESRH.En= 1, ER.En/ERH.En= 1, or CER.En/CERH.En= 1), which results in the setting of a corresponding event bit in SER/SERH (SER.En/SERH.En = 1), it implies that the corresponding DMA event is in the queue. Once a bit corresponding to an event is set in SER/SERH, the EDMA3CC does not prioritize additional events on the same DMA channel. Depending on the condition that lead to the setting of the SER bits, either the EDMA3CC hardware or the software (using SECR/SECRH) needs to clear the SER/SERH bits for the EDMA3CC to evaluate subsequent events (subsequent transfers) on the same channel. For additional conditions that can cause the secondary event registers to be set, see EDMA Overview. This register is part of a set of registers that pertain to the 64 DMA channels. The 64 DMA channels consist of a set of registers (with exception of DMAQNUMn) that each have 64 bits and the bit position of each register matches the DMA channel number. Each register is named with the format reg\_name that corresponds to DMA channels 0 through 31 and reg\_name\_High that corresponds to DMA channels 32 through 64. For example, the event register (ER) corresponds to DMA channel 0 through 31 and the event register high register (ERH) corresponds to DMA channel 32 through 63. The register is typically called the event register. The DMA channel registers are accessible via read/writes to the global address range. They are also accessible via read/writes to the shadow address range. The read/write ability to the registers in the shadow region are controlled by the DMA region access registers (DRAEm/DRAEHm).

**Figure 10-101. SER Register**

**Table 10-85. SER Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	En	R	0h	<p>Secondary event register.</p> <p>The secondary event register is used along with the event register (ER) to provide information on the state of an event.</p> <p>0h (R/W) = Event is not currently stored in the event queue.</p> <p>1h (R/W) = Event is currently stored in the event queue. Event arbiter will not prioritize additional events.</p>

#### 10.4.1.61 SERH Register (offset = 103Ch) [reset = 0h]

SERH is shown in [Figure 10-102](#) and described in [Table 10-86](#).

The secondary event registers (SER/SERH) provide information on the state of a DMA channel or event (0 through 63). If the EDMA3CC receives a TR synchronization due to a manual-trigger, event-trigger, or chained-trigger source (ESR.En/ESRH.En= 1, ER.En/ERH.En= 1, or CER.En/CERH.En= 1), which results in the setting of a corresponding event bit in SER/SERH (SER.En/SERH.En = 1), it implies that the corresponding DMA event is in the queue. Once a bit corresponding to an event is set in SER/SERH, the EDMA3CC does not prioritize additional events on the same DMA channel. Depending on the condition that lead to the setting of the SER bits, either the EDMA3CC hardware or the software (using SECR/SECRH) needs to clear the SER/SERH bits for the EDMA3CC to evaluate subsequent events (subsequent transfers) on the same channel. For additional conditions that can cause the secondary event registers to be set, see EDMA Overview. This register is part of a set of registers that pertain to the 64 DMA channels. The 64 DMA channels consist of a set of registers (with exception of DMAQNUMn) that each have 64 bits and the bit position of each register matches the DMA channel number. Each register is named with the format reg\_name that corresponds to DMA channels 0 through 31 and reg\_name\_High that corresponds to DMA channels 32 through 64. For example, the event register (ER) corresponds to DMA channel 0 through 31 and the event register high register (ERH) corresponds to DMA channel 32 through 63. The register is typically called the event register. The DMA channel registers are accessible via read/writes to the global address range. They are also accessible via read/writes to the shadow address range. The read/write ability to the registers in the shadow region are controlled by the DMA region access registers (DRAEm/DRAEHm).

**Figure 10-102. SERH Register**

**Table 10-86. SERH Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	En	R	0h	<p>Secondary event register.</p> <p>The secondary event register is used along with the event register high (ERH) to provide information on the state of an event.</p> <p>0h (R/W) = Event is not currently stored in the event queue.</p> <p>1h (R/W) = Event is currently stored in the event queue. Event submission/prioritization logic will not prioritize additional events.</p>

### 10.4.1.62 SECR Register (offset = 1040h) [reset = 0h]

SECR is shown in [Figure 10-103](#) and described in [Table 10-87](#).

The secondary event clear registers (SECR/SECRH) clear the status of the secondary event registers (SER/SERH). CPU writes of 1 clear the corresponding set bits in SER/SERH. Writes of 0 have no effect. This register is part of a set of registers that pertain to the 64 DMA channels. The 64 DMA channels consist of a set of registers (with exception of DMAQNUMn) that each have 64 bits and the bit position of each register matches the DMA channel number. Each register is named with the format reg\_name that corresponds to DMA channels 0 through 31 and reg\_name\_High that corresponds to DMA channels 32 through 64. For example, the event register (ER) corresponds to DMA channel 0 through 31 and the event register high register (ERH) corresponds to DMA channel 32 through 63. The register is typically called the event register. The DMA channel registers are accessible via read/writes to the global address range. They are also accessible via read/writes to the shadow address range. The read/write ability to the registers in the shadow region are controlled by the DMA region access registers (DRAEm/DRAEHm).

**Figure 10-103. SECR Register**

**Table 10-87. SECR Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	En	W	0h	Secondary event clear register. 0h (R/W) = No effect. 1h (R/W) = Corresponding bit in the secondary event register (SER) is cleared (En = 0).

### 10.4.1.63 SECRH Register (offset = 1044h) [reset = 0h]

SECRH is shown in [Figure 10-104](#) and described in [Table 10-88](#).

The secondary event clear registers (SECR/SECRH) clear the status of the secondary event registers (SER/SERH). CPU writes of 1 clear the corresponding set bits in SER/SERH. Writes of 0 have no effect. This register is part of a set of registers that pertain to the 64 DMA channels. The 64 DMA channels consist of a set of registers (with exception of DMAQNUMn) that each have 64 bits and the bit position of each register matches the DMA channel number. Each register is named with the format reg\_name that corresponds to DMA channels 0 through 31 and reg\_name\_High that corresponds to DMA channels 32 through 64. For example, the event register (ER) corresponds to DMA channel 0 through 31 and the event register high register (ERH) corresponds to DMA channel 32 through 63. The register is typically called the event register. The DMA channel registers are accessible via read/writes to the global address range. They are also accessible via read/writes to the shadow address range. The read/write ability to the registers in the shadow region are controlled by the DMA region access registers (DRAEm/DRAEHm).

**Figure 10-104. SECRH Register**

**Table 10-88. SECRH Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	En	W	0h	Secondary event clear register. 0h (R/W) = No effect. 1h (R/W) = Corresponding bit in the secondary event registers high (SERH) is cleared (En = 0).

### 10.4.1.64 IER Register (offset = 1050h) [reset = 0h]

IER is shown in [Figure 10-105](#) and described in [Table 10-89](#).

Interrupt enable registers (IER/IERH) are used to enable/disable the transfer completion interrupt generation by the EDMA3CC for all DMA/QDMA channels. The IER/IERH cannot be written to directly. To set any interrupt bit in IER/IERH, a 1 must be written to the corresponding interrupt bit in the interrupt enable set registers (IESR/IESRH). Similarly, to clear any interrupt bit in IER/IERH, a 1 must be written to the corresponding interrupt bit in the interrupt enable clear registers (IECR/IECRH). All DMA/QDMA channels can be set to assert an EDMA3CC completion interrupt to the CPU on transfer completion, by appropriately configuring the PaRAM entry associated with the channels. This register is used for the transfer completion interrupt reporting/generating by the EDMA3CC. For more details on EDMA3CC completion interrupt generation, see EDMA3 Interrupts.

**Figure 10-105. IER Register**

**Table 10-89. IER Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	In_	R	0h	Interrupt enable for channels 0 to 31. 0h (R/W) = Interrupt is not enabled. 1h (R/W) = Interrupt is enabled.

### 10.4.1.65 IERH Register (offset = 1054h) [reset = 0h]

IERH is shown in [Figure 10-106](#) and described in [Table 10-90](#).

Interrupt enable registers (IER/IERH) are used to enable/disable the transfer completion interrupt generation by the EDMA3CC for all DMA/QDMA channels. The IER/IERH cannot be written to directly. To set any interrupt bit in IER/IERH, a 1 must be written to the corresponding interrupt bit in the interrupt enable set registers (IESR/IESRH). Similarly, to clear any interrupt bit in IER/IERH, a 1 must be written to the corresponding interrupt bit in the interrupt enable clear registers (IECR/IECRH). All DMA/QDMA channels can be set to assert an EDMA3CC completion interrupt to the CPU on transfer completion, by appropriately configuring the PaRAM entry associated with the channels. This register is used for the transfer completion interrupt reporting/generating by the EDMA3CC. For more details on EDMA3CC completion interrupt generation, see EDMA3 Interrupts.

**Figure 10-106. IERH Register**

**Table 10-90. IERH Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	In	R	0h	Interrupt enable for channels 32 to 63. 0h (R/W) = Interrupt is not enabled. 1h (R/W) = Interrupt is enabled.

### 10.4.1.66 IECR Register (offset = 1058h) [reset = 0h]

IECR is shown in [Figure 10-107](#) and described in [Table 10-91](#).

The interrupt enable clear registers (IECR/IECRH) are used to clear interrupts. Writes of 1 to the bits in IECR/IECRH clear the corresponding interrupt bits in the interrupt enable registers (IER/IERH); writes of 0 have no effect. All DMA/QDMA channels can be set to assert an EDMA3CC completion interrupt to the CPU on transfer completion, by appropriately configuring the PaRAM entry associated with the channels. This register is used for the transfer completion interrupt reporting/generating by the EDMA3CC. For more details on EDMA3CC completion interrupt generation, see EDMA3 Interrupts.

**Figure 10-107. IECR Register**

**Table 10-91. IECR Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	In	W	0h	Interrupt enable clear for channels 0 to 31. 0h (R/W) = No effect. 1h (R/W) = Corresponding bit in the interrupt enable register (IER) is cleared (In = 0).

### 10.4.1.67 IECRH Register (offset = 105Ch) [reset = 0h]

IECRH is shown in [Figure 10-108](#) and described in [Table 10-92](#).

The interrupt enable clear registers (IECR/IECRH) are used to clear interrupts. Writes of 1 to the bits in IECR/IECRH clear the corresponding interrupt bits in the interrupt enable registers (IER/IERH); writes of 0 have no effect. All DMA/QDMA channels can be set to assert an EDMA3CC completion interrupt to the CPU on transfer completion, by appropriately configuring the PaRAM entry associated with the channels. This register is used for the transfer completion interrupt reporting/generating by the EDMA3CC. For more details on EDMA3CC completion interrupt generation, see EDMA3 Interrupts.

**Figure 10-108. IECRH Register**

**Table 10-92. IECRH Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	In	W	0h	Interrupt enable clear for channels 32 to 63. 0h (R/W) = No effect. 1h (R/W) = Corresponding bit in the interrupt enable register high (IERH) is cleared (In = 0).

### 10.4.1.68 IESR Register (offset = 1060h) [reset = 0h]

IESR is shown in [Figure 10-109](#) and described in [Table 10-93](#).

The interrupt enable set registers (IESR/IESRH) are used to enable interrupts. Writes of 1 to the bits in IESR/IESRH set the corresponding interrupt bits in the interrupt enable registers (IER/IERH); writes of 0 have no effect. All DMA/QDMA channels can be set to assert an EDMA3CC completion interrupt to the CPU on transfer completion, by appropriately configuring the PaRAM entry associated with the channels. This register is used for the transfer completion interrupt reporting/generating by the EDMA3CC. For more details on EDMA3CC completion interrupt generation, see EDMA3 Interrupts.

**Figure 10-109. IESR Register**

**Table 10-93. IESR Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	In	W	0h	Interrupt enable set for channels 0 to 31. 0h (R/W) = No effect. 1h (R/W) = Corresponding bit in the interrupt enable register (IER) is set (In = 1).

### 10.4.1.69 IESRH Register (offset = 1064h) [reset = 0h]

IESRH is shown in [Figure 10-110](#) and described in [Table 10-94](#).

The interrupt enable set registers (IESR/IESRH) are used to enable interrupts. Writes of 1 to the bits in IESR/IESRH set the corresponding interrupt bits in the interrupt enable registers (IER/IERH); writes of 0 have no effect. All DMA/QDMA channels can be set to assert an EDMA3CC completion interrupt to the CPU on transfer completion, by appropriately configuring the PaRAM entry associated with the channels. This register is used for the transfer completion interrupt reporting/generating by the EDMA3CC. For more details on EDMA3CC completion interrupt generation, see EDMA3 Interrupts.

**Figure 10-110. IESRH Register**

**Table 10-94. IESRH Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	In	W	0h	Interrupt enable clear for channels 32 to 63. 0h (R/W) = No effect. 1h (R/W) = Corresponding bit in the interrupt enable register high (IERH) is set (In = 1).

### 10.4.1.70 IPR Register (offset = 1068h) [reset = 0h]

IPR is shown in [Figure 10-111](#) and described in [Table 10-95](#).

If the TCINTEN and/or ITCINTEN bit in the channel option parameter (OPT) is set in the PaRAM entry associated with the channel (DMA or QDMA), then the EDMA3TC (for normal completion) or the EDMA3CC (for early completion) returns a completion code on transfer or intermediate transfer completion. The value of the returned completion code is equal to the TCC bit in OPT for the PaRAM entry associated with the channel. When an interrupt transfer completion code with TCC = n is detected by the EDMA3CC, then the corresponding bit is set in the interrupt pending register (IPR.In, if n = 0 to 31; IPRH.In, if n = 32 to 63). Note that once a bit is set in the interrupt pending registers, it remains set; it is your responsibility to clear these bits. The bits set in IPR/IPRH are cleared by writing a 1 to the corresponding bits in the interrupt clear registers (ICR/ICRH). All DMA/QDMA channels can be set to assert an EDMA3CC completion interrupt to the CPU on transfer completion, by appropriately configuring the PaRAM entry associated with the channels. This register is used for the transfer completion interrupt reporting/generating by the EDMA3CC. For more details on EDMA3CC completion interrupt generation, see EDMA3 Interrupts.

**Figure 10-111. IPR Register**

**Table 10-95. IPR Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	In	R	0h	<p>Interrupt pending for TCC = 0 to 31.</p> <p>0h (R/W) = Interrupt transfer completion code is not detected or was cleared.</p> <p>1h (R/W) = Interrupt transfer completion code is detected (In = 1, n = EDMA3TC[2:0]).</p>

### 10.4.1.71 IPRH Register (offset = 106Ch) [reset = 0h]

IPRH is shown in [Figure 10-112](#) and described in [Table 10-96](#).

If the TCINTEN and/or ITCINTEN bit in the channel option parameter (OPT) is set in the PaRAM entry associated with the channel (DMA or QDMA), then the EDMA3TC (for normal completion) or the EDMA3CC (for early completion) returns a completion code on transfer or intermediate transfer completion. The value of the returned completion code is equal to the TCC bit in OPT for the PaRAM entry associated with the channel. When an interrupt transfer completion code with TCC = n is detected by the EDMA3CC, then the corresponding bit is set in the interrupt pending register (IPR.In, if n = 0 to 31; IPRH.In, if n = 32 to 63). Note that once a bit is set in the interrupt pending registers, it remains set; it is your responsibility to clear these bits. The bits set in IPR/IPRH are cleared by writing a 1 to the corresponding bits in the interrupt clear registers (ICR/ICRH). All DMA/QDMA channels can be set to assert an EDMA3CC completion interrupt to the CPU on transfer completion, by appropriately configuring the PaRAM entry associated with the channels. This register is used for the transfer completion interrupt reporting/generating by the EDMA3CC. For more details on EDMA3CC completion interrupt generation, see EDMA3 Interrupts.

**Figure 10-112. IPRH Register**

**Table 10-96. IPRH Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	In	R	0h	<p>Interrupt pending for TCC = 32 to 63.</p> <p>0h (R/W) = Interrupt transfer completion code is not detected or was cleared.</p> <p>1h (R/W) = Interrupt transfer completion code is detected (In = 1, n = EDMA3TC[2:0]).</p>

### 10.4.1.72 ICR Register (offset = 1070h) [reset = 0h]

ICR is shown in [Figure 10-113](#) and described in [Table 10-97](#).

The bits in the interrupt pending registers (IPR/IPRH) are cleared by writing a 1 to the corresponding bits in the interrupt clear registers(ICR/ICRH). Writes of 0 have no effect. All set bits in IPR/IPRH must be cleared to allow EDMA3CC to assert additional transfer completion interrupts. All DMA/QDMA channels can be set to assert an EDMA3CC completion interrupt to the CPU on transfer completion, by appropriately configuring the PaRAM entry associated with the channels. This register is used for the transfer completion interrupt reporting/generating by the EDMA3CC. For more details on EDMA3CC completion interrupt generation, see EDMA3 Interrupts.

**Figure 10-113. ICR Register**

**Table 10-97. ICR Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	In	W	0h	Interrupt clear register for TCC = 0 to 31. 0h (R/W) = No effect. 1h (R/W) = Corresponding bit in the interrupt pending register (IPR) is cleared (In = 0).

### 10.4.1.73 ICRH Register (offset = 1074h) [reset = 0h]

ICRH is shown in [Figure 10-114](#) and described in [Table 10-98](#).

The bits in the interrupt pending registers (IPR/IPRH) are cleared by writing a 1 to the corresponding bits in the interrupt clear registers(ICR/ICRH). Writes of 0 have no effect. All set bits in IPR/IPRH must be cleared to allow EDMA3CC to assert additional transfer completion interrupts. All DMA/QDMA channels can be set to assert an EDMA3CC completion interrupt to the CPU on transfer completion, by appropriately configuring the PaRAM entry associated with the channels. This register is used for the transfer completion interrupt reporting/generating by the EDMA3CC. For more details on EDMA3CC completion interrupt generation, see EDMA3 Interrupts.

**Figure 10-114. ICRH Register**

**Table 10-98. ICRH Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	In	W	0h	Interrupt clear register for TCC = 32 to 63. 0h (R/W) = No effect. 1h (R/W) = Corresponding bit in the interrupt pending register high (IPRH) is cleared (In = 0).

### 10.4.1.74 IEVAL Register (offset = 1078h) [reset = 0h]

IEVAL is shown in [Figure 10-115](#) and described in [Table 10-99](#).

The interrupt evaluate register (IEVAL) is the only register that physically exists in both the global region and the shadow regions. In other words, the read/write accessibility for the shadow region IEVAL is not affected by the DMA/QDMA region access registers (DRAEm/DRAEHm, QRAEn/QRAEHn). IEVAL is needed for robust ISR operations to ensure that interrupts are not missed by the CPU. All DMA/QDMA channels can be set to assert an EDMA3CC completion interrupt to the CPU on transfer completion, by appropriately configuring the PaRAM entry associated with the channels. This register is used for the transfer completion interrupt reporting/generating by the EDMA3CC. For more details on EDMA3CC completion interrupt generation, see EDMA3 Interrupts.

### 10.4.1.75 QER Register (offset = 1080h) [reset = 0h]

QER is shown in [Figure 10-116](#) and described in [Table 10-100](#).

The QDMA event register (QER) channel n bit is set (En = 1) when the CPU or any EDMA3 programmer (including EDMA3) performs a write to the trigger word (using the QDMA channel mapping register (QCHMAPn)) in the PaRAM entry associated with QDMA channel n (which is also programmed using QCHMAPn). The En bit is also set when the EDMA3CC performs a link update on a PaRAM address that matches the QCHMAPn settings. The QDMA event is latched only if the QDMA event enable register (QEER) channel n bit is also enabled (QEER.En = 1). Once a bit is set in QER, then the corresponding QDMA event (auto-trigger) is evaluated by the EDMA3CC logic for an associated transfer request submission to the transfer controllers. For additional conditions that can lead to the setting of QER bits, see EDMA Overview. The setting of an event is a higher priority relative to clear operations (via hardware). If set and clear conditions occur concurrently, the set condition wins. If the event was previously set, then the QDMA event missed register (QEMR) would be set because an event is lost. If the event was previously clear, then the event remains set and is prioritized for submission to the event queues. The set bits in QER are only cleared when the transfer request associated with the corresponding channels has been processed by the EDMA3CC and submitted to the transfer controller. If the En bit is already set and a QDMA event for the same QDMA channel occurs prior to the original being cleared, then the second missed event is latched in QEMR (En = 1). QER is part of a set of register that control the QDMA channels in EDMA3CC. QDMA channels (with the exception of the QDMA queue number register) consist of a set of registers, each of which have a bit location. Each bit position corresponds to a QDMA channel number. The QDMA channel registers are accessible via read/writes to the global address range. They are also accessible via read/writes to the shadow address range. The read/write accessibility in the shadow region address region is controlled by the QDMA region access registers (QRAEn/QRAEHn).

Bit	Field	Type	Reset	Description
31-8	RESERVED	R	0h	
7-0	En	R	0h	QDMA event for channels 0 to 7. 0h (R/W) = No effect. 1h (R/W) = Corresponding QDMA event is prioritized versus other pending DMA/QDMA events for submission to the EDMA3TC.

### 10.4.1.76 QEER Register (offset = 1084h) [reset = 0h]

QEER is shown in [Figure 10-117](#) and described in [Table 10-101](#).

The EDMA3CC provides the option of selectively enabling/disabling each channel in the QDMA event register (QER) by using the QDMA event enable register (QEER). If any of the event bits in QEER is set (using the QDMA event enable set register, QEESR), it will enable that corresponding event. Alternatively, if any event bit in QEER is cleared (using the QDMA event enable clear register, QEECR), it will disable the corresponding QDMA channel. The QDMA event register will not latch any event for a QDMA channel, if it is not enabled via QEER. QEER is part of a set of register that control the QDMA channels in EDMA3CC. QDMA channels (with the exception of the QDMA queue number register) consist of a set of registers, each of which have a bit location. Each bit position corresponds to a QDMA channel number. The QDMA channel registers are accessible via read/writes to the global address range. They are also accessible via read/writes to the shadow address range. The read/write accessibility in the shadow region address region is controlled by the QDMA region access registers (QRAEn/QRAEHn).

QDMA event will not be recognized and will not latch in the QDMA event register (QER). 1h (R/W) = QDMA channel n is enabled. QDMA events will be recognized and will get latched in the QDMA event register (QER).

### 10.4.1.77 QEECR Register (offset = 1088h) [reset = 0h]

QEECR is shown in [Figure 10-118](#) and described in [Table 10-102](#).

The QDMA event enable register (QEER) cannot be modified by directly writing to the register, to ease the software burden when multiple tasks are attempting to simultaneously modify these registers. The QDMA event enable clear register (QEECR) is used to disable events. Writes of 1 to the bits in QEECR clear the corresponding QDMA channel bits in QEER; writes of 0 have no effect. QEECR is part of a set of register that control the QDMA channels in EDMA3CC. QDMA channels (with the exception of the QDMA queue number register) consist of a set of registers, each of which have a bit location. Each bit position corresponds to a QDMA channel number. The QDMA channel registers are accessible via read/writes to the global address range. They are also accessible via read/writes to the shadow address range. The read/write accessibility in the shadow region address region is controlled by the QDMA region access registers (QRAEn/QRAEHn).

### 10.4.1.78 QEESR Register (offset = 108Ch) [reset = 0h]

QEESR is shown in [Figure 10-119](#) and described in [Table 10-103](#).

The QDMA event enable register (QEER) cannot be modified by directly writing to the register, to ease the software burden when multiple tasks are attempting to simultaneously modify these registers. The QDMA event enable set register (QEESR) is used to enable events. Writes of 1 to the bits in QEESR set the corresponding QDMA channel bits in QEER; writes of 0 have no effect.

**Figure 10-119. QEESR Register**

**Table 10-103. QEESR Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-8	RESERVED	R	0h	
7-0	En	W	0h	QDMA event enable set for channels 0 to 7. 0h (R/W) = No effect. 1h (R/W) = QDMA event is enabled. Corresponding bit in the QDMA event enable register (QEER) is set (En = 1).

### 10.4.1.79 QSER Register (offset = 1090h) [reset = 0h]

QSER is shown in [Figure 10-120](#) and described in [Table 10-104](#).

The QDMA secondary event register (QSER) provides information on the state of a QDMA event. If at any time a bit corresponding to a QDMA channel is set in QSER, that implies that the corresponding QDMA event is in the queue. Once a bit corresponding to a QDMA channel is set in QSER, the EDMA3CC does not prioritize additional events on the same QDMA channel. Depending on the condition that lead to the setting of the QSER bits, either the EDMA3CC hardware or the software (using QSECR) needs to clear the QSER bits for the EDMA3CC to evaluate subsequent QDMA events on the channel. Based on whether the associated TR request is valid, or it is a null or dummy TR, the implications on the state of QSER and the required user actions to submit another QDMA transfer might be different. For additional conditions that can cause the secondary event registers (QSER\SER) to be set, see EDMA Overview. QSER is part of a set of register that control the QDMA channels in EDMA3CC. QDMA channels (with the exception of the QDMA queue number register) consist of a set of registers, each of which have a bit location. Each bit position corresponds to a QDMA channel number. The QDMA channel registers are accessible via read/writes to the global address range. They are also accessible via read/writes to the shadow address range. The read/write accessibility in the shadow region address region is controlled by the QDMA region access registers (QRAEn/QRAEHn).

### 10.4.1.80 QSECR Register (offset = 1094h) [reset = 0h]

QSECR is shown in [Figure 10-121](#) and described in [Table 10-105](#).

The QDMA secondary event clear register (QSECR) clears the status of the QDMA secondary event register (QSER) and the QDMA event register (QER). CPU writes of 1 clear the corresponding set bits in QSER and QER. Writes of 0 have no effect. Note that this differs from the secondary event clear register (SECR) operation, which only clears the secondary event register (SER) bits and does not affect the event registers. QSECR is part of a set of register that control the QDMA channels in EDMA3CC. QDMA channels (with the exception of the QDMA queue number register) consist of a set of registers, each of which have a bit location. Each bit position corresponds to a QDMA channel number. The QDMA channel registers are accessible via read/writes to the global address range. They are also accessible via read/writes to the shadow address range. The read/write accessibility in the shadow region address region is controlled by the QDMA region access registers (QRAEn/QRAEHn).

### 10.4.2.10 RDRATE Register (offset = 140h) [reset = 0h]

RDRATE is shown in [Figure 10-131](#) and described in [Table 10-116](#).

The EDMA3 transfer controller issues read commands at a rate controlled by the read rate register (RDRATE). The RDRATE defines the number of idle cycles that the read controller must wait before issuing subsequent commands. This applies both to commands within a transfer request packet (TRP) and for commands that are issued for different transfer requests (TRs). For instance, if RDRATE is set to 4 cycles between reads, there are 3 inactive cycles between reads. RDRATE allows flexibility in transfer controller access requests to an endpoint. For an application, RDRATE can be manipulated to slow down the access rate, so that the endpoint may service requests from other masters during the inactive EDMA3TC cycles. Note: The RDRATE value for a transfer controller is expected to be static, as it is decided based on the application requirement. It is not recommended to change the RDRATE value on the fly.

**Figure 10-131. RDRATE Register**

2-0	RDRATE	R/W	0h	Read rate. Controls the number of cycles between read commands. This is a global setting that applies to all TRs for this EDMA3TC. 0h (R/W) = Reads issued as fast as possible. 1h (R/W) = 4 cycles between reads. 2h (R/W) = 8 cycles between reads. 3h (R/W) = 16 cycles between reads. 4h (R/W) = 32 cycles between reads. 5h (R/W) = Reserved. 6h (R/W) = Reserved. 7h (R/W) = Reserved.

### 10.4.2.11 SAOPT Register (offset = 240h) [reset = 0h]

SAOPT is shown in [Figure 10-132](#) and described in [Table 10-117](#).

The Source Active Options Register (SAOPT) is an EDMA3TC channel register. This EDMA3TC channel register is part of the Source Active Register Set. It is read-only and provided to facilitate debugging by providing a window into how the transfer controller (TC) was programmed by the channel controller (CC), as well as showing the status of the transfer controller (TC) during a transfer.

0	SAM	R	0h	Source address mode within an array 0h (R/W) = Increment (INCR) mode. Source addressing within an array increments. 1h (R/W) = Constant addressing (CONST) mode. Source addressing within an array wraps around upon reaching FIFO width.

### 10.4.2.12 SASRC Register (offset = 244h) [reset = 0h]

SASRC is shown in [Figure 10-133](#) and described in [Table 10-118](#).

The Source Active Source Address Register (SASRC) is an EDMA3TC channel register. This EDMA3TC channel register is part of the Source Active Register Set. It is read-only and provided to facilitate debugging by providing a window into how the transfer controller (TC) was programmed by the channel controller (CC), as well as showing the status of the transfer controller (TC) during a transfer.

**Figure 10-133. SASRC Register**

15-0	ACNT	R	0h	A dimension count remaining for the Source Active Register Set. Number of bytes to be transferred in first dimension.

### 10.4.2.14 SADST Register (offset = 24Ch) [reset = 0h]

SADST is shown in [Figure 10-135](#) and described in [Table 10-120](#).

The Source Active Destination Address Register (SADST) is an EDMA3TC channel register. This EDMA3TC channel register is part of the Source Active Register Set. It is read-only and provided to facilitate debugging by providing a window into how the transfer controller (TC) was programmed by the channel controller (CC), as well as showing the status of the transfer controller (TC) during a transfer.

Note: Destination address is not applicable for Source Active Register Set. Read returns 0.

**Figure 10-135. SADST Register**

### 10.4.2.15 SABIDX Register (offset = 250h) [reset = 0h]

SABIDX is shown in [Figure 10-136](#) and described in [Table 10-121](#).

The Source Active Source B-Dimension Index Register (SABIDX) is an EDMA3TC channel register. This EDMA3TC channel register is part of the Source Active Register Set. It is read-only and provided to facilitate debugging by providing a window into how the transfer controller (TC) was programmed by the channel controller (CC), as well as showing the status of the transfer controller (TC) during a transfer.

**Figure 10-136. SABIDX Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

R-0h																R-0h															

**Table 10-121. SABIDX Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	DBIDX	R	0h	B-Index offset between destination arrays. Represents the offset in bytes between the starting address of each destination array (there are BCND arrays of ACNT elements). DBIDX is always used regardless of whether DAM is in Increment or FIFO mode.
15-0	SBIDX	R	0h	B-Index offset between source arrays. Represents the offset in bytes between the starting address of each source array (there are BCNT arrays of ACNT elements). SBIDX is always used regardless of whether SAM is in Increment or FIFO mode. Value 0 to FFFFh.

### 10.4.2.16 SAMPPRXY Register (offset = 254h) [reset = 0h]

SAMPPRXY is shown in [Figure 10-137](#) and described in [Table 10-122](#).

The Source Active Memory Protection Proxy Register (SAMPPRXY) is an EDMA3TC channel register. This EDMA3TC channel register is part of the Source Active Register Set. It is read-only and provided to facilitate debugging by providing a window into how the transfer controller (TC) was programmed by the channel controller (CC), as well as showing the status of the transfer controller (TC) during a transfer.

31-9	RESERVED	R	0h	
8	PRIV	R	0h	Privilege level. The privilege level used by the host to set up the parameter entry in the channel controller. This field is set up when the associated TR is submitted to the EDMA3TC. The privilege ID is used while issuing read and write command to the target endpoints so that the target endpoints can perform memory protection checks based on the PRIV of the host that set up the DMA transaction. 0h (R/W) = User-level privilege. 1h (R/W) = Supervisor-level privilege.
7-4	RESERVED	R	0h	
3-0	PRIVID	R	0h	Privilege ID. This contains the privilege ID of the host that set up the parameter entry in the channel controller. This field is set up when the associated TR is submitted to the EDMA3TC. This PRIVID value is used while issuing read and write commands to the target endpoints so that the target endpoints can perform memory protection checks based on the PRIVID of the host that set up the DMA transaction. Value 0 to Fh.

### 10.4.2.17 SACNTRLD Register (offset = 258h) [reset = 0h]

SACNTRLD is shown in [Figure 10-138](#) and described in [Table 10-123](#).

The Source Active Count Reload Register (SACNTRLD) is an EDMA3TC channel register. This EDMA3TC channel register is part of the Source Active Register Set. It is read-only and provided to facilitate debugging by providing a window into how the transfer controller (TC) was programmed by the channel controller (CC), as well as showing the status of the transfer controller (TC) during a transfer.

**Figure 10-138. SACNTRLD Register**

15-0	ACNTRLD	R	0h	A-count reload value. Represents the originally programmed value of ACNT. The reload value is used to reinitialize ACNT after each array is serviced (that is, ACNT decrements to 0) by the source offset in bytes between the starting address or each source array (there are BCNT arrays of ACNT bytes). Value 0 to FFFFh.

### 10.4.2.18 SASRCBREF Register (offset = 25Ch) [reset = 0h]

SASRCBREF is shown in [Figure 10-139](#) and described in [Table 10-124](#).

The Source Active Source Address B-Reference Register (SASRCBREF) is an EDMA3TC channel register. This EDMA3TC channel register is part of the Source Active Register Set. It is read-only and provided to facilitate debugging by providing a window into how the transfer controller (TC) was programmed by the channel controller (CC), as well as showing the status of the transfer controller (TC) during a transfer.

**Figure 10-139. SASRCBREF Register**

31-0	SADDRBREF	R	0h	Source address B-reference. Represents the starting address for the array currently being read. The next array's starting address is calculated as the reference address plus the source b-idx value. Value 0 to FFFF FFFFh.

### 10.4.2.19 SADSTBREF Register (offset = 260h) [reset = 0h]

SADSTBREF is shown in [Figure 10-140](#) and described in [Table 10-125](#).

The Source Active Destination Address B-Reference Register (SADSTBREF) is an EDMA3TC channel register. This EDMA3TC channel register is part of the Source Active Register Set. It is read-only and provided to facilitate debugging by providing a window into how the transfer controller (TC) was programmed by the channel controller (CC), as well as showing the status of the transfer controller (TC) during a transfer. Note: Destination address reference is not applicable for the Source Active Register Set. Read returns 0.

**Figure 10-140. SADSTBREF Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### 10.4.2.20 DFCNTRLD Register (offset = 280h) [reset = 0h]

DFCNTRLD is shown in [Figure 10-141](#) and described in [Table 10-126](#).

The Destination FIFO Count Reload Register (DFCNTRLD) is an EDMA3TC channel register. This EDMA3TC channel register is part of the Destination Register FIFO Register Set. It is read-only and provided to facilitate debugging by providing a window into how the transfer controller (TC) was programmed by the channel controller (CC), as well as showing status of the transfer controller (TC) during a transfer. The number of destination FIFO register sets depends on the destination FIFO depth. TC0, TC1, and TC2 each have a destination FIFO depth of 4, so there are four sets of destination FIFO registers for each of these transfer controllers.

**Figure 10-141. DFCNTRLD Register**

**Table 10-128. DFDSTBREF Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	DADDRBREF	R	0h	Destination address reference for the destination FIFO register set. Represents the starting address for the array currently being written. The next array's starting address is calculated as the reference address plus the destination B-Index value. Value 0 to FFFF FFFFh.

### 10.4.2.23 DFOPT0 Register (offset = 300h) [reset = 0h]

DFOPT0 is shown in [Figure 10-144](#) and described in [Table 10-129](#).

The Destination FIFO Options Register (DFOPT) is an EDMA3TC channel register. This EDMA3TC channel register is part of the Destination Register FIFO Register Set. It is read-only and provided to facilitate debugging by providing a window into how the transfer controller (TC) was programmed by the channel controller (CC), as well as showing status of the transfer controller (TC) during a transfer. The number of destination FIFO register sets depends on the destination FIFO depth. TC0, TC1, and TC2 each have a destination FIFO depth of 4, so there are four sets of destination FIFO registers for each of these transfer controllers.

### 10.4.2.24 DFSRC0 Register (offset = 304h) [reset = 0h]

DFSRC0 is shown in [Figure 10-145](#) and described in [Table 10-130](#).

The Destination FIFO Source Address Register (DFSRC) is an EDMA3TC channel register. This EDMA3TC channel register is part of the Destination Register FIFO Register Set. It is read-only and provided to facilitate debugging by providing a window into how the transfer controller (TC) was programmed by the channel controller (CC), as well as showing status of the transfer controller (TC) during a transfer. The number of destination FIFO register sets depends on the destination FIFO depth. TC0, TC1, and TC2 each have a destination FIFO depth of 4, so there are four sets of destination FIFO registers for each of these transfer controllers. Note: Source address is not applicable for Destination FIFO Register Set. Read returns 0.

### 10.4.2.25 DFCNT0 Register (offset = 308h) [reset = 0h]

DFCNT0 is shown in [Figure 10-146](#) and described in [Table 10-131](#).

The Destination FIFO Count Register (DFCNT) is an EDMA3TC channel register. This EDMA3TC channel register is part of the Destination Register FIFO Register Set. It is read-only and provided to facilitate debugging by providing a window into how the transfer controller (TC) was programmed by the channel controller (CC), as well as showing status of the transfer controller (TC) during a transfer. The number of destination FIFO register sets depends on the destination FIFO depth. TC0, TC1, and TC2 each have a destination FIFO depth of 4, so there are four sets of destination FIFO registers for each of these transfer controllers.

**Table 10-131. DFCNT0 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	BCNT	R	0h	B-dimension count remaining for Destination Register Set. Represents the amount of data remaining to be written. For the final TR in the Destination Register FIFO: TC decrements ACNT and BCNT as necessary after each write dataphase is issued. The final value should be 0 when TR is complete. For a non-final TR in the Destination Register FIFO: CNT will hold the originally programmed value or the optimized BCNT value after 2D optimization calculation.
15-0	ACNT	R	0h	A-dimension count remaining for Destination Register Set. Represents the amount of data remaining to be written. For the final TR in the Destination Register FIFO: TC decrements ACNT and BCNT as necessary after each write dataphase is issued. The final value should be 0 when TR is complete. For a non-final TR in the Destination Register FIFO: CNT will hold the originally programmed value or the optimized BCNT value after 2D optimization calculation. Value 0 to FFFFh.

### 10.4.2.26 DFDST0 Register (offset = 30Ch) [reset = 0h]

DFDST0 is shown in [Figure 10-147](#) and described in [Table 10-132](#).

The Destination FIFO Destination Address Register (DFDST) is an EDMA3TC channel register. This EDMA3TC channel register is part of the Destination Register FIFO Register Set. It is read-only and provided to facilitate debugging by providing a window into how the transfer controller (TC) was programmed by the channel controller (CC), as well as showing status of the transfer controller (TC) during a transfer. The number of destination FIFO register sets depends on the destination FIFO depth. TC0, TC1, and TC2 each have a destination FIFO depth of 4, so there are four sets of destination FIFO registers for each of these transfer controllers.

### 10.4.2.27 DFBIDX0 Register (offset = 310h) [reset = 0h]

DFBIDX0 is shown in [Figure 10-148](#) and described in [Table 10-133](#).

The Destination FIFO B-Index Register (DFBIDX) is an EDMA3TC channel register. This EDMA3TC channel register is part of the Destination Register FIFO Register Set. It is read-only and provided to facilitate debugging by providing a window into how the transfer controller (TC) was programmed by the channel controller (CC), as well as showing status of the transfer controller (TC) during a transfer. The number of destination FIFO register sets depends on the destination FIFO depth. TC0, TC1, and TC2 each have a destination FIFO depth of 4, so there are four sets of destination FIFO registers for each of these transfer controllers.

**Table 10-133. DFBIDX0 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	DBIDX	R	0h	B-Index offset between destination arrays for the Destination FIFO Register Set. Represents the offset in bytes between the starting address of each destination array (there are BCNT arrays of ACNT elements). DBIDX is always used regardless of whether DAM is in Increment or FIFO mode. Value 0 to FFFFh.
15-0	SBIDX	R	0h	B-Index offset between source arrays for the Destination FIFO Register Set. Represents the offset in bytes between the starting address of each source array (there are BCNT arrays of ACNT elements). SBIDX is always used regardless of whether SAM is in Increment or FIFO mode.

#### 10.4.2.28 DFMPPRXY0 Register (offset = 314h) [reset = 0h]

DFMPPRXY0 is shown in [Figure 10-149](#) and described in [Table 10-134](#).

The Destination FIFO Memory Protection Proxy Register (DFMPPRXY) is an EDMA3TC channel register. This EDMA3TC channel register is part of the Destination Register FIFO Register Set. It is read-only and provided to facilitate debugging by providing a window into how the transfer controller (TC) was programmed by the channel controller (CC), as well as showing status of the transfer controller (TC) during a transfer. The number of destination FIFO register sets depends on the destination FIFO depth. TC0, TC1, and TC2 each have a destination FIFO depth of 4, so there are four sets of destination FIFO registers for each of these transfer controllers.

This PRIVID value is used while issuing read and write commands to the target endpoints so that the target endpoints can perform memory protection checks based on the PRIVID of the host that set up the DMA transaction. Value 0 to Fh.

### 10.4.2.29 DFOPT1 Register (offset = 340h) [reset = 0h]

DFOPT1 is shown in [Figure 10-150](#) and described in [Table 10-135](#).

The Destination FIFO Options Register (DFOPT) is an EDMA3TC channel register. This EDMA3TC channel register is part of the Destination Register FIFO Register Set. It is read-only and provided to facilitate debugging by providing a window into how the transfer controller (TC) was programmed by the channel controller (CC), as well as showing status of the transfer controller (TC) during a transfer. The number of destination FIFO register sets depends on the destination FIFO depth. TC0, TC1, and TC2 each have a destination FIFO depth of 4, so there are four sets of destination FIFO registers for each of these transfer controllers.

3-2	RESERVED	R	0h	
1	DAM	R	0h	Destination address mode within an array 0h (R/W) = Increment (INCR) mode. Destination addressing within an array increments. 1h (R/W) = Constant addressing (CONST) mode. Destination addressing within an array wraps around upon reaching FIFO width.
0	SAM	R	0h	Source address mode within an array 0h (R/W) = Increment (INCR) mode. Source addressing within an array increments. 1h (R/W) = Constant addressing (CONST) mode. Source addressing within an array wraps around upon reaching FIFO width.

### 10.4.2.36 DFSRC2 Register (offset = 384h) [reset = 0h]

DFSRC2 is shown in [Figure 10-157](#) and described in [Table 10-142](#).

The Destination FIFO Source Address Register (DFSRC) is an EDMA3TC channel register. This EDMA3TC channel register is part of the Destination Register FIFO Register Set. It is read-only and provided to facilitate debugging by providing a window into how the transfer controller (TC) was programmed by the channel controller (CC), as well as showing status of the transfer controller (TC) during a transfer. The number of destination FIFO register sets depends on the destination FIFO depth. TC0, TC1, and TC2 each have a destination FIFO depth of 4, so there are four sets of destination FIFO registers for each of these transfer controllers. Note: Source address is not applicable for Destination FIFO Register Set. Read returns 0.

### 10.4.2.37 DFCNT2 Register (offset = 388h) [reset = 0h]

DFCNT2 is shown in [Figure 10-158](#) and described in [Table 10-143](#).

The Destination FIFO Count Register (DFCNT) is an EDMA3TC channel register. This EDMA3TC channel register is part of the Destination Register FIFO Register Set. It is read-only and provided to facilitate debugging by providing a window into how the transfer controller (TC) was programmed by the channel controller (CC), as well as showing status of the transfer controller (TC) during a transfer. The number of destination FIFO register sets depends on the destination FIFO depth. TC0, TC1, and TC2 each have a destination FIFO depth of 4, so there are four sets of destination FIFO registers for each of these transfer controllers.

**Table 10-143. DFCNT2 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	BCNT	R	0h	B-dimension count remaining for Destination Register Set. Represents the amount of data remaining to be written. For the final TR in the Destination Register FIFO: TC decrements ACNT and BCNT as necessary after each write dataphase is issued. The final value should be 0 when TR is complete. For a non-final TR in the Destination Register FIFO: CNT will hold the originally programmed value or the optimized BCNT value after 2D optimization calculation.
15-0	ACNT	R	0h	A-dimension count remaining for Destination Register Set. Represents the amount of data remaining to be written. For the final TR in the Destination Register FIFO: TC decrements ACNT and BCNT as necessary after each write dataphase is issued. The final value should be 0 when TR is complete. For a non-final TR in the Destination Register FIFO: CNT will hold the originally programmed value or the optimized BCNT value after 2D optimization calculation. Value 0 to FFFFh.

### 10.4.2.38 DFDST2 Register (offset = 38Ch) [reset = 0h]

DFDST2 is shown in [Figure 10-159](#) and described in [Table 10-144](#).

The Destination FIFO Destination Address Register (DFDST) is an EDMA3TC channel register. This EDMA3TC channel register is part of the Destination Register FIFO Register Set. It is read-only and provided to facilitate debugging by providing a window into how the transfer controller (TC) was programmed by the channel controller (CC), as well as showing status of the transfer controller (TC) during a transfer. The number of destination FIFO register sets depends on the destination FIFO depth. TC0, TC1, and TC2 each have a destination FIFO depth of 4, so there are four sets of destination FIFO registers for each of these transfer controllers.

**Table 10-145. DFBIDX2 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	DBIDX	R	0h	B-Index offset between destination arrays for the Destination FIFO Register Set. Represents the offset in bytes between the starting address of each destination array (there are BCNT arrays of ACNT elements). DBIDX is always used regardless of whether DAM is in Increment or FIFO mode. Value 0 to FFFFh.
15-0	SBIDX	R	0h	B-Index offset between source arrays for the Destination FIFO Register Set. Represents the offset in bytes between the starting address of each source array (there are BCNT arrays of ACNT elements). SBIDX is always used regardless of whether SAM is in Increment or FIFO mode.

#### 10.4.2.40 DFMPPRXY2 Register (offset = 394h) [reset = 0h]

DFMPPRXY2 is shown in [Figure 10-161](#) and described in [Table 10-146](#).

The Destination FIFO Memory Protection Proxy Register (DFMPPRXY) is an EDMA3TC channel register. This EDMA3TC channel register is part of the Destination Register FIFO Register Set. It is read-only and provided to facilitate debugging by providing a window into how the transfer controller (TC) was programmed by the channel controller (CC), as well as showing status of the transfer controller (TC) during a transfer. The number of destination FIFO register sets depends on the destination FIFO depth. TC0, TC1, and TC2 each have a destination FIFO depth of 4, so there are four sets of destination FIFO registers for each of these transfer controllers.

Value 0 to Fh.

## 10.5 Appendix A

### 10.5.1 Debug Checklist

This section lists some tips to keep in mind while debugging applications using the EDMA3.

The following table provides some common issues and their probable causes and resolutions.

**Table 10-153. Debug List**

Issue	Description/Solution
The transfer associated with the channel does not happen. The channel does not get serviced.	<p>The EDMA3CC may not service a transfer request, even though the associated PaRAM set is programmed appropriately. Check for the following:</p> <ol style="list-style-type: none"> <li>1) Verify that events are enabled, i.e., if an external/peripheral event is latched in Event Registers (ER/ERH), make sure that the event is enabled in the Event Enable Registers (EER/EERH). Similarly, for QDMA channels, make sure that QDMA events are appropriately enabled in the QDMA Event Enable Register (QEER).</li> <li>2) Verify that the DMA or QDMA Secondary Event Register (SER/SERH/QSERH) bits corresponding to the particular event or channel are not set.</li> </ol>
The Secondary Event Registers bits are set, not allowing additional transfers to occur on a channel.	<p>It is possible that a trigger event was received when the parameter set associated with the channel/event was a NULL set for a previous transfer on the channel. This is typical in two cases:</p> <ol style="list-style-type: none"> <li>1) QDMA channels: Typically if the parameter set is non-static and expected to be terminated by a NULL set (i.e., OPT.STATIC = 0, LINK = 0xFFFF), the parameter set is updated with a NULL set after submission of the last TR. Because QDMA channels are auto-triggered, this update caused the generation of an event. An event generated for a NULL set causes an error condition and results in setting the bits corresponding to the QDMA channel in the QEMR and QSER. This will disable further prioritization of the channel.</li> <li>2) DMA channels used in a continuous mode: The peripheral may be set up to continuously generate infinite events (for instance, in case of McASP, every time the data shifts out from the DXR register, it generates an XEVT). The parameter set may be programmed to expect only a finite number of events and to be terminated by a NULL link. After the expected number of events, the parameter set is reloaded with a NULL parameter set. Because the peripheral will generate additional events, an error condition is set in the SER.Ex and EMR.Ex set, preventing further event prioritization. You must ensure that the number of events received is limited to the expected number of events for which the parameter set is programmed, or you must ensure that bits corresponding to particular channel or event are not set in the Secondary event registers (SER/SERH/QSER) and Event Missed Registers (EMR/EMRH/QEMR) before trying to perform subsequent transfers for the event/channel.</li> </ol>
Completion interrupts are not asserted, or no further interrupts are received after the first completion interrupt.	<p>You must ensure the following:</p> <ol style="list-style-type: none"> <li>1) The interrupt generation is enabled in the OPT of the associated PaPARAM set (TCINTEN = 1 and/or ITCINTEN = 1).</li> <li>2) The interrupts are enabled in the EDMA3 Channel Controller, via the Interrupt Enable Registers (IER/IERH).</li> <li>3) The corresponding interrupts are enabled in the device interrupt controller.</li> <li>4) The set interrupts are cleared in the interrupt pending registers (IPR/IPRH) before exiting the transfer completion interrupt service routine (ISR). See <a href="#">Section 10.3.9.1.2</a> for details on writing EDMA3 ISRs.</li> <li>5) If working with shadow region interrupts, make sure that the DMA Region Access registers (DRAE/DRAEH) are set up properly, because the DRAE/DRAEH registers act as secondary enables for shadow region completion interrupts, along with the IER/IERH registers.</li> </ol> <p>If working with shadow region interrupts, make sure that the bits corresponding to the transfer completion code (TCC) value are also enabled in the DRAE/DRAEH registers. For instance, if the PaPARAM set associated with Channel 0 returns a completion code of 63 (OPT.TCC=63), ensure that DRAEH.E63 is also set for a shadow region completion interrupt because the interrupt pending register bit set will be IPRH.I63 (not IPR.I0).</p>

### 10.5.2 Miscellaneous Programming/Debug Tips

1. For several registers, the setting and clearing of bits needs to be done via separate dedicated registers. For example, the Event Register (ER/ERH) can only be cleared by writing a 1 to the corresponding bits in the Event Clear Registers (ECR/ECRH). Similarly, the Event Enable Register (EER/EERH) bits can only be set with writes of 1 to the Event Enable Set Registers (EESR/EESRH) and cleared with writes of 1 to the corresponding bits in the Event Enable Clear Register (EECR/EECRH).
2. Writes to the shadow region memory maps are governed by region access registers (DRAE/DRAEH/QRAE). If the appropriate channels are not enabled in these registers, read/write access to the shadow region memory map is not enabled.
3. When working with shadow region completion interrupts, ensure that the DMA Region Access Registers (DRAE/DRAEH) for every region are set in a mutually exclusive way (unless it is a requirement for an application). If there is an overlap in the allocated channels and transfer completion codes (setting of Interrupt Pending Register bits) in the region resource allocation, it results in multiple

shadow region completion interrupts. For example, if DRAE0.E0 and DRAE1.E0 are both set, then on completion of a transfer that returns a TCC=0, they will generate both shadow region 0 and 1 completion interrupts.

4. While programming a non-dummy parameter set, ensure the CCNT is not left to zero.
5. Enable the EDMA3CC error interrupt in the device controller and attach an interrupt service routine (ISR) to ensure that error conditions are not missed in an application and are appropriately addressed with the ISR.
6. Depending on the application, you may want to break large transfers into smaller transfers and use self-chaining to prevent starvation of other events in an event queue.
7. In applications where a large transfer is broken into sets of small transfers using chaining or other methods, you might choose to use the early chaining option to reduce the time between the sets of transfers and increase the throughput. However, keep in mind that with early completion, all data might have not been received at the end point when completion is reported because the EDMA3CC internally signals completion when the TR is submitted to the EDMA3TC, potentially before any data has been transferred.
8. The event queue entries can be observed to determine the last few events if there is a system failure (provided the entries were not bypassed).

### 10.5.3 Setting Up a Transfer

The following list provides a quick guide for the typical steps involved in setting up a transfer.

**Step 1. Initiating a DMA/QDMA channel**

- (a) Determine the type of channel (QDMA or DMA) to be used.
- (b) Channel mapping
  - (i) If using a QDMA channel, program the QCHMAP with the parameter set number to which the channel maps and the trigger word.
  - (ii) If using a DMA channel, program the DCHMAP with the parameter set number to which the channel maps.
- (c) If the channel is being used in the context of a shadow region, ensure the DRAE/DRAEH for the region is properly set up to allow read write accesses to bits in the event registers and interrupt registers in the Shadow region memory map. The subsequent steps in this process should be done using the respective shadow region registers. (Shadow region descriptions and usage are provided in [Section 10.3.7.1](#).)
- (d) Determine the type of triggering used.
  - (i) If external events are used for triggering (DMA channels), enable the respective event in EER/EERH by writing into EESR/EESRH.
  - (ii) If QDMA Channel is used, enable the channel in QEER by writing into QEESR.
- (e) Queue setup
  - (i) If a QDMA channel is used, set up the QDMAQNUM to map the channel to the respective event queue.
  - (ii) If a DMA channel is used, set up the DMAQNUM to map the event to the respective event queue.

**Step 2. Parameter set setup**

- (a) Program the PaRAM set number associated with the channel. Note that if it is a QDMA channel, the PaRAM entry that is configured as trigger word is written to last. Alternatively, enable the QDMA channel (step 1-b-ii above) just before the write to the trigger word.  
See [Section 10.3.19](#) for parameter set field setups for different types of transfers. See the sections on chaining ([Section 10.3.8](#)) and interrupt completion ([Section 10.3.9](#)) on how to set up final/intermediate completion chaining and/or interrupts.

**Step 3. Interrupt setup**

- (a) Enable the interrupt in the IER/IERH by writing into IESR/IESRH.
- (b) Ensure that the EDMA3CC completion interrupt (either the global or the shadow region interrupt) is enabled properly in the device interrupt controller.
- (c) Ensure the EDMA3CC completion interrupt (this refers to either the Global interrupt or the shadow region interrupt) is enabled properly in the Device Interrupt controller.
- (d) Set up the interrupt controller properly to receive the expected EDMA3 interrupt.

**Step 4. Initiate transfer**

(a) This step is highly dependent on the event trigger source:

- (i) If the source is an external event coming from a peripheral, the peripheral will be enabled to start generating relevant EDMA3 events that can be latched to the ER transfer.
- (ii) For QDMA events, writes to the trigger word (step 2-a above) will initiate the transfer.
- (iii) Manually triggered transfers will be initiated by writes to the Event Set Registers (ESR/ESRH).
- (iv) Chained-trigger events initiate when a previous transfer returns a transfer completion code equal to the chained channel number.

**Step 5. Wait for completion**

- (a) If the interrupts are enabled as mentioned in step 3 above, then the EDMA3CC will generate a completion interrupt to the CPU whenever transfer completion results in setting the corresponding bits in the interrupt pending register (IPR/IPRH). The set bits must be cleared in the IPR/IPRH by writing to corresponding bit in ICR/ICRH.
- (b) If polling for completion (interrupts not enabled in the device controller), then the application code can wait on the expected bits to be set in the IPR/IPRH. Again, the set bits in the IPR/IPRH must be manually cleared via ICR/ICRH before the next set of transfers is performed for the same transfer completion code values.

## ***ADC0: Touchscreen Controller***

---

---

This chapter describes the touchscreen controller of the device.

<b>Topic</b>	<b>Page</b>

## 11.1 Introduction

The touchscreen controller and analog-to-digital converter subsystem (TSC\_ADC\_SS or ADC0) contains a single-channel ADC connected to an 8-to-1 analog multiplexer which operates as a general-purpose analog-to-digital converter (ADC) with optional support for interleaving touchscreen (TS) conversions for a 4-wire, 5-wire, or 8-wire resistive panel. The TSC\_ADC\_SS can be configured for use in one of the following applications:

- 8 general-purpose ADC channels
- 4-wire TSC with 4 general-purpose ADC channels
- 5-wire TSC with 3 general-purpose ADC channels
- 8-wire TSC

### 11.1.1 TSC\_ADC (ADC0) Features

The main features of the TSC\_ADC\_SS include:

- Support for 4-wire, 5-wire, and 8-wire resistive TS panels
- Support for interleaving TS capture and general-purpose ADC modes
- Programmable FSM sequencer that supports 16 steps:
  - Software register bit for start of conversion
  - Optional start of conversion HW synchronized to Pen touch or external HW event (but not both)
  - Single conversion (one-shot)
  - Continuous conversions
  - Sequence through all input channels based on a mask
  - Programmable OpenDelay for each FSM step
  - Programmable sampling delay for each FSM step
  - Programmable averaging of input samples: 16/8/4/2/1
  - Differential or singled ended mode setting for each FSM step
  - Store data in either of two FIFO groups
  - Option to encode step ID number with data
  - Support for servicing FIFOs via DMA or CPU
  - Programmable DMA Request event (for each FIFO)
  - Dynamically enable or disable channel inputs during operation
  - Stop bit to end conversion
- Support for the following interrupts and status, with masking:
  - Interrupt for HW pen event (Pen-down)
  - Interrupt for HW Pen-up event
  - Interrupt after a sequence of conversions (all non-masked channels)
  - Interrupt for FIFO threshold levels
  - Interrupt if sampled data is out of a programmable range
  - Interrupt for FIFO overflow and underflow conditions
  - Status bit to indicate if ADC is busy converting

### 11.1.2 Unsupported TSC\_ADC\_SS (ADC0) Features

This device supports all TSC\_ADC\_SS features.

Figure 11-1 shows the integration of the TSC\_ADC (ADC0) module in the device.

### Figure 11-1. TSC\_ADC (ADC0) Integration

pr1\_host\_intr[0:7] corresponds to Host-2 to Host-9 of the PRU-ICSS interrupt controller.

The general connectivity attributes for the TSC\_ADC module are summarized in [Table 11-1](#).

### Table 11-1. TSC\_ADC (ADC0) Connectivity Attributes

Attributes	Type
Power domain	Wakeup Domain
Clock domain	PD_PER_L3S_GCLK (OCP) PD_WKUP_ADC_FCLK (Func)
Reset signals	WKUP_DOM_RST_N
Idle/Wakeup signals	Smart idle Wakeup
Interrupt request	1 interrupt to MPU Subsystem (ADC0_GENINT), PRU-ICSS (gen_intr_pend), and Wakeup Processor Swakeup to Wake Processor
DMA request	2 Events (adc0_FIFO0, adc0_FIFO1)
Physical address	L3 Slow slave port (DMA) L4 Wkup slave port (MMR)

### 11.2.2 TSC\_ADC (ADC0) Clock and Reset Management

The TSC\_ADC has two clock domains. The ADC uses the adc\_clk. The bus interfaces, FIFOs, sequencer, and all other logic use the ocp\_clk.

**Table 11-2. TSC\_ADC (ADC0) Clock Signals**

Clock Signal	Max Freq	Reference / Source	Comments
ocp_clk OCP / Functional clock	100 MHz	CORE_CLKOUTM4 / 2	pd_per_ls3_gclk From PRCM
adc_clk ADC clock	24 MHz (typ)	CLK_M_OSC	pd_wkup_adc_fclk From PRCM

### 11.2.3 TSC\_ADC (ADC0) Pin List

The TSC\_ADC external interface signals are shown in [Table 11-3](#).

**Table 11-3. TSC\_ADC (ADC0) Pin List**

Pin	Type	Description
ADC0_AIN[7:0]	I	Analog Input
VREFN	Analog	Analog Reference Input Negative Terminal
VREFP	Analog	Analog Reference Input Positive Terminal

## 11.3 Functional Description

Before enabling the TSC\_ADC\_SS module, the user must first program the Step Configuration registers in order to configure a channel input to be sampled. There are 16 programmable Step Configuration registers which are used by the sequencer to control which switches to turn on or off (inputs to the AFE), which channel to sample, and which mode to use (hardware-triggered or software-enabled, one-shot or continuous, averaging, where to save the FIFO data, and more).

### 11.3.1 Hardware Synchronized or Software Enabled

The user can control the start behavior of each step by deciding if a channel should be sampled immediately (software-enabled) after it is enabled, or if the channel should wait for a hardware (HW) event to occur first (a HW event must either be mapped to the touch screen PEN event or mapped to the HW event input signal, but not both). Each step can be configured independently using the STEPCONFIG\_x register.

### 11.3.2 Open Delay and Sample Delay

The user can program the delay between driving the inputs to the AFE and the time to send the start of conversion signal. This delay can be used to allow the voltages to stabilize on the touch screen panel before sampling. This delay is called “open delay” and can also be programmed to zero. The user also has control of the sampling time (width of the start of conversion signal) to the AFE which is called the “sample delay”. The open delay and sample delay for each step can be independently configured using the STEPDELAY\_x register.

### 11.3.3 Averaging of Samples (1, 2, 4, 8, and 16)

Each step has the capability to average the sampled data. The valid averaging options are 1 (no average), 2, 4, 8, and 16. If averaging is turned on, then the channel is immediately sampled again (up to 16 times) and final averaged sample data is stored in the FIFO. Each step can be independently configured using the STEPCONFIG\_x registers.

### 11.3.4 One-Shot (Single) or Continuous Mode

When the sequencer finishes cycling through all the enabled steps, the user can decide if the sequencer should stop (one-shot), or loop back and schedule the step again (continuous).

If one-shot mode is selected, the sequencer will take care of disabling the step enable bit after the conversion. If continuous mode is selected, it is the software's responsibility to turn off the step enable bit.

### 11.3.5 Interrupts

The following interrupts are supported through enable bits and are maskable.

The HW Pen event interrupt, also known as the Pen-down interrupt, is generated when the user presses the touchscreen. This can only occur if the AFE is configured properly (that is, one of the Pen Ctrl bits must be enabled, and also the correct setting for a path to ground in the STEPCONFIG\_x registers). Although the Pen-down interrupt can be disabled by the software (SW), the event will still trigger the sequencer to start if the step is configured as a HW-synchronized event. The Pen-down interrupt is an asynchronous event and can be used even if the TSC\_ADC\_SS clocks are disabled. The Pen-down interrupt can be used as a wakeup source.

An END\_OF\_SEQUENCE interrupt is generated after the sequencer finishes servicing the last enabled step.

A Pen-up event interrupt, also known as the Pen-up interrupt, can only be generated when using HW steps with the charge steps enabled. If a Pen-down event caused the HW steps to be scheduled and no Pen-down is present after the sequencer finished servicing the charge step, then a Pen-up interrupt is generated. To detect Pen-up interrupts, the charge step must share the same configuration as the idle step.

Each FIFO has support for generating interrupts when the FIFO word count has reached a programmable threshold level. The user can program the desired word count at which the CPU should be interrupted. Whenever the threshold counter value is reached, it sets the FIFOTHR\_x interrupt flag, and the CPU is interrupted if the FIFOTHR\_x interrupt enable bit is set. The user can clear the interrupt flag, after emptying the FIFO, by writing a '1' to the FIFOTHR\_x interrupt status bit. To determine how many samples are currently in the FIFO at a given moment, the FIFOCOUNT\_x register can be read by the CPU.

The FIFO can also generate FIFOx\_OVERRUN and FIFOx\_UNDERFLOW interrupts. The user can mask these events by programming the IRQEN\_CLR register. To clear a FIFO underflow or FIFO overrun interrupt, the user should write a '1' to the status bit in the IRQSTS register. The TSC\_ADC\_SS does not recover from these conditions automatically. Therefore, the software will need to disable and then again enable the TSC\_ADC\_SS. Before the user can turn the module back on, the user must read the ADCSTAT register to check if the status of the ADC FSM is idle and the current step is the idle step.

### 11.3.6 DMA Requests

Each FIFO group can be serviced by either a DMA or by the CPU. To generate DMA requests, the user must set the enable bit in the DMAEN\_SET Register. Also, the user can program the desired number of words to generate a DMA request using the DMAxREQ register. When the FIFO level reaches or exceeds that value, a DMA request is generated.

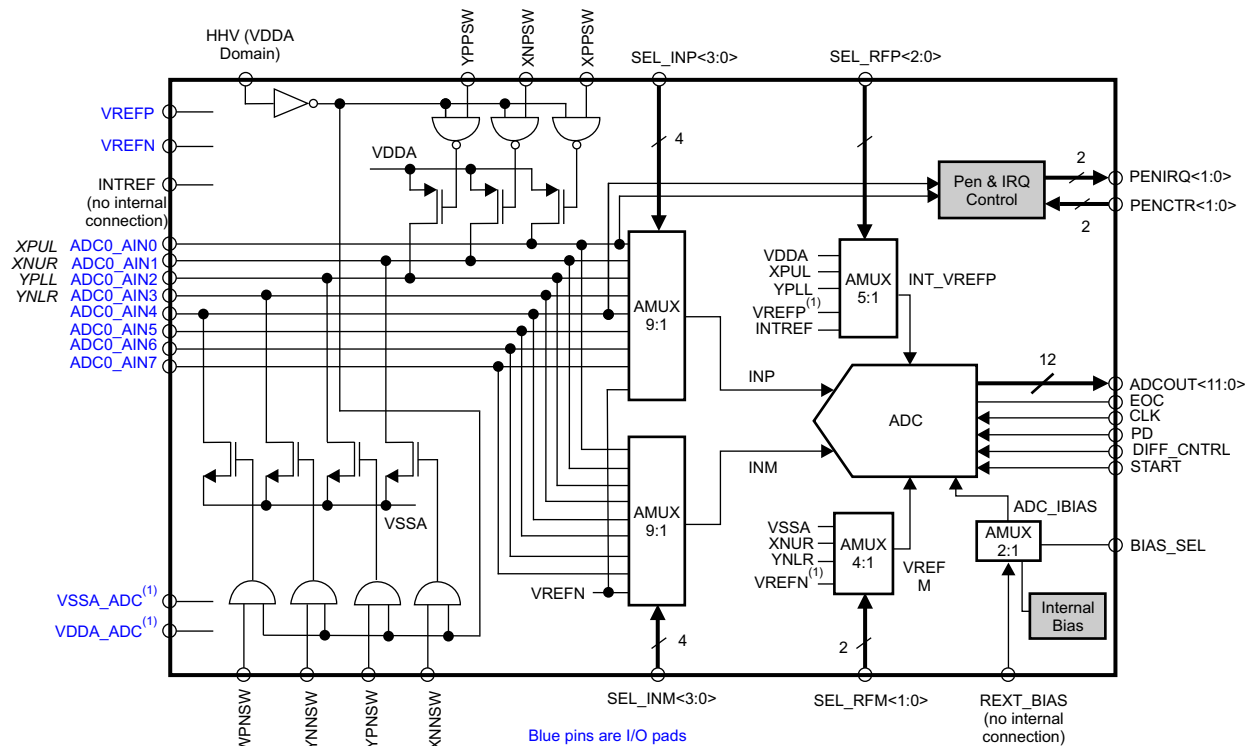

The DMA slave port allows for burst reads in order to effectively move the FIFO data. Internally, the OCP DMA address (MSB) is decoded for either FIFO 0 or FIFO 1. The lower bits of the DMA addresses are ignored since the FIFO pointers are incremented internally.

### 11.3.7 Analog Front End (AFE) Functional Block Diagram

The AFE features are listed below, and some are controlled by the TSC\_ADC\_SS:

- 12-bit ADC
- Sampling rate can be as fast as every 15 ADC clock cycles
- Support for internal ADC clock divider logic
- Support for configuring the delay between samples also the sampling time

Figure 11-2. Functional Block Diagram

(1) In the device-specific datasheet:

- VDDA\_ADC and VSSA\_ADC are referred to as "Internal References"
- VREFP and VREFN are referred to as "External References"

## 11.4 Operational Modes

The sequencer is completely controlled by software and behaves accordingly to how the **Step Registers** are programmed. A **step** is the general term for sampling a channel input. It is defined by the programmer who decides which input values to send to the AFE as well as how and when to sample a channel input.

The choices for each step can all be programmed using the STEPCONFIG\_x registers.

A step requires using these registers:

- STEPEN: Enables or disables the step
- STEPCONFIG\_x: Controls the input values to the ADC (the reference voltages, the pull up/down transistor biasing, which input channel to sample, differential control, HW synchronized or SW enabled, averaging, and which FIFO group to save the data)
- STEPDELAY\_x: Controls the OpenDelay (the time between driving the AFE inputs until sending the SOC signal to the AFE), and also controls the SampleDelay (the time for the ADC to sample the input signal)

The sequencer supports a total of 16 programmable steps, a touchscreen charge step, and an idle step. Each step requires using the registers listed above. However, the idle step does not have an enable bit, so it will always be enabled, or a delay register. In addition, the ADC does not actually sample a channel during the idle and touchscreen charge steps.

Assuming all the steps are configured as general-purpose mode (no touchscreen), then the steps would be configured as SW enabled. When the TSC\_ADC\_SS is first enabled, the sequencer will always start in the Idle step and then wait for a STEPEN[n] bit to turn on. After a step is enabled, the sequencer will start with the lowest step (1) and continue until step (16). If a step is not enabled, then sequencer will skip to the next step. If all steps are disabled, then the sequencer will remain in the IDLE state and continue to apply the settings in the IDLECONFIG register.

Assuming a touchscreen-only mode (no general-purpose channels) the steps could be configured as HW synchronized triggered (mapped to the Pen event). The sequencer would wait in the IDLE state until a Pen-down event occurred and then begin the HW step conversions. The charge step, which occurs after the last HW-synchronized step is finished, is designed to charge the capacitance in a touch panel when the appropriate bias transistor is enabled. The purpose of the charge step is to prepare the TSC for the next Pen-down event.

Assuming a mixed mode application (touchscreen and general-purpose channels), the user can configure the steps as either HW-triggered (mapped to a Pen event) or SW-enabled. If the sequencer is in the idle state and a Pen-down event occurs, the HW-synchronized steps are always scheduled first, followed by the charge step, and cannot be preempted by SW steps. If there is no HW event, then the SW-enabled steps are scheduled instead.

If a Pen-down event occurs while the sequencer is in the middle of scheduling the SW steps, the user can program the scheduler to allow preemption. If the HW preemption control bit is enabled in the CTRL register, the sequencer will stop the scheduled SW sequence and schedule the HW steps. After the last HW step and charge step are completed, the sequencer will continue from the next SW step (before the preemption occurred). If the HW preemption is disabled, then the touch event will be ignored until the last software step is completed; if the touch event is removed before the last software step is finished, then the touch event will be missed.

Even if a touchscreen is not present, the user can still configure the steps to be HW-synchronized by mapping to the ext\_hw\_event signal shown in [Figure 11-1](#). This HW event input signal can be driven at the SOC from a number of external inputs chosen by the ADC0\_EVT\_CAPT register in the Control Module.

When mapping is set for the ext\_hw\_event signal, then the TSC\_ADC\_SS will wait for a rising edge transition (from low to high) before starting. The ext\_hw\_event signal is captured on the internal L4 OCP clock domain. The ext\_hw\_event signal should be held for at least two TSC\_ADC\_SS OCP clocks (L4 frequency).

An END\_OF\_SEQUENCE interrupt is generated after the last active step is completed before going back to the IDLE state. The END\_OF\_SEQUENCE interrupt does not mean data is in the FIFO (should use the FIFO interrupts and FIFOCOUNT\_x register).

### 11.4.1 PenCtrl and PenIRQ

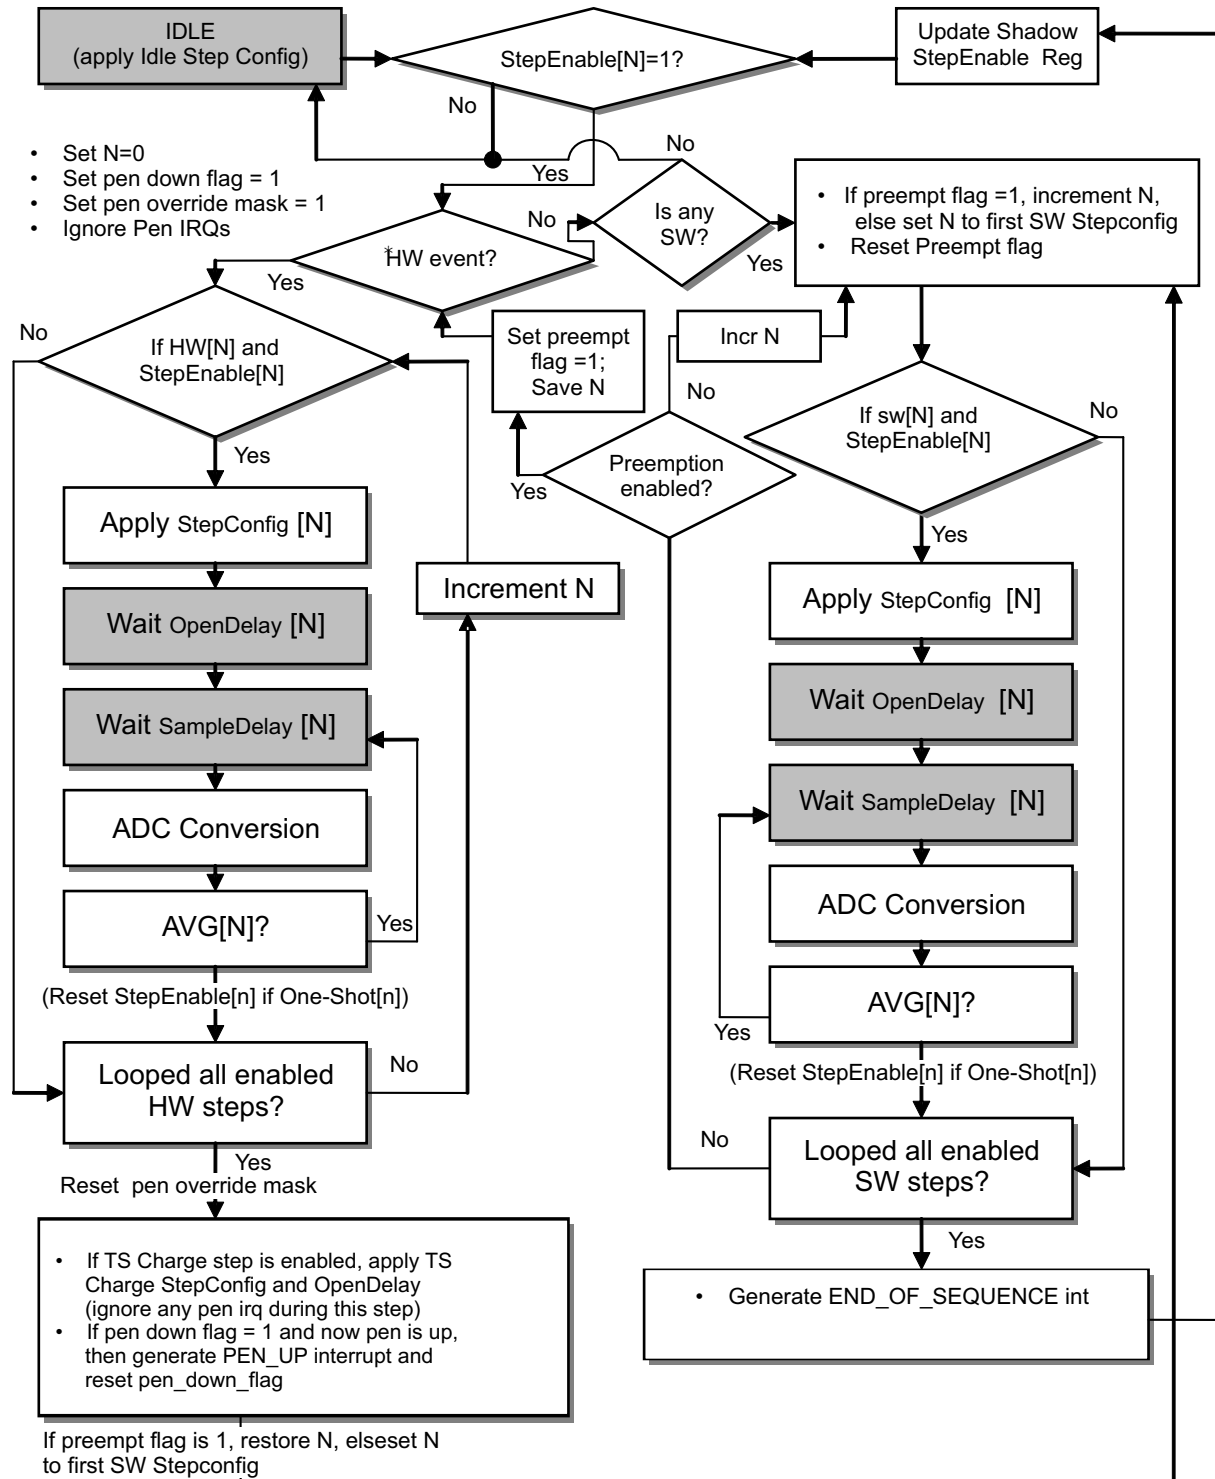

The Pen IRQ can only occur if the correct AFE\_Pen\_Ctrl bits are high in the CTRL register and if the correct ground transistor biasing is set in the STEPCONFIG\_x and IDLECONFIG registers.

Setting the AFE\_Pen\_Ctrl bits in the CTRL register will enable a weak internal pull-up resistor on ADC0\_AIN for 4-wire configurations and ADC0\_AIN for 5-wire.

If a step is configured as HW-synchronized, the sequencer will override the AFE\_Pen\_Ctrl bits set by the software (bits 6:5) once it transitions from the Idle step. The sequencer will automatically mask the AFE\_Pen\_Ctrl bits (override them and turn them off) so that the ADC can get an accurate measurement from the x and y-axes. After the last HW-synchronized step, the sequence will go to the Charge step and the pen override mask is removed and the values set by the software (bits 6:5) will have control. The Pen-down events will be temporarily ignored during the Charge step (HW will mask any potential glitches that may occur)

If the sequencer is not using the HW synchronized approach, (all the steps are configured as software enabled), then it is the software programmer's responsibility to correctly turn on and off the AFE\_Pen\_Ctrl bits to receive the correct measurements from the touchscreen. The software must enable the Charge step and ignore any potential glitches.

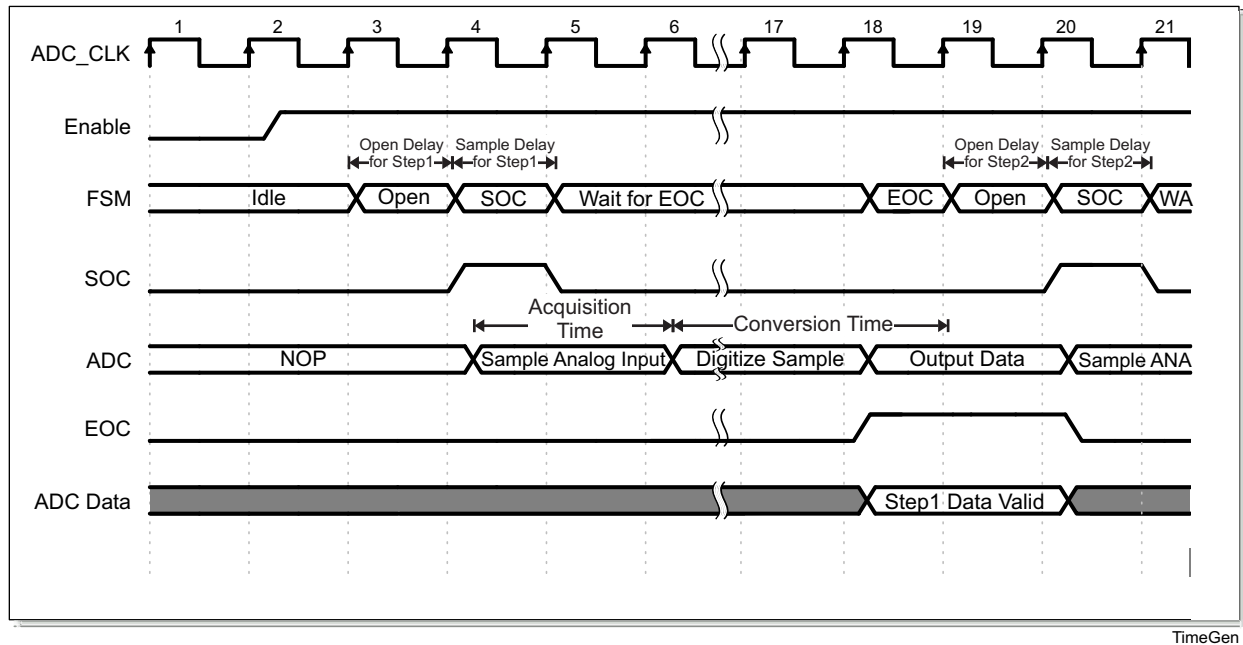

It is also possible to detect the Pen-down event even if all the STEPEN[n] bits are off. By setting the appropriate AFE\_Pen\_Ctrl bit to 1, and configuring the IDLECONFIG register to bias the correct transistor to ground, the Pen-down event will generate. The flowchart for the sequencer is shown in [Figure 11-3](#) and an example timing diagram in [Figure 11-4](#).

**Figure 11-3. Sequencer FSM**

\* HW event can either be Pen-down or input HW event, but not both

Figure 11-3 does not actually represent clock cycles but instead illustrates how the scheduler will work. However, each shaded box above does represent a FSM state and will use a clock cycle. Using the minimum delay values, the ADC can sample at 15 ADC clocks per sample. Below is an example timing diagram illustrating the states of the sequencer and also the showing when the STEPCONFIG\_x and the STEPDELAY\_x registers values are applied. The below example assumes the steps are software controlled, and averaging is turned off.

**Figure 11-4. Example Timing Diagram for Sequencer**

The idle step is always enabled and applied when the FSM is in the IDLE state (that is, either waiting for a HW event or waiting for a step to be enabled). The idle step cannot be disabled.

Once the TSC\_ADC\_SS is enabled and assuming at least one step is active, the FSM will transition from the idle state and apply the first active STEPCONFIG\_x and STEPDELAY\_x register settings. It is possible for the Open Delay to be 0, and, as a result, the FSM will immediately skip to the Sample Delay. The ADC will begin sampling once the SoC signal goes high. The ADC will continue to sample for at least 1 clock cycle, which is the Sample Delay minimum, after the SoC. The ADC will then take 12 cycles to digitize the sample followed by 1 cycle to send the EOC for a minimum total of 15 ADC\_CLK cycles per sample. Once the EOC has been sent, the FSM will begin the next active step.

This process is repeated and continued (from step 1 to step 16) until the last active step is completed.

## 11.5 ADC0 Registers

### 11.5.1 ADC0 Registers

Table 11-4 lists the memory-mapped registers for the ADC0. All register offset addresses not listed in Table 11-4 should be considered as reserved locations and the register contents should not be modified.

## ***ADC1: Magnetic Card Reader***

This chapter describes the Magnetic Card Reader (ADC1) of the device.

Topic	Page
<b>12.1 Introduction .....</b>	<b>1830</b>
<b>12.2 Integration .....</b>	<b>1832</b>
<b>12.3 Functional Description .....</b>	<b>1834</b>
<b>12.4 Registers .....</b>	<b>1846</b>

## 12.1 Introduction

The magnetic card reader (MCR) and analog-to-digital converter (ADC) subsystem (MCR\_ADC\_SS), also known as ADC1, implements several enhancements to the basic general-purpose ADC which allows it to be connected directly to magnetic card heads and operated as a magnet card reader.

ADC1 contains two major components: a digital finite-state machine sequencer (FSM sequencer) and analog front-end (AFE).

The FSM sequencer is set up and controlled by software using a 32-bit OCP interface and supports up to 16 programmable logical steps (a step defines how and when to sample a physical input). The ADC conversion data is stored in either of two FIFOs and can be read by the processor or DMA. Interrupts can be generated when the FIFO data has reached a programmable level. The FSM sequencer supports continuous sampling as well as single-shot modes.

The AFE consists of a single 12-bit successive approximation ADC, 4 programmable gain differential preamplifiers, 4 analog multiplexers, and 8 analog inputs. Analog multiplexers allow the 8 analog inputs to be configured as 4 differential inputs or 8 single-ended inputs when the preamplifiers are bypassed.

---

**NOTE:** The magnetic card reader function is not supported on the AM437x product family. ADC1 should only be used as a general-purpose ADC when using an AM437x device.

---

### 12.1.1 MagneticCard Reader Features

The main features of the MagneticCard Reader include:

- Programmable FSM sequencer that supports 16 steps:
  - Software register bit for start of sequence
  - Optional start of sequence with hardware events
    - External hardware event connected to the EXT\_HW\_TRIGGER input
    - ADC data value exceeds a programmable swipe threshold
  - Option to discard ADC data until it exceeds a programmable swipe threshold
    - Supported in software and hardware event modes
  - Continuous or one-shot single sequence
  - Sequence through up to 16 individually enabled steps
  - Programmable analog input selector for each step
  - Programmable Open Delay between steps
  - Programmable Sampling Delay (acquisition period) for each step
  - Programmable averaging of input samples - 16/8/4/2/1
  - Differential or singled ended mode setting for each step
  - Store data in either of two FIFOs
  - Option to encode physical step number with ADC data
  - FIFOs serviced by the processor or DMA
  - Programmable DMA level interrupt (for each FIFO)
  - Programmable FIFO level interrupt (for each FIFO)
  - Stop bit to end conversion
- Support for following interrupts/status, with masking:
  - Interrupt when ADC data is greater than or equal to a programmable swipe threshold
  - Interrupt after a sequence of enabled steps has completed (end\_of\_sequence)
  - Interrupt when FIFO fills to a programmable threshold
  - Interrupt if sampled data is out of a programmable range
  - Interrupt for FIFO overflow and underflow conditions
  - Status bit to indicate if ADC is busy converting

- Status bits to indicate which step is currently being executed

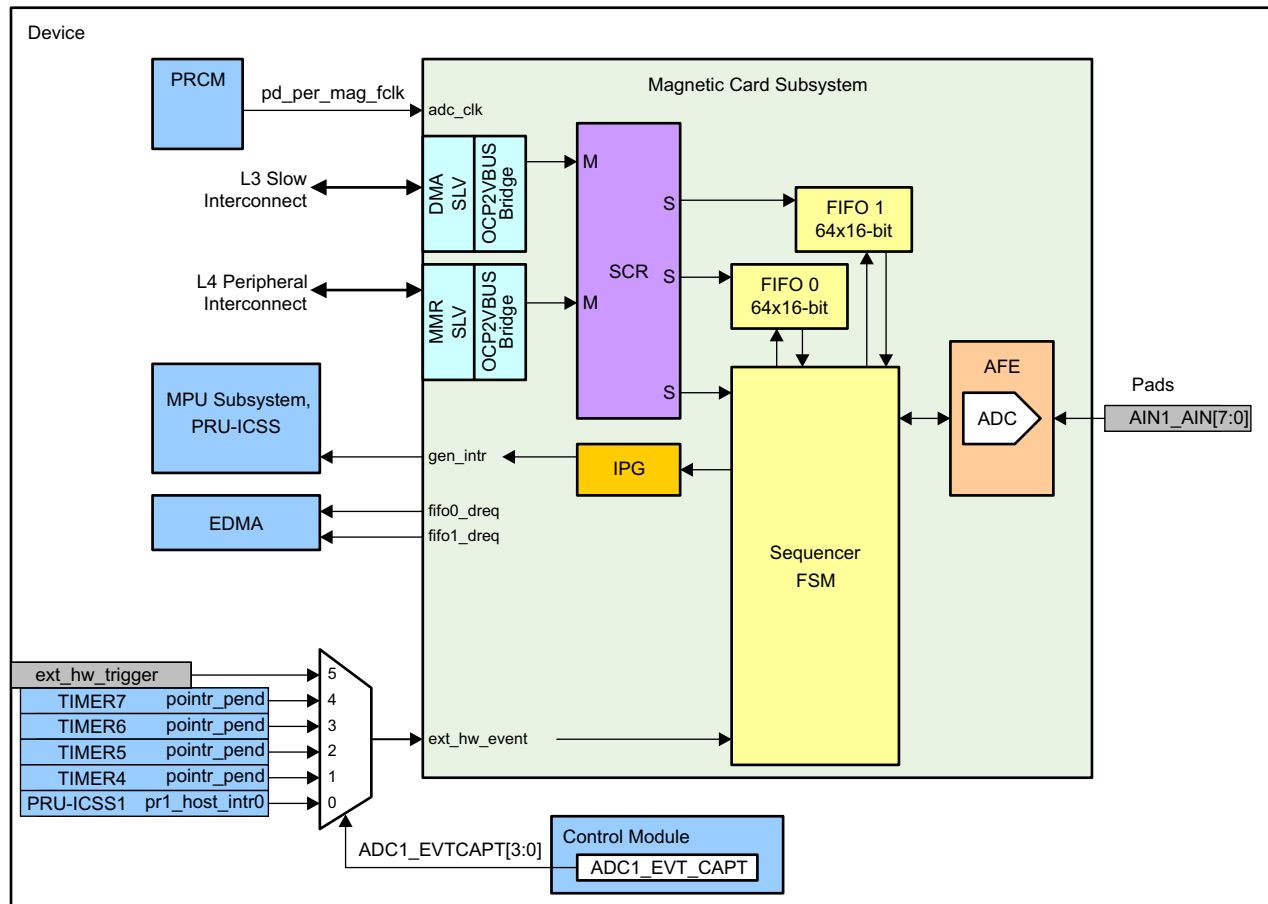

### **12.1.2 *Unsupported Features***

The magnetic card reader function is not supported on the AM437x product family. ADC1 should only be used as a general-purpose ADC when using an AM437x device.

## 12.2 Integration

Figure 12-1 shows how the MCR\_ADC (ADC1) module is integrated into the device.

**Figure 12-1. MagneticCard Reader Integration**

### 12.2.1 MagneticCard Reader Connectivity Attributes

The general connectivity attributes for the MagneticCard Reader are shown in Table 12-1.

**Table 12-1. MagneticCard Reader Connectivity Attributes**

Attributes	Type
Power Domain	Peripheral Domain
Clock Domain	PD_PER_L3S_GCLK (OCP) PD_PER_MAG_FCLK (Functional)
Reset Signals	PER_DOM_RST_N
Idle/Wakeup Signals	Idle
Interrupt Requests	1 interrupt to MPU Subsystem, PRU-ICSS
DMA Requests	1 event Edge event signals to EDMA
Physical Address	L3 slow slave port (DMA) L4 peripheral slave port (MMR)

## 12.2.2 MagneticCard Reader Clock and Reset Management

The MagneticCard Reader has two clock domains. The OCP2VBUS bridges, SCR, IPG, FIFOs, and portions of the FSM Sequencer use the ocp\_clk. The ADC AFE and portions of the FSM Sequencer use the adc\_clk.

**Table 12-2. MagneticCard Reader Clock Signals**

Clock Signal	Maximum Frequency	Reference Source	Comments
ocp_clock Interface / functional clock	100 MHz	CORE_CLKOUTM4 / 2	pd_per_l3s_gclk from PRCM
adc_clk ADC clock	19.2, 24, 25, or 26 MHz	CLK_M_OSC	pd_per_mgc_fgclk from PRCM
	192 MHz	PER_CLKOUTM2	

The frequency of ocp\_clock must be greater than or equal to six times the frequency of adc\_clk.

## 12.2.3 MagneticCard Reader Pin List

The MagneticCard Reader interface pins are summarized in [Table 12-3](#).

**Table 12-3. MagneticCard Reader Pin List**

Pin	Type	Description
ADC1_AIN[7:0] <sup>(1)</sup>	I	Analog inputs
ADC1_VREFN <sup>(2)</sup>	Analog	Negative External Reference Voltage Input
ADC1_VREFP <sup>(3)</sup>	Analog	Positive External Reference Voltage Input

<sup>(1)</sup> Unused analog inputs should be open-circuit.

<sup>(2)</sup> Connect ADC1\_VREFN to VSSA\_ADC when not using a negative external reference voltage.

<sup>(3)</sup> Connect ADC1\_VREFP to VDDA\_ADC1 when not using a positive external reference voltage.

If ADC1 is not used, connect all ADC1 terminals (ADC1\_AIN[7:0], ADC1\_VREFN, ADC1\_VREFP, VDDA\_ADC1, and VSSA\_ADC) to the same ground as all VSS terminals.

## 12.3 Functional Description

### 12.3.1 FSM Sequencer Functional Description

The FSM sequencer supports up to 17 steps. One of the 17 steps is the Idle step which is always enabled and does not perform any analog-to-digital conversions. The other 16 steps always perform analog-to-digital conversions but they can be independently enabled or disabled.

The 16 steps which perform analog-to-digital conversions can individually be enabled and configured to operate as software enabled steps or hardware enabled steps. Each of these steps has their own programmable step configuration and step delay registers that allow users to configure the ADC operation on a per-step basis.

The FSM sequencer remains in the Idle step when it is not executing one of the 16 programmable steps. The Idle step does not have an enable bit in the step enable register or step delay register since this step does not perform any ADC operation.

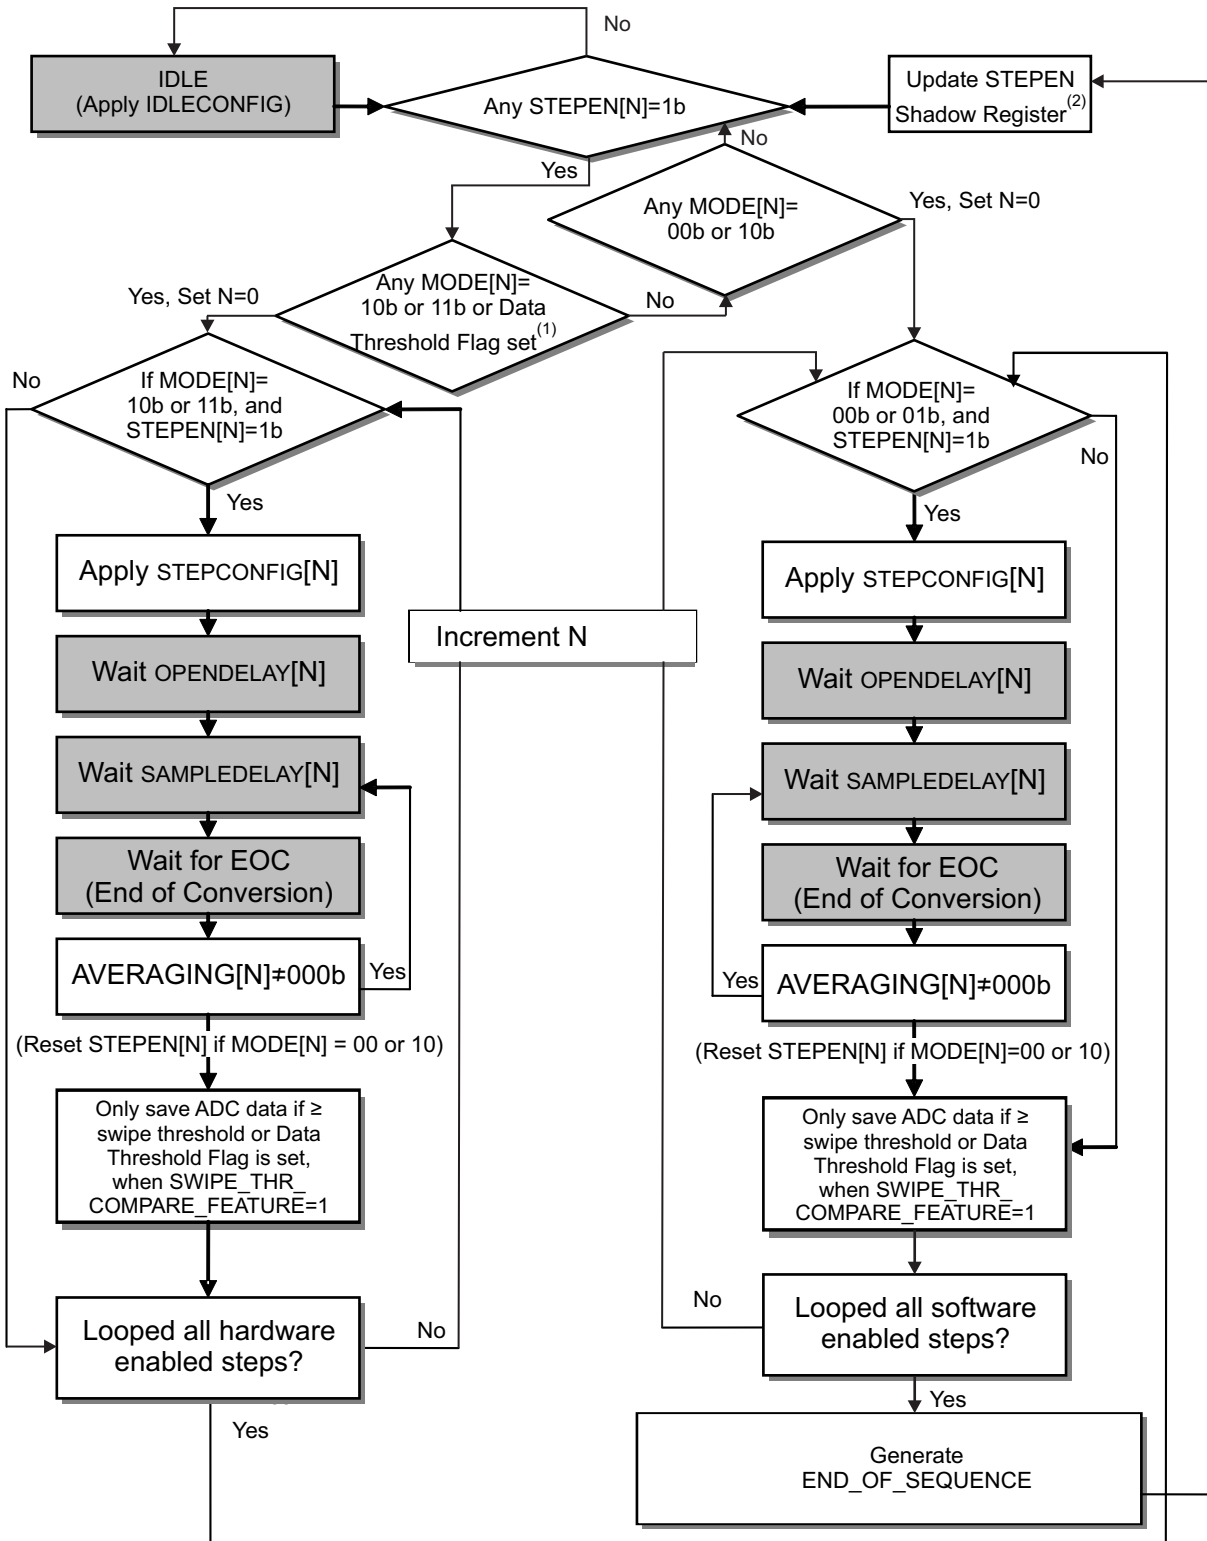

The FSM sequencer enters the Idle step and configures the AFE as defined by the idle configuration register immediately after ADC1 is enabled. It remains in the Idle step waiting for any of the 16 programmable steps to be enabled. When one or more step is enabled, the FSM sequencer will begin executing or skipping each step starting with the lowest and incrementing up through each step until the highest step has been executed or skipped. The FSM sequencer will execute enabled steps and skip disabled steps. Once all of the steps have been executed or skipped, the FSM sequencer will return to the Idle step or immediately begin repeating steps configured for continuous mode.

If the swipe threshold compare feature is enabled, the ADC output data will be compared to one of four swipe threshold registers. If the ADC output data value is lower than the swipe threshold, the ADC data is discarded (not saved in the FIFO), and the FSM sequencer continues to the next step. Once any step has reached or exceeded its swipe threshold, the FSM sequencer will save the ADC output data from the current step and all future steps without comparing ADC output data to the swipe threshold.

An end\_of\_sequence interrupt can be generated after the last enabled step has been executed. If any software enabled steps are configured for continuous operation and they are still enabled when the FSM sequencer has incremented through all the steps, the FSM sequencer will start the sequence again with the first enabled step. Hardware enabled steps are mapped to a hardware event and will need the hardware event to occur before being scheduled.

[Figure 12-2](#) illustrates how the FSM sequencer works. Each shaded box represents a FSM state. **Note:** [Figure 12-2](#) does not represent the number of adc\_clk cycles required by each state since some states implement user programmable delays that may require more than one adc\_clk cycle to complete.

Figure 12-2. FSM Sequencer

(1) A hardware event can be triggered by an external event or start of swipe interrupt, but the Data Threshold Flag is only set with the start of swipe interrupt and is only cleared when ADC1 is disabled.

(2) The STEPEN shadow register is updated after the FSM sequencer schedules the last step in order to queue up the next step.

### 12.3.1.1 Step Enable

A step is enabled or disabled via the STEPEN register.

The system software should only write to the STEPEN register when ADC1 is disabled or the FSM sequencer is in the Idle step. Therefore, it may be necessary to disable ADC1 before updating the STEPEN register if the FSM sequencer is executing back-to-back steps where it never enters the Idle step.

### 12.3.1.2 Step Configuration

#### 12.3.1.2.1 One-Shot (Single) or Continuous Mode

Each step can be configured, via the least significant bit of the MODE bit-field in the respective STEPCONFIGx register, to operate in one-shot or continuous mode. Steps configured for one-shot mode will perform a single conversion before being disabled by the FSM sequencer. Steps configured for continuous mode will automatically be re-enabled by the FSM sequencer after each conversion until disabled by software.

#### 12.3.1.2.2 Software- or Hardware-Enabled Steps

The user can configure each step to begin immediately after the step is enabled by software (SW Enabled), or wait for a hardware event to occur (HW Enabled). One of two sources can be selected for the hardware event.

One option is an internal comparator that compares the value of ADC output data to the value programmed into one of four swipe threshold registers. The hardware event will be triggered if the ADC output data value is greater than or equal to the selected swipe threshold when this option is selected. When using this option, an internal Data Threshold Flag will be set once the hardware event has occurred and this flag tells the FSM sequencer to continuously repeat all HW Enabled steps until ADC1 is disabled.

The other option is the EXT\_HW\_TRIGGER input signal which can be sourced from a device input terminal. When this option is selected, the hardware event will be triggered after the EXT\_HW\_TRIGGER input signal transitions from low to high and is held high for a period greater than two cycles of ocp\_clock. This hardware event will only schedule one complete sequence, even for continuous mode. If HW Enabled steps need to be executed again, a new hardware event must be generated after the previously triggered sequence has completed.

The EXT\_HW\_TRIGGER input cannot be used as a hardware event when the FSM sequencer is configured to use the start of swipe interrupt as a hardware event.

Each step can be configured to operate in SW Enabled mode or HW Enabled mode independently via the most significant bit of the MODE bit-field in the respective STEPCONFIGx register. However, the hardware event source is applied globally to all HW Enabled steps and configured via the CTRL register.

#### 12.3.1.2.3 Averaging of Samples

Each step can be configured, via the respective STEPCONFIGx register, to sample an input 1, 2, 4, 8, or 16 times and provide an average data value. If a step is configured to sample more than once, the additional samples are taken back-to-back immediately after the first sample. However, Open Delay is only applied to the first sample while Sample Delay is applied to all samples. Once the last sample has been taken the average data value will be stored in the FIFO unless the swipe threshold compare feature is enabled and the average data value is less than the swipe threshold.

#### 12.3.1.2.4 Preamplifier Gain Control

Four differential preamplifiers with a programmable voltage gain of 12, 14, 16, or 18 were added to ADC1 as one of several magnet card reader enhancements. Each step provides individual gain control for each preamplifier via the respective STEPCONFIGx register.

#### 12.3.1.2.5 *Swipe Threshold Compare Feature*

The swipe threshold compare feature is another magnet card reader enhancement. When this feature is enabled, via the respective STEPCONFIGx register, the FSM sequencer will automatically discard ADC data until it has exceeded a programmable swipe threshold value.

An internal Data Threshold Flag will be set once this hardware event has occurred and this flag tells the FSM sequencer to continuously repeat all HW Enabled steps until ADC1 is disabled.

#### 12.3.1.2.6 *Analog Multiplexer Input Select*

The AFE contains 4 analog multiplexers. Two 9-to-1 multiplexers are used to select the source connected to the positive input (INP) and negative input (INM) of the ADC. A 6-to-1 multiplexer is used to select the source connected to the positive reference input (ADC\_REFP) of the ADC. A 4-to-1 multiplexer is used to select the source connected to the negative reference input (ADC\_REFN) of the ADC.

Each step can be configured, via the respective STEPCONFIGx register, to select the appropriate ADC input sources. For more information, refer to the ADC1 AFE Functional Block Diagram ([Figure 12-5](#)) and the STEPCONFIG register field descriptions.

#### 12.3.1.2.7 *Differential Control*

ADC1 supports differential inputs and each step can be configured, via the respective STEPCONFIGx register, to select single-ended input mode or differential input mode.

Each enabled step should be configured for Differential mode when the AFE preamplifiers are not bypassed. Refer to the CTRL register field descriptions for information related to bypassing the AFE preamplifiers.

#### 12.3.1.2.8 *FIFO Select*

ADC1 contains two FIFOs and each step can be configured, via the respective STEPCONFIGx register, to store its ADC data into either FIFO.

#### 12.3.1.2.9 *Range Check Interrupt Enable*

Each step can be configured, via the respective STEPCONFIGx register, to compare the value of ADC data to high and low limits programmed in the ADCRANGE register. The out-of-range interrupt is generated if the value of ADC data is greater than the value of THR\_HIGH\_RANGE\_DATA or less than the value of THR\_LOW\_RANGE\_DATA. Refer to the ADCRANGE register field descriptions for information related to setting the high and low limits that trigger the out-of-range interrupt.

#### 12.3.1.2.10 *Swipe Threshold Register Pointer*

ADC1 provides four swipe threshold registers and each step can be configured, via the respective STEPCONFIGx register, to use one of these four swipe thresholds when the swipe threshold compare feature is enabled.

### 12.3.1.3 *Open Delay and Sample Delay*

The FSM sequencer provides two programmable delays for each step. Open Delay is used to control when the acquisition begins after the step starts and Sample Delay is used to control the acquisition period. Delays for each of the 16 steps can be configured independently via the respective STEPDELAYx register.

#### 12.3.1.3.1 *Open Delay*

Open Delay defaults to a value of zero which causes the acquisition period to begin as soon as the step starts. The start of the acquisition period can be delayed one adc\_clk clock period for each incremental value of Open Delay.

#### 12.3.1.3.2 Sample Delay

Sample Delay defaults to a value of zero which causes the acquisition period to be equal to two `adc_clk` clock periods. The acquisition period can be extended one `adc_clk` clock for each incremental value of Sample Delay.

When the AFE preamplifiers are not bypassed, the value of Sample Delay must be configured to provide a minimum acquisition period of 0.6  $\mu$ s which provides enough time for the preamplifiers outputs to settle. When the AFE preamplifiers are bypassed, the value of Sample Delay should be configured to provide enough time for the respective external voltage source to completely charge the AFE input capacitance during the acquisition period.

#### 12.3.1.4 Interrupts

ADC1 has 9 internal events that can trigger an interrupt to the processor. These events are logically or'ed together to produce a single interrupt to the processor. The user can individually enable or disable each interrupt source via the `IRQEN_SET` and `IRQEN_CLR` registers. Once an interrupt is generated, the `IRQSTS` register can be read to determine which interrupt source(s) interrupted the processor. The interrupt source(s) can be cleared by writing a '1' to the corresponding bit of the `IRQSTS` register.

##### 12.3.1.4.1 End of Sequence

An `END_OF_SEQUENCE` interrupt is generated after the FSM sequencer completes the last enabled step.

##### 12.3.1.4.2 FIFO Threshold

Each FIFO has the ability to generate an interrupt when the FIFO word count has reached a programmable threshold value. The `FIFO0_THR/FIFO1_THR` interrupts are generated when the value of `FIFO0COUNT/FIFO1COUNT` registers equals the word count threshold programmed in the respective `FIFO0THR/FIFO1THR` registers.

##### 12.3.1.4.3 FIFO Overrun and Underflow

Each FIFO also has the ability to generate overrun and underflow interrupts. To clear a FIFO underflow or FIFO overrun interrupt, the user should write a '1' to the status bit. ADC1 does not recover from these conditions automatically. Therefore, software will need to disable and re-enable ADC1 after this occurs. Before user can turn the module back on, they must first check if the FSM sequencer is in the Idle step by reading the `ADC_STATUS_REG` register.

##### 12.3.1.4.4 Out of Range

The `OUT_OF_RANGE` interrupt can be enabled or disabled on each step. If enabled, the ADC data value is compared to the low and high thresholds programmed in the global `ADCRANGE` register. The `OUT_OF_RANGE` interrupt is generated if the ADC data value is greater than the value programmed in `THR_HIGH_RANGE_DATA` or less than the value programmed in `THR_LOW_RANGE_DATA`.

##### 12.3.1.4.5 Start of Swipe

The `START_OF_SWIPE` interrupt can be enabled or disabled on each step. If enabled, the ADC data value is compared to one of four swipe threshold registers. The `START_OF_SWIPE` interrupt is generated if the ADC data value is greater than or equal to the value programmed in the swipe threshold register being pointed to by the respective `SWIPE_THR_REG_POINTER`. This interrupt can be configured as a hardware event which can be used to trigger HW enabled steps.

#### 12.3.1.5 DMA Requests

Each FIFO can be serviced by the processor or DMA. The user can individually enable or disable each FIFO DMA request via the `DMAEN_SET` and `DMAEN_CLR` registers.

A DMA request is generated when the value of `FIFO0COUNT/FIFO1COUNT` registers equals the word count threshold programmed in the respective `DMA0REQ/DMA1REQ` registers.

The DMA slave port allows for burst reads in order to effectively move the FIFO data. Refer to the DMA section for more information.

### 12.3.2 AFE Functional Description

The AFE contains a single 12-bit successive approximation ADC which can be connected to one of eight user selectable analog inputs for each step executed by the FSM sequencer. There is also an option to configure the ADC to operate in differential mode where it samples the differential voltage applied to two of eight user selectable analog inputs. When operating in differential mode, the user also has the option of routing the differential input signal through a programmable gain preamplifier.

The ADC sits idle until the FSM sequencer sends a Start of Conversion (SOC) pulse. Once the FSM sequencer sends a SOC pulse to the ADC, it begins sampling the analog input signal on the rising edge of SOC and continues sampling the analog input signal one cycle of `adc_clk` after the falling edge of SOC. The SOC pulse width will be the value of Sample Delay plus one `adc_clk` periods, so the total ADC acquisition time will be the value of Sample Delay plus two `adc_clk` periods. The ADC captures the analog input signal at the end of the acquisition period and starts conversion, which requires thirteen `adc_clk` periods to digitize the sampled input. An EOC signal is returned to the FSM sequencer to indicate the digital data is ready.

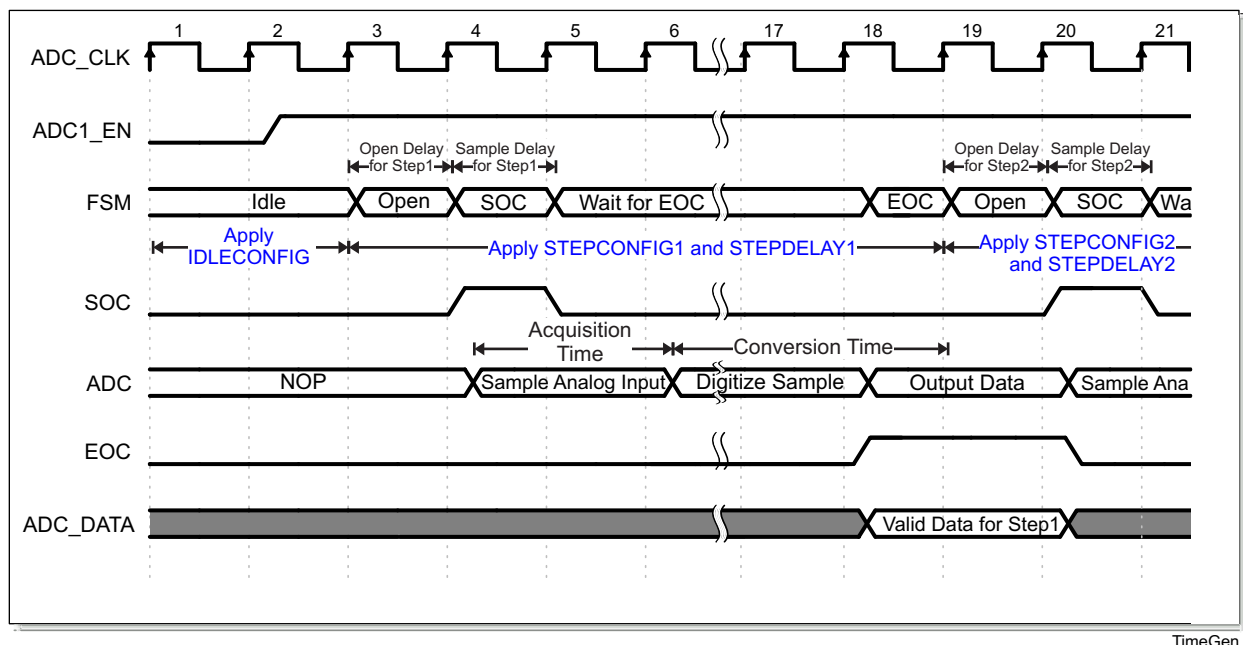

The ADC output is positive binary weighted data ranging from 0 to  $(2^{12} - 1)$ . When configured for single-ended mode, ADC output data values 0 to  $(2^{12} - 1)$  represents a corresponding input voltage that ranges from the ADC negative reference (REFM) voltage to the ADC positive reference (REFP) voltage. When configured for differential mode, ADC output data values 0 to  $((2^{12}/2) - 1)$  represents a corresponding negative differential input voltage that ranges from the ADC REFP voltage to the ADC REFM voltage and output data values  $(2^{12}/2)$  to  $(2^{12} - 1)$  represents a corresponding positive differential input voltage that ranges from the ADC REFM voltage to the ADC REFP voltage.

Using the minimum values of Open Delay and Sample Delay, the ADC can sample an analog input every 15 `adc_clk` periods.

Figure 12-3 illustrates the operation of the FSM sequencer and ADC, with indicators showing when the hardware configuration defined by `STEPCONFIGx` and `STEPDELAYx` registers are applied.

Figure 12-3 assumes both steps shown are software enabled with averaging turned off, an `OPENDELAY` value of 1, and `SAMPLEDELAY` value of 0. The analog input is sampled for the duration of the SOC pulse plus one cycle of the `ADC_CLK`. If the value of `OPENDELAY` were 0, it would appear as if the time associated with the Open portion of the FSM waveform would be removed from all the waveforms.

Figure 12-3. Example Timing Diagram for FSM Sequencer

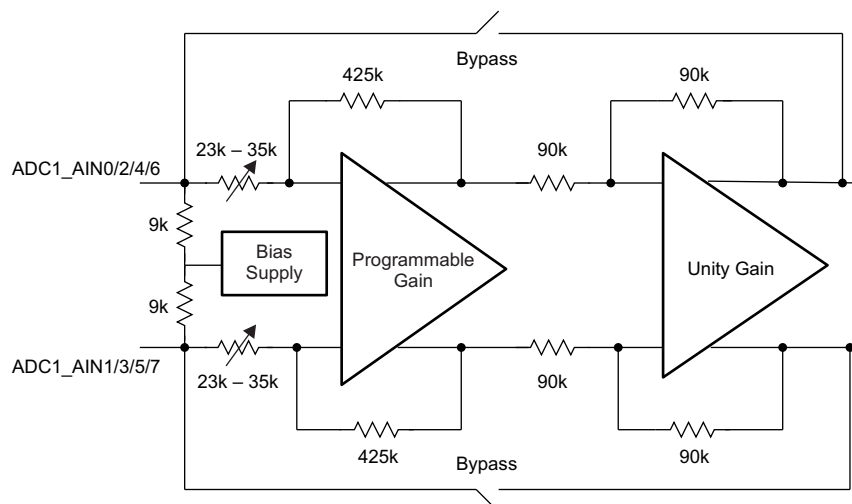

TimeGen

### 12.3.2.1 AFE Functional Block Diagram

The AFE has 8 analog inputs which can be configured as either singled-ended or differential inputs to the ADC. Each analog input has an internal bias resistor connected to a mid-supply voltage source of  $V_{DDA\_ADC1}$  divided by 2 that is shared with the other input associated with the preamplifier. A schematic of the input bias resistors, bias supply, and preamplifier is shown in [Figure 12-4](#).

**Figure 12-4. Input Bias Resistors, Bias Supply, and Preamplifier Schematic**

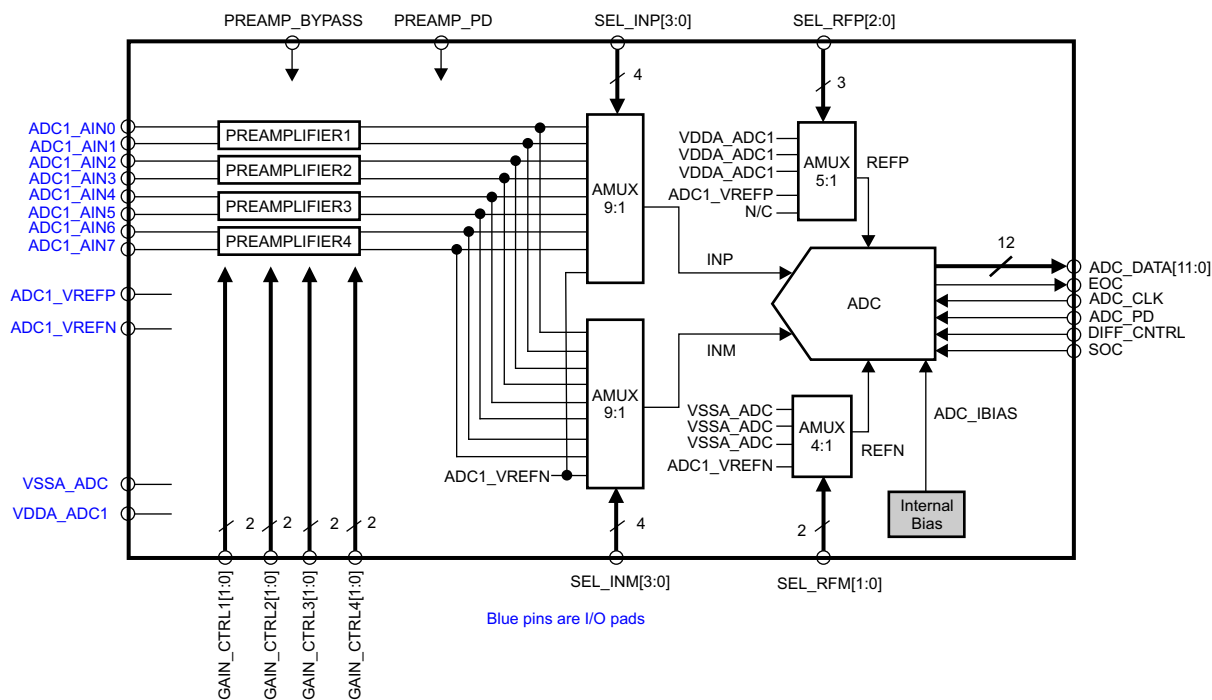

NOTE: The resistor values shown are typical values.

The four preamplifiers have individual programmable voltage gain of 12, 14, 16, or 18.

If the preamplifiers are not bypassed, the ADC must be configured to operate in differential mode with one of the following four input topologies. ADC1\_AIN1 paired with ADC1\_AIN2 where ADC1\_AIN1 is the positive input and ADC1\_AIN2 is the negative input to Preamplifier1. ADC1\_AIN3 paired with ADC1\_AIN4 where ADC1\_AIN3 is the positive input and ADC1\_AIN4 is the negative input to Preamplifier2. ADC1\_AIN5 paired with ADC1\_AIN6 where ADC1\_AIN5 is the positive input and ADC1\_AIN6 is the negative input to Preamplifier3. ADC1\_AIN7 paired with ADC1\_AIN8 where ADC1\_AIN7 is the positive input and ADC1\_AIN8 is the negative input to Preamplifier4. The differential input impedance of each preamplifier is 18 kohms biased to  $V_{DDA\_ADC1}$  divided by 2 with a 22k-50k ohm source.

If the preamplifiers are bypassed, the user may configure a step to use any 1 of the 8 inputs when operating in single-ended mode or any 2 of the 8 inputs when operating in differential mode. However, the effect of the bias resistors and bias supply on the attached voltage source(s) should be considered when using ADC1 as a general purpose ADC. Each internal bias supply has a high output impedance when turned off which will be the case when bypassing the preamplifiers. In this use case, the majority of the input leakage current from any of the analog inputs will be based on the external voltage source connected to the other input associated with the preamplifier. For example, the ADC would measure 0.975 volts on ADC1\_AIN1 if it were connected to a 1.0 volt, 1 kohm source while ADC1\_AIN2 is connected to a 0.5 volt, 1 kohm source. The error caused by the internal bias resistors can be minimized by connecting the analog inputs to low impedance voltage sources or leaving the other input associated with the preamplifier open-circuit.

Figure 12-5. AFE Functional Block Diagram

**Table 12-4. ADC1 AFE Signal List (see Figure 12-5)**

Signal	Type	Function
ADC_CLK	In	ADC clock input.

VSSA_ADC <sup>(1)</sup>	Power	ADC0 and ADC1 Analog Ground

<sup>(1)</sup> Signal connects to device terminals.

### 12.3.3 FIFOs and DMA

#### 12.3.3.1 FIFOs

The processor can read ADC data directly from the FIFO by using the respective FIFO0DATA or FIFO1DATA register. The internal logic will pop the next data from the FIFO and increment the FIFO read pointers.

The FIFO data will no longer be accessible after ADC1 is disabled because the FIFO pointers are reset. Therefore, it is important to read all FIFO data before disabling ADC1.

#### 12.3.3.2 DMA

ADC1 has a dedicated slave port for the DMA which allows it to perform continuous burst reads when accessing the FIFOs.

Each FIFO has its own DMA request which can be enabled via the DMAEN\_SET register and disabled via the DMAEN\_CLR register.

The first DMA request is generated after the FIFO leaves the EMPTY state and fills to the level programmed in the DMA\_REQUEST\_LEVEL bit field of the respective DMA0REQ or DMA1REQ register.

Subsequently, a new DMA request is automatically generated on the next clock cycle after the current DMA access completes if the previous DMA access did not empty the FIFO.

### 12.3.4 Power Management

ADC1 supports smart-idle mode where it shares slave idle/request handshaking with the PRCM that allows ADC1 to automatically enter an idle state when it is disabled or the FSM sequencer is in the Idle state with all the steps disabled.

Software also has the option to directly turn off power to the ADC by setting the ADC\_POWER\_DOWN bit in the CTRL register.

The preamplifiers in the AFE can be powered down by setting the PREAMP\_PD bit in the CTRL register. The preamplifiers are automatically powered down when they are bypassed by setting the PREAMP\_BYPASS bit in the CTRL register.

It is the software's responsibility to empty the FIFO before allowing ADC1 to enter the idle state. There should be no activity on the DMA slave port or MMR slave ports while ADC1 is in the idle state.

### 12.3.5 Magnetic Card Operation (Use Cases)

The AFE implemented in ADC1 provides four differential inputs with integrated preamplifiers that can be connected directly to magnetic heads to implement a magnetic card reader.

#### 12.3.5.1 Use Case 1

**Continuously sample a single differential analog input while comparing the ADC output data to a programmable swipe threshold value to detect a card swipe, then read one or more tracks of card data.**

The FSM sequencer should be configured to enable one software enabled continuous step that samples the appropriate differential input with its swipe compare feature enabled (bit 11 in STEPCONFIGx register). If more than one track is being read from the card after the swipe is detected, the FSM sequencer must also be configured with hardware enabled steps that sample the differential inputs associated with the other tracks.

This configuration will cause the FSM sequencer to continuously sample the input being sampled by the software enabled step and compare the ADC output data to the swipe threshold value that is programmed in one of four threshold registers. The appropriate threshold register is selected with the swipe threshold register pointer (bits 31:30 in STEPCONFIGx register). If the ADC output data corresponding to the analog input is less than swipe threshold, the ADC output data is discarded and the analog input is sampled again.

When the analog input produces an ADC output data value that is equal to or greater than the swipe threshold, the ADC output data will be stored in the FIFO and the start of swipe interrupt will be generated if enabled. The start of swipe interrupt can be configured to automatically enable the hardware enabled steps which sample the other differential inputs.

This example describes how a single track on the magnetic card can be used to detect a card swipe which causes all tracks of the magnetic card to be continuously sampled and resulting ADC output data stored in the FIFO until FSM sequencer is disabled (bit 0 in CTRL register).

The FSM sequencer will perform the following operations to implement this use case:

- Sample input associated with software enabled step (if data < swipe threshold, discard data),
- Sample input associated with software enabled step until data >= swipe threshold (save data, generate start of swipe interrupt),
- Sample inputs associated with hardware enabled steps then sample input associated with software enabled step (save data in the order samples were taken),
- Repeat previous sequence until ADC1 is disabled.

#### 12.3.5.2 Use Case 2

**Continuously sample all four differential analog inputs while comparing the ADC output data of each sample to its programmable swipe threshold value to detect a card swipe, then read four tracks of card data.**

The FSM sequencer should be configured to enable four software enabled continuous steps such that each step samples one of the four differential inputs with each step having its swipe compare feature enabled (bit 11 in STEPCONFIGx register).

This configuration will cause the FSM sequencer to continuously sample all four differential inputs and compare the ADC output data from each step to its respective swipe threshold value that is programmed in one of four threshold registers. The appropriate threshold register is selected with the swipe threshold register pointer (bits 31:30 in STEPCONFIGx register). If the ADC output data corresponding to the analog input is less than swipe threshold, the ADC output data is discarded and the next analog input is sampled.

When any of the four analog inputs produces an ADC output data value that is equal to or greater than its respective swipe threshold, the ADC output data from that step will be stored in the FIFO and the start of swipe interrupt will be generated if enabled. The FSM sequencer will continue executing the same sequence of steps with the next step being the one that follows the step which triggered the swipe interrupt. The ADC output data from each step following the swipe interrupt will be stored in the FIFO.

This example describes how all four tracks on the magnetic card can be used to detect a card swipe which causes all tracks of the magnetic card to be continuously sampled and resulting ADC output data stored in the FIFO until FSM sequencer is disabled (bit 0 in CTRL register).

The FSM sequencer will perform the following operations to implement this use case:

- Sample input associated with first software enabled step (if data < swipe threshold, discard data),
- Sample input associated with second software enabled step (if data < swipe threshold, discard data),
- Sample input associated with third software enabled step (if data < swipe threshold, discard data),
- Sample input associated with forth software enabled step (if data < swipe threshold, discard data),
- Repeat above sequence of steps until data >= swipe threshold (save data, generate start of swipe interrupt),
- Resume the same sequence of steps (save data in the order samples were taken),
- Continue until ADC1 is disabled.

### 12.3.6 Simultaneous Control of ADC0

ADC1 can be configured to control the AFE in ADC0. This feature is enabled by setting the SIMULTANEOUS\_CTRL bit in the CTRL register. When enabled, the ADC1 FSM sequencer sources the AFE control signals to both ADC0 AFE and ADC1 AFE. This causes the ADC0 AFE to perform the same operations as ADC1 AFE, but ADC0 AFE will be sampling ADC0 analog inputs while ADC1 AFE is sampling ADC1 analog inputs.

The ADC output data from ADC0 AFE is returned to the ADC1 FSM sequencer which stores this data in FIFO1 while storing ADC output data from ADC1 AFE in FIFO0. The FSM sequencer packs the 12 bits of ADC data and optional 4-bit step ID from both AFEs into a single 32-bit value when the processor or DMA reads FIFO0 when simultaneous control mode is enabled.

The ADC output data from ADC0 AFE is returned to the ADC1 FSM sequencer which stores this data in FIFO1 while storing ADC output data from ADC1 AFE in FIFO0. The FSM sequencer packs the 12 bits of ADC data and optional 4-bit step ID from both AFEs into a single 32-bit value when the processor or DMA reads FIFO0 when simultaneous control mode is enabled.

Figure 12-6 and Table 12-5 describe the contents of the ADC1\_FIFO0DATA read by the processor or DMA when ADC1 is operating in simultaneous control mode.

For a description of ADC1\_FIFO0DATA when ADC1 is not operating in simultaneous control mode, see Section 12.4.1.55.

**Figure 12-6. ADC1\_FIFO0DATA Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ADC0CHNLID				ADC0DATA											
R-0h				R-0h											
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ADC1CHNLID				ADC1DATA											
R-0h				R-0h											

**Table 12-5. ADC1\_FIFO0DATA Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-28	ADC0CHNLID	R	0h	ADC0 Step ID Tag of step that captured ADC0 data. These bits will be 0000b if STEP_ID_TAG = 0b.
27-16	ADC0DATA	R	0h	12-bit ADC0 data.
15-12	ADC1CHNLID	R	0h	ADC1 Step ID Tag of step that captured ADC1 data. These bits will be 0000b if STEP_ID_TAG = 0b.
11-0	ADC1DATA	R	0h	12-bit ADC1 data.

All DMA requests and FIFO interrupts are initiated by the ADC1 FSM sequencer based on the conditions of FIFO0 data only. All DMA requests and FIFO interrupts related to FIFO1 should be disabled.

Below is a block diagram for the integration of ADC0 and ADC1 when operating in simultaneous mode.

**Figure 12-7. Integration of ADC0 and ADC1 in Simultaneous Mode**

## 12.4 Registers

ADC1 only supports 32-bit aligned read/write register accesses.

### 12.4.1 ADC1 Registers

Table 12-6 lists the memory-mapped registers for the ADC1. All register offset addresses not listed in Table 12-6 should be considered as reserved locations and the register contents should not be modified.

Generated Address Block

0	RESERVED	R		

#### 12.4.1.4 ADC1\_IRQSTS Register (offset = 28h) [reset = 0h]

ADC1\_IRQSTS is shown in [Figure 12-11](#) and described in [Table 12-10](#).

**Figure 12-11. ADC1\_IRQSTS Register**

**Table 12-10. ADC1\_IRQSTS Register Field Descriptions**

Bit	Field	Type	Reset	Description
9	START_OF_SWIPE	R/W	0h	Write 0: No action. Read 0: No (enabled) event pending. Read 1: Event pending. Write 1: Clear (raw) event.
8	OUT_OF_RANGE	R/W	0h	Write 0: No action. Read 0: No (enabled) event pending. Read 1: Event pending. Write 1: Clear (raw) event.
7	FIFO1_UNDERFLOW	R/W	0h	Write 0: No action. Read 0: No (enabled) event pending. Read 1: Event pending. Write 1: Clear (raw) event.
6	FIFO1_OVERRUN	R/W	0h	Write 0: No action. Read 0: No (enabled) event pending. Read 1: Event pending. Write 1: Clear (raw) event.
5	FIFO1_THR	R/W	0h	Write 0: No action. Read 0: No (enabled) event pending. Read 1: Event pending. Write 1: Clear (raw) event.
4	FIFO0_UNDERFLOW	R/W	0h	Write 0: No action. Read 0: No (enabled) event pending. Read 1: Event pending. Write 1: Clear (raw) event.
3	FIFO0_OVERRUN	R/W	0h	Write 0: No action. Read 0: No (enabled) event pending. Read 1: Event pending. Write 1: Clear (raw) event.
2	FIFO0_THR	R/W	0h	Write 0: No action. Read 0: No (enabled) event pending. Read 1: Event pending. Write 1: Clear (raw) event.
1	END_OF_SEQUENCE	R/W	0h	Write 0: No action. Read 0: No (enabled) event pending. Read 1: Event pending. Write 1: Clear (raw) event.
0	RESERVED	R		

### 12.4.1.5 ADC1\_IRQEN\_SET Register (offset = 2Ch) [reset = 0h]

ADC1\_IRQEN\_SET is shown in [Figure 12-12](#) and described in [Table 12-11](#).

**Figure 12-12. ADC1\_IRQEN\_SET Register**

**Table 12-11. ADC1\_IRQEN\_SET Register Field Descriptions**

Bit	Field	Type	Reset	Description
9	START_OF_SWIPE	R/W	0h	Write 0: No action. Read 0: Interrupt disabled (masked). Read 1: Interrupt enabled. Write 1: Enable interrupt.
8	OUT_OF_RANGE	R/W	0h	Write 0: No action. Read 0: Interrupt disabled (masked). Read 1: Interrupt enabled. Write 1: Enable interrupt.
7	FIFO1_UNDERFLOW	R/W	0h	Write 0: No action. Read 0: Interrupt disabled (masked). Read 1: Interrupt enabled. Write 1: Enable interrupt.
6	FIFO1_OVERRUN	R/W	0h	Write 0: No action. Read 0: Interrupt disabled (masked). Read 1: Interrupt enabled. Write 1: Enable interrupt.
5	FIFO1_THR	R/W	0h	Write 0: No action. Read 0: Interrupt disabled (masked). Read 1: Interrupt enabled. Write 1: Enable interrupt.
4	FIFO0_UNDERFLOW	R/W	0h	Write 0: No action. Read 0: Interrupt disabled (masked). Read 1: Interrupt enabled. Write 1: Enable interrupt.
3	FIFO0_OVERRUN	R/W	0h	Write 0: No action. Read 0: Interrupt disabled (masked). Read 1: Interrupt enabled. Write 1: Enable interrupt.
2	FIFO0_THR	R/W	0h	Write 0: No action. Read 0: Interrupt disabled (masked). Read 1: Interrupt enabled. Write 1: Enable interrupt.
1	END_OF_SEQUENCE	R/W	0h	Write 0: No action. Read 0: Interrupt disabled (masked). Read 1: Interrupt enabled. Write 1: Enable interrupt.
0	RESERVED	R		

### 12.4.1.6 ADC1\_IRQEN\_CLR Register (offset = 30h) [reset = 0h]

ADC1\_IRQEN\_CLR is shown in [Figure 12-13](#) and described in [Table 12-12](#).

**Figure 12-13. ADC1\_IRQEN\_CLR Register**

**Table 12-12. ADC1\_IRQEN\_CLR Register Field Descriptions**

Bit	Field	Type	Reset	Description
9	START_OF_SWIPE	R/W	0h	Write 0: No action. Read 0: Interrupt disabled (masked). Read 1: Interrupt enabled. Write 1: Disable interrupt.
8	OUT_OF_RANGE	R/W	0h	Write 0: No action. Read 0: Interrupt disabled (masked). Read 1: Interrupt enabled. Write 1: Disable interrupt.
7	FIFO1_UNDERFLOW	R/W	0h	Write 0: No action. Read 0: Interrupt disabled (masked). Read 1: Interrupt enabled. Write 1: Disable interrupt.
6	FIFO1_OVERRUN	R/W	0h	Write 0: No action. Read 0: Interrupt disabled (masked). Read 1: Interrupt enabled. Write 1: Disable interrupt.
5	FIFO1_THR	R/W	0h	Write 0: No action. Read 0: Interrupt disabled (masked). Read 1: Interrupt enabled. Write 1: Disable interrupt.
4	FIFO0_UNDERFLOW	R/W	0h	Write 0: No action. Read 0: Interrupt disabled (masked). Read 1: Interrupt enabled. Write 1: Disable interrupt.
3	FIFO0_OVERRUN	R/W	0h	Write 0: No action. Read 0: Interrupt disabled (masked). Read 1: Interrupt enabled. Write 1: Disable interrupt.
2	FIFO0_THR	R/W	0h	Write 0: No action. Read 0: Interrupt disabled (masked). Read 1: Interrupt enabled. Write 1: Disable interrupt.
1	END_OF_SEQUENCE	R/W	0h	Write 0: No action. Read 0: Interrupt disabled (masked). Read 1: Interrupt enabled. Write 1: Disable interrupt.
0	RESERVED	R		

### 12.4.1.7 ADC1\_DMAEN\_SET Register (offset = 38h) [reset = 0h]

ADC1\_DMAEN\_SET is shown in [Figure 12-14](#) and described in [Table 12-13](#).

**Figure 12-14. ADC1\_DMAEN\_SET Register**

**Table 12-13. ADC1\_DMAEN\_SET Register Field Descriptions**

Bit	Field	Type	Reset	Description
1	EN1	R/W	0h	Enable DMA request FIFO1. Write 0: No action. Read 0: DMA line disabled. Read 1: DMA line enabled. Write 1: Enable DMA line.
0	EN0	R/W	0h	Enable DMA request FIFO0. Write 0: No action. Read 0: DMA line disabled. Read 1: DMA line enabled. Write 1: Enable DMA line.

### 12.4.1.8 ADC1\_DMAEN\_CLR Register (offset = 3Ch) [reset = 0h]

ADC1\_DMAEN\_CLR is shown in [Figure 12-15](#) and described in [Table 12-14](#).

**Figure 12-15. ADC1\_DMAEN\_CLR Register**

**Table 12-14. ADC1\_DMAEN\_CLR Register Field Descriptions**

Bit	Field	Type	Reset	Description
1	EN1	R/W	0h	Disable DMA request FIFO1. Write 0: No action. Read 0: DMA line disabled. Read 1: DMA line enabled. Write 1: Disable DMA line.
0	EN0	R/W	0h	Disable DMA request FIFO0. Write 0 : No action. Read 0 : DMA line disabled. Read 1: DMA line enabled. Write 1: Disable DMA line.

### 12.4.1.9 ADC1\_CTRL Register (offset = 40h) [reset = 0h]

ADC1\_CTRL is shown in [Figure 12-16](#) and described in [Table 12-15](#).

**Figure 12-16. ADC1\_CTRL Register**

**Table 12-15. ADC1\_CTRL Register Field Descriptions**

Bit	Field	Type	Reset	Description
9	RESERVED	R		
8	HW_EVT_MAPPING	R/W	0h	0->Map hardware event to the start of swipe interrupt. 1->Map hardware event to hardware event input (external).
7	RESERVED	R		
6	PREAMP_BYPASS	R/W	0h	Analog input will bypass the PreAmplifier: 0: PreAmp is enabled by default. 1 : Write 1 to bypass PreAmp.
5	PREAMP_PD	R/W	0h	PreAmp Power Down control. 0: PreAmp is powered up (default). 1 : Write 1 to power down PreAmp.
4	ADC_POWER_DOWN	R/W	0h	ADC Power Down control. 0: AFE is powered up (default). 1 : Write 1 to power down AFE.
3	RESERVED	R		
2	SIMULTANEOUS_CTRL	R/W	0h	Enables Simultaneous Control of both AFEs. 0 -> Control only MCR_AFE. 1 -> Control both MCR_AFE and TSC_AFE. See the Programmers/Usage guide section for Simultaneous Mode Features/Limitations.
1	STEP_ID_TAG	R/W	0h	Writing 1 to this bit will store the Step ID number with the captured ADC data in the FIFO. 0: Write zeros. 1: Store the channel ID tag.
0	ADC1_EN	R/W	0h	ADC1 module enable bit. After programming all the steps and configuration registers, write a 1 to this bit to turn on ADC1. Writing a 0 will disable the module (after the current conversion is completed).

### 12.4.1.10 ADC1\_ADCSTAT Register (offset = 44h) [reset = 10h]

ADC1\_ADCSTAT is shown in [Figure 12-17](#) and described in [Table 12-16](#).

**Figure 12-17. ADC1\_ADCSTAT Register**

**Table 12-16. ADC1\_ADCSTAT Register Field Descriptions**

Bit	Field	Type	Reset	Description
5	FSM_BUSY	R	0h	Status of OCP FSM and ADC FSM. 0 idle. 1 - busy.
4-0	STEP_ID	R	10h	Below are encoded values: 10000 Idle. 10001 Reserved. 00000 Step 1. 00001 Step 2. 00010 Step 3. 00011 Step 4. 00100 Step 5. 00101 Step 6. 00110 Step 7. 00111 Step 8. 01000 Step 9. 01001 Step 10. 01010 Step 11. 01011 Step 12. 01100 Step 13. 01101 Step 14. 01110 Step 15. 01111 Step 16.

### 12.4.1.11 ADC1\_ADCRANGE Register (offset = 48h) [reset = 0h]

ADC1\_ADCRANGE is shown in [Figure 12-18](#) and described in [Table 12-17](#).

**Figure 12-18. ADC1\_ADCRANGE Register**

**Table 12-17. ADC1\_ADCRANGE Register Field Descriptions**

Bit	Field	Type	Reset	Description
27-16	THR_HIGH_RANGE_DATA	R/W	0h	Sampled ADC data is compared to this value. If the interrupt is enabled, and if the sampled data is > value then interrupt is generated. Each step can enable or disable this check.
15-12	RESERVED	R		
11-0	THR_LOW_RANGE_DATA	R/W	0h	Sampled ADC data is compared to this value. If the interrupt is enabled, and if the sampled data is < value then interrupt is generated. Each step can enable or disable this check.

### 12.4.1.12 ADC1\_CLKDIV Register (offset = 4Ch) [reset = 0h]

ADC1\_CLKDIV is shown in [Figure 12-19](#) and described in [Table 12-18](#).

**Figure 12-19. ADC1\_CLKDIV Register**

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ADC_CLKDIV															
R/W-0h															

**Table 12-18. ADC1\_CLKDIV Register Field Descriptions**

Bit	Field	Type	Reset	Description
15-0	ADC_CLKDIV	R/W	0h	The input ADC clock will be divided by this value and sent to the AFE. Program to the value minus 1.

### 12.4.1.13 ADC1\_STEPEN Register (offset = 54h) [reset = 0h]

ADC1\_STEPEN is shown in [Figure 12-20](#) and described in [Table 12-19](#).

**Figure 12-20. ADC1\_STEPEN Register**

**Table 12-19. ADC1\_STEPEN Register Field Descriptions**

Bit	Field	Type	Reset	Description
16	STEP16	R/W	0h	Enable step 16.
15	STEP15	R/W	0h	Enable step 15.
14	STEP14	R/W	0h	Enable step 14.
13	STEP13	R/W	0h	Enable step 13.
12	STEP12	R/W	0h	Enable step 12.
11	STEP11	R/W	0h	Enable step 11.
10	STEP10	R/W	0h	Enable step 10.
9	STEP9	R/W	0h	Enable step 9.
8	STEP8	R/W	0h	Enable step 8.
7	STEP7	R/W	0h	Enable step 7.
6	STEP6	R/W	0h	Enable step 6.
5	STEP5	R/W	0h	Enable step 5.
4	STEP4	R/W	0h	Enable step 4.
3	STEP3	R/W	0h	Enable step 3.
2	STEP2	R/W	0h	Enable step 2.
1	STEP1	R/W	0h	Enable step 1.
0	RESERVED	R		

### 12.4.1.14 ADC1\_IDLECONFIG Register (offset = 58h) [reset = 0h]

ADC1\_IDLECONFIG is shown in [Figure 12-21](#) and described in [Table 12-20](#).

**Figure 12-21. ADC1\_IDLECONFIG Register**

**Table 12-20. ADC1\_IDLECONFIG Register Field Descriptions**

Bit	Field	Type	Reset	Description
29-28	GAIN_CTRL4	R/W	0h	00: Gain of 12. 01: Gain of 14. 10: Gain of 16. 11: Gain of 18.
27-26	RESERVED	R		
25	DIFF_CNTRL	R/W	0h	Differential Control Pin. 0 -> Single Ended. 1 -> Differential Pair Enable.
24-23	SEL_RFM_SWC_1_0	R/W	0h	SEL_RFM pins software configuration. 00 - VSSA. 01 - VSSA. 10 - VSSA. 11 ADCREFM.
22-19	SEL_INP_SWC_3_0	R/W	0h	SEL_INP pins software configuration. 0000 -> Channel 1. 0111 -> Channel 8. 1xxx -> ADCREFM.
18-15	SEL_INM_SWM_3_0	R/W	0h	SEL_INM pins for neg differential. 0000 -> Channel 1. 0111 -> Channel 8. 1xxx -> ADCREFM.
14-12	SEL_RFP_SWC_2_0	R/W	0h	SEL_RFP pins software configuration. 000 - VDDA. 001 - VDDA. 010 - VDDA. 011 - ADCREFP. 1xx - Reserved.
11	RESERVED	R		
10-9	GAIN_CTRL3	R/W	0h	00: Gain of 12. 01: Gain of 14. 10: Gain of 16. 11: Gain of 18.
8-7	GAIN_CTRL2	R/W	0h	00: Gain of 12. 01: Gain of 14. 10: Gain of 16. 11: Gain of 18.
6-5	GAIN_CTRL1	R/W	0h	00: Gain of 12. 01: Gain of 14. 10: Gain of 16. 11: Gain of 18.

Bit	Field	Type	Reset	Description
31-24	SAMPLEDELAY	R/W	0h	This register will control the number of ADC clock cycles to sample (hold SoC high). Any value programmed here will be added to the minimum requirement of 1 clock cycle.
23-18	RESERVED	R		
17-0	OPENDELAY	R/W	0h	Program the number of ADC clock cycles to wait after applying the step configuration registers and before sending the start of ADC conversion.

**12.4.1.49 ADC1\_FIFO0COUNT Register (offset = E4h) [reset = 0h]**

ADC1\_FIFO0COUNT is shown in [Figure 12-56](#) and described in [Table 12-55](#).

**Figure 12-56. ADC1\_FIFO0COUNT Register**

**Table 12-55. ADC1\_FIFO0COUNT Register Field Descriptions**

Bit	Field	Type	Reset	Description
6-0	WORDS_IN_FIFO0	R	0h	Number of words currently in the FIFO0.

#### 12.4.1.50 ADC1\_FIFO0THR Register (offset = E8h) [reset = 0h]

ADC1\_FIFO0THR is shown in [Figure 12-57](#) and described in [Table 12-56](#).

**Figure 12-57. ADC1\_FIFO0THR Register**

**Table 12-56. ADC1\_FIFO0THR Register Field Descriptions**

Bit	Field	Type	Reset	Description
5-0	FIFO0_THR_LEVEL	R/W	0h	Program the desired FIFO0 data sample level to reach before generating interrupt to CPU (program to value minus 1).

### 12.4.1.51 ADC1\_DMA0REQ Register (offset = ECh) [reset = 0h]

ADC1\_DMA0REQ is shown in [Figure 12-58](#) and described in [Table 12-57](#).

**Figure 12-58. ADC1\_DMA0REQ Register**

**Table 12-57. ADC1\_DMA0REQ Register Field Descriptions**

Bit	Field	Type	Reset	Description
5-0	DMA_REQUEST_LEVEL	R/W	0h	Number of words in FIFO0 before generating a DMA request (program to value minus 1).

#### 12.4.1.52 ADC1\_FIFO1COUNT Register (offset = F0h) [reset = 0h]

ADC1\_FIFO1COUNT is shown in [Figure 12-59](#) and described in [Table 12-58](#).

**Figure 12-59. ADC1\_FIFO1COUNT Register**

**Table 12-58. ADC1\_FIFO1COUNT Register Field Descriptions**

Bit	Field	Type	Reset	Description
6-0	WORDS_IN_FIFO1	R	0h	Number of words currently in the FIFO1.

### 12.4.1.53 ADC1\_FIFO1THR Register (offset = F4h) [reset = 0h]

ADC1\_FIFO1THR is shown in [Figure 12-60](#) and described in [Table 12-59](#).

**Figure 12-60. ADC1\_FIFO1THR Register**

**Table 12-59. ADC1\_FIFO1THR Register Field Descriptions**

Bit	Field	Type	Reset	Description
5-0	FIFO1_THR_LEVEL	R/W	0h	Program the desired FIFO1 data sample level to reach before generating interrupt to CPU (program to value minus 1).

#### 12.4.1.54 ADC1\_DMA1REQ Register (offset = F8h) [reset = 0h]

ADC1\_DMA1REQ is shown in [Figure 12-61](#) and described in [Table 12-60](#).

**Figure 12-61. ADC1\_DMA1REQ Register**

**Table 12-60. ADC1\_DMA1REQ Register Field Descriptions**

Bit	Field	Type	Reset	Description
5-0	DMA_REQUEST_LEVEL	R/W	0h	Number of words in FIFO1 before generating a DMA request (program to value minus 1).

#### 12.4.1.55 ADC1\_FIFO0DATA Register (offset = 100h) [reset = 0h]

ADC1\_FIFO0DATA is shown in [Figure 12-62](#) and described in [Table 12-61](#).

**Figure 12-62. ADC1\_FIFO0DATA Register**

**Table 12-61. ADC1\_FIFO0DATA Register Field Descriptions**

Bit	Field	Type	Reset	Description
19-16	ADCCHNLID	R	0h	Optional ID tag of channel that captured the data. If tag option is disabled, these bits will be 0.
15-12	RESERVED	R		
11-1	ADCDATA	R	0h	12 bit sampled ADC converted data value stored in FIFO0.
0	RESERVED	R		

### 12.4.1.56 ADC1\_FIFO1DATA Register (offset = 200h) [reset = 0h]

ADC1\_FIFO1DATA is shown in [Figure 12-63](#) and described in [Table 12-62](#).

**Figure 12-63. ADC1\_FIFO1DATA Register**

**Table 12-62. ADC1\_FIFO1DATA Register Field Descriptions**

Bit	Field	Type	Reset	Description
19-16	ADCCHNLID	R	0h	Optional ID tag of channel that captured the data. If tag option is disabled, these bits will be 0.

## 13.1 Introduction

### 13.1.1 DSS Features

The general features of the DSS module include:

- Display Controller
  - Display Modes
    - Programmable pixel memory formats (Palletized: 1, 2, 4, 8-bit per pixel; RGB 16, and 24-bit per pixel; and YUV 4:2:2)
    - Programmable display size (up to 2048 x 2048)
    - 256 x 24-bit entries palette in RGB
    - Programmable pixel rate (up to 100 MHz)
  - Display Support
    - Four types of displays are supported: Passive and Active colors, Passive and Active monochromes.
    - 4-/8-bit Monochrome Passive panel interface support (15 grayscale levels supported using dithering block)
    - RGB 8-bit Color Passive panel interface support (3,375 colors supported for color panel using dithering block).
    - RGB 12/16/18/24-bit Active panel interface support (replicated or dithered encoded pixel values).
    - Remote Frame Buffer (embedded in the LCD panel) support through the RFBI module
    - Partial refresh of the remote frame buffer through the RFBI module
    - Partial display
    - Multiple cycles output format on 8/9/12/16bit interface (TDM)
  - Signal Processing
    - Overlay and Windowing support for one Graphics layer (RGB or CLUT) and two Video layers (YUV 4:2:2, RGB16 and RGB24)
    - RGB 24-bit support on the display interface, optionally dithered to RGB 18-bit pixel output + 6-Bit Frame rate Control (spatial and temporal)
    - Transparency color key (source and destination)
    - Synchronized buffer update
    - Gamma Curve Support
    - Multiple-buffer support
    - Cropping Support
    - Merge capability of the DMA FIFO for use by a single pipeline in case of DVFS
    - Color Phase rotation
  - Interrupt line and DMA line trigger signals
    - The LCD DMA is a secure transaction initiator on the L3 interconnect.
- Remote Frame Buffer Interface
  - Access to RFB's "direct MPU interface"
    - Sending commands to the RFB panel.
    - Sending data to the RFB panel, received from the Display controller or from the MPU (through the L4 OCP slave port)
    - Reading data/status from the RFB to the OCP slave port.
  - RFB interface
    - 8/9/12/16-bit parallel interface (up to QVGA@30fps at nominal voltage)
    - Two programmable configurations for two devices connected to the RFBI module.

- Tearing Effect control logic (Horizontal Synchronization (HSync) and Vertical Synchronization (VSync) embedded in a single signal (TE) or using two signals (HS+VS)).
- Data formats
  - Programmable pixel memory formats (12-, 16-, 18- and 24-bit-per-pixel modes in RGB format)
  - Programmable output formats on one/multiple cycles per pixel (data from Display controller and from L4) (TDM)

### 13.1.2 **Unsupported Features**

The display subsystem does not support the following features.

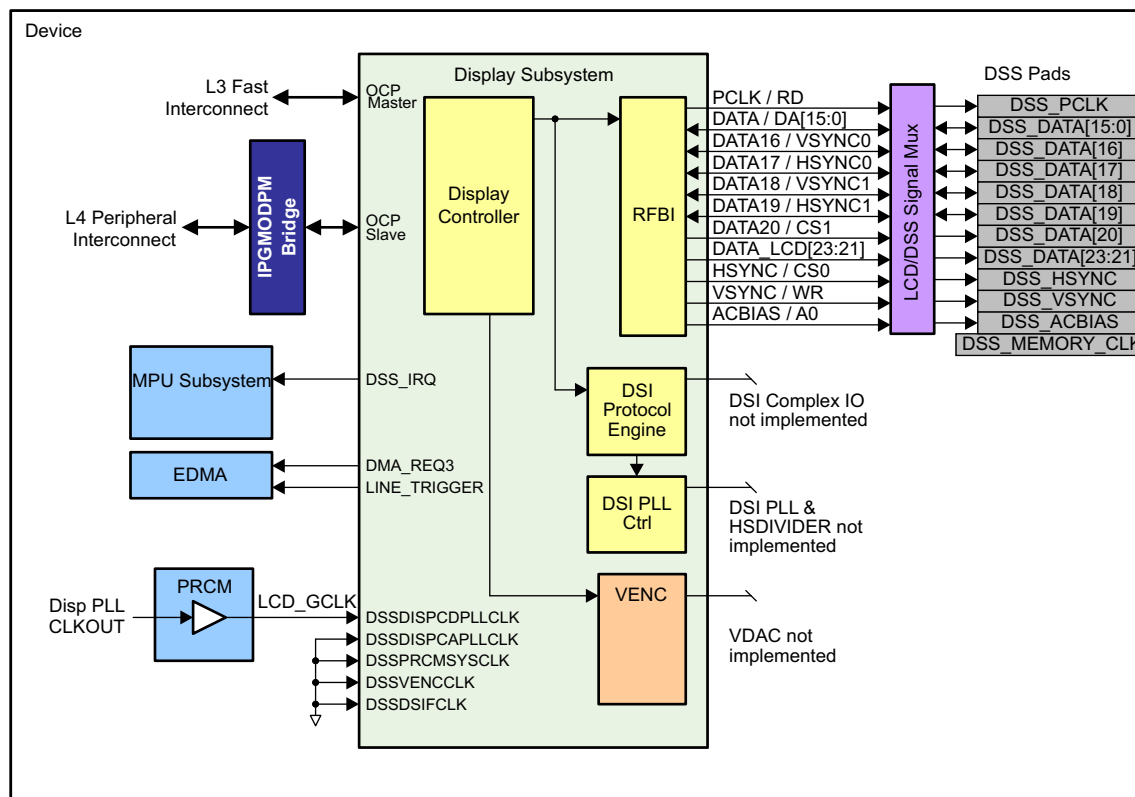

**Table 13-1. Unsupported Display Subsystem Features**

Feature	Reason
FlatLink Serial Display	SDI Complex I/Os not implemented
MIPI Serial Displays	DSI Complex I/Os not implemented
NTSC/PAL Displays	Video DAC not implemented
Rotation/Mirroring	No SDRAM rotation engine implemented on device

## 13.2 Integration

This device includes a Display Subsystem (DSS) that reads display data from external memory and drives several different types of LCD displays. The Display Subsystem integration is shown in [Figure 13-1](#).

**Figure 13-1. DSS Integration**

### 13.2.1 DSS Connectivity Attributes

The general connectivity attributes for the DSS module are shown in [Table 13-2](#).

**Table 13-2. DSS Connectivity Attributes**

Attributes	Type
Power Domain	Peripheral Domain
Clock Domain	PD_PER_L3_GCLK (OCP master clock) PD_PER_L4LS_GCLK (OCP slave clock) PD_PER_LCD_GCLK (Functional clock)
Reset Signals	PER_DOM_RST_N
Idle/Wakeup Signals	Standby Smart Idle
Interrupt Requests	1 interrupt to MPU Subsystem (DSSINT)
DMA Requests	2 DMA requests to EDMA
Physical Address	L4 peripheral slave port

### 13.2.2 DSS Clock and Reset Management

The DSS module uses the OCP interface and multiple functional clocks. The L4 slave interface runs at half the frequency of the L3 Master interface. The functional clocks come from the device's display PLL rather than a dedicated DSI\_PLL. When the display PLL is in bypass mode, its output is sourced by either CORE\_CLKOUTM6 or PER\_CLKOUTM2.

**Table 13-3. DSS Clock Signals**

Clock Signal	Maximum Frequency	Reference Source	Comments
LCDL3OCPIFCLK Master interface	200 MHz	CORE_CLKOUTM4	pd_per_l3_gclk from PRCM
LCDL3OCPIFENAB L3 phase clock enable used to create L4 clock	100 MHz	CORE_CLKOUTM4 / 2	pd_per_l4ls_gclk from PRCM
LCDPRCMSYSCLK Functional clock	N/A	N/A	DSI PLL source clock not needed since DSI PLL is not present
LCDDISPCAPLLCLK L3 phase clock enable used to create L4 clock	N/A	N/A	DSSDISPCDPLLCLK is default display controller clock source
LCDDISPCDPLLCLK	200 MHz	Display PLL CLKOUT	pd_per_lcd_gclk from PRCM
LCDVENCCLK Video encoder functional clock	N/A	N/A	VENC not supported
LCDDSIIFCLK DSI functional clock	N/A	N/A	DSI not supported

### 13.2.3 DSS Pin List

The display subsystem external interface pins are shown in [Table 13-4](#). Pin function depends on the operating mode (bypass or RFBI). The DSSLCDIR[2:0] control signals are used to control the pad OEN of the associated signals as shown.

**Table 13-4. DSS Pin List**

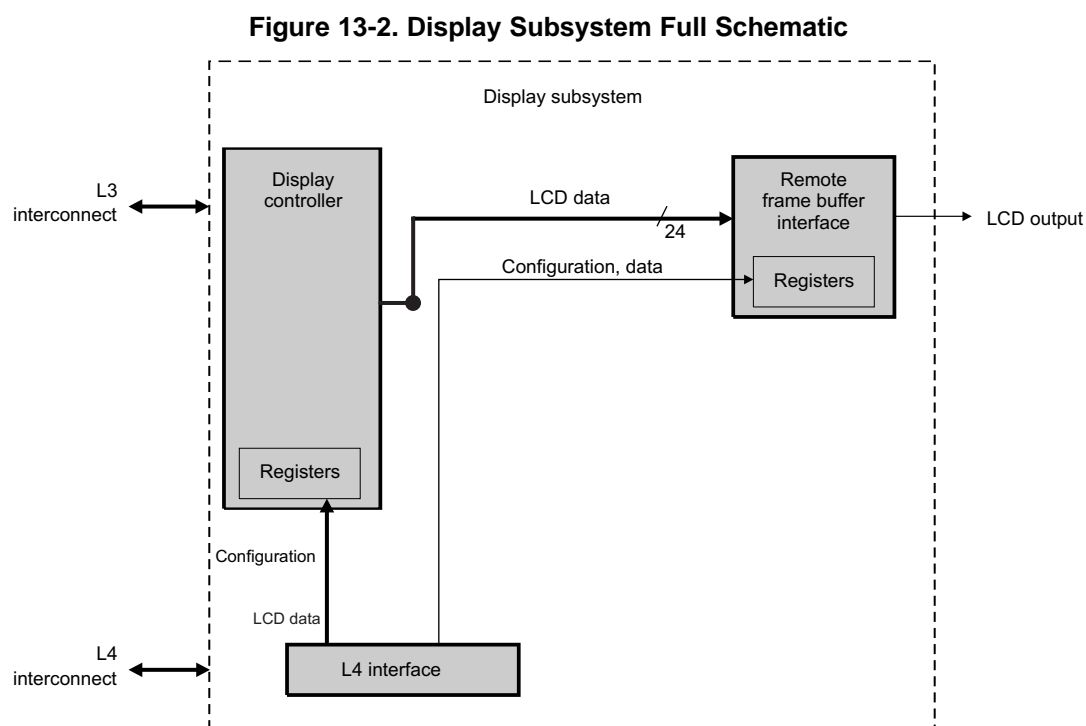

Pin Name	Pin Function	Type	Description	DSSLCDIR Control Signal
dss_pclk	DISPC_PCLK / RFBI_RD	O	Pixel Clock / RFBI Read Enable	1
dss_data[15:0]	DISPC_DATA_LCD / RFBI_DA[15:0]	I/O/Z	Pixel Data Bus / RFBI Data	0
dss_data16	DISPC_DATA_LCD16 / RFBI_TE_VSYNC0	I/O/Z	Pixel Data Bus / RFBI Tearing Effect or Vertical Sync 0	2
dss_data17	DISPC_DATA_LCD17 / RFBI_HSYNC0	I/O/Z	Pixel Data Bus / RFBI Horizontal Sync 0	2
dss_data18	DISPC_DATA_LCD18 / RFBI_TE_VSYNC1	I/O/Z	Pixel Data Bus / RFBI Tearing Effect Vertical Sync 1	2
dss_data19	DISPC_DATA_LCD19 / RFBI_HSYNC1	I/O/Z	Pixel Data Bus / RFBI Horizontal Sync 1	2
dss_data20	DISPC_DATA_LCD20 / RFBI_CS1	O	Pixel Data Bus / RFBI Chip Select 0	1
dss_data[23:21]	DISPC_DATA_LCD[23:21]	O	Pixel Data Bus	1
dss_hsync	DISPC_HSYNC / RFBI_CS0	O	Horizontal Sync / RFBI Chip Select 0	1
dss_vsync	DISPC_VSYNC / RFBI_WR	O	Vertical Sync / RFBI Write Enable	1
dss_ac_bias_en	DISPC_ACBIAS / RFBI_A0	O	AC Bias Enable / RFBI Command/Data indicator	1

## 13.3 Functional Description

This section describes the functions of the LCD display support by describing the display controller and RFBI modules.

### 13.3.1 Block Diagram

Figure 13-2 is a schematic of the display subsystem.

### 13.3.2 Display Subsystem Environment

This section describes the two main functions handled by the display subsystem:

- LCD support
- TV display support

#### 13.3.2.1 LCD Support

LCD panels can be connected to the display subsystem of the device using parallel and/or serial interfaces.

[Table 13-5](#) provides more details on the supported interfaces to LCD panels, and the respective pad and signal configurations.

**Table 13-5. LCD Interface Signals and Configurations**

Pads and Signals Configuration

**Table 13-5. LCD Interface Signals and Configurations (continued)**

Pads and Signals Configuration						
Pad names at device level boundary.	Pads Property	Basic signal multiplexing on pads		Additional signal multiplexing on pads		Sequential
		Parallel Interface, Bypass Mode.	Parallel Interface, RFBI mode.	Parallel Interface, Bypass Mode.	Parallel Interface, RFBI mode.	
sys_boot0	System control module			DISPC_DATA_LCD18		"1. Parallel Interface, RFBI-0 mode 16-bit 2. Parallel Interface, RFBI-1 mode 16-bit"
sys_boot1				DISPC_DATA_LCD19		
sys_boot3				DISPC_DATA_LCD20		
sys_boot4				DISPC_DATA_LCD21		
sys_boot5				DISPC_DATA_LCD22		
sys_boot6				DISPC_DATA_LCD23		

The DISPC\_DATA\_LCD[23:18] data is additionally multiplexed on the sys\_boot device pads.

**NOTE:** Table 13-5 shows only the DSS capabilities of supporting sequential LCD interfaces due to the additional signal multiplexing, without describing explicitly all possible configurations.

For more information on signals multiplexing, see the device-specific datasheet.

The parallel interface connectivity is detailed in [Section 13.3.2.1.1](#), *Parallel Interface*.

### 13.3.2.1.1 Parallel Interface

In parallel interface, the paths of the display subsystem modules are the display controller and the RFBI.

The display controller provides the required control signals to interface the memory frame buffer (SDRAM or SRAM) directly to the external displays. The display controller is connected to the memory through the L3 interconnect and has its own DMA (with embedded FIFOs) to read data from the system memory. The L3 interconnect is the master port, while the L4 interconnect is the slave port of the display subsystem.

The display controller has two I/O pad modes at the module level:

- RFBI mode (RFBI enabled), which implements the MIPI DBI 2.0 protocol
- Bypass mode (RFBI disabled), which implements the MIPI DPI 1.0 protocol

The DSS.DISPC\_CTRL[16:15] GPOUT[1:0] bits control selection of the display subsystem modules (see [Table 13-6](#)).

**Table 13-6. I/O Pad Mode Selection**

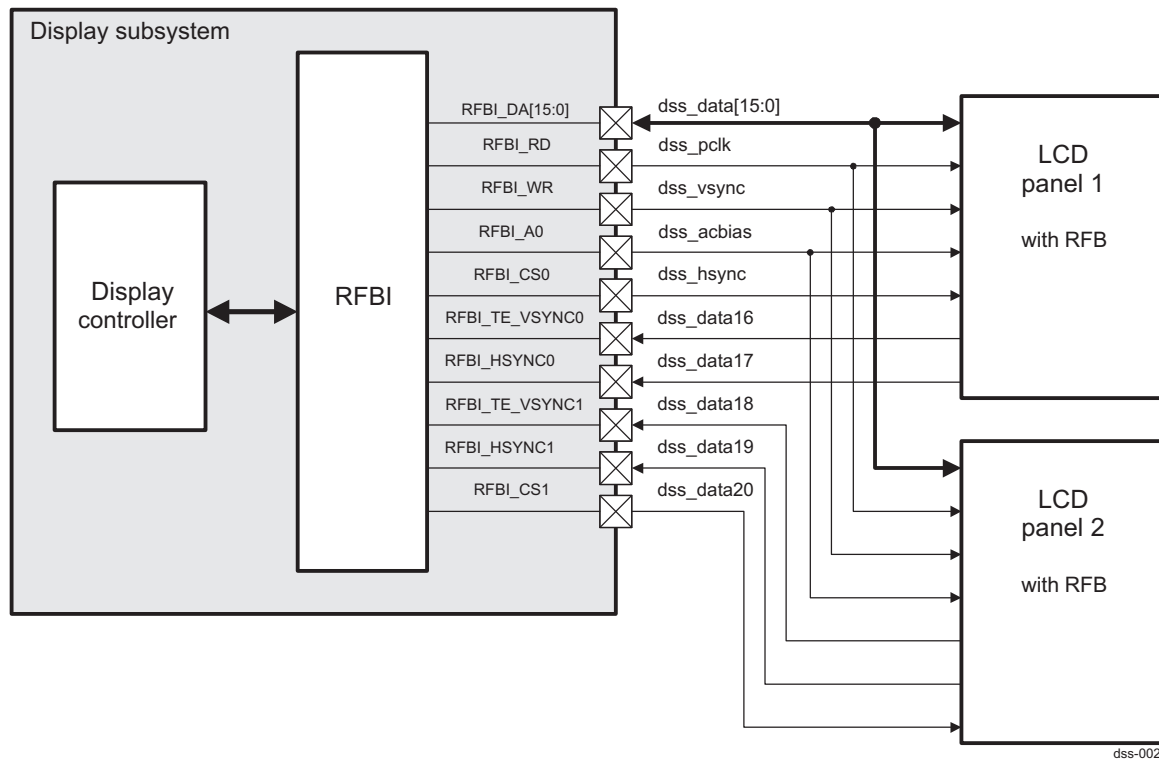

DSS.DISPC_CTRL[16] GPOUT1	DSS.DISPC_CTRL[15] GPOUT0	Mode
0	0	Reset
0	1	RFBI mode
1	0	Invalid
1	1	Bypass mode

The RFB of the LCD panel is connected directly to the RFBI module of the device. The RFBI controls the reads/writes from/to the RFB. The RFBI receives the output from the DISPC (which takes data from the memory) and generates the signals to control the LCD panel. Through the RFBI, the MPU can send commands or parameter/display data to the LCD panel and directly set the DISPC registers to read/write the data from/to the memory in the LCD panel. The RFBI can manage up to two LCD panels when the serial interface is not used.

### 13.3.2.1.1.1 Parallel Interface in RFBI Mode (MIPI DBI Protocol)

Figure 13-3 shows the LCD support parallel interface in RFBI mode (example for 16-bit data interface).

**Figure 13-3. LCD Support Parallel Interface (RFBI Mode)**

**NOTE:** Configure the DSS.RFBI\_CTRL[3:2] CONFIG\_SELECT bit field to drive signals for LCD 1 only, LCD 2 only, or both LCD 1 and LCD 2.

Table 13-7 describes the interface signals to/from the LCD panel in RFBI mode.

**Table 13-7. LCD Interface Signals (RFBI Mode)**

Signal Name	Type <sup>(1)</sup>	Description
RFBI_DA[15:0]	I/O	RFBI I/O data
RFBI_RD	O	Read access signal
RFBI_WR	O	Write access signal
RFBI_A0	O	Command/data selection signal
RFBI_CS0	O	Chip-select (CS) signal for LCD 1
RFBI_CS1	O	CS signal for LCD 2
RFBI_TE_VSYNC0	I	Tearing effect (TE) synchronization signal (TE or VSYNC for LCD panel 1)
RFBI_HSYNC0	I	HSYNC from LCD panel 1
RFBI_TE_VSYNC1	I	TE synchronization signal (TE or VSYNC for LCD panel 2)
RFBI_HSYNC1	I	HSYNC from LCD panel 2

<sup>(1)</sup> I = Input, O = Output, I/O = Input/Output

- RFBI\_DA[15:0]: The pixel data comprises the RFBI pixel data (bits 15:0). A write/read command must be sent to the LCD panel to send/read the data.

Before any data access, the application must send commands and parameters when it is necessary to configure an LCD panel. The data is used as input in read operations during production test and also to read the status of the registers in the LCD panel and pixels from the embedded frame buffer in the

LCD panel module. RFBI\_DA is multiplexed at the chip-level boundary with dss\_data [15:0].

- **RFBI\_RD:** This is the read-enable signal used to indicate when a read from the embedded memory in the LCD panel is ongoing. The RFBI registers describe the behavior of the read signal (off/on/cycle time). The polarity of the read-enable signal is programmable. This signal is multiplexed at the chip-level boundary with dss\_pclk. The read is used to get status/data information from the LCD panel.
- **RFBI\_WR:** The write-enable signal is used to indicate when a write is ongoing. The RFBI registers describe the behavior of the write signal (off/on/cycle time). The polarity of the write-enable signal is programmable. This signal is multiplexed at the chip-level boundary with dss\_vsync.
- **RFBI\_A0:** The signal is asserted to indicate its status: Command or data. The polarity is programmable and the status of the signal depends on the RFBI registers written by the application (CMD/READ/STATUS/PARAM/PIXEL). The register in use by the hardware defines the status of RFBI\_A0. The order of the writes/reads to the RFBI registers CMD/READ/STATUS/PARAM/PIXEL defines the transitions of A0. This signal is multiplexed at the chip-level boundary with dss\_acbias.
- **RFBI\_CSx:** The signal is the chip-select (CSx) asserted to indicate which LCD panel is selected and must be ready to receive/transmit commands and data. When RE or WE is on, CSx must not be changed (x = 0 for LCD panel 1; x = 1 for LCD panel 2). CS0 is multiplexed at the chip-level boundary with dss\_hsync, and CS1 is multiplexed at the chip-level boundary with dss\_data[20].
- **RFBI\_TE\_VSYNcx:** Based on the trigger mode selected, the signal is the TE pulse signal or the LCD panel VSYNC (vertical synchronization) pulse signal. RFBI\_TE\_VSYNcx is used by the TE logic as the synchronization signal to send the pixel to the LCD panel.

To select the trigger mode, configure the DSS.RFBI\_CONFIG\_i[3:2] TRIGGER\_MODE bit field (0x0: Internal trigger mode with the DSS.RFBI\_CTRL[4] ITE bit, 0x1: External trigger mode with the TE signal RFBI\_TE\_VSYNcx, 0x2: External trigger mode with the RFBI\_TE\_VSYNcx, and RFBI\_HSYNcx signals with the programmable line counter).

These signals are multiplexed at the chip-level boundary with dss\_data[16] (RFBI\_TE\_VSYNC0) and dss\_data[18] (RFBI\_TE\_VSYNC1) (LCD panel 1: x = 0; LCD panel 2: x = 1).

- **RFBI\_HSYNcx:** The HSYNC pulse signals indicate to the RFBI module when horizontal synchronization occurs. The polarity of the HSYNC signals is programmable. The minimum pulse width of the signal is two L4 cycles. RFBI\_HSYNcx is used by the TE logic as a synchronization signal to send the pixel to the LCD panel. These signals are multiplexed at the chip-level boundary with dss\_data[17] (RFBI\_HSYNC0) and dss\_data[19] (RFBI\_HSYNC1) (LCD panel 1: x = 0; LCD panel 2: x = 1).

### 13.3.2.1.1.1 Description of the TE Pulse Signal

The externally-generated TE synchronization signal is a logical OR or AND operation between the HSYNC and VSYNC signals (see [Figure 13-4](#)). The logical operation (OR or AND) depends on the HSYNC and VSYNC signals polarity. The VSYNC signal indicates to the RFBI module when vertical synchronization occurs; the HSYNC signal indicates to the RFBI module when horizontal synchronization occurs.

**Figure 13-4. External Generation of TE Signal Based on Logical OR Operation Between HSYNC and VSYNC (Active-High)**

The RFBI module detects the VSYNC and HSYNC pulses embedded in the received signal. VSYNC is detected based on the minimum pulse width defined by the DSS.RFBI\_VSYNc\_WIDTH register.

HSYNC is detected based on the minimum pulse width defined by the DSS.RFBI\_HSYNC\_WIDTH register.

The signal is generated from external logic based on the VSYNC/HSYNC of the LCD panel. The automatic trigger can be programmed based on the RFBI\_TE signal or use a bit field in the RFBI registers to start data capture.

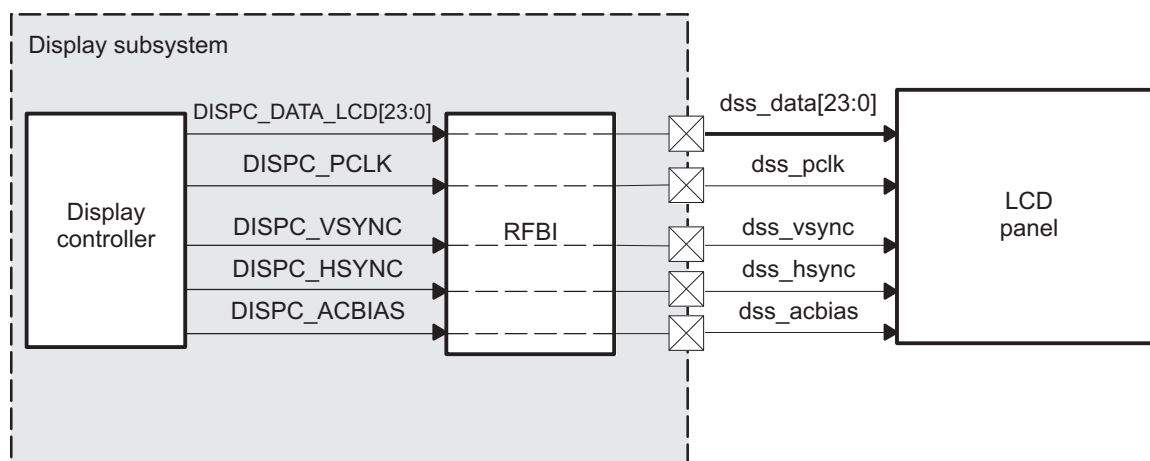

The polarity of the TE signal is programmable. The HSYNC and VSYNC pulses embedded in the TE signal have the same polarity, which is active high for an ORed signal and active low for an ANDed signal. The minimum pulse width of the signal is two L4 cycles. Hardware resets the line counter when the VSYNC occurs and increments it at every HSYNC. Transfer to the LCD panel begins when the line counter reaches the programmable line number.

### 13.3.2.1.1.2 Parallel Interface in Bypass Mode (MIPI DPI Protocol)

When bypass mode is enabled, the display controller must be set to use it.

Figure 13-5 shows the LCD support parallel interface in bypass mode.

**Figure 13-5. LCD Support Parallel Interface (Bypass Mode)**

dss-004

Table 13-8 describes the interface signals to/from the LCD panel in bypass mode.

**Table 13-8. LCD Interface Signals (Bypass Mode)**

Signal Name	Type <sup>(1)</sup>	Description
DISPC_DATA_LCD[23:0]	O	LCD data from the display controller module
DISPC_PCLK	O	Pixel CLK from the display controller module
DISPC_VSYNC	O	VSYNC from the display controller module
DISPC_HSYNC	O	HSYNC from the display controller module
DISPC_ACBIAS	O	ACBIAS from the display controller module

<sup>(1)</sup> I = Input, O = Output, I/O = Input/Output

- DISPC\_DATA\_LCD[23:0]: The panel pixel data comes directly from the display controller module. DISPC\_DATA\_LCD is connected at the chip-level boundary with dss\_data[23:0].
- DISPC\_PCLK: This signal is the pixel clock that comes directly from the display controller. This signal is multiplexed at the chip-level boundary with dss\_pclk.
- DISPC\_VSYNC: Uses the vertical synchronization signal from the display controller. The LCD frame clock (VSYNC) toggles after all the lines in a frame are transmitted to the LCD panel and a programmable number of line clock cycles has elapsed both at the beginning and at the end of each frame. This signal is multiplexed with dss\_vsync at the chip-level boundary.
- DISPC\_HSYNC: Uses the horizontal synchronization signal from the display controller. The LCD line clock (HSYNC) toggles after all pixels in a line are transmitted to the LCD panel and a programmable

number of pixel clock wait-states elapse, both at the beginning and at the end of each line. This signal is multiplexed on the chip-level boundary with dss\_hsync.

- DISPC\_ACBIAS: Uses the ac-bias signal from the display controller.
  - In passive matrix technology, the ac-bias signal is configured to transition each time a programmable number of line clocks occurs. To prevent a dc charge within the screen pixels, the power and ground supplies of the panel are periodically switched. The DISPC signals the panel to switch the polarity by toggling the ac-bias pin.
  - In active matrix technology, the ac-bias signal acts as an output-enable signal to indicate when data must be latched using the pixel clock. This signal is multiplexed on the chip-level boundary with dss\_acbias.

### 13.3.2.1.1.3 LCD Output and Data Format for the Parallel Interface

This section describes the pixel data bus and shows timing diagrams of transactions and synchronizations in both RFBI and bypass modes.

Figure 13-6 through Figure 13-12 show the pixel data bus for bypass mode, depending on the use of 4-, 8-, 12-, 16-, 18-, or 24-pixel data output pins. In RFBI mode, the pixel data bus is reformatted in accordance with the input and output data bus width.

Table 13-9 lists the number of displayed pixels per pixel clock cycle based on the type of display panel.

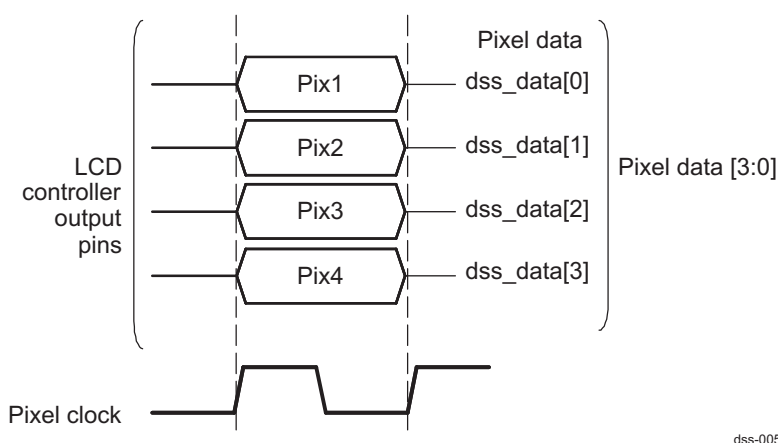

**Table 13-9. Number of Displayed Pixels per Pixel Clock Cycle Based on Display Type**

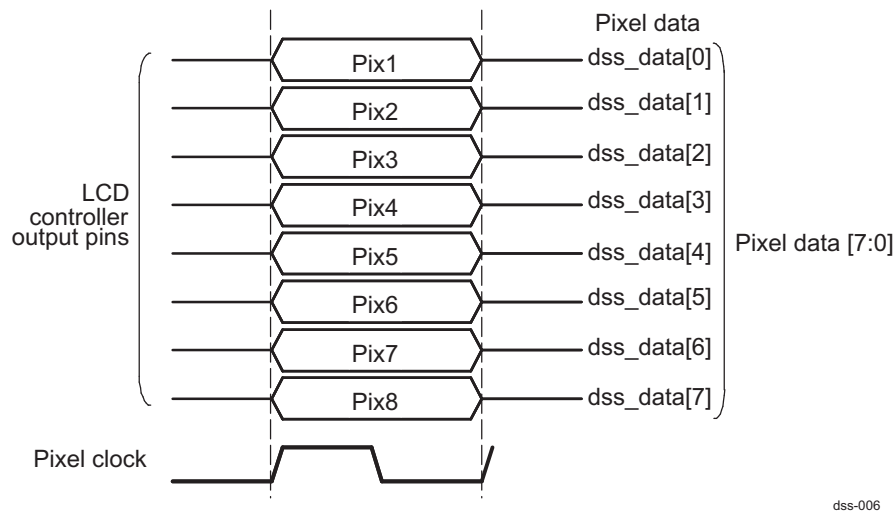

Display Panel	Number of Displayed Pixels per Pixel Clock Cycle
Monochrome 4-bit	4
Monochrome 8-bit	8
Passive matrix color	8/3
Active matrix	1

- Passive matrix technology, Monochrome mode  
Monochrome displays use either a 4-bit or 8-bit interface. Each bit represents one pixel (on or off), which means that either 4 or 8 pixels are sent to the LCD at each pixel clock.

Figure 13-6 and Figure 13-7 show 4- and 8-bit monochrome displays, respectively.

**Figure 13-6. LCD Pixel Data Monochrome4 Passive Matrix**

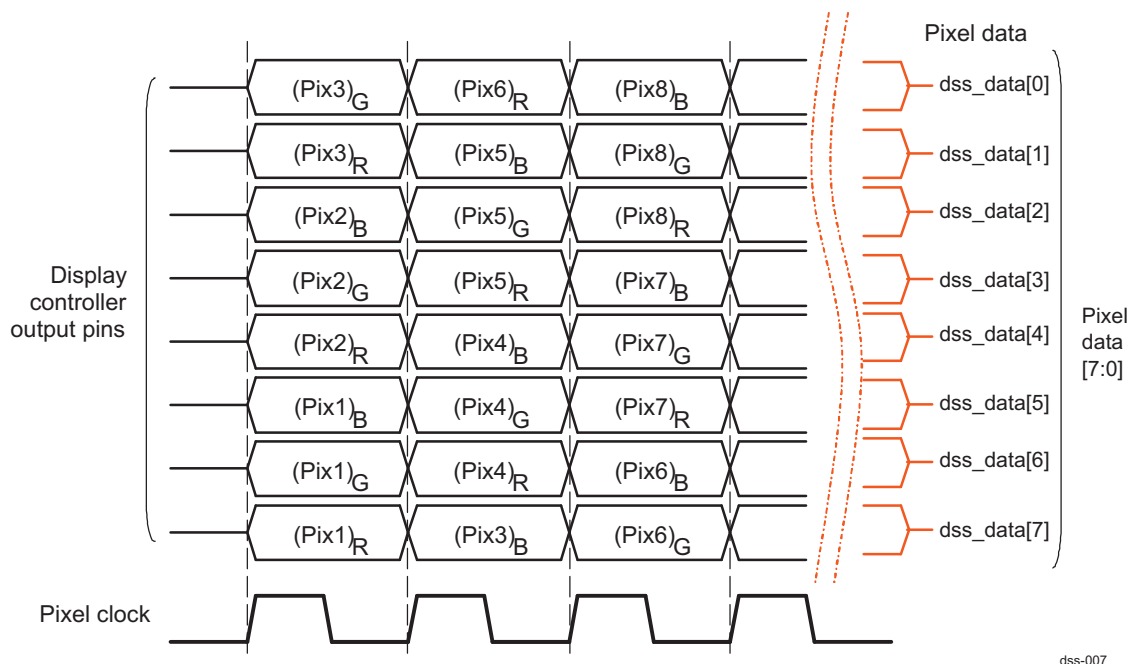

**Figure 13-7. LCD Pixel Data Monochrome8 Passive Matrix**

- Passive matrix technology, color mode

Color passive displays use 8-bit data input lines. In a given pixel clock cycle, each line represents one color component (red, green, or blue).

Figure 13-8 shows an 8-bit color passive matrix display.

**Figure 13-8. LCD Pixel Data Color Passive Matrix**

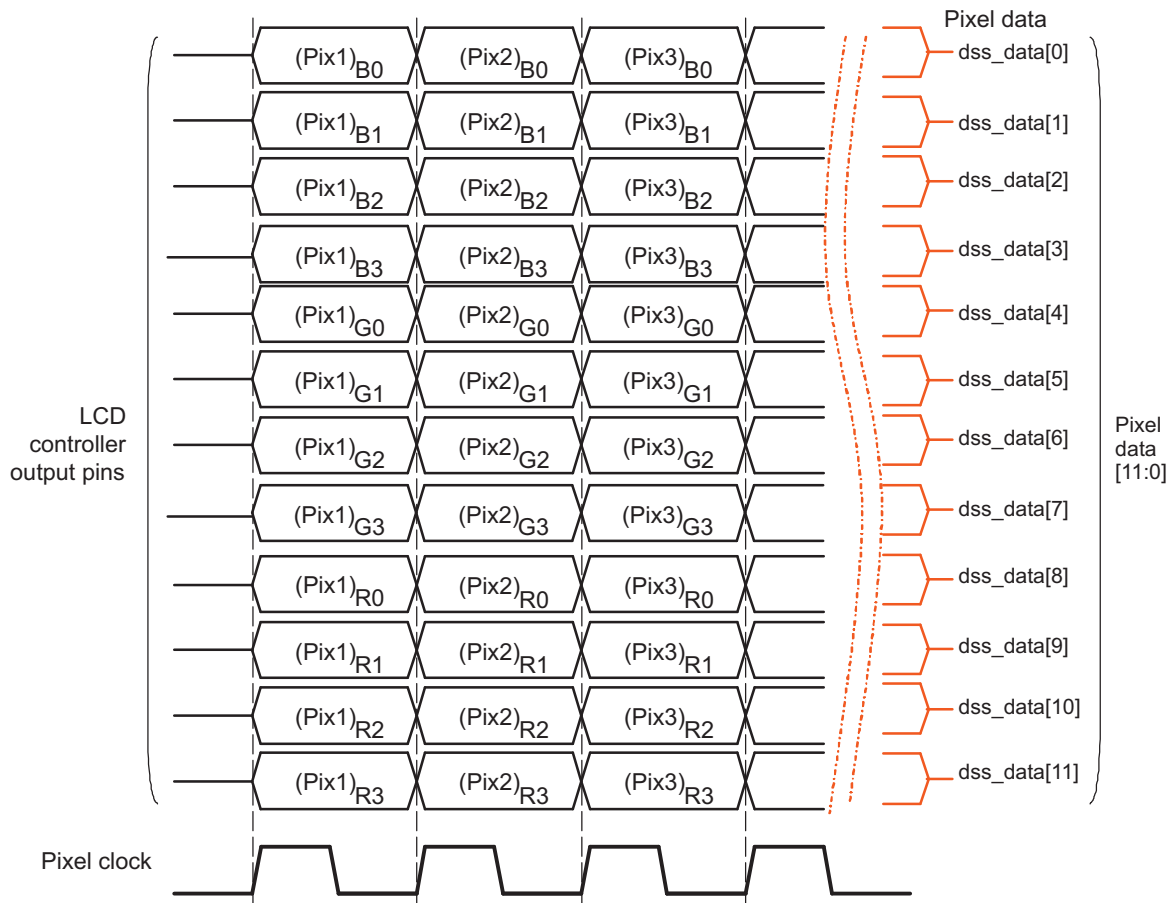

- Active matrix technology

Active matrix displays bypass the STN dithering logic block and the output FIFO. Each line represents one pixel.

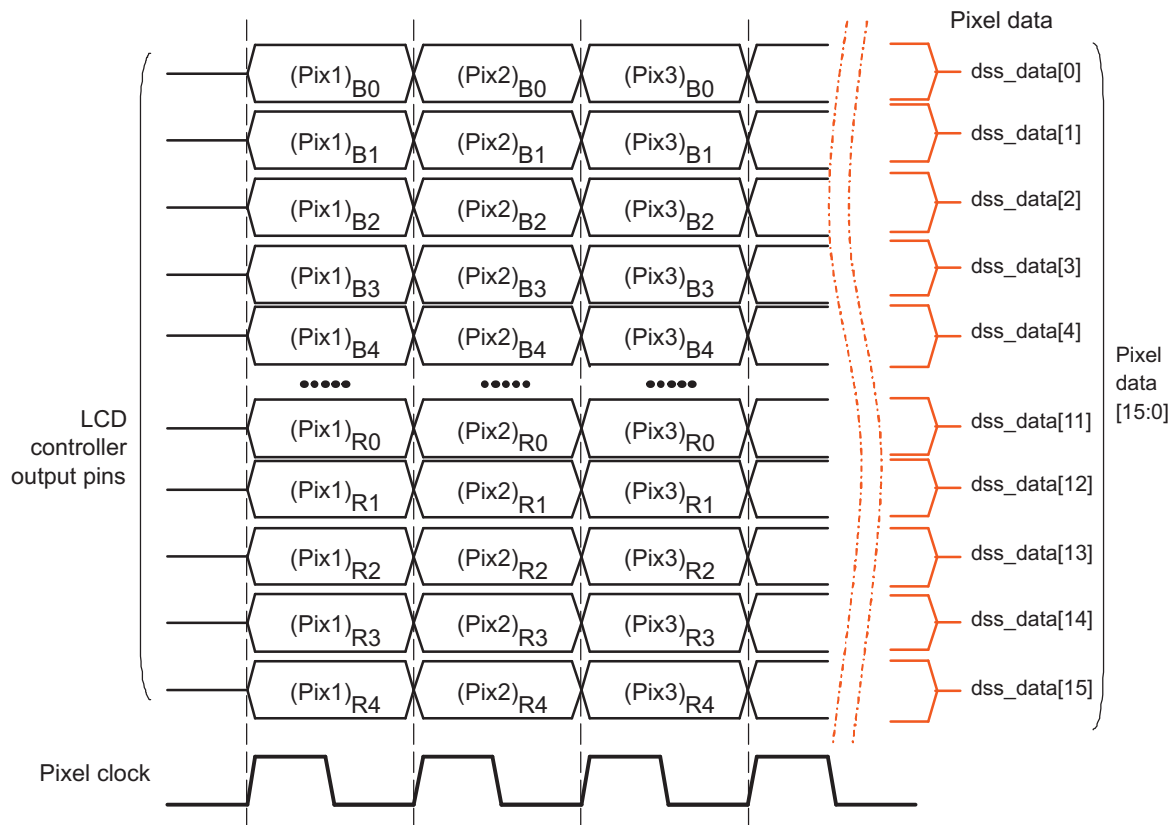

Figure 13-9 through Figure 13-12 show 12-, 16-, 18-, and 24-active matrix displays, respectively.

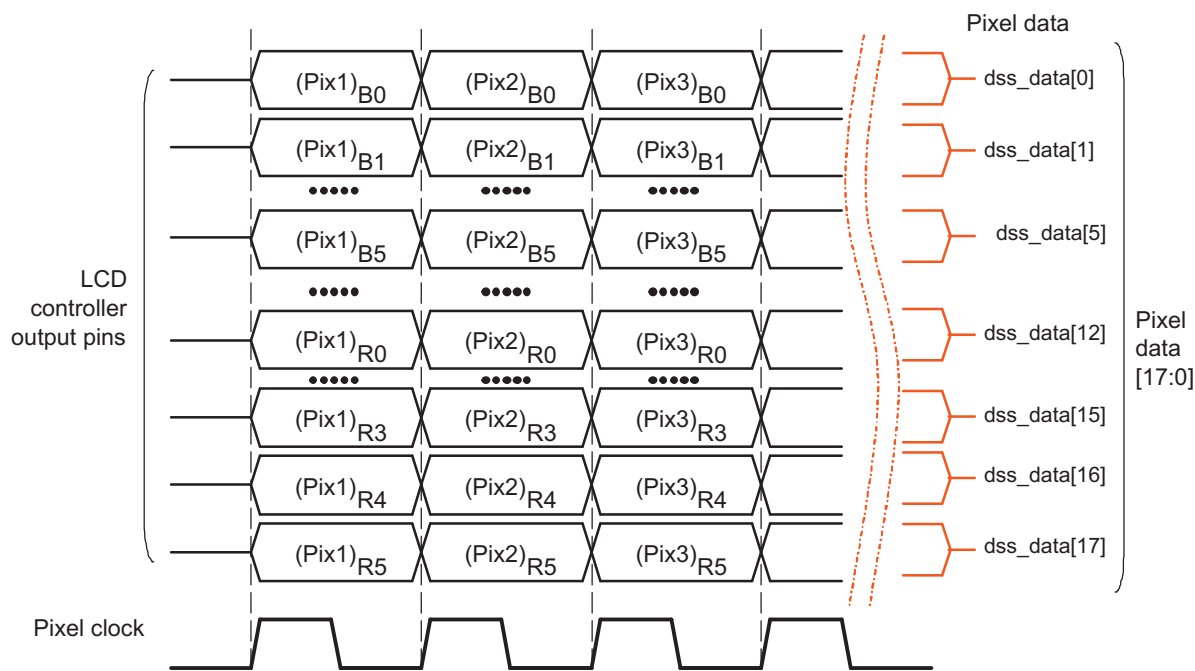

**Figure 13-9. LCD Pixel Data Color12 Active Matrix**

dss-008

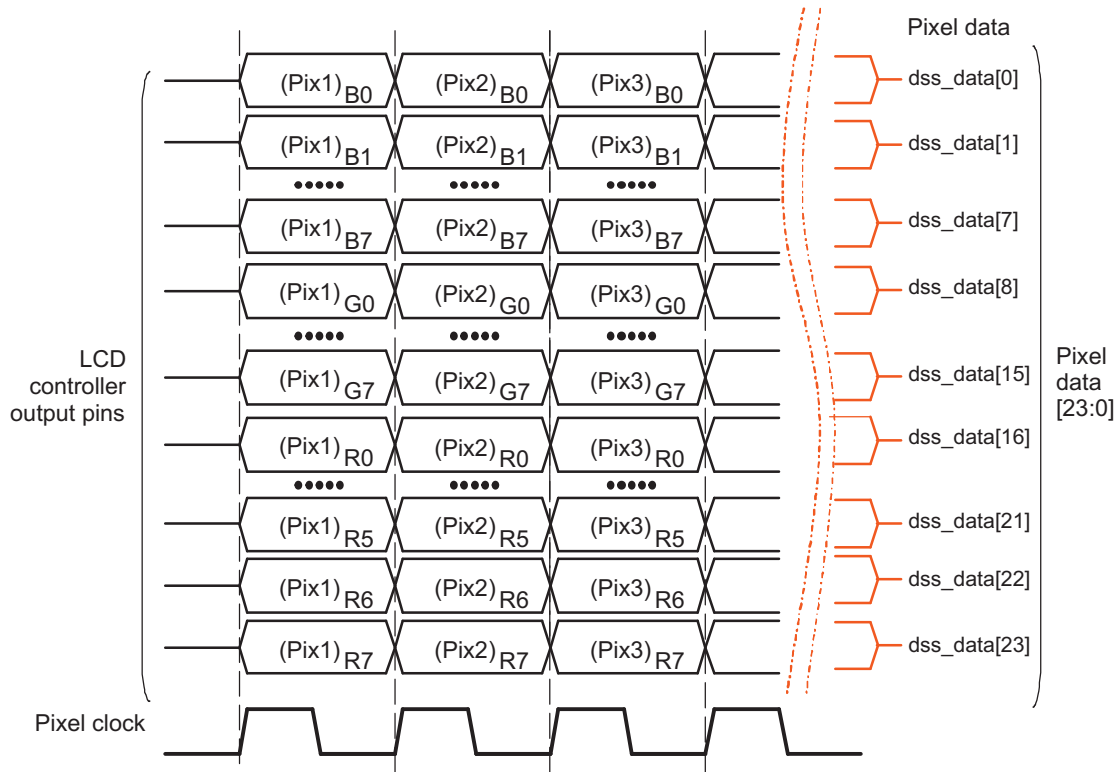

**Figure 13-10. LCD Pixel Data Color16 Active Matrix**

dss-009

dss-010

Figure 13-12. LCD Pixel Data Color24 Active Matrix

dss-011

#### 13.3.2.1.1.4 Transaction Timing Diagrams

- Timing diagrams in flow control mode
  - Stall signal

The stall signal is used in RFBI mode. In the case of RFBI mode, it is used to indicate when the display controller must stop sending data over the LCD output interface. The RFBI module asserts the stall signal to stop data output by the display controller. It is deasserted to indicate when new data must be outputted by the display controller.

Figure 13-13. RFBI Data Stall Signal Diagram

dss-134

To avoid underflow of the DMA FIFO, the FIFO handcheck feature can be enabled by setting the DSS.DISPC\_CFG[16] FIFOHANDCHECK bit to 1. The fullness of the FIFOs associated with the pipelines used for the LCD output is checked when the STALL signal is inactive before providing data to the pipeline. This prevents emptying the FIFO when the RFBI module requests data and there is not enough data in the display controller DMA FIFO. This feature must be enabled only when the STALL mode is used (DSS.DISPC\_CTRL[11] STALL\_MODE bit set to 1).

When the FIFO handcheck feature is activated, the pixel transfer to the RFBI module during STALL inactivity period can be stopped (no DISPC\_PCLK pulse) and restarted when there is enough data in the FIFO. The FIFO handcheck ensures that underflow cannot occur for the pipelines associated with the LCD output in RFBI mode. Figure 13-14 details the RFBI data stall with FIFO handcheck mode activated.

**Figure 13-14. RFBI Data Stall Signal Diagram With Handcheck**

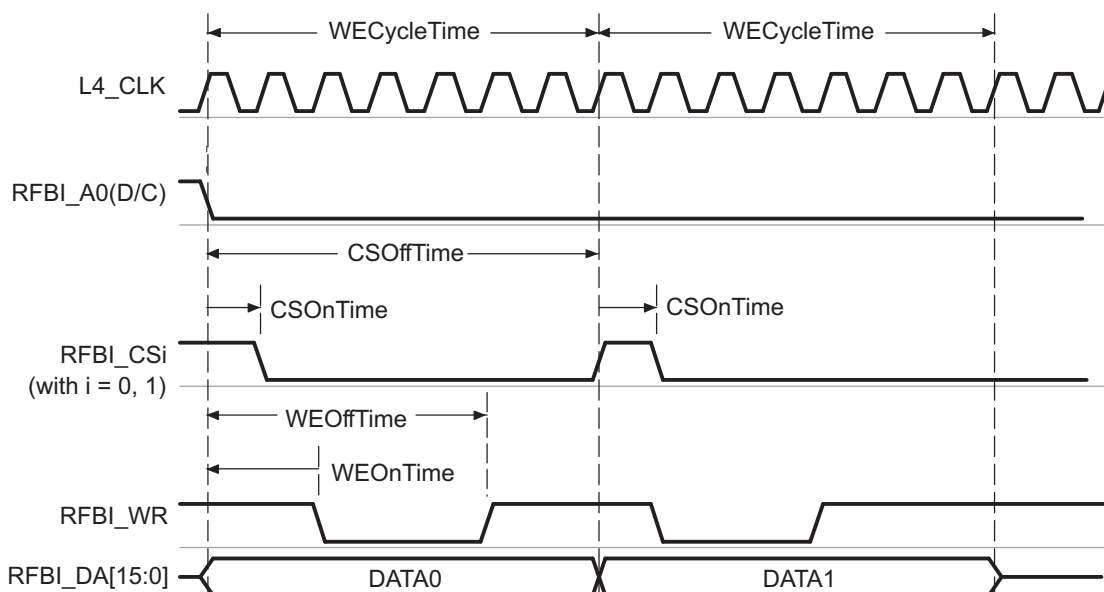

dss-135

– RFBI timing diagrams

Table 13-10 lists the programmable timing fields. Figure 13-15 through Figure 13-17 show timing diagrams of read/write transactions to the LCD panel for the RFBI mode.

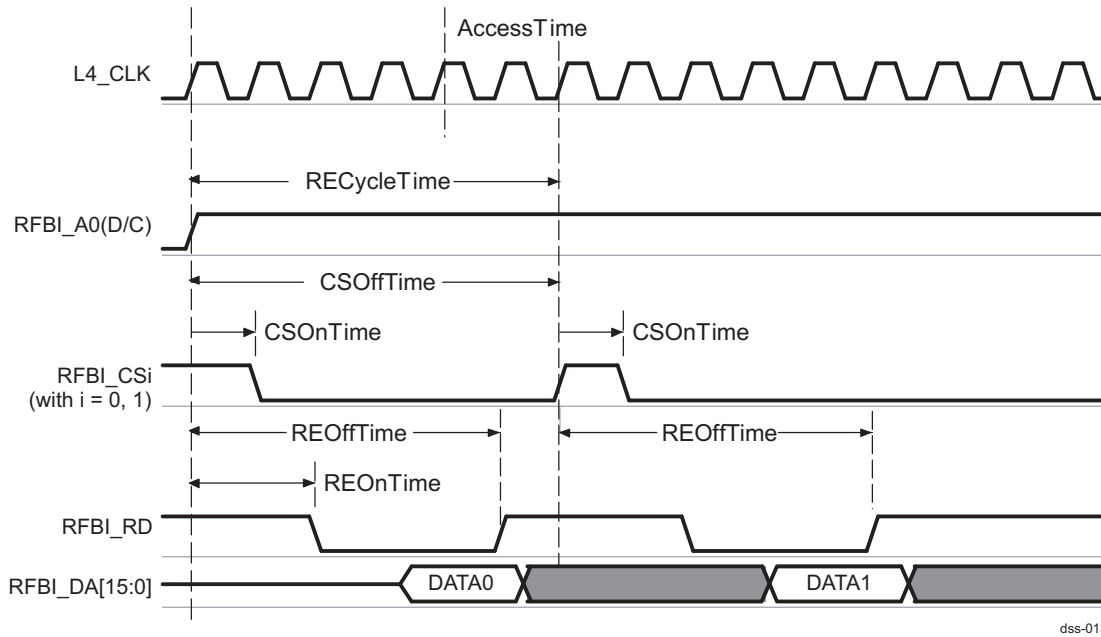

**Table 13-10. Programmable Timing Fields in RFBI Mode**

Timing Name	Register Field	Description
CSONTime	DSS.RFBI_ONOFF_TIMEi[3:0] CS_ONTIME (with I = 0 or 1)	CS assertion time from start access time
CSOffTime	DSS.RFBI_ONOFF_TIMEi[9:4] CS_OFFTIME (with I = 0 or 1)	CS deassertion time from start access time
WeCycleTime	DSS.RFBI_CYCLE_TIMEi[5:0] WE_CYCLE_TIME (with I = 0 or 1)	The time when A0 becomes valid until write cycle completion
WEOnTime	DSS_RFBI_ONOFF_TIMEi[13:10] WE_ONTIME (with I = 0 or 1)	WE assertion delay time from start access time
WEOffTime	DSS_RFBI_ONOFF_TIMEi[19:14] WE_OFFTIME (with I = 0 or 1)	WE deassertion delay time from start access time
RECycleTime	DSS.RFBI_CYCLE_TIMEi[11:6] RECYCLE_TIME (with I = 0 or 1)	The time when A0 becomes valid until read cycle completion
REOnTime	DSS_RFBI_ONOFF_TIMEi[23:20] RE_ONTIME (with I = 0 or 1)	RE assertion delay time from start access time
REOffTime	DSS.RFBI_ONOFF_TIMEi[29:24] RE_OFFTIME (with I = 0 or 1)	RE assertion delay time from start access time
CSPulseWidth	DSS.RFBI_CYCLE_TIMEi[17:12] CS_PULSE_WIDTH (with I = 0 or 1)	The time when write cycle time or read cycle time completes

**Figure 13-15. Command Data Write**

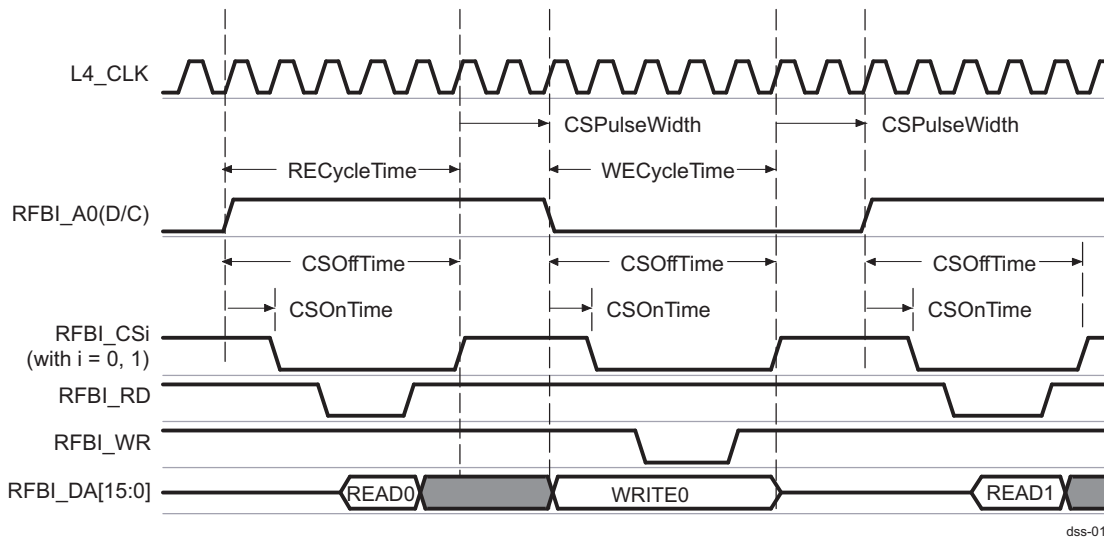

dss-012

**Figure 13-16. Display Data Read**

dss-013

**Figure 13-17. Read to Write and Write to Read**

dss-014

- Timing diagrams in bypass mode

Figure 13-18 through Figure 13-33 show timing diagrams of synchronization signals and pixel clock in bypass mode for both passive matrix and active matrix panels. The display controller directly drives these signals, which are related to the programmable fields described in Table 13-11.

**Table 13-11. Programmable Fields in Bypass Mode**

Name	Register	Description
PPL	DSS.DISPC_SIZE_LCD[10:0] PPL bit field value + 1	Pixels per line (PPL)
LPP	DSS.DISPC_SIZE_LCD[26:16] LPP bit field value + 1	Lines per panel

### 13.3.3 Display Controller Functionalities

The display controller can read and display the encoded pixel data stored in memory (see Figure 13-34).

**Figure 13-34. Display Controller Architecture Overview**

dss-038

Several processes can be configured to manage the graphics pipeline (palette, gamma table correction) and video pipeline (color space conversion, upsampling, downsampling, overlay, and transparency features).

The internal timing generator logic generates the LCD input signals. The external timing generator generates the appropriated signals to drive the digital output. The data from the two overlay managers are sent on the two concurrent 24-bit buses outside the display controller module. The memory accessed by the display controller is either the SDRAM memory or the SRAM memory.

### 13.3.3.1 Display Modes

#### 13.3.3.1.1 LCD Output

The display subsystem supports two types of display technologies (both monochrome and color modes):

- Passive matrix displays
- Active matrix displays

The passive matrix display mode supports 3375 possible colors, allowing 16, 256, or 3375 colors to be displayed in each frame, depending on the color depth. The monochrome LCD has 15 grayscale levels available.

In active matrix display mode, the configuration of colors depends on the color depth:

- 24 BPP supports 16,777,216 colors.
- 18 BPP supports 262,144 colors.
- 16 BPP supports 65,536 colors.
- 12 BPP supports 4096 colors.

#### 13.3.3.1.2 Digital Output

The digital output is always a 24-bit RGB value based on an external pixel request.

### 13.3.3.2 Graphics Pipeline

The graphics pipeline is connected to the graphics FIFO controller for the input port and to the two overlay managers (LCD and digital). It consists of one 256-entry palette and some programmable replication logic. The replication logic is used to convert the RGB pixels, excluding the RGB24 format, into RGB24 format based on user programming (replication of the most-significant bits [MSBs] for the RGB24 LSBs or use of 0s). The first unit connected to the input port of the graphics pipeline is the replication logic used for RGB pixels, then the second unit is the palette for concerned pixels.

#### 13.3.3.2.1 Graphics Memory Format

The supported formats for the graphics layer are CLUT bitmaps (1-, 2-, 4-, and 8-BPP) and true color bitmaps in RGB formats (12-, 16-, and 24-BPP [packet and nonpacket RGB24]) and in ARGB or RGBA formats (ARGB 16-, and 32-BPP, and RGBA 32-BPP) as follows:

- BITMAP 1-BPP data memory organization (CLUT) (little endian)

dss-T039

- BITMAP 1-BPP data memory organization (CLUT) (little endian + nibble mode)

dss-T040

- BITMAP 1-BPP data memory organization (CLUT) (big endian)

dss-T060

- BITMAP 1-BPP data memory organization (CLUT) (big endian + nibble mode)

dss-T061

- BITMAP 2-BPP data memory organization (CLUT) (little endian)

- BITMAP 2-BPP data memory organization (CLUT) (little endian + nibble mode)

- BITMAP 2-BPP data memory organization (CLUT) (big endian)

- BITMAP 2-BPP data memory organization (CLUT) (big endian + nibble mode)

- BITMAP 4-BPP data memory organization (CLUT) (little endian)

- BITMAP 4-BPP data memory organization (CLUT) (little endian + nibble mode)

- BITMAP 4-BPP data memory organization (CLUT) (big endian)

- BITMAP 4-BPP data memory organization (CLUT) (big endian + nibble mode)

- BITMAP 8-BPP data memory organization (CLUT) (little endian)

- BITMAP 8-BPP data memory organization (CLUT) (big endian)

- RGB 12-BPP data memory organization (little endian)

- RGB 12-BPP data memory organization (big endian)

- RGB 16-BPP data memory organization (little endian)

- RGB 16-BPP data memory organization (big endian)

dss-T070

- ARGB 16-BPP data memory organization (little endian)

dss-T049

- ARGB 16-BPP data memory organization (big endian)

dss-T069

- RGB 24-BPP data memory organization (little or big endian)

dss-T050

- ARGB 32-BPP data memory organization (little or big endian)

dss-T051

- RGBA 32-BPP data memory organization (little or big endian)

dss-T052

- RGB 24-BPP packet data memory organization (little or big endian)

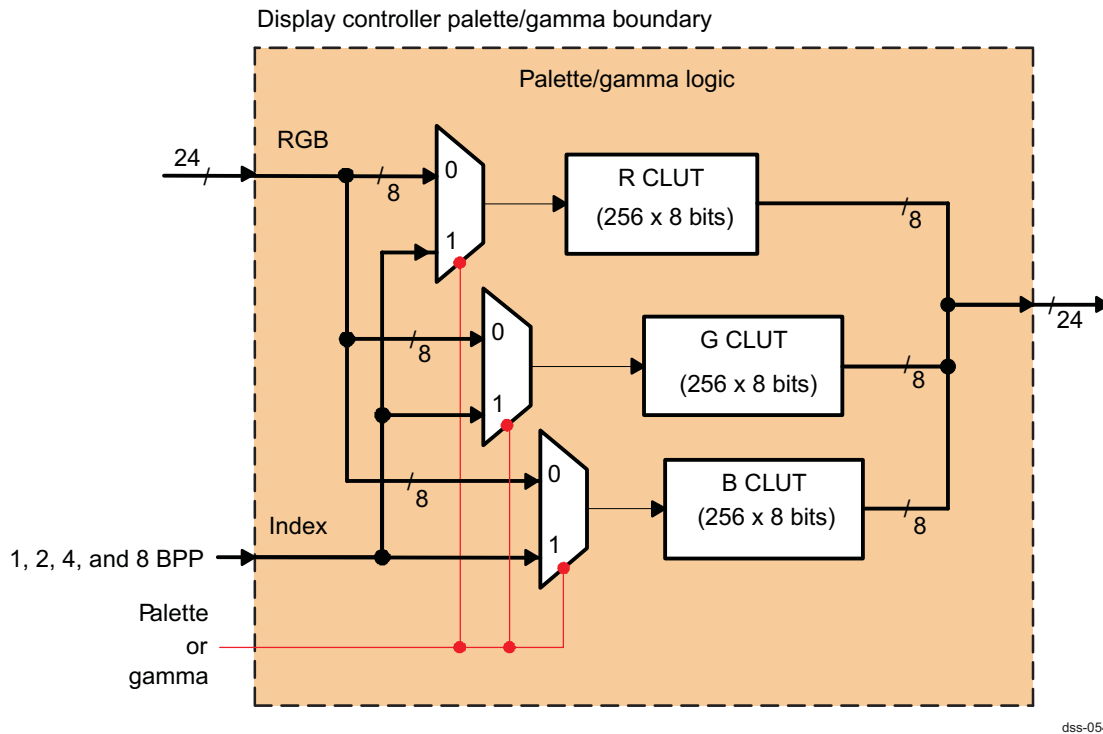

dss-T053

### 13.3.3.2.2 Color Look-Up Table/Gamma Table

The graphics path supports the palette/gamma table. [Figure 13-35](#) shows the internal architecture of the color look-up/gamma table.

The palette is split into three memories of 256-bit x 8-bit entries. For bitmap (CLUT) indexes, the same value (1-, 2-, 4-, or 8-BPP) indexes the three memories. For gamma curve correction, each R, G, and B component indexes the corresponding memory to combine the three gamma curve values into a 24-bit value. The table can be reloaded every frame, once or never (at the beginning of the frame before fetching the pixels for the graphics and/or video windows).

**Figure 13-35. Palette/Gamma Correction Architecture**

#### 13.3.3.2.1 Color Look-Up Table

The palette mode uses the encoded pixel values from the input graphics FIFO as pointers to index the 24-bit-wide palette: 1-BPP pixels address 2 palette entries, 2-BPP pixels address 4 palette entries, 4-BPP pixels address 16 palette entries, and 8-BPP pixels address 256 palette entries.

When a palette entry is selected by the encoded pixel value, the content of the entry is sent to the color/grayscale space/time base passive matrix dithering circuit, or to the color time base active matrix dithering circuit.

In color mode, the value within the palette is made up of three 8-bit fields, one for each color component (red, green, and blue). For color operation, an individual frame is limited to a selection of 256 colors (the number of palette entries). The format of one of the palette values in the memory is as follows:

- 24-BPP Data Memory Organization (Little Endian or Nibble)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Unused								R								G								B							

In monochrome mode, only one 8-bit value is present.

- 24-BPP Data Memory Organization (Little Endian or Nibble)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Unused								Unused								Unused								Gray							

After passing through the palette, 256 gray scales and 16,777,216 colors are numbers obtained. A redundancy introduced in the dithering logic step reduces these numbers when displaying. For passive matrix panels, the colors are limited to 15 gray scales and 3375 colors.

- Passive matrix technology  
The palette is bypassed in 12, 16, and 24 BPP. The palette is not used.
- Active matrix technology

The palette is bypassed in 12, 16, and 24 BPP, allowing up to  $2^{24} = 16,777,216$  colors to be displayed.

### 13.3.3.2.2.2 Gamma Table

In the gamma curve mode, the selected encoded pixel values based on the color keys from the video or graphics paths are sent to the gamma curve table. The mode is available only if the color look-up palette is not used for graphics. The output of the gamma curve processing is always sent to the LCD output. It is not available on digital output.

Each component of encoded pixel value is used as a pointer to index 1 out of 256 24-bit gamma curve entries in the table. Each 8-bit component is replaced with the 8-bit table value corresponding to an R, G, or B component. The format of one of the gamma curve values in the memory is as follows:

- 24-BPP Data Memory Organization (Little or Big Endian)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Unused								Gamma-R								Gamma-G								Gamma-B							

### 13.3.3.2.2.2.1 Replication Logic

The replication logic increases the color depth of the graphics and video encoded pixels (from true color RGB 12-, and 16-BPP to 24-BPP). The encoded value is shifted to the 24-bit alignment. The MSB bits are copied to the LSB missing ones. Then the graphics are merged with the video data based on the transparency color keys. When the replication logic is not selected, the encoded pixel values are shifted to the MSB boundary of the 24-bit format. The missing bit values are filled up with 0s.

This is an example for RGB16 extension:

- Original 16-BPP data:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R4	R3	R2	R1	R0	G5	G4	G3	G2	G1	G0	B4	B3	B2	B1	B0

dss-T055

- If replication logic is ON:

23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R4	R3	R2	R1	R0	R4	R3	R2	G5	G4	G3	G2	G1	G0	G5	G4	B4	B3	B2	B1	B0	B4	B3	B2

dss-T056

- If replication logic is OFF:

23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R4	R3	R2	R1	R0	0	0	0	G5	G4	G3	G2	G1	G0	0	0	B4	B3	B2	B1	B0	0	0	0

dss-T057

### 13.3.3.3 Video Pipeline

The video pipeline is connected to the video FIFO controller for the input port and to the two overlay managers (LCD and digital). It consists of the Re-Sampling unit, the Color Space Conversion Unit, and some programmable replication logic. The replication logic is used to convert the RGB pixels, excluding the RGB24 format, into RGB24 format based on user programming (replication of the MSBs for the RGB24 LSBs or use of 0s). The first unit connected to the input port of the video pipeline is the Re-Sampling Unit, then the replication logic used for RGB pixels, then the Color Space Conversion Unit for YUV4:2:2 pixels.

### 13.3.3.3.1 Video Memory Formats

The display subsystem supports the following formats for the video layer: YUV2, UYVY, RGB12, RGB16, RGB24 (non-packed and packed formats), ARGB16 (video channel 2 only), ARGB32 (video channel 2 only), and RGBA32 (video channel 2 only).

- RGB 12-BPP data memory organization (little endian)

- RGB 12-BPP data memory organization (big endian)

- RGB 16-BPP data memory organization (little endian)

- RGB 16-BPP data memory organization (big endian)

- ARGB 16-BPP data memory organization (little endian + video 2 channel only)

- ARGB 16-BPP data memory organization (big endian + video 2 channel only)

- RGB 24-BPP data memory organization (little or big endian)

- RGB 24-BPP packet data memory organization (little or big endian)

- ARGB 32-BPP data memory organization (little or big endian + video 2 channel only)

- RGBA 32-BPP data memory organization (little or big endian + video 2 channel only)

- UYVY 4:2:2 data memory organization (little endian)

- UYVY 4:2:2 data memory organization (big endian)

- YUV2 4:2:2 data memory organization (little endian)

- YUV2 4:2:2 data memory organization (big endian)

### 13.3.3.3.2 Color Space Conversion

The color space conversion module converts the video-encoded pixel values from YCbCr 4:2:2 format into RGB24. Figure 13-36 and Figure 13-37 detail the YCbCr 4:2:2 conversion to YCbCr 4:4:4 depending on the rotation parameters.

Figure 13-36. YCbCr 4:2:2 to YCbCr 4:4:4 (0- or 180-Degree Rotation)

Figure 13-37. YCbCr 4:2:2 to YCbCr 4:4:4 (90- or 270-Degree Rotation)

The interpolation of the missing chrominance component is given by the equation in Figure 13-38.

Figure 13-38. Interpolation of the Missing Chrominance Component

$$Cb_n(YCbCr\ 444) = \frac{Cb_{n-1}(YCbCr\ 422) + Cb_{n+1}(YCbCr\ 422)}{2} \text{ (n odd)}$$

$$Cr_n(YCbCr\ 444) = \frac{Cr_{n-1}(YCbCr\ 422) + Cr_{n+1}(YCbCr\ 422)}{2} \text{ (n odd)}$$

dss-E062

First, to convert the YCbCr 4:2:2 encoded pixel values into YCbCr 4:4:4 format, the missing chrominance samples (Cb and Cr) are interpolated using the average values of the two closest values on the same line (1/2, 1/2) or are repeated from the second pixel in the same 32-bit container.

- In case of rotation 0-degree, for the last pixel, the chrominance samples are duplicated using the values from the previous pixel; otherwise, the chrominance samples are averaged using the two adjacent values.
- In case of 180-degree rotation, for the first pixel the chrominance samples missing are duplicated from

the adjacent pixel; otherwise, the chrominance samples are averaged using the two adjacent values.

- In case of rotation 90- and 270-degree, the missing chrominance components are duplicated from the adjacent pixel in the same 32-bit container.

In case of 5-tap configuration for the vertical filtering, the missing chrominance samples are always duplicated using the second chrominance samples in the same 32-bit value.

Then the pixels are converted from YCbCr color space into the RGB color space, because the output format of the color space conversion is RGB24 (8-bit value per component: Red, green, and blue). The following matrices show the 11-bit coefficients registers used to convert from YCbCr 4:4:4 into RGB24. Users set the coefficients according to the standard used to encode the pixel data in YCbCr color space.

In case of resampling, the YUV4:2:2 format is converted into YUV4:4:4. The YUV4:2:2-to-YUV4:4:4 processing is bypassed in the color space conversion unit.

If the active range for the luminance samples (Y) is [16:235] and [16:240] for the chrominance samples (Cb and Cr), the values of R, G, and B output components are clipped to the range [0:255]. The equation shown in [Figure 13-39](#) gives the 11-bit coefficients of the YCbCr to RGB color space conversion.

**Figure 13-39. YCbCr to RGB Registers (VIDFULLRANGE = 0)**

$$\begin{bmatrix} R \\ G \\ B \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} RY & RCr & RCb \\ GY & GCr & GCb \\ BY & BCr & BCb \end{bmatrix} * \begin{bmatrix} Y - 16 \\ Cr - 128 \\ Cb - 128 \end{bmatrix}$$

dss-E063

If the active range for the luminance samples (Y) and chrominance samples (Cb and Cr) is [0:255], the values of R, G, and B output components are clipped to the range [0:255]. The equation shown in [Figure 13-40](#) gives the 11-bit coefficients of the YCbCr-to-RGB color space conversion.

**Figure 13-40. YCbCr to RGB Registers (VIDFULLRANGE = 1)**

$$\begin{bmatrix} R \\ G \\ B \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} RY & RCr & RCb \\ GY & GCr & GCb \\ BY & BCr & BCb \end{bmatrix} * \begin{bmatrix} Y \\ Cr - 128 \\ Cb - 128 \end{bmatrix}$$

dss-E064

[Figure 13-41](#) describes the computation for the calculation of the R component. The same computation applies for the G and B components:

**Figure 13-41. Color Space Conversion Macro-Architecture**

dss-065

### 13.3.3.3.3 Hardware Cursor

The video layer can be used to display the hardware cursor. The encoded pixel data for the cursor image are in RGB12, RGB16 or RGB24 formats and the color space conversion block is bypassed. The transparency color key can be used when a non rectangle shape is used.

The alpha blending can be used to show a partial transparent cursor. When the alpha blender is enabled, the graphics layer is on top of the video layers. The cursor uses the graphics layer. The pixel alpha blending or the transparency color key can be used.

### 13.3.3.3.4 Up-/Down-Sampling

The video layer has a dedicated resizing block to upsample and downsample the video-encoded pixels. The supported input formats from memory are RGB24, RGB16, and YUV4:2:2

(RGB12 and all the alpha formats like ARGB and RGBA are not supported)

Users must set the right size and position of the original video before resizing for the upsampled/downsampled video to be inside the display screen boundaries.

The filtering applies on each component independently R, G, and B).

For the horizontal up/downsampling, the equation is R component with five taps):

$$R_{out}(n) = \left( \sum_{i=-2}^{i=2} C_i(\Phi) \times R_{in}(n+i) \right) \gg 7$$

dss-E066

(5)

For the vertical up/downsampling, the equation is R component with three taps):

$$Rout(n) = \left( \sum_{i=-1}^{i=1} Ci(\Phi) \times Rin(n+i) \right) \gg 7 \quad \text{dss-E067} \quad (6)$$

For the vertical up/downsampling, the equation is R component with five taps):

$$Rout(n) = \left( \sum_{i=-2}^{i=2} Ci(\Phi) \times Rin(n+i) \right) \gg 7 \quad \text{dss-E068} \quad (7)$$

*Rout*: R component output

$Ci(\Phi)$   
dss-E069 : FIR filter coefficients

*Rin*: R component input

The pixel (n + 1) is older than pixel (n). The line (n + 1) is older than line (n).

---

**NOTE:** The coefficients  $Ci()$  depend on the phase between input and output pixels.

---

**NOTE:** If the 5-tap resizer is used for RGB16 and YUV4:2:2 picture formats, the width of the input picture must be a multiple of 2 pixels and more than 5 pixels:

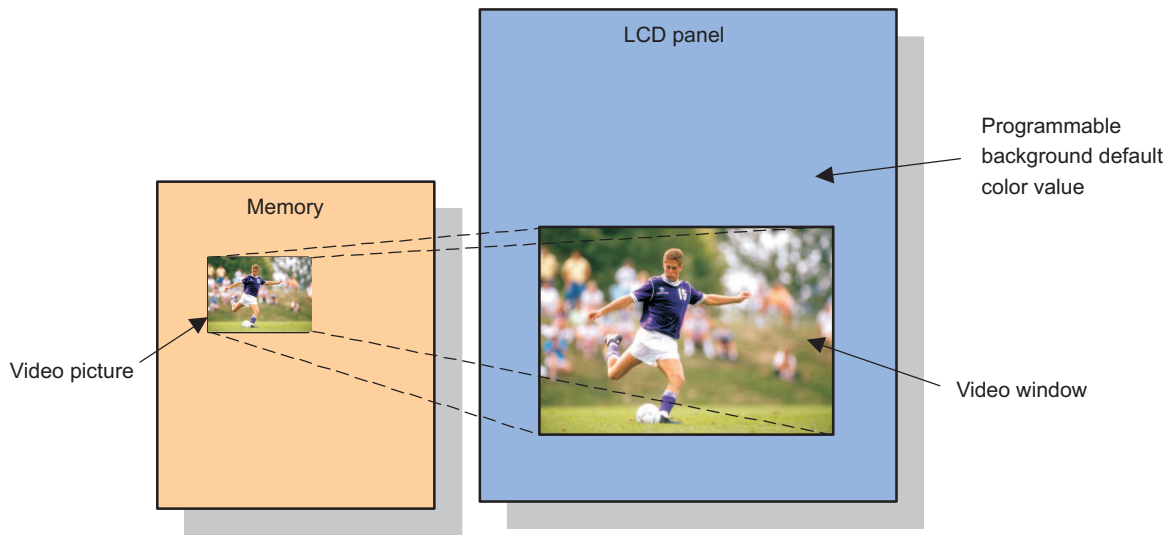

DISPC\_VIDn\_ATTRS[21] VERTICAL\_TAPS == 1

DISPC\_VIDn\_PICTURE\_SIZE[10:0] VID\_ORG\_SIZE\_X 4 and even

---

Figure 13-42 shows an example of video upsampling.

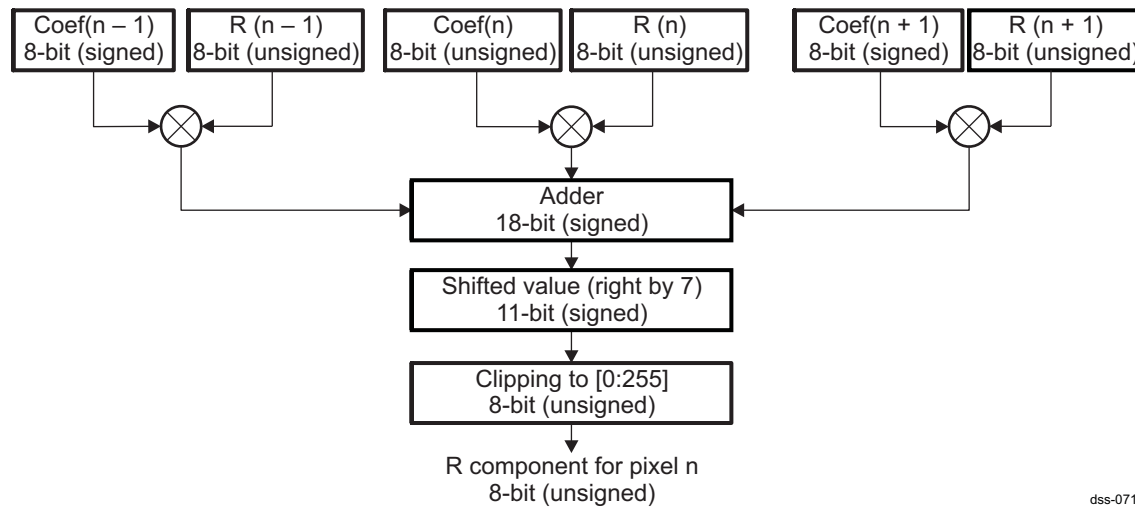

**Figure 13-42. Video Upsampling**

dss-070

### Filter Description

The up/downsampling filter is a poly-phase filter with five taps and eight phases for the horizontal filter and a programmable number of taps (three or five) and eight phases for vertical filter. The upsampling ratio is up to x8. The downsampling ratio using 3-tap configuration is  $1/2$ . The downsampling ratio using 5-tap configuration is  $1/4$ . The vertical filter is first applied to the encoded input pixel data; and then the horizontal filter is applied on the resulting pixel values to generate the output pixel values. Figure 13-43 shows the computation for the R component in the case of three coefficients (vertical filtering). The same computation applies to the G and B components.

**Figure 13-43. Resampling Macro-Architecture (3-Coefficient Processing)**

To determine if the minimum functional clock matches the down sampling ratio and the desired Pixel clock, the following formula must be used in conjunction with [Table 13-12](#) and [Table 13-13](#).

**Ratio V when performing a vertical down-sampling only**

$$h\_ratio = \frac{DISPC\_SIZE\_LCD.PPL}{DISPC\_VID\_SIZE.Vid\_Size\_X}$$

$$v\_ratio = \frac{DISPC\_VID\_PICTURE\_SIZE.Vid\_Org\_Size\_Y}{DISPC\_VID\_SIZE.Vid\_Size\_Y}$$

$$Ratio = \frac{v\_ratio}{2 \times h\_ratio} \quad \text{If } 1 < v\_ratio \leq 2$$

$$Ratio = \max\left(\frac{v\_ratio}{2 \times h\_ratio}, \frac{v\_ratio - 2}{2 \times (h\_ratio - 1)}\right) \quad \text{If } 2 < v\_ratio \leq 4$$

dss\_swpu108-E135

**NOTE:** For frequency ratio calculation on the TV output, it is correct to replace DISPC\_SIZE\_LCD with DISPC\_SIZE\_DIG.

When the down-sampling ratio is below 0.5, it is not possible to use a video in full screen.

**Ratio H when performing a horizontal down-sampling only**

$$Ratio = \frac{DISPC\_VID\_PICTURE\_SIZE.Vid\_Org\_Size\_X}{DISPC\_VID\_SIZE.Vid\_Size\_X}$$

dss\_swpu108-E136

**Ratio H+V when performing a horizontal and vertical down-sampling**

Ratio = max (horizontal Ratio, vertical Ratio) as previously defined.

**Table 13-12. Functional Clock Frequency Requirement in RGB16 YUV4:2:2—Active Matrix Display**

Minimum Functional Clock (MHz)		Horizontal Resampling				
		Off	Up	1:1 – 1:2	1:2 – 1:3	1:3 – 1:4
Vertical Resampling	Off	AxPCLK	AxPCLK	2xPCLK	3xPCLK	4xPCLK
	Up	AxPCLK	AxPCLK	2xPCLK	3xPCLK	4xPCLK
	3-tap 1:1 to 1:2	2xPCLK	2xPCLK	4xPCLK	6xPCLK	8xPCLK
	5-tap 1:1 to 1:4	RatioxPCLK	RatioxPCLK	RatioxPCLK	RatioxPCLK	RatioxPCLK

With A = 1 in case all the data and synchronization signals are asserted and deasserted on the rising edge of the PCLK; otherwise, A = 2.

**Table 13-13. Functional Clock Frequency Requirement in RGB24—Active Matrix Display**

Minimum Functional Clock (MHz)		Horizontal Resampling				
		Off	Up	1:1 – 1:2	1:2 – 1:3	1:3 – 1:4
Vertical Resampling	Off	AxPCLK	AxPCLK	2xPCLK	3xPCLK	4xPCLK
	Up	AxPCLK	AxPCLK	2xPCLK	3xPCLK	4xPCLK
	3-tap 1:1 to 1:2	2xPCLK	2xPCLK	4xPCLK	6xPCLK	8xPCLK
	5-tap 1:1 to 1:4	RatioxPCLK	RatioxPCLK	2xRatioxPCLK	2xRatioxPCLK	2xRatioxPCLK

With A = 1 in case all the data and synchronization signals are asserted and deasserted on the rising edge of the PCLK; otherwise, A = 2.

#### Use case example:

An input picture of 1024\*768 is scaled to an output picture of size of 800\*600 and displayed onto a LCD of resolution 1280\*768 at a PCLK of 74.25 MHz with a DSS functional clock of 133 MHz.

In this example, a H+V down-sampling is done on the input picture. Firstly the Ratio V and H are determined and the resulting maximum value is taken to calculate the functional clock frequency required.

**Ratio V:**  $h\_ratio = 1.6$  and  $v\_ratio = 1.28$  then  $Ratio = 0.4$

**Ratio H:**  $Ratio = 1.28$

**Ratio H+V:**  $Ratio = \max(1.28, 0.4) = 1.28$

In this use case, the horizontal and vertical down sampling range are 1:1–1:2. The 3-tap or 5-tap configuration can be taken into consideration. Therefore, from [Table 13-12](#) and [Table 13-13](#), If in RGB16-YUV4:2:2:

- 3-taps → DSS functional clock =  $4 * PCLK = 297$  MHz
- 5-taps → DSS functional clock =  $Ratio * PCLK = 95.36$  MHz

If in RGB24,

- 3-taps → DSS functional clock =  $4 * PCLK = 297$  MHz
- 5-taps → DSS functional clock =  $2 * Ratio * PCLK = 190.72$  MHz

In this use case, the pixel format supported is RGB16-YUV4:2:2 in a 5-tap configuration.

### 13.3.3.4 Overlay Support

#### CAUTION

Enabling overlay optimization (setting the DSS.DISPC\_CTRL [12] OVLY\_OPT bit) if no overlay region effectively exists (the DSS.DISPC\_VIDn\_ATTRS [0] EN bit is cleared, with n = 1, 2) leads to unpredictable behavior. The overlay optimization feature must be enabled only when an overlay area exists. Before enabling the overlay optimization, the DSS.DISPC\_GFX\_WINDOW\_SKIP[31:0] GFX\_WINDOW\_SKIP bit field must be first set according to the video1 and graphics windows overlap.

The overlay mechanism consists of displaying more than one layer (graphics and video layers) using rules based on priority and transparency color keys.

When the pixel format is ARGB or RGBA, the color key match logic uses only the RGB value defined by ARGB or RGBA. The alpha blending factor is ignored.

The overlay managers are based on the same rules for priority and transparency color keys (see [Figure 13-46](#)).

Each data pipeline is assigned a single overlay related to a single display controller output.

The overlay manager is connected to all three outputs of the pipelines (graphics, video1 and video2). The output of the LCD overlay manger is connected to the Spatial/Temporal Dithering, and Passive Matrix units and back to the palette unit in the case of Gamma correction.

#### 13.3.3.4.1 Priority Rule

The overlay manager can be configured in two distinct modes:

- Alpha mode (only source color key with the graphics layer)
- Normal mode (no alpha support)

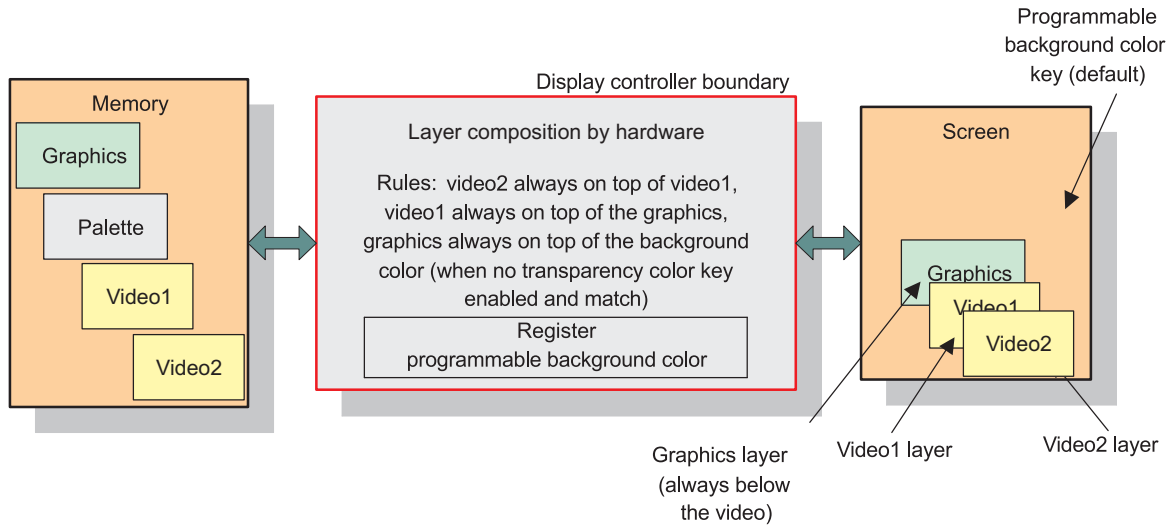

The following rules apply in normal mode:

The video1 layer is always on top of the graphics layer. The video2 layer is always on top of the video1 and graphics. The display controller reads the data for each buffer from the system memory and, depending on the transparency color key values, displays either the pixels in the video layer, the pixels in the graphics layer, or the solid background color.

Each layer can have any size up to full-display screen. If there are no graphics or video-encoded pixels at a specific position, the programmable, solid background color appears (see [Figure 13-48](#)).

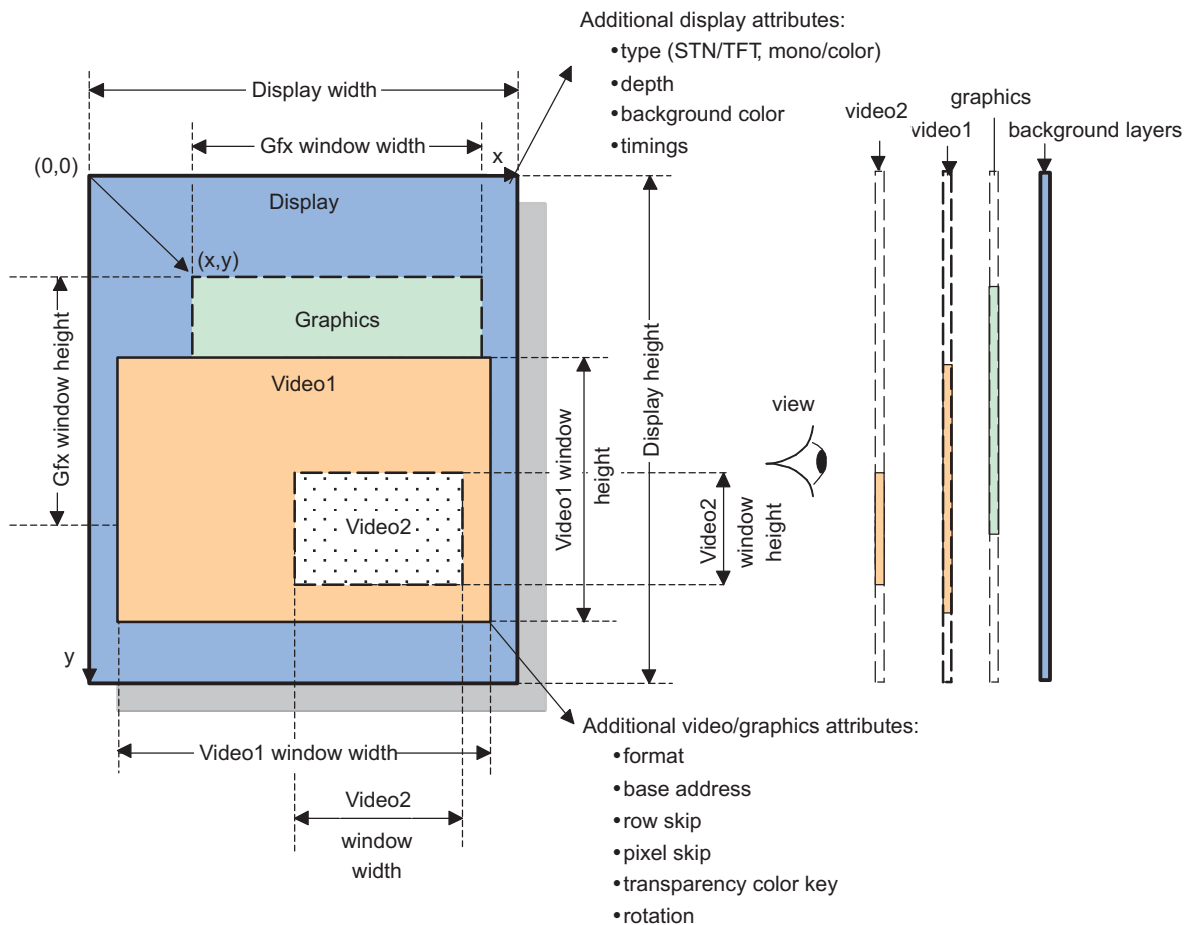

**Figure 13-44. Overlay Manager in Normal Mode**

dss-072

**Figure 13-45. Display Attributes in Normal Mode**

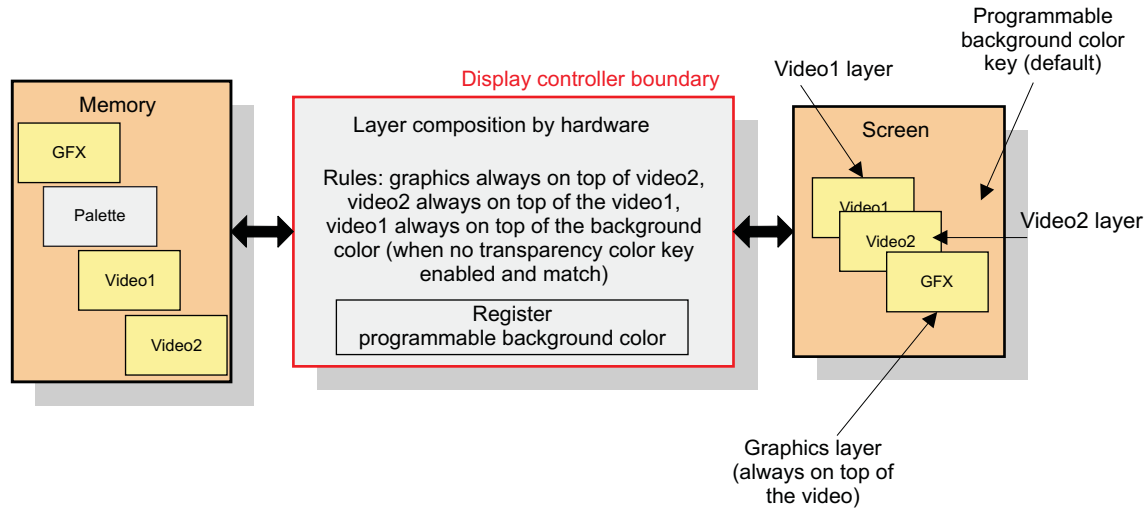

dss-073

The following rules apply in alpha mode:

The video2 layer is always on top of the video1 layer. The graphics layer is always on top of the video1 and video2. The display controller reads the data for each buffer from the system memory and, depending on the transparency color key values, displays either the pixels in the video layer, the pixels in the graphics layer, or the solid background color.

Each layer can have any size up to full-display screen. If there are no graphics or video-encoded pixels at a specific position, the programmable, solid background color appears (see [Figure 13-48](#)).

**Figure 13-46. Overlay Manager in Alpha Mode**

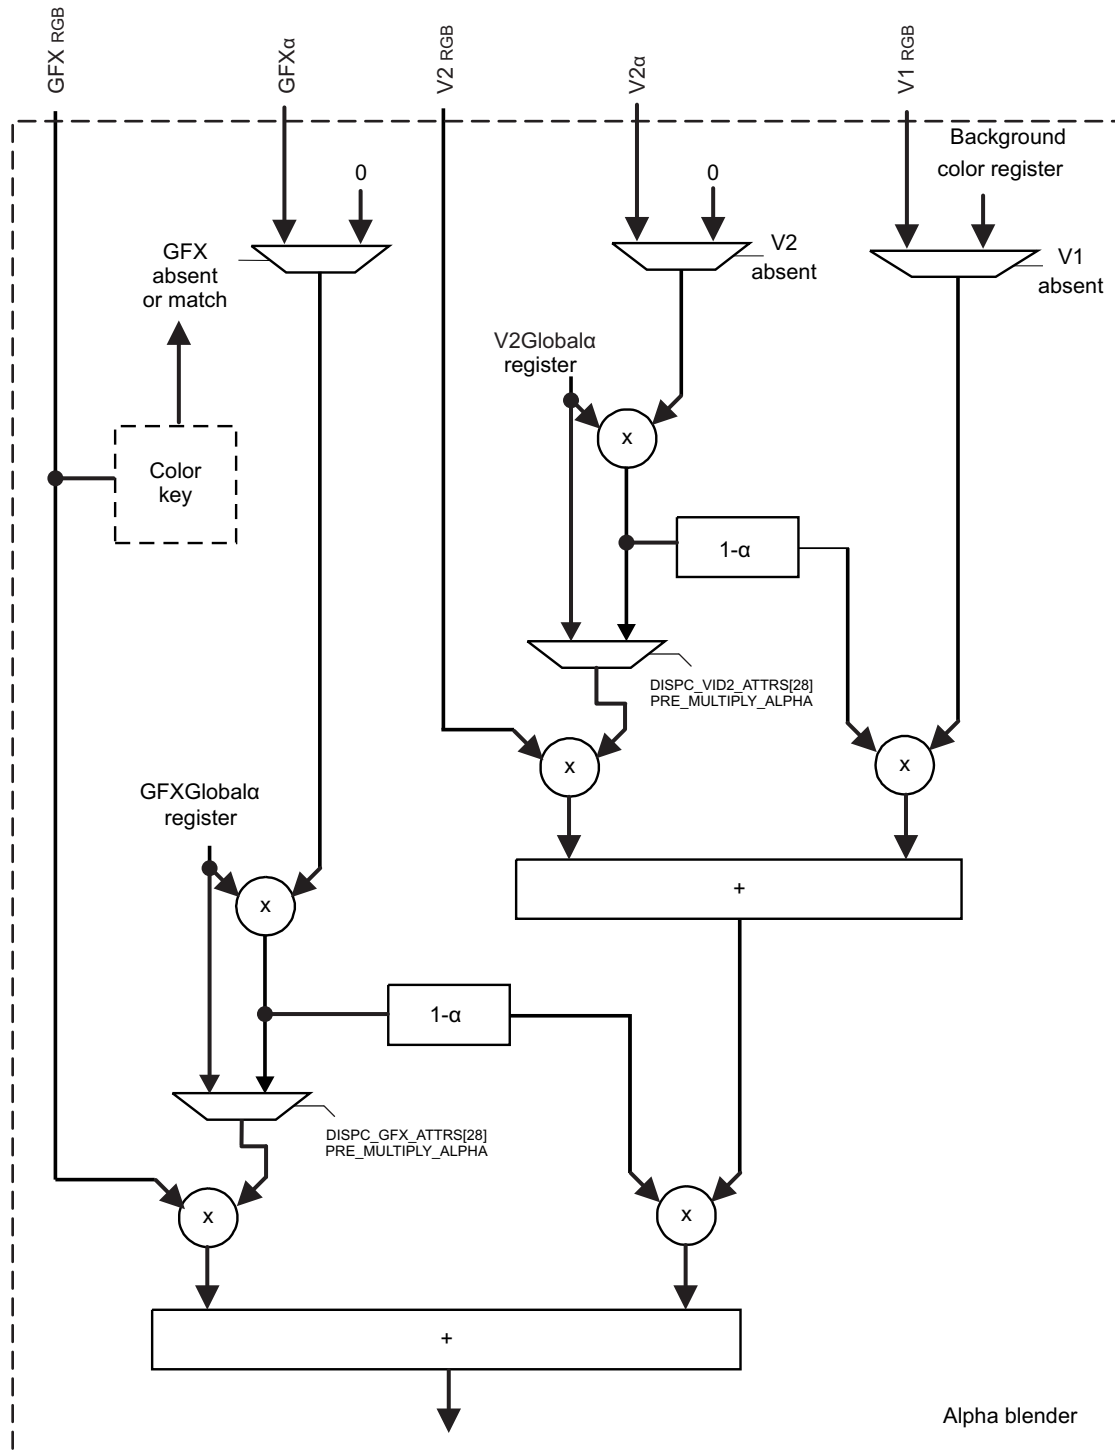

dss-163

**Figure 13-47. Display Attributes in Alpha Mode**

dss-164

Figure 13-48 shows the alpha blending processing in detail.

**Figure 13-48. Alpha Blending Macro Architecture with Pre-multiplied Alpha Support**

**NOTE:** "1-alpha" operator corresponds to the basic 1's complement operation.

The pre-multiplied alpha option is accessible through DSS.DISPC\_GFX\_ATTRS[28] PRE\_MULTIPLY\_ALPHA and DSS.DISPC\_VIDn\_ATTRS[28] PRE\_MULTIPLY\_ALPHA registers bits. The following settings are available:

- PRE\_MULTIPLY\_ALPHA bit = '0' : Source is not pre-multiplied with alpha. Full blending is done in the

DISPC.

- PRE\_MULTIPLY\_ALPHA bit = '1' : Source is pre-multiplied with alpha. Partial blending is done.

**NOTE:** The pre-multiplied alpha option is only valid when bit fields DSS.DISPC\_GFX\_ATTRS[4:1] GFX\_FMT and DSS.DISPC\_VIDn\_ATTRS[4:1] VID\_FMT, respectively, are set to ARGB or RGBA formats. Otherwise, the PRE\_MULTIPLY\_ALPHA bit fields are ignored by the hardware.

The alpha blending value is defined by the pixel value (ARGB or RGBA formats). A global alpha blending value can be defined and used in combination with the pixel alpha blending value. If the pixel format contains no alpha blending value, the pixel alpha value is considered to be 0xFF.

In case of ARGB-444, the alpha blending is defined using a 4-bit value. It is converted into an 8-bit value by duplicating the 4-bit value. [Table 13-14](#) details the alpha blending 4-bit values and the corresponding blending percentage.

**Table 13-14. Alpha Blending 4-Bit Values**

Alpha Blending 4-Bit Value (ARGB-444)	Alpha Blending 8-Bit Value (Converted Value)	% Blending
0x0	0x00	100% (transparent)
0x1	0x11	93.33%
0x2	0x22	86.6%
...	...	...
0xE	0xEE	6.6%
0xF	0xFF	0% (opaque)

### 13.3.3.4.2 Transparency Color Keys

#### 13.3.3.4.2.1 Normal Mode

This section describes the features available in normal mode.

The two transparency color keys are the video source transparency color key and the graphics destination transparency color key. The encoded pixel color value is compared to the transparency color key. For CLUT bitmaps, the palette index is compared to the transparency color key and not to the palette value pointed out by the palette index.

**NOTE:** The video source transparency color key and graphics destination transparency color key cannot be active at the same time.

- Video source transparency color key value:

The video source transparency color key value defines the encoded pixel data considered as the transparent pixel. The encoded pixel values with the source color key value are pixels not visible on the screen, and the underlayer encoded pixel values or solid background color are visible.

The video source transparency color key can be used only if the color space conversion and the up/down-scaling modules are disabled. The format of the data is RGB 16. (This feature handles the hardware cursor displayed by one of the video layers.)

To enable the video source transparency color key, set to 0x1 the DSS.DISPC\_CFG[11] TCK\_LCD\_SELECTION bit for LCD output or the DSS.DISPC\_CFG[13] TCK\_DIG\_SELECTION bit for digital output. Program the DSS.DISPC\_CFG[10] TCK\_LCD\_EN bit (LCD output) or the DSS.DISPC\_CFG[12] TCK\_DIG\_EN bit (digital output) to enable or disable the transparency color key.

An example is shown in [Figure 13-49](#): The video source transparency is applied on video1 (VID1) and video2 (VID2) layers. The pixels with the transparency color key are not displayed; instead, underlying layers are shown.

**Figure 13-49. Video Source Transparency Example**

dss-074

- Graphics destination transparency color key value:

The graphics destination transparency color key value defines the encoded pixels in the video layers to be displayed. The encoded pixel values with the destination color key value are pixels not visible on the screen and the pixels different from the transparency color key are displayed over the video layers. The destination transparency color key is applicable only in the graphics region when graphics and video overlap; otherwise, the destination transparency color key is ignored.

To enable the graphics destination transparency color key, set to 0x0 the DSS.DISPC\_CFG[11] TCK\_LCD\_SELECTION bit for LCD output or the DSS.DISPC\_CFG[13] TCK\_DIG\_SELECTION bit for digital output. Program the DSS.DISPC\_CFG[10] TCK\_LCD\_EN bit (LCD output) or the DSS.DISPC\_CFG[12] TCK\_DIG\_EN bit (digital output) to enable or disable the transparency color key.

An example is shown in [Figure 13-50](#): The destination transparency is applied on graphics (GFX) layer and the pixels without the transparency color key are displayed over the overlying layers.

**Figure 13-50. Graphics Destination Transparency Example**

dss-075

### 13.3.3.4.2.2 Alpha Mode

This section describes the features available in alpha mode.

Only the graphics source transparency color key is available. The encoded graphics pixel color value is compared to the transparency color key. The encoded pixel values with the source transparency key are not visible and the under-layer encoded pixel values or solid background color are visible. To enable the graphics source transparency color key, set to 0x0 the DSS.DISPC\_CFG[11] TCK\_LCD\_SELECTION bit for LCD output or the DSS.DISPC\_CFG[13] TCK\_DIG\_SELECTION bit for digital output. Program the DSS.DISPC\_CFG[10] TCK\_LCD\_EN bit (LCD output) or the DSS.DISPC\_CFG[12] TCK\_DIG\_EN bit (digital output) to enable or disable the transparency color key. In the case of CLUT bit maps, the palette index is compared to the transparency color key and not the palette value pointed out by the palette index.

### 13.3.3.4.3 Overlay Optimization (Only Available in Normal Mode)

The display controller can be configured to take advantage of the fact that the graphics pixels under video window 1 are not visible when the transparency color key is not used. The optimization can be selected to reduce the bandwidth used to fetch the pixels for graphics. The color key must be disabled. The graphics pixels under the video window 1 are not fetched from system memory. At least the video window 1 and the graphics window must be enabled. The following graphic formats are supported: RGB (RGB16 and RGB24 packed and unpacked), YUV4:2:2, and BITMAP 8. The formats BITMAP 1, 2, and 4 are not supported. The video format can be RGB (RGB16, RGB24 packed and unpacked, and YUV4:2:2 formats). The DMA engine does not fetch the unnecessary graphics pixels to avoid extra bandwidth use. Only visible pixels from graphics and video buffers in system memory are fetched and displayed by the display controller.

### 13.3.3.5 Active/Passive Matrix Display Data Path

For active matrix display data path, the following blocks are serial and each of them can be bypassed:

- Color phase rotation
- Spatial/temporal dithering
- Multiple cycle data format

For passive matrix display data path, the following blocks are serial and each of them can be bypassed:

- Color phase rotation
- Spatial/temporal dithering
- Passive matrix technology

#### 13.3.3.5.1 Color Phase Rotation

The Color Phase Rotation (CPR) can be used to correct the LCD output colorimetry in case of non pure white backlight.

The color phase rotation can be selected for passive matrix and active matrix panel. The logic is integrated after the LCD overlay manager or the palette while using the gamma correction and before the spatial/temporal dithering. The color phase rotation can be selected to correct the nonpure white backlight of the LCD module by using a programmable matrix to convert the 24-bit RGB pixel value into a new 24-bit RGB pixel value. The matrix is programmed through a set of nine 10-bit signed coefficients. The output of the calculation is clipped to [0:255]. The color phase rotation is processed by the equation shown in [Figure 13-51](#).

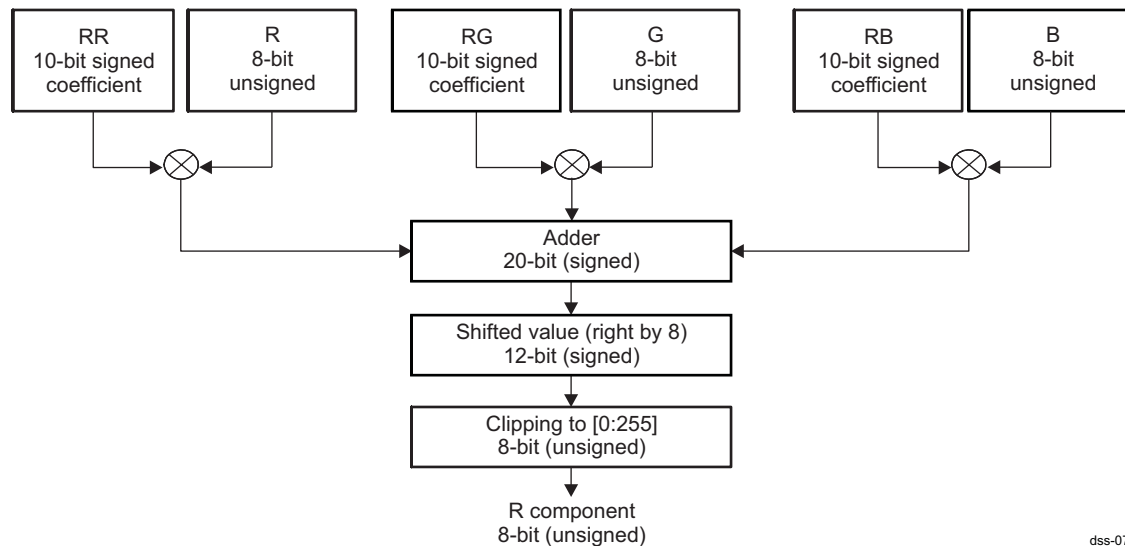

**Figure 13-51. Color Phase Rotation Matrix**

$$\begin{bmatrix} Rout \\ Gout \\ Bout \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} RR & RG & RB \\ GR & GG & GB \\ BR & BG & BB \end{bmatrix} * \begin{bmatrix} Rin \\ Gin \\ Bin \end{bmatrix}$$

dss-E076

Figure 13-52 shows the color phase rotation macro-architecture.

**Figure 13-52. Color Phase Rotation Macro Architecture**

dss-077

#### 13.3.3.5.1.1 Spatial/Temporal Dithering

The spatial/temporal dithering logic can be selected for passive matrix and active matrix panel. The dithering logic is integrated after the color phase rotation and before the TDM and passive matrix units. The spatial/temporal dithering logic can be selected to enhance the quality of the passive matrix and active matrix outputs. The dithering logic can process the pixels over a single frame, two frames, or four frames. In the case of a single frame, only spatial processing is applied. In the case of multiple frames, spatial and temporal processing is applied to the pixels.

- **Passive Matrix Technology:** The passive matrix display dithering logic path is used. The spatial/temporal dithering logic can be selected. When selected, the pixels are preprocessed by the spatial/temporal dithering logic before the passive matrix display dithering logic. The output format of the spatial/temporal dithering logic is RGB 12-bit (not configurable).
- **Active Matrix Technology:** The encoded pixel values are used by spatial/temporal dithering logic to display the data in a lower color depth on the LCD panel. The spatial/temporal dithering algorithm is based on the (x,y) pixel position, the value of removed bits and the frame number. The picture quality is improved when enabling the spatial/temporal dithering logic. When spatial/temporal dithering is not enabled, the three MSBs of the pixel color components are output on the interface data bus if the interface data bus is smaller than the pixel format size. If the interface data bus is wider than the pixel format size, by programming the pixel components replication active/inactive, the MSB is replicated to the LSB of the interface data bus or the LSB is filled with 0s.

#### 13.3.3.5.2 Passive Matrix Display Dithering Logic

- **Passive matrix technology**

After the graphics data are merged with the video data from the video layers depending on the transparency status, the result is sent to the color/grayscale space-/time-based dither generator. The monochrome data and each RGB color component are encoded on 4 bits, which are the 4 MSBs of the pixel-encoded component 8-bit value defined by the merge of the graphics data and the video data. These 4-bit values are used to select on the 16 intensity levels. The gray/color intensity is controlled by turning individual pixels on and off at varying period rates, making the average time the pixel is off longer than the average time the pixel is on, thus producing more intense grays/colors. The dithering generator also uses the intensity of adjacent pixels in the calculation to give the screen image a smooth appearance. The proprietary dither algorithm is optimized to provide a range of intensity values that matches the visual perception of color/gray graduations.

- **Active matrix technology**

The passive matrix dithering logic is always bypassed in active displays.

**NOTE:** If the interface data bus is smaller than the pixel format size, dithering logic can be enabled. If the interface data bus is wider than the pixel format size, the dithering logic cannot be enabled and replication feature can be used.

#### 13.3.3.5.3 Passive Matrix Display Output FIFO

- Passive matrix technology

The display controller contains a 2-entry by 8-bit-wide output FIFO used to store pixel data before it is driven out to the LCD pins. Each time a modulated pixel value is output from the dither generator, it is placed into a serial shifter. The shifter can be configured to be 4 or 8 bits wide. Single-panel monochrome screens use either four or eight data lines; single-panel color screens use eight data pins.

- Active matrix technology

The output FIFO is bypassed in active matrix mode.

#### 13.3.3.5.4 Multiple Cycle Output Format

The pixels after the active matrix display processing are formatted on one or multiple cycles (from one to three cycles). The interface width can be 8-, 9-, 12-, or 16-bit. On three cycles, two pixels can concatenate and send to the panel. When the TDM is disabled, the display controller outputs the pixels using the conventional formats: Passive matrix display/active matrix display monochrome/color.

The following example shows an output configuration based on the interface width (8-bit) and the pixel format output (24-bit) (also see [Table 13-15](#)):

- The DSS.DISPC\_CTRL[24:23] TDM\_CYCLE\_FMT bit field is set to 0x2 (three cycles for one pixel).
- The DSS.DISPC\_DATA\_CYCLEk (k=0) register is set to 0x00000008 (8 bits from pixel 1 for the first cycle).
- The DSS.DISPC\_DATA\_CYCLEk (k=1) register is set to 0x00000008 (8 bits from pixel 1 for the second cycle).
- The DSS.DISPC\_DATA\_CYCLEk (k=2) register is set to 0x00000008 (8 bits from pixel 1 for the third cycle).

**Table 13-15. 8-Bit Interface Configuration/24-Bit Mode**

	24-Bit Mode		
	1st Cycle	2nd Cycle	3rd Cycle
Data[7]	R0[7]	G0[7]	B0[7]
Data[6]	R0[6]	G0[6]	B0[6]
Data[5]	R0[5]	G0[5]	B0[5]
Data[4]	R0[4]	G0[4]	B0[4]
Data[3]	R0[3]	G0[3]	B0[3]
Data[2]	R0[2]	G0[2]	B0[2]
Data[1]	R0[1]	G0[1]	B0[1]
Data[0]	R0[0]	G0[0]	B0[0]

#### 13.3.3.6 Video Line Buffer

The line buffer size is 1024 x 24-bit. There are six line buffers (1024 x 24-bit) that can be merged into three lines (2048 x 24-bit). [Table 13-16](#) lists the maximum width depending on the TAP configuration and the pixel format.

**Table 13-16. Maximum Width Allowed**

Vertical Tap	Pixel Format	Maximum Width (Pixels)
3	RGB16	2048
	RGB24	
	YUV4:2:2	
5	RGB16	1024
	RGB24	
	YUV4:2:2	

### 13.3.3.7 Synchronized Buffer Update

A synchronization mismatch between the frame buffer and the display refreshes, named tearing effect, can lead to images that appear to be stretched on the screen. To avoid this, a synchronization mechanism is needed between the display controller and the process that updates the buffer. An interrupt is generated when the display reaches a predefined line number. This PROGRAMMEDLINENUMBER interrupt is a level signal and stays active during the programmed line of the display.

### 13.3.3.8 Multiple Buffer Support

Users update the base address of the buffer when the update of the working buffer has finished and is ready to be displayed. The register that contains the base address of the buffer is a shadow register that is read by the hardware at the next Vertical Front Porch (VFP).

## 13.3.4 RFBI Functionalities

The RFBI module can capture the output pixel from the display controller and send the data to the RFB in the LCD panel. The application configures the RFBI module, sends commands, reads data, and configures the display controller to send data fetched from the system memory by the display controller DMA engine. The commands/data are sent using an 8-, 9-, 12-, or 16-bit parallel interface.

The display controller is configured to send the data in 12-, 16-, 18-, or 24-BPP format. In the video port FIFO, the encoded pixel values are in an LSB alignment independently of the endianness in system memory.

[Figure 13-53](#) shows an overview of the RFBI architecture.

Figure 13-53. RFBF Architecture Overview

#### 13.3.4.1 RFBF FIFO

The input video port FIFO receives data from the display controller at the pixel clock. The data in the video port FIFO are read by the RFBF and are sent to the LCD panel. The video port FIFO is 24 bits wide and each pixel in 12-, 16-, 18-, and 24-BPP format is stored in the video port FIFO using one 24-bit value aligned on the 24-bit LSB. [Section 13.3.4.4, Output Parallel Modes](#), shows an example of an output configuration based on the interface width (16 bits) and the pixel format output (24 bits).

#### 13.3.4.2 RFBF Interconnect FIFO

The interconnect FIFO receives the data from RFBF\_DATA write requests to the L4 interconnect slave port. The data in the interconnect FIFO are read by the RFBF and sent to the LCD panel. The width of the interconnect FIFO is 32 bits. The size of the interconnect FIFO is 24 words of 32 bits (that is, 24 words of RFBF\_DATA).

#### 13.3.4.3 Input Pixel Formats

The supported pixel formats in the RFBF module are: RGB24-888, RGB18-666, RGB16-565, and RGB12-444 as output from the display controller and from the L4 (for writing parameters). In both cases, the pixels are formatted in accordance with the configuration of the output interfaces (multiple cycles).

#### 13.3.4.4 Output Parallel Modes

The RFBF output modes are 8-, 9-, 12-, and 16-bit interfaces. Any mode can be selected regardless of the pixel format. Set the right configuration in the cycle registers to define a valid configuration for each output cycle.

The following example is an output configuration based on the 16-bit interface width and the 24-bit pixel format ( $i = 0$  or  $1$ ) (see also [Table 13-17](#)):

- The DSS.RFBF\_CONFIG\_i[10:9] CYCLE\_FMT bit field is set to 0x3 (three cycles for two pixels).

- The DSS.RFBI\_DATA\_CYCLE1\_i register is set to 0x00000010 (16 bits from pixel 1 for the first cycle).
- The DSS.RFBI\_DATA\_CYCLE2\_i register is set to 0x00080808 (8 bits from pixel 1 and pixel 2 and alignment of 8 bits from pixel 2 for the second cycle).
- The DSS.RFBI\_DATA\_CYCLE3\_i register is set to 0x00100000 (16 bits from pixel 2 for the third cycle).

**Table 13-17. 16-Bit Interface Configuration/24-Bit Mode**

	24-Bit Mode		
	1st Cycle	2nd Cycle	3rd Cycle
Data[15]	R0[7]	B0[7]	G1[7]
Data[14]	R0[6]	B0[6]	G1[6]
Data[13]	R0[5]	B0[5]	G1[5]
Data[12]	R0[4]	B0[4]	G1[4]
Data[11]	R0[3]	B0[3]	G1[3]
Data[10]	R0[2]	B0[2]	G1[2]
Data[9]	R0[1]	B0[1]	G1[1]
Data[8]	R0[0]	B0[0]	G1[0]
Data[7]	G0[7]	R1[7]	B1[7]
Data[6]	G0[6]	R1[6]	B1[6]
Data[5]	G0[5]	R1[5]	B1[5]
Data[4]	G0[4]	R1[4]	B1[4]
Data[3]	G0[3]	R1[3]	B1[3]
Data[2]	G0[2]	R1[2]	B1[2]
Data[1]	G0[1]	R1[1]	B1[1]
Data[0]	G0[0]	R1[0]	B1[0]

#### 13.3.4.5 Unmodified Bits

In a cycle, if every bit in the interface does not have a pixel value, the status of the unused bits can be programmed to be 0, 1, or the previous value (I/O power consumption optimization).

#### 13.3.4.6 Bypass Mode

In bypass mode, the RFBI path is bypassed and the display controller data and signals are sent directly to the output interface of the RFBI.

#### 13.3.4.7 Send Commands

The commands are written through the L4 interconnect and into the DSS.RFBI\_CMD register. After a command is sent, another one can be accepted by the module and set. If the processing of a command is not complete, the MPU access to change the command stalls.

#### 13.3.4.8 Read/Write

Depending on the status of A0, WE, and RE, the commands and display/parameter data are written to the panel (handled by the state-machine for the commands/parameter data and stored in memory for the display data), or the display data/status values are read from the LCD panel (status and display data in the LCD panel memory). The polarity of A0 (RFBI\_A0 signal), WE (RFBI\_WR signal), RE (RFBI\_RD signal), and CSx (RFBI\_CSx signal, with x = 0, 1) is programmable.

[Table 13-18](#) describes the read/write function.

**Table 13-18. Read/Write Function Description**

A0 (RFBI_A0)	WE (RFBI_WR)	RE (RFBI_RD)	Function Description
1	0	1	Display data write, parameter data write
1	1	0	Display data read
0	1	0	Status read
0	0	1	Command data write

A minimum of RFBI\_Cs cycle time, as defined in [Table 13-19](#), is required to keep the RFBI\_CSx signal asserted between write transfers of multiple pixels.

[Table 13-19](#) indicates the minimum cycle time for RFBI\_CSx, depending on the source of pixels (display controller or L4 interconnect slave port) and the cycle format (1 pixel/cycle, 1 pixel/2 cycles, 1 pixel/3 cycles, or 2 pixels/3 cycles).

**Table 13-19. Minimum Cycle Time for CSx/WE Always Asserted**

RFBI Performance	RFBI_CONFIG_i[10:9] CYCLE_FMT	RFBI_CONFIG_i[8:7] L4_FMT	Minimum Cycle Time (in Number of L4 Cycles)
L4 interconnect	1 pixel/cycle	1 pixel	5
	1 pixel/2 cycles	1 pixel	4
	1 pixel/3 cycles	1 pixel	4
	2 pixels/3 cycles	1 pixel	6
	1 pixel/cycle	2 pixels	4
	1 pixel/2 cycles	2 pixels	4
	1 pixel/3 cycles	2 pixels	4
	2 pixels/3 cycles	2 pixels	6
Display Controller	1 pixel/cycle	N/A	4
	1 pixel/2 cycles	N/A	3
	1 pixel/3 cycles	N/A	3
	2 pixels/3 cycles	N/A	6

## 13.3.5 Hardware Requests

### 13.3.5.1 Display Controller DMA Request (Line Trigger)

One DMA synchronization line (DSS\_LINE\_TRIGGER) is connected to the sDMA by the sDMA controller (S\_DMA\_5) input line. This DMA request is not a classical one but a synchronization signal from the display subsystem to the sDMA informing the sDMA that a programmable number of lines are output to the LCD, and that the system memory can be updated. This allows the sDMA channel to be synchronized with the display subsystem internal DMA controller. In other words, it allows to synchronize a memory to memory frame buffer update based on the scan line of the frame buffer in system memory (SDRAM or SRAM) by the display controller. The DSS\_LINE\_TRIGGER DMA request is generated at a programmable line number defined in DSS.DISPC\_LINE\_NUMBER[10:0] LINE\_NUMBER bit field.

### 13.3.5.2 RFBI DMA Request

The RFBI\_DMA\_REQ is used to receive data into the RFBI FIFO. The DMA request is always generated when there is enough room in the FIFO to accept the full burst.

### 13.3.5.3 DISPC Interrupt Request

The interrupt line indicates when one or more events are detected by the hardware. Each event is independently maskable by setting the DSS.DISPC\_IRQEN register.

To check when a particular interrupt event occurs and to reset a particular event, the DSS.DISPC\_IRQSTS register must be accessed. This register regroups all the status of the module internal events that generate an interrupt (read 0: No interrupt occurred; read 1: Interrupt occurred; write 1: Status bit reset). See the registers in [Section 13.6](#) for more information on checking and clearing interrupt events. [Table 13-20](#) lists the display subsystem interrupt events.

**Table 13-20. Display Subsystem Interrupts**

Interrupt Name	Description
FRAMEDONE	Active frame is complete and LCD output is disabled.
VSYNC	VSYNC interrupt occurred at the end of the frame.
EVSYNC_EVEN <sup>(1)</sup>	EVSYNC_EVEN interrupt occurred at the end of the frame. (EVSYNC is received and the field polarity is even.)
EVSYNC_ODD <sup>(1)</sup>	EVSYNC_ODD interrupt occurred at the end of the frame. (EVSYNC is received and the field polarity is odd.)
ACBIASCOUNTSTATUS	The ac-bias transition counter decremented to 0.
PROGRAMMEDLINENUMBER	The LCD reached the user-programmed line number.
GFXFIFOUNDERFLOW	The input graphics FIFO goes underflow.
GFXENDWINDOW	The screen reached the end of the graphics window. All data for the graphics window are fetched from memory and displayed on the screen.
PALETTEGAMMALOADING	The palette/gamma table is loaded.
OCPEERROR	L3 interconnect sent SResp = ERR.
VID1FIFOUNDERFLOW	The input video1 FIFO goes underflow.
VID1ENDWINDOW	The screen reached the end of video1 window. All data for the video window are fetched from the memory and displayed on the screen.
VID2FIFOUNDERFLOW	The input video2 FIFO goes underflow.
VID2ENDWINDOW	The screen reached the end of video2 window. All data for the video window are fetched from the memory and displayed on the screen.
SYNCLOST	Interrupt occurs when VSYNC width/front or back porches are not wide enough to load the pipelines with data (LCD output).
SYNC_LOST_DIGITAL	Interrupt occurs when the display controller is not ready to output data when a digital request occurs. This interrupt informs that the timings of the NTSC/PAL video encoder are not set correctly.
WAKEUP	Occurs when the wakeup signal is asserted

<sup>(1)</sup> EVYNC interrupts (EVSYSNc\_EVEN and EVSYNc\_ODD) are external interrupts received by the display controller and generated by the video encoder (VENC) module.

---

**NOTE:** To clear a synchronization lost interrupt, follow this sequence:

1. Clear the DSS.DISPC\_CTRL[0] LCD\_EN (LCD: SYNCLOST interrupt) or DSS.DISPC\_CTRL[1] DIGITAL\_EN (TV: SYNC\_LOST\_DIGITAL interrupt) bits.

Check the interrupts.

LCD: Verify that a FRAMEDONE interrupt occurs.

TV : Verify that EVSYNC\_EVEN or EVSYNC\_ODD interrupts occur.

2. Set the DSS.DSS\_SYSCONFIG[1] SOFTRESET bit to reset the display subsystem.
  3. Set the display subsystem registers again.
- 

**NOTE:** The SYNC\_LOST\_DIGITAL interrupts, which occur before the first VSYNC pulse signal (from the video encoder), must not be considered.

After the first VSYNC pulse signal, the SYNC\_LOST\_DIGITAL interrupt status bit must be cleared by writing 1 in the DSS.DISPC\_IRQSTS[15] SYNC\_LOST\_DIGITAL bit; then the SYNC\_LOST\_DIGITAL interrupt can be enabled by setting the DSS.DISPC\_IRQEN[15] SYNC\_LOST\_DIGITAL bit.

---

## 13.4 Programming Model

This section describes how to configure the display subsystem for the desired functionalities and also describes the programming models of the display controller, the RFBI and the video encoder.

The main configuration scenarios are:

- LCD panel support (bypass or RFBI mode)  
Configure the RFBI module (only if in RFBI mode; otherwise, the default values must remain), and then configure the display controller to the desired functionalities before the activities start.
- TV set support  
Configure the video encoder and then the display controller.
- Both LCD panel support (bypass or RFBI mode) and TV set support  
Configure the RFBI module (only if in RFBI mode; otherwise, leave the default values), configure the video encoder, and then configure the display controller.

### 13.4.1 Display Subsystem Reset

The display subsystem can receive a software reset that is propagated through all of the submodules to initialize the subsystem. The following procedure describes a possible sequence:

1. If the LCD is on, stop the LCD by setting the DSS.DISPC\_CTRL[0] LCD\_EN bit to 0.
  - (a) Reset the frame done status bit by writing 1 in the DSS.DISPC\_IRQSTS[0] FRMDONE bit.
  - (b) Wait until the DSS.DISPC\_IRQSTS[0] FRMDONE bit is set to 1. This shows that the end of frame has taken place and the LCD stop is complete.
2. To take the display subsystem out of reset, all clocks related to the display subsystem must be enabled and the DPLL4 must be enabled. The following clocks must be enabled to take the display subsystem out of reset:
  - PRCM.CM\_FCLKEN\_DSS[0] EN\_DSS1 bit set to 1
  - PRCM.CM\_FCLKEN\_DSS[1] EN\_DSS2 bit set to 1
  - PRCM.CM\_FCLKEN\_DSS[2] EN\_TV bit set to 1
  - PRCM.CM\_ICLKEN\_DSS[0] EN\_DSS bit set to 1
 Once the clocks are enabled as shown, the display subsystem can be taken out of reset.
3. Write 1 in the DSS.DSS\_SYSCONFIG[1] SOFTRESET bit to apply the soft reset to the subsystem.
4. Read the DSS.DSS\_SYSSTS[0] RESETDONE bit. If this bit is 1, the reset sequence is complete; otherwise, read this bit again (the reset sequence is not completed).

### 13.4.2 Display Subsystem Configuration Phase

The display subsystem configuration phase is important to configure the data flow for using the LCD panel or the TV set. Use the following flow:

1. To configure the top level of the functional clock of the display controller clock, set the DSS.DSS\_CONTROL[0] DSS\_CLK\_SWITCH bit.
2. To configure the top level of the video encoder, set the DSS.DSS\_CONTROL[2] VENC\_CLOCK\_MODE bit and the DSS.DSS\_CONTROL[3] VENC\_CLOCK\_X4\_EN bit for TV set support.
3. To configure the top level of the DAC stage, set the DSS.DSS\_CONTROL[4] DAC\_DEMEN bit for TV set support (if required).
4. Configure the RFBI module and/or the video encoder as needed.
5. Configure the display controller.

### 13.4.3 Display Controller Basic Programming Model

Some display controller registers are termed *shadow registers*, which are associated with the digital output and/or the LCD output. A shadow register change has no direct effect on the configuration of the display controller unless the DSS.DISPC\_CTRL[5] GO\_LCD bit is set for the LCD output and/or the DSS.DISPC\_CTRL[6] GO\_DIGITAL bit is set for the digital output.

In the case of the digital output, after programming the shadow registers, the DSS.DISPC\_CTRL[6] GO\_DIGITAL bit must be set to 1. If this bit is not set, the configuration of the display controller will have no effect. This setting indicates that all display controller shadow registers are programmed and that hardware can update the internal registers at the external EVSYNC.

In the case of the LCD output, after programming the shadow registers, the DSS.DISPC\_CTRL[5] GO\_LCD bit must be set to 1. If this bit is not set, the configuration of the display controller will have no effect. This setting indicates that all display controller shadow registers are programmed and that hardware can update the internal registers at the VFP start period.

Before setting either the DSS.DISPC\_CTRL[5] GO\_LCD or DSS.DISPC\_CTRL[6] GO\_DIGITAL bit, ensure that the bit is cleared.

Table 13-21 lists the shadow registers.

**Table 13-21. Shadow Registers**

Shadow Register Name	Updated on VFP Start Period (LCD output)	Updated on External VSYNC (Digital output)
DSS.DISPC_CTRL	X <sup>(1)</sup>	X <sup>(1)</sup>
DSS.DISPC_CFG	X	X
DSS.DISPC_DEFAULT_COLOR_m (m = 0)	X	
DSS.DISPC_DEFAULT_COLOR_m (m = 1)		X
DSS.DISPC_TRANS_COLOR_m (m = 0)	X	
DSS.DISPC_TRANS_COLOR_m (m = 1)		X
DSS.DISPC_LINE_NUMBER	X	
DSS.DISPC_TIMING_H	X	
DSS.DISPC_TIMING_V	X	
DSS.DISPC_POL_FREQ	X	
DSS.DISPC_DIVISOR	X	
DSS.DISPC_SIZE_DIG		X
DSS.DISPC_SIZE_LCD	X	
DSS.DISPC_GFX_BA <sub>j</sub> (j = 0,1)	X	X
DSS.DISPC_GFX_POSITION	X	X
DSS.DISPC_GFX_SIZE	X	X
DSS.DISPC_GFX_ATTRS	X	X
DSS.DISPC_GFX_FIFO_THR	X	X
DSS.DISPC_GFX_ROW_INC	X	X
DSS.DISPC_GFX_PIXEL_INC	X	X
DSS.DISPC_GFX_WINDOW_SKIP	X	X
DSS.DISPC_GFX_TBL_BA	X	X
DSS.DISPC_GFX_PRELOAD	X	X
DSS.DISPC_CPR_COEF_R	X	
DSS.DISPC_CPR_COEF_G	X	
DSS.DISPC_CPR_COEF_B	X	
DSS.DISPC_VIDn_BA <sub>j</sub> (j = 0,1)	X	X
DSS.DISPC_VIDn_POSITION	X	X
DSS.DISPC_VIDn_SIZE	X	X
DSS.DISPC_VIDn_ATTRS	X	X

<sup>(1)</sup> Some of the register bit fields are shadow bits. For more information, see [Section 13.6, Display Subsystem Register Manual](#).

**Table 13-21. Shadow Registers (continued)**

Shadow Register Name	Updated on VFP Start Period (LCD output)	Updated on External VSYNC (Digital output)
DSS.DISPC_VIDn_FIFO_THR	X	X
DSS.DISPC_VIDn_ROW_INC	X	X
DSS.DISPC_VIDn_PIXEL_INC	X	X
DSS.DISPC_VIDn_FIR	X	X
DSS.DISPC_VIDn_PICTURE_SIZE	X	X
DSS.DISPC_VIDn_ACCUI (I = 0,1)	X	X
DSS.DISPC_VIDn_FIR_COEF_H_i (i = 0 to 7)	X	X
DSS.DISPC_VIDn_FIR_COEF_HV_i (i = 0 to 7)	X	X
DSS.DISPC_VIDn_FIR_COEF_Vi (i = 0 to 7)	X	X
DSS.DISPC_VIDn_CONV_COEFi (i = 0 to 4)	X	X
DSS.DISPC_VIDn_PRELOAD	X	X
DSS.DISPC_DATA_CYCLEk (k = 0 to 3)	X	

### 13.4.3.1 Display Controller Configuration

The following registers define the display controller configuration:

- DSS.DISPC\_SYSCFG
- DSS.DISPC\_SYSSTS
- DSS.DISPC\_IRQSTS
- DSS.DISPC\_IRQEN

### 13.4.3.2 Graphics Layer Configuration

The graphics layer configuration is common to the LCD and the TV set.

#### 13.4.3.2.1 Graphics DMA Registers

The following registers define the graphics DMA engine configuration:

- DSS.DISPC\_CTRL
- DSS.DISPC\_GFX\_BA<sub>j</sub>
- DSS.DISPC\_GFX\_ATTRS
- DSS.DISPC\_GFX\_ROW\_INC
- DSS.DISPC\_GFX\_PIXEL\_INC
- DSS.DISPC\_GFX\_FIFO\_THR
- DSS.DISPC\_GFX\_TBL\_BA

The following fields define the attributes of the graphics DMA engine:

- Graphics layer enable (DSS.DISPC\_GFX\_ATTRS[0] GFX\_EN bit): The default value of this bit at reset time is 0x0 (Disabled). The graphics DMA engine fetches encoded pixels from the system memory only when the graphics layer is enabled (a valid configuration is programmed for the graphics layer). The graphics window is present and the graphics pipeline is active.
- Burst size (DSS.DISPC\_GFX\_ATTRS[7:6] GFX\_BURST\_SIZE field): The default burst size at reset time is 4 x 32 bytes. The possible values are 4 x 32, 8 x 32, and 16 x 32 bytes. The burst size is initialized at boot time by the software and never changes as long as the display controller is enabled. This field indicates the maximum burst size for the specific pipeline. In case of misalignment, the DMA engine may issue single and/or smaller burst requests because the burst size must be aligned to the burst boundary.
- Preload configuration (DSS.DISPC\_GFX\_ATTRS[11] GFX\_FIFO\_PRELOAD bit): The default preload configuration uses the DSS.DISPC\_GFX\_PRELOAD register value (the reset value is 256 bytes) to

define the number of bytes to be fetched from system memory into the display controller graphics FIFO. By programming the DSS.DISPC\_GFX\_ATTRS[11] GFX\_FIFO\_PRELOAD bit, software users select between preload register (with 256 bytes as the reset value) and the high threshold value for preload of the encoded pixels. For best performance, the configuration of thresholds is defined using the FIFO size (in bytes) minus 1 for the high threshold, and the FIFO size (in bytes) minus the burst size (in bytes) for the low threshold, which provides 960, 992, and 1008, respectively, for burst sizes 16x32, 8x32, and 4x32. Note also that the preload value is defined based on the following display types:

- Active matrix (TFT) display: DSS.DISPC\_GFX\_PRELOAD[11:0] PRELOAD = 0x60 (value is 96)
- Color passive matrix (STN) display: DSS.DISPC\_GFX\_PRELOAD[11:0] PRELOAD = 0x72 (value is 114)
- Monochrome passive matrix (STN) display: DSS.DISPC\_GFX\_PRELOAD[11:0] PRELOAD = 0xE0 (value is 224)
- Base address of the graphics buffer in system memory (DSS.DISPC\_GFX\_BA<sub>j</sub> registers): The default value of these two registers at reset time is 0x0. The horizontal resolution is one pixel because the base address is aligned on a pixel size boundary. In case of 4 BPP, the resolution is two pixels; for 2 BPP, resolution is four pixels; for 1 BPP, resolution is eight pixels; and for RGB24 packed format, the resolution is four pixels. The vertical resolution is one line. The register DSS.DISPC\_GFX\_BA0 defines the base address of the even field; and DSS.DISPC\_GFX\_BA1 defines the base of the odd field in the case of an external synchronization and based on the value of the input signal DISPC\_FID and the polarity. To improve system throughput, the base address should be aligned on the burst size boundary.
- Graphics FIFO threshold (DSS.DISPC\_GFX\_FIFO\_THR register): The low threshold (DSS.DISPC\_GFX\_FIFO\_THR[11:0] GFX\_FIFO\_LOW\_THR) and the high threshold (DSS.DISPC\_GFX\_FIFO\_THR[27:16] GFX\_FIFO\_HIGH\_THR) values define the FIFO DMA behavior. When the low level is reached, one or more requests are issued to the L3-based interconnect to fill up the FIFO to reach the high threshold. A request is issued as long as the FIFO has enough space available to accept a burst. The DMA engine then waits until the low level is reached to restart the requests. By setting the DSS.DISPC\_CFG[14] FIFO\_MERGE bit to 1, users merge the three FIFOs (GFX, VID1, and VID2). In this case, the low threshold (the DSS.DISPC\_GFX\_FIFO\_THR[11:0] GFX\_FIFO\_LOW\_THR bit field) and the high threshold (DSS.DISPC\_GFX\_FIFO\_THR[27:16] GFX\_FIFO\_HIGH\_THR bit field) values must be programmed with a multiplier factor of three (3 x value). By default, the FIFOs are not merged (the DSS.DISPC\_CFG[14] FIFO\_MERGE bit reset value is 0).
- Palette/gamma table used (DSS.DISPC\_CFG[3] PALETTEGAMMA\_TBL bit): The bit indicates if the palette must be loaded before the graphics data for the following frame. The bit is set by software and reset by hardware.
- Base address of the palette/gamma table buffer in system memory (DSS.DISPC\_GFX\_TBL\_BA register): The default value of this register at reset time is 0x0. The base address is aligned on a 32-bit address. Depending on the pixel size of graphics data (1, 2, 4, or 8 BPP), 16 (1, 2, or 4 BPP), or 256 (8 BPP) x 32-bit values are loaded from system memory into the internal table memory. To load the table when using the memory as a gamma table, the graphics pipeline is enabled and then disabled by the software when the palette loaded interrupt is generated. The overlay manager ignores the graphics pipe when the table is used as a gamma table.

---

**NOTE:** In case of RGB16 format and optimization enabled, the base address is aligned on a 32-bit boundary and the number of bytes to skip is a multiple of 4 bytes.

---

- Graphics Priority (DSS.DISPC\_GFX\_ATTRS[14] GFX\_ARBITRATION): The default value at reset time is 0x0. It is used to change between normal priority (value of 0) to high priority (value of 1) to change priority for the graphics channel vs. video channels. It can be used to give higher priority to the pipelines with real time constraint vs. non real time pipelines. For that is, pipelines associated to the LCD output in RFBI mode should have lower priority than pipelines associated to TV output.
- Graphics Self-Refresh (DSS.DISPC\_GFX\_ATTRS[15] GFX\_SELF\_REFRESH): The default value at reset time is 0x0. It is used to use the DMA FIFO without accessing the interconnect for multiple frames. Once, the data have been loaded to the DMA FIFO for displaying the frame, they are used for the following frames.

The sequence to activate the self-refresh is the following:

- Frame t: The bit field should be set at anytime during frame
- Frame t+1: Fetch of the data in the DMA FIFO and display of the frame
- Frame t+2: No access to the L3 interconnect, DMA FIFO uses to provide the pixels

The sequence to deactivate the self-refresh is the following:

- Frame t: No access to the L3 interconnect, DMA FIFO uses to provide the pixels, bit field can be changed at any time during the frame
- Frame t+1: Fetch of the data from system memory using the L3 interconnect

### 13.4.3.2.2 Graphics Layer Configuration Registers

The following registers define the graphics layer configuration:

- DSS.DISPC\_CFG
- DSS.DISPC\_GFX\_POSITION
- DSS.DISPC\_GFX\_SIZE
- DSS.DISPC\_GFX\_ATTRS

The graphics layer is enabled/disabled by setting/resetting the DSS.DISPC\_GFX\_ATTRS[0] GFX\_EN bit. When the graphics layer is disabled, the graphics window does not exist on the screen and the graphics pipeline and DMA are inactive.

Set a valid configuration before enabling the graphics layer. After a register change, either the DSS.DISPC\_CTRL[6] GO\_DIGITAL or DSS.DISPC\_CTRL[5] GO\_LCD bit must be set. The software must wait for the hardware to reset the bit before setting it. The software reset is not recommended because the application cannot ensure that the bit is reset before the hardware reset.

### 13.4.3.2.3 Graphics Window Attributes

The following fields define the attributes of the graphics window:

- Graphics format (DSS.DISPC\_GFX\_ATTRS[4:1] GFX\_FMT bit field): The default value of this bit field at reset time is 0x0 (BITMAP 1-BPP). The graphics format can be either: BITMAP1, BITMAP2, BITMAP4, or BITMAP8 (CLUT) or RGB12, RGB16, or RGB24 (true-color formats).
- Graphics window X-position (DSS.DISPC\_GFX\_POSITION[10:0] GFX\_POSX bit field): The default value at reset time is 0x0. The window X-position is from 0 to 2047 columns. All integer values in the range [0:2047] are allowed.
- Graphics window Y-position (DSS.DISPC\_GFX\_POSITION[26:16] GFX\_POSY bit field): The default value of this bit field at reset time is 0x0. The window Y-position is from 0 to 2047 rows. All integer values in the range [0:2047] are allowed.
- Graphics window width (DSS.DISPC\_GFX\_SIZE[10:0] GFX\_SIZEX bit field): The default value at reset time is 0x0 (1 pixel). The window width is from 1 to 2048 pixels. All integer values in the range [1:2048] are allowed for the following formats: 8 BPP, RGB12, RGB16, and RGB24. The width must be a multiple of eight pixels for 1 BPP, four pixels for 2 BPP, and two pixels for 4 BPP. The maximum bandwidth efficiency for accessing the pixels in system memory is reached when the width of the graphics window (in bytes) is a multiple of the graphics burst size defined in the DSS.DISPC\_GFX\_ATTRS[7:6] GFX\_BURST\_SIZE bit field (in bytes).

---

**NOTE:** When the RGB24 packed format is selected, the width must be a multiple of 12 bytes when the DSS.DISPC\_GFX\_ROW\_INC register is not 1. When DSS.DISPC\_GFX\_ROW\_INC register is 1, the width can be any size from 1 to 2048 pixels.

The entire pixels of the graphics window must be inside the LCD screen. Depending on the width of the buffer to be displayed in the graphics layer and the position, the width should be adjusted by software to limit the right edge of the window inside the screen.

---

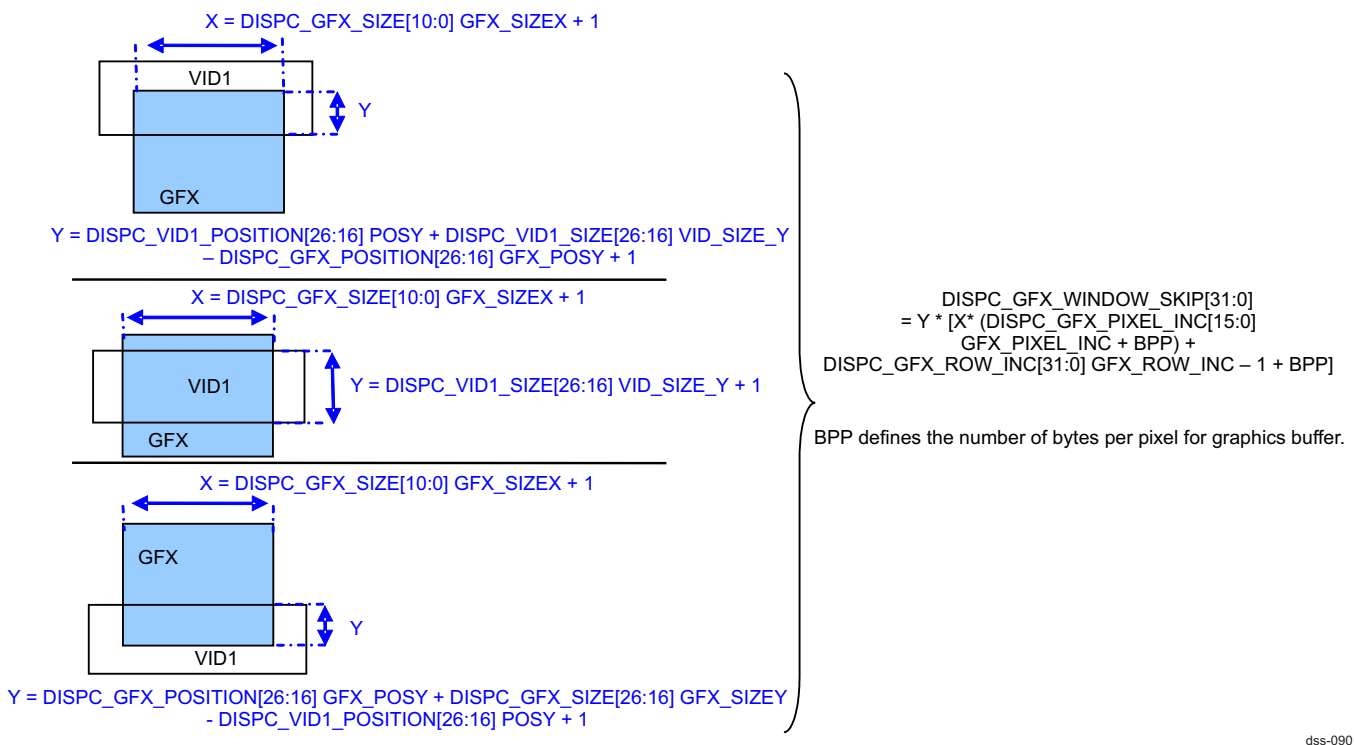

- Graphics window height (DSS.DISPC\_GFX\_SIZE[26:16] GFX\_SIZEY bit field): The default value at reset time is 0x0 (1 pixel). The window height is from 1 to 2048 pixels. All integer values in the range [1:2048] are allowed. The entire pixels of the graphics window must be inside the LCD screen.

Depending on the height of the buffer to be displayed in the graphics layer and the position, the height should be adjusted by software to limit the bottom edge of the window inside the screen

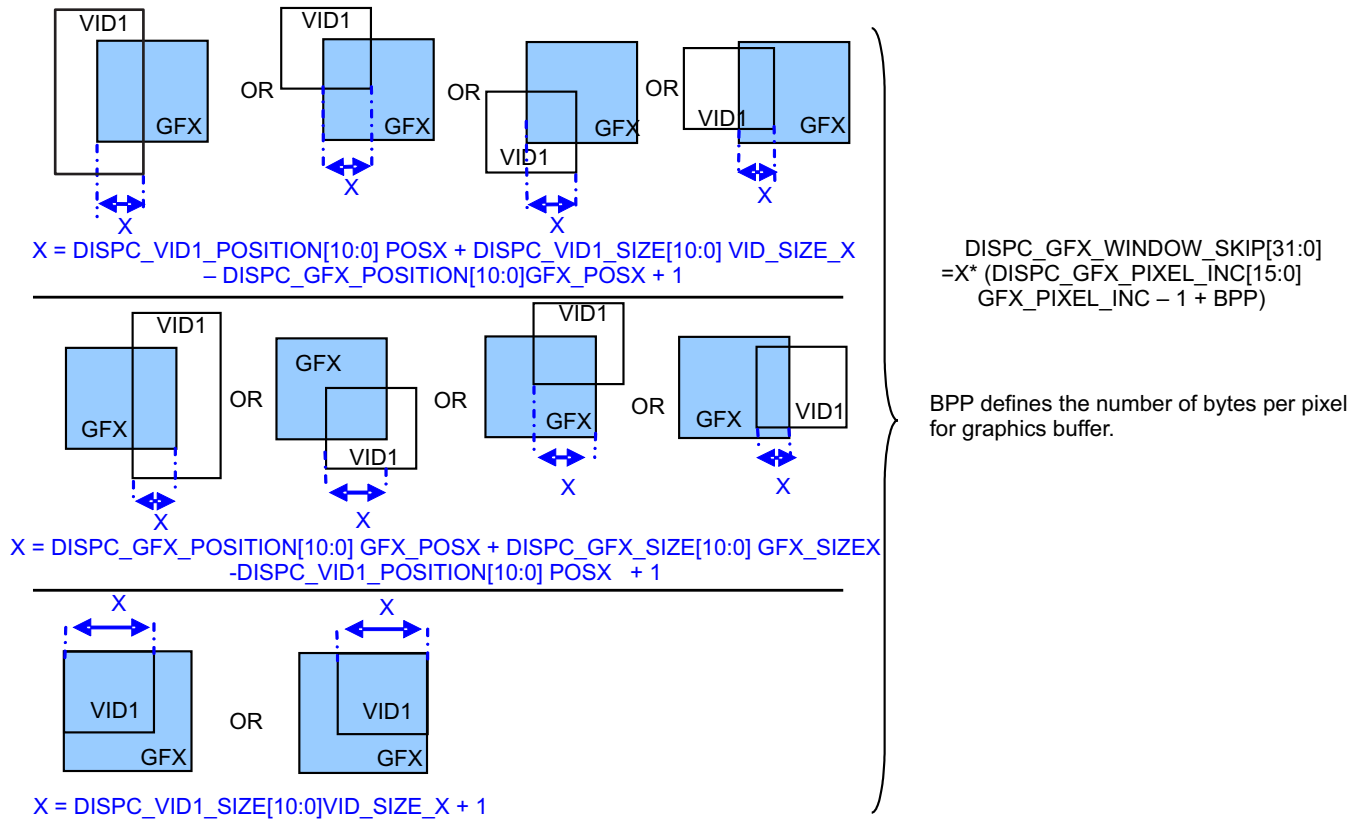

- Graphics data endianness (DSS.DISPC\_GFX\_ATTRS[10] GFX\_ENDIAN bit): This bit indicates the endianness (little or big) of the graphics pixels. The default value at reset time is 0x0 (little endian).
- Graphics data nibble mode (DSS.DISPC\_GFX\_ATTRS[9] GFX\_NIBBLE\_MODE bit): This bit indicates the nibble mode of the graphics pixels. The default value at reset time is 0x0 (Disable).
- Graphics replication logic enable (DSS.DISPC\_GFX\_ATTRS[5] GFX\_REPLICATION\_EN bit): The default value at reset time is 0x0 (Disable). The encoded pixel data in RGB format (RGB16) can be extended to 24-bit format with or without replication of the MSB part to fill up the LSB due to the 24-bit left alignment. If the replication logic is turned off, the LSB part is filled up with 0s.
- Graphics window skip enable (DSS.DISPC\_CTRL[12] OVLY\_OPT bit): By setting/resetting the bit, the overlay optimization is enabled or disabled. Before enabling the overlay optimization, the DSS.DISPC\_GFX\_WINDOW\_SKIP[31:0] GFX\_WINDOW\_SKIP bit field must be set according to the video1 and graphics windows overlap. The default value at reset time is 0x0 (Disable). When video1 is not present, the DSS.DISPC\_GFX\_WINDOW\_SKIP[31:0] GFX\_WINDOW\_SKIP bit field should be reset. When the color key is used, the DSS.DISPC\_GFX\_WINDOW\_SKIP[31:0] GFX\_WINDOW\_SKIP bit field should be reset.
- Graphics window skip (DSS.DISPC\_GFX\_WINDOW\_SKIP[31:0] GFX\_WINDOW\_SKIP bit field): The bit field represents the number of bytes to skip while fetching the graphics-encoded pixels when reaching the beginning of the video window. The optimization allows fetching only the visible graphics pixels. The color key cannot be selected because the graphics pixels under the video window are not present. The default value at reset time is 0x0 (0 byte).

Figure 13-54 through Figure 13-57 give examples of how to program the GFX\_WINDOW\_SKIP field for overlay optimization:

### 13.4.3.3 Video Layer Configuration

The video layer configuration is common to the LCD and the TV set.

#### 13.4.3.3.1 Video DMA Registers

The following registers define the video DMA engine configuration:

- DSS.DISPC\_CTRL
- DSS.DISPC\_VIDn\_BAj
- DSS.DISPC\_VIDn\_ATTRS
- DSS.DISPC\_VIDn\_ROW\_INC
- DSS.DISPC\_VIDn\_PIXEL\_INC
- DSS.DISPC\_VIDn\_FIFO\_THR
- DSS.DISPC\_VIDn\_PICTURE\_SIZE

The following fields define the attributes of the graphics DMA engine:

- Video layer enable (DSS.DISPC\_VIDn\_ATTRS[0] EN bit): The default value of this bit at reset time is 0x0 (Disabled). The video DMA engine fetches encoded pixels from the system memory only when the video layer is enabled (a valid configuration is programmed for the video layer). The video window is present and the video pipeline is active.
- Burst size (DSS.DISPC\_VIDn\_ATTRS[15:14] BURST\_SIZE bit field): The default burst size at reset time is 4 x 32 bytes. The possible values are 4 x 32, 8 x 32, and 16 x 32 bytes. The burst size is initialized at boot time by the software and never changes as long as the display controller is enabled. This bit field indicates the maximum burst size for the specific pipeline. In case of misalignment, the DMA engine may issue single and/or smaller burst requests, because the burst size must be aligned to the burst boundary.
- Preload configuration (DSS.DISPC\_VIDn\_ATTRS[19] FIFO\_PRELOAD bit): The default preload configuration uses the DSS.DISPC\_VIDn\_PRELOAD register value (the reset value is 256 bytes) to define the number of bytes to be fetched from system memory into the display controller graphics FIFO. By programming the DSS.DISPC\_VIDn\_ATTRS[19] FIFO\_PRELOAD bit, software users select between preload register (with 256 bytes as the reset value) and the high threshold value for preload of the encoded pixels. For best performance, the configuration of thresholds is defined using the FIFO size (in bytes) minus 1 for the high threshold, and the FIFO size (in bytes) minus the burst size (in bytes) for the low threshold, which provides 960, 992, and 1008, respectively, for burst sizes 16x32, 8x32, and 4x32. Note also that the preload value is defined based on the following display types:
  - Active matrix (TFT) display: DSS.DISPC\_VIDn\_PRELOAD[11:0] PRELOAD = 0xB0 (value is 176)
  - Color passive matrix (STN) display: DSS.DISPC\_VIDn\_PRELOAD[11:0] PRELOAD = 0x110 (value is 272)
  - Monochrome passive matrix (STN) display: DSS.DISPC\_VIDn\_PRELOAD[11:0] PRELOAD = 0x1B0 (value is 432)

- Base address of the video buffer in system memory (DSS.DISPC\_VIDn\_BA<sub>j</sub> registers): The default value at reset time is 0x0. The horizontal resolution is one pixel because the base address is aligned on pixel size boundary. In case of YCbCr 4:2:2 formats, the resolution is 2 pixels. In case of RGB24 packed format, the resolution is 4 pixels. The vertical resolution is one line. The register DSS.DISPC\_VIDn\_BA<sub>0</sub> defines the base address of the even field, and DSS.DISPC\_VIDn\_BA<sub>1</sub> defines the base of the odd field in the case of an external synchronization and based on the value of the input signal DISPC\_FID and the polarity. To improve system throughput, the base address should be aligned on the burst size boundary.
- Video FIFO threshold (DSS.DISPC\_VIDn\_FIFO\_THR register): The low threshold (DSS.DISPC\_VIDn\_FIFO\_THR[11:0] VID\_FIFO\_LOW\_THR) and the high threshold (DSS.DISPC\_VIDn\_FIFO\_THR[27:16] VID\_FIFO\_HIGH\_THR) values define the FIFO DMA behavior. When the low level is reached, one or more requests are issued to the L3-based interconnect to fill up the FIFO to reach the high threshold. A request is issued as long as the FIFO has enough space available to accept a burst. The DMA engine then waits until the low level is reached to restart the requests. By setting the DSS.DISPC\_CFG[14] FIFO\_MERGE bit to 1, users merge the three FIFOs (GFX, VID1, and VID2). In this case, the low threshold (the DSS.DISPC\_VIDn\_FIFO\_THR[11:0] VID\_FIFO\_LOW\_THR bit field with n corresponding to the active video channel 1 or 2) and the high threshold (DSS.DISPC\_VIDn\_FIFO\_THR[27:16] VID\_FIFO\_HIGH\_THR bit field with n corresponding to the active video channel 1 or 2) values must be programmed with a multiplier factor of three (3 x value). By default, the FIFOs are not merged (the DSS.DISPC\_CFG[14] FIFO\_MERGE bit reset value is 0).
- Video buffer width (DSS.DISPC\_VIDn\_PICTURE\_SIZE[10:0] VID\_ORG\_SIZE\_X): The default value at reset time is 0x0 (1 pixel). The buffer width in system memory is from 1 up to 2048 pixels. All the integer values in the range [1:2048] are allowed. Software users must program this bit field to the value minus 1.
- Video buffer height (DSS.DISPC\_VIDn\_PICTURE\_SIZE[26:16] VID\_ORG\_SIZE\_Y): The default value at reset time is 0x0 (1 pixel). The buffer height in system memory is from 1 up to 2048 pixels. All the integer values in the range [1:2048] are allowed. Software users must program this field to the value minus 1.
- Video data endianness (DSS.DISPC\_VIDn\_ATTRS[17] ENDIAN bit, with n=1 or 2): This bit indicates the endianness (little or big) of the video pixels. The default value at reset time is 0x0 (little endian).

#### 13.4.3.3.2 Video Configuration Register

The following shadow registers define video layer n (with n = 1 or 2) configuration:

- DSS.DISPC\_CFG
- DSS.DISPC\_VIDn\_POSITION
- DSS.DISPC\_VIDn\_SIZE
- DSS.DISPC\_VIDn\_ATTRS
- DSS.DISPC\_VIDn\_FIR
- DSS.DISPC\_VIDn\_PICTURE\_SIZE
- DSS.DISPC\_VIDn\_FIR\_COEF\_H<sub>i</sub> (with i = 0 to 7)
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV<sub>i</sub> (with i = 0 to 7)
- DSS.DISPC\_VIDn\_CONV\_COEF<sub>i</sub> (with i = 0 to 4)
- The video layer n (with n = 1 or 2) is enabled/disabled by setting/resetting the DSS.DISPC\_VIDn\_ATTRS[0] EN field. If the video layer is disabled, the video window does not exist on the screen and the whole video pipeline and DMA are inactive. Before enabling the video layer, a valid configuration must be set. After a register change, either the DSS.DISPC\_CTRL[6] GO\_DIGITAL or DSS.DISPC\_CTRL[5] GO\_LCD bit must be set. The software must wait for the hardware to reset the bit before setting this bit. The software reset is not recommended because the application cannot ensure that the bit is reset before the hardware reset.

#### 13.4.3.3.3 Video Window Attributes

The following fields define the attributes of video window n:

- Video format (DSS.DISPC\_VIDn\_ATTRS[4:1] FMT bit field, with n = 1 or 2): The default value at reset time is 0x0 (BITMAP 1 BPP, nonsupported format by the video pipeline). The video format can be RGB16, RGB24, YUV2 4:2:2 co-DSS sited, and UYVY 4:2:2 co-sited.
- Video window X-position (DSS.DISPC\_VIDn\_POSITION[10:0] POSX bit field, with n = 1 or 2): The default value at reset time is 0x0 (first column starting on the left edge of the screen). The window X-position is from 0 to 2047 columns. All integer values in the range [0:2047] are allowed.
- Video window Y-position (DSS.DISPC\_VIDn\_POSITION[26:16] POSY bit field, with n = 1 or 2): The default value at reset time is 0x0 (first row starting at the top of the screen). The window Y-position is from 0 to 2047 rows. All integer values in the range [0:2047] are allowed.
- Video window width (DSS.DISPC\_VIDn\_SIZE[10:0] VID\_SIZE\_X bit field, with n = 1 or 2): The default value at reset time is 0x0 (1 pixel). The window width is from 1 to 2048 pixels. All integer values in the range [1:2048] are allowed. The maximum bandwidth efficiency for accessing the pixels in system memory is reached when the width (in bytes) of the video window is a multiple of the video burst size defined in the DSS.DISPC\_VIDn\_ATTRS[15:14] VID\_BURST\_SIZE bit field (in bytes).

**NOTE:** When the RGB24 packed format is selected, the width must be a multiple of 12 bytes when the DSS.DISPC\_VIDn\_ROW\_INC register is not 1. When the DSS.DISPC\_VIDn\_ROW\_INC register is 1, the width can be any size from 1 to 2048 pixels.

The entire pixels of the video window must be inside the LCD screen. Depending on the width of the buffer to be displayed in the video layer and the position, the width should be adjusted by software to limit the right edge of the window inside the screen.

- Video window height (DSS.DISPC\_VIDn\_SIZE[26:16] VID\_SIZE\_Y bit field, with n = 1 or 2): The default value at reset time is 0x0 (1 pixel). The window height is from 1 to 2048 pixels. All integer values in the range [1:2048] are allowed. The entire pixels of the video window must be inside the LCD screen. Depending on the height of the buffer to be displayed in the video layer and the position, the height should be adjusted by software to limit the bottom edge of the window inside the screen.
- Video picture width in system memory (DSS.DISPC\_VIDn\_PICTURE\_SIZE[10:0] VID\_ORG\_SIZE\_X bit field, with n = 1 or 2): The default value at reset time is 0x0 (1 pixel). The window width is from 1 to 2048 pixels. All integer values in the range [1:2048] are allowed with RGB16 and RGB24 video data. For YUV2 4:2:2 and UYVY 4:2:2 formats, the width must be a multiple of two pixels. The maximum bandwidth efficiency for accessing the pixels in system memory is reached when the width (in bytes) of the video picture is a multiple of the video burst size defined in the DSS.DISPC\_VIDn\_ATTRS[15:14] VID\_BURST\_SIZE bit field (in bytes).
- Video picture height in system memory (the DSS.DISPC\_VIDn\_PICTURE\_SIZE[26:16] VID\_ORG\_SIZE\_Y bit field, with n = 1 or 2): The default value at reset time is 0x0 (1 pixel). The window width is from 1 to 2048 pixels. All integer values in the range [1:2048] are allowed.
- Video Priority (DSS.DISPC\_VIDn\_ATTRS[23] ARBITRATION): The default value at reset time is 0x0. It is used to change between normal priority (value of 0) to high priority (value of 1) to change priority for the video channel vs. other channels. It can be used to give higher priority to the pipelines with real time constraint vs. non real time pipelines. For that is, pipelines associated to the LCD output in RFBI mode should have lower priority than pipelines associated to TV output.
- Video Self-Refresh (DSS.DISPC\_VIDn\_ATTRS[24] SELF\_REFRESH): The default value at reset time is 0x0. It is used to use the DMA FIFO without accessing the interconnect for multiple frames. Once, the data have been loaded to the DMA FIFO for displaying the frame, they are used for the following frames.

The sequence to activate the self-refresh is the following:

- Frame t: The bit field should be set at anytime during frame
- Frame t+1: Fetch of the data in the DMA FIFO and display of the frame
- Frame t+2: No access to the L3 interconnect, DMA FIFO uses to provide the pixels

The sequence to deactivate the self-refresh is the following:

- Frame t: No access to the L3 interconnect, DMA FIFO uses to provide the pixels, bit field can be changed at any time during the frame
- Frame t+1: Fetch of the data from system memory using the L3 interconnect

#### 13.4.3.3.4 Video Up-/Down-Sampling Configuration

The video horizontal up/downsampling block for video pipeline n (with n = 1 or 2) is enabled/disabled by setting/resetting the DSS.DISPC\_VIDn\_ATTRS[5] RESIZE\_EN bit.

The video vertical up/downsampling block for video pipeline n is enabled/disabled by setting/resetting the DSS.DISPC\_VIDn\_ATTRS[6] RESIZE\_EN bit.

Set a valid configuration before enabling the video up/downsampling block.

---

**NOTE:** Vertical and horizontal downsampling are limited to a 1/4 resize factor.

---

After a register change, either the DSS.DISPC\_CTRL[6] GO\_DIGITAL or DSS.DISPC\_CTRL[5] GO\_LCD bit must be set. The software must wait until the hardware resets this bit before setting it. The software reset is not recommended because the application cannot ensure that the bit is reset before the hardware reset.

The following fields define the configuration of the video up/downsampling block for video pipeline n:

- Vertical up/downsampling increment value (DSS.DISPC\_VIDn\_FIR[27:16] FIR\_V\_INC bit field, with n = 1 or 2): The unsigned integer value range is [1:4096]. The software calculates the value using the following equation:

$$FIR\_V\_INC[12:0] = 1024 \times \left( \frac{VID\_ORG\_SIZE\_Y[10:0]}{VID\_SIZE\_Y[10:0]} \right)$$

(8)

---

**NOTE:**

- If the FIR\_V\_INC[11:0] bit field value is greater than 4096, it is clipped to 4096. If VID\_SIZE\_Y[10:0] equals 0x1, VID\_SIZE\_Y[10:0] is replaced by 0x2 in the previous equation.
  - The VID\_ORG\_SIZE\_Y[10:0] and VID\_SIZE\_Y[10:0] bit field values must be programmed with the value desired minus 1.
- 
- Horizontal up/downsampling increment value (DSS.DISPC\_VIDn\_FIR[11:0] FIR\_H\_INC bit field, with n = 1 or 2): The unsigned integer value range is [1:4096]. The software calculates the value using the following equation:

$$FIR\_H\_INC[12:0] = 1024 \times \left( \frac{VID\_ORG\_SIZE\_X[10:0]}{VID\_SIZE\_X[10:0]} \right)$$

(9)

---

**NOTE:**

- If the FIR\_H\_INC[11:0] bit field value is greater than 4096, it is clipped to 4096. If VID\_SIZE\_X[10:0] equals 1, VID\_SIZE\_X[10:0] is replaced by 2 in the previous equation.
  - The VID\_ORG\_SIZE\_X[10:0] and VID\_SIZE\_X[10:0] bit field values must be programmed with the value desired minus 1.
- 
- Vertical up/downsampling accumulator value (DSS.DISPC\_VIDn\_ACCUI[25:16] VERTICAL\_ACCU bit field): The unsigned integer value range is [0:1023]. The accumulator value indicates in which phase the vertical filtering starts. The value 0 indicates that 0 is the first phase used by the hardware to generate the first data (see [Table 13-22](#)).
  - Vertical up/downsampling line buffer configuration (DSS.DISPC\_VIDn\_ATTRS[22] LINE\_BUFFER\_SPLIT bit): The default value at reset time is 0x0 (line buffers are not split). The backward compatibility is maintained versus OMAP2420 and OMAP2430 devices. When the bit field is set, each line buffer is split into two line buffers to be able to use six line buffers instead of three.
  - Vertical up/downsampling line buffer configuration (DSS.DISPC\_VIDn\_ATTRS[21] VERTICAL\_TAPS bit): The default value at reset time is 0x0 (3-tap configuration is used). If the bit field is reset, the 3-tap configuration is used. The backward compatibility is maintained versus OMAP2420 and OMAP2430 devices. When the bit field is set, the 5-tap configuration is used and the

DSS.DISPC\_VIDn\_ATTRS[22] LINE\_BUFFER\_SPLIT bit must be set to 1.

- Vertical up/downsampling line buffer configuration (DSS.DISPC\_VIDn\_ATTRS[20] OPTIMIZATION bit): The default value at reset time is 0x0 (no optimization). If the bit is set, the DMA engine fetches two pixels for each 32-bit OCP request (RGB16 and YUV4:2:2) while doing 90- and 270-degree rotation. If the bit is clear, the DMA engine fetches one pixel for each 32-bit OCP request (RGB16 and YUV4:2:2) while doing 90- and 270-degree rotation. The width and height of picture should be even to use the optimization. Even width is required for the input picture when the 5-tap configuration is used.

**NOTE:** If the 5-tap resizer is used for RGB16 and YUV4:2:2 picture formats, the width of the input picture must be a multiple of 2 pixels and more than 5 pixels. This leads to the following register configuration:

```
DISPC_VIDn_ATTRS[21] VERTICAL_TAPS == 1
DISPC_VIDn_PICTURE_SIZE[10:0] VID_ORG_SIZE_X 4 and even
```

- Horizontal up/downsampling accumulator value (DSS.DISPC\_VIDn\_ACCUI[9:0] HORIZONTAL\_ACCU bit field): The unsigned integer value range is [0:1023]. The accumulator value indicates in which phase the horizontal filtering starts. The value 0 indicates that 0 is the first phase used by the hardware to generate the first data (see [Table 13-22](#)).

**Table 13-22. Vertical/Horizontal Accumulator Phase**

Accumulator Value	Phases f
0	0
128	1
256	2
384	3
512	4
640	5
768	6
896	7

- Vertical up/downsampling coefficients (DSS.DISPC\_VIDn\_FIR\_COEF\_HV\_i registers, with n = 1 or 2, i = 0 to 7): The 3-tap vertical up/downsampling coefficients are defined in these registers. There are eight registers for the eight phases with three coefficients for each, or a total of 24 programmable coefficients for the vertical up/downsampling block. Each register contains two 8-bit signed coefficients and one 8-bit unsigned coefficient (the central one).

In addition, there are 2-tap vertical up/downsampling coefficients defined in DSS.DISPC\_VIDn\_FIR\_COEF\_Vi registers. There are 8 registers for the 8 phases with 2 coefficients for each of them so a total of 16 programmable coefficients for the vertical up/downsampling block used in addition of the 3-tap registers defined above. Each register contains two 8-bit signed coefficients. In case of 5-tap configuration, both sets of registers DSS.DISPC\_VIDn\_FIR\_COEF\_HV\_i and DSS.DISPC\_VIDn\_FIR\_COEF\_Vi are used. In case of 3-tap configuration, only one set of registers DSS.DISPC\_VIDn\_FIR\_COEF\_HV\_i is used.

- Horizontal up/downsampling coefficients (DSS.DISPC\_VIDn\_FIR\_COEF\_H\_i and DISPC\_VIDn\_FIR\_COEF\_HV\_i registers, with n = 1 or 2, i = 0 to 7): The DSS.DISPC\_VIDn\_FIR\_COEF\_H\_i register and the DSS.DISPC\_VIDn\_FIR\_COEF\_HV\_i register define the 5-tap horizontal up/downsampling coefficients. There are eight registers for the eight phases with five coefficients for each register, or a total of 40 programmable coefficients for the horizontal up/downsampling block.

Each DSS.DISPC\_VIDn\_FIR\_COEF\_H\_i register contains three 8-bit signed coefficients and one 8-bit unsigned coefficient (the central one). Each DSS.DISPC\_VIDn\_FIR\_COEF\_HV\_i register contains one 8-bit signed coefficient.

The programmable coefficient for the FIR up/downsampling method must be adjusted based on application needs. For more details on scaling programming settings, see [Section 13.5.1](#).

### 13.4.3.3.5 Video Color Space Conversion Configuration

The DSS.DISPC\_VIDn\_CONV\_COEFi registers (with i = 0 to 4) has nine 11-bit coefficients defined for the programmable color space conversion block for video pipeline n (with n = 1 or 2).

The standard register coefficients are:

#### YCbCr-to-RGB Registers (VidFullRange=0)

$$\begin{bmatrix} R \\ G \\ B \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} RY & RCr & RCb \\ GY & GCr & GCb \\ BY & BCr & BCb \end{bmatrix} * \begin{bmatrix} Y - 16 \\ Cr - 128 \\ Cb - 128 \end{bmatrix} \quad \text{dssE095} \quad (10)$$

#### YCbCr to RGB Registers (VidFullRange=1)

$$\begin{bmatrix} R \\ G \\ B \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} RY & RCr & RCb \\ GY & GCr & GCb \\ BY & BCr & BCb \end{bmatrix} * \begin{bmatrix} Y \\ Cr - 128 \\ Cb - 128 \end{bmatrix} \quad \text{dss-E096} \quad (11)$$

Table 13-23 lists the color space conversion register values.

**Table 13-23. Color Space Conversion Register Values**

Coefficients	BT.601-5	BT.601-5 Range [0:255]	BT.709	BT.709 Range [0:255]
RY	298	256	298	256
RCr	409	351	459	394
RCb	0	0	0	0
GY	298	256	298	256
GCr	-208	-179	-137	-118
GCb	-100	-86	-55	-47
BY	298	256	298	256
BCr	0	0	0	0
BCb	517	443	541	465
VidFullRange	0	1	0	1

### 13.4.3.4 LCD-Specific Control Registers

The following registers define the LCD output configuration:

- DSS.DISPC\_CTRL
- DSS.DISPC\_CFG
- DSS.DISPC\_DEFAULT\_COLOR\_m (m=0)
- DSS.DISPC\_TRANS\_COLOR\_m (m=0)
- DSS.DISPC\_TIMING\_H
- DSS.DISPC\_TIMING\_V
- DSS.DISPC\_POL\_FREQ
- DSS.DISPC\_DIVISOR
- DSS.DISPC\_SIZE\_LCD
- DSS.DISPC\_DATA\_CYCLEk

- DSS.DISPC\_CPR\_COEF\_R, DSS.DISPC\_CPR\_COEF\_G, DSS.DISPC\_CPR\_COEF\_B

Setting/resetting the DSS.DISPC\_CTRL[0] LCD\_EN bit enables/disables the LCD output. A valid configuration must be set before enabling the LCD output.

#### 13.4.3.4.1 LCD Attributes

The following fields define the attributes of the panel connected to the display controller:

- Monochrome or color panel (the DSS.DISPC\_CTRL[2] MONO\_COLOR bit)
- Passive Matrix or active Matrix panel (the DSS.DISPC\_CTRL[3] STNTFT bit)
- Color depth (the DSS.DISPC\_CTRL[9:8] TFT\_DATA\_LINES bit field)
- Number of lines per panel (the DSS.DISPC\_SIZE\_LCD[26:16] LPP bit field)
- Number of pixels per line (the DSS.DISPC\_SIZE\_LCD[10:0] PPL bit field)
- 4- or 8-bit interface for Passive Matrix monochrome panel (the DSS.DISPC\_CTRL[4] M8B bit)

#### 13.4.3.4.2 LCD Timings

The following bit fields define the timing generation of HSYNC/VSNC:

- Horizontal front porch (the DSS.DISPC\_TIMING\_H[19:8] HFP bit field)
- Horizontal back porch (the DSS.DISPC\_TIMING\_H[31:20] HBP bit field)
- Horizontal synchronization pulse width (the DSS.DISPC\_TIMING\_H[7:0] HSW bit field)
- Vertical front porch (the DSS.DISPC\_TIMING\_V[19:8] VFP bit field)
- Vertical back porch (the DSS.DISPC\_TIMING\_V[31:20] VBP bit field)
- Vertical synchronization pulse width (the DSS.DISPC\_TIMING\_V[7:0] VSW bit field)
- On/Off control of HSYNC/VSNC pixel clock (the DSS.DISPC\_POL\_FREQ[17] ONOFF bit)
- Program HSYNC/VSNC rise or fall (the DSS.DISPC\_POL\_FREQ[16] RF bit)
- Invert HSYNC (the DSS.DISPC\_POL\_FREQ[13] IHS bit)
- Invert VSNC (the DSS.DISPC\_POL\_FREQ[12] IVS bit)
- HSYNC gated (the DSS.DISPC\_CFG[6] HSYNC\_GATED bit)
- VSNC gated (the DSS.DISPC\_CFG[7] VSNC\_GATED bit)

Table 13-24 describes the programming rules for LCD timing.

**Table 13-24. Programming Rules**

	No Downsampling	Downsampling H or V	Downsampling H + V
(HBP + HSW + HFP) * PCD	8	10	20

Figure 13-58 shows the timing values description in the case of an active matrix display.

**Figure 13-58. Timing Values Description (Active Matrix Display)**

dss-102

The following bit fields define the timing generation of ac-bias (output enable in active matrix mode):

- Invert output enable (DSS.DISPC\_POL\_FREQ[15] IEO bit)
- ac-bias pin frequency (DSS.DISPC\_POL\_FREQ[7:0] ACB bit field)
- ac-bias pin transitions per interrupt (DSS.DISPC\_POL\_FREQ[11:8] ACBI bit field)
- ac-bias gated (DSS.DISPC\_CFG[8] ACBIASGATED)

The following bit fields define the timing generation of the pixel clock:

- Pixel clock divisor (DSS.DISPC\_DIVISOR[7:0] PCD bit field)
- Invert pixel clock (DSS.DISPC\_POL\_FREQ[14] IPC bit)
- Pixel clock gated (DSS.DISPC\_CFG[5] PIXEL\_CLK\_GATED bit)

The 8-bit pixel clock divider (the DSS.DISPC\_DIVISOR[7:0] PCD bit field) selects the pixel clock frequency. This bit field generates a range of pixel clock frequencies from LC/1 to LC/255, where LC is the logic clock from the divided functional clock of the display controller by the DSS.DISPC\_DIVISOR[23:16] LCD bit field.

The pixel clock is defined by the following equation:

$$\text{Pixel Clock} = (\text{FunctionalClock}/\text{LCD}[7:0])/\text{PCD}[7:0]$$

Table 13-25 through Table 13-28 show the pixel clock frequency limitations depending the panel type (active or passive matrix) and the mode (color or monochrome).

**Table 13-25. Pixel Clock Frequency Limitations - RGB16 and YUV4:2:2 Active Matrix Display**

Min PCD Values		Horizontal Resampling				
		Off	Up	1:1 - 1:2	1:2 - 1:3	1:3 - 1:4
Vertical Resampling	Off	2 (1) <sup>(1)</sup>	2 (1)	2	3	4
	Up	2 (1)	2 (1) <sup>(1)</sup>	2	3	4
	1:1 - 1:2	3-tap	2	2	4	6
		5-tap	PCDmin	PCDmin	PCDmin	PCDmin
	1:2 - 1:4		PCDmin	PCDmin	PCDmin	PCDmin

<sup>(1)</sup> The PCD value can be 1 in case all the data and synchronization signals are asserted and deasserted on the rising edge of the pixel clock.

**Table 13-26. Pixel Clock Frequency Limitations - RGB16 and YUV4:2:2 Passive Matrix Display - Mono4**

Min PCD Values		Horizontal Resampling				
		Off	Up	1:1 - 1:2	1:2 - 1:3	1:3 - 1:4
Vertical Resampling	Off	4	4	8	12	16
	Up	4	4	8	12	16
	1:1 - 1:2	3-tap	8	8	16	24
		5-tap	4xPCDmin	4xPCDmin	4xPCDmin	4xPCDmin
	1:2 - 1:4		4xPCDmin	4xPCDmin	4xPCDmin	4xPCDmin

**Table 13-27. Pixel Clock Frequency Limitations - RGB16 and YUV4:2:2 Passive Matrix Display - Mono8**

Min PCD Values		Horizontal Resampling				
		Off	Up	1:1 - 1:2	1:2 - 1:3	1:3 - 1:4
Vertical Resampling	Off	8	8	16	24	32
	Up	8	8	16	24	32
	1:1 - 1:2	3-tap	16	16	32	48
		5-tap	8xPCDmin	8xPCDmin	4xPCDmin	8xPCDmin
	1:2 - 1:4		8xPCDmin	8xPCDmin	4xPCDmin	8xPCDmin

**Table 13-28. Pixel Clock Frequency Limitations - RGB16 and YUV4:2:2 Passive Matrix Display - Color**

Min PCD Values		Horizontal Resampling				
		Off	Up	1:1 - 1:2	1:2 - 1:3	1:3 - 1:4
Vertical Resampling	Off	3	3	6	9	12
	Up	3	3	6	9	12
	1:1 - 1:2	3-tap	6	6	12	18
		5-tap	3xPCDmin	3xPCDmin	3xPCDmin	3xPCDmin
	1:2 - 1:4		3xPCDmin	3xPCDmin	3xPCDmin	3xPCDmin

**NOTE:** In case of RGB24 format, [Figure 13-59](#) is still valid, except the PCDmin values which must be multiplied by two.

The PCDmin for vertical downsampling only is defined by the following equations:

**Figure 13-59. PCDmin Formulas (V Down-Sampling Only)**

$$h\_ratio = \frac{DISPC\_SIZE\_LCD[10:0]PLL}{DISPC\_VIDn\_SIZE[10:0]VID\_SIZE\_X}$$

$$v\_ratio = \frac{DISPC\_VIDn\_PICTURE\_SIZE[10:0]VID\_ORG\_SIZE\_Y}{DISPC\_VIDn\_SIZE[10:0]VID\_SIZE\_Y}$$

$$PCDmin = \frac{v\_ratio}{2 \times h\_ratio} \quad 1 < v\_ratio \leq 2$$

$$PCDmin = \max\left(\frac{v\_ratio}{2 \times h\_ratio}, \frac{v\_ratio - 2}{2 \times (h\_ratio - 1)}\right) \quad 2 < v\_ratio \leq 4$$

dss-E103

The PCDmin for horizontal downsampling only is defined by the following formula:

While downsampling by  $n$ ,  $PCDmin = n$

For H+V downsampling, the formula is the following:

$PCDmin = \max(PCDmin\ H\ only, PCDmin\ V\ only)$  as defined above

The refresh rate depends on the following parameters:

- Horizontal front porch (the DSS.DISPC\_TIMING\_H[19:8] HFP bit field)
- Horizontal back porch (the DSS.DISPC\_TIMING\_H[31:20] HBP bit field)
- Horizontal synchronization pulse width (the DSS.DISPC\_TIMING\_H[7:0] HSW bit field)
- Vertical front porch (the DSS.DISPC\_TIMING\_V[19:8] VFP bit field)
- Vertical back porch (the DSS.DISPC\_TIMING\_V[31:20] VBP bit field)
- Vertical synchronization pulse width (the DSS.DISPC\_TIMING\_V[7:0] VSW bit field)
- Number of lines per panel (the DSS.DISPC\_SIZE\_LCD[26:16] LPP bit field)
- Number of pixels per line (the DSS.DISPC\_SIZE\_LCD[10:0] PPL bit field)
- 4- or 8-bit interface for the passive matrix monochrome panel (the DSS.DISPC\_CTRL[4] M8B bit)

The following bit fields define the behavior of the internal blocks:

- Spatial/temporal dithering logic enabled (DSS.DISPC\_CTRL[7] ST\_DITHER\_EN bit)
- Spatial/temporal dithering logic number of frames (DSS.DISPC\_CTRL[31:30] SPATIALTEMPORALDITHERFRAMES bit field). The default value of this bit field at reset time is 0x0, which is 1 frame only (spatial processing without temporal dithering). The possible values are 0x0 (one frame), 0x1 (two frames), and 0x2 (four frames). The number of frames is initialized before enabling the spatial/temporal dithering unit. The software must not change this bit field value while the spatial/temporal unit is enabled.

The following bit field defines the clock gating strategy:

- In active matrix mode, the pixel clock is always gated or only when valid data are present (the DSS.DISPC\_CFG[0] PIXEL\_GATED bit).

#### 13.4.3.4.3 LCD Overlay

The following bit fields define the overlay attributes of the LCD output:

- Transparency color key (the DSS.DISPC\_TRANS\_COLOR0i register ( $i = 0$ ))
- Transparency color key enable (the DSS.DISPC\_CFG[10] TCK\_LCD\_EN bit)
- Transparency color key selection between the destination graphics transparency color key and the source video transparency color key (the DSS.DISPC\_CFG[11] TCK\_LCD\_SELECTION bit)
- The default solid background color is defined in the DSS.DISPC\_DEFAULT\_COLOR\_m[23:0] DEFAULT\_COLOR bit field ( $i=0$ ).
- Alpha blender Enable (DSS.DISPC\_CFG[18] LCD\_ALPHABLDR\_EN)
- Global alpha blending values (DSS.DISPC\_GLOBAL\_ALPHA[23:16] VID2\_GLOBAL\_ALPHA and DSS.DISPC\_GLOBAL\_ALPHA[7:0] GFX\_GLOBAL\_ALPHA). The value 0xFF corresponds to 100% opaque and 0 to 100% transparent

---

**NOTE:** The destination graphics transparency color key is available only to the overlay with which the graphics pipeline is connected. The software must set the correct configuration of the LCD and digital overlays.

---

---

**NOTE:** When the alpha blender is enabled, the destination transparency color key is not available and the source transparency color key applies to the graphics pixels and not the video pixels.

---

When all of these fields are set to the appropriate values, set the DSS.DISPC\_CTRL[5] GO\_LCD bit to indicate that all shadow registers of the pipelines connected to the LCD output are latched by the hardware (only if the DSS.DISPC\_CTRL[0] LCD\_EN bit is already set to 1). If the LCD output is disabled, the new values will be updated when the DSS.DISPC\_CTRL[0] LCD\_EN bit will be set to 1.

#### 13.4.3.4.4 LCD TDM

The following fields define the multiple cycle output configuration:

- First cycle (the DSS.DISPC\_DATA\_CYCLEk (k=0) register)
- Second cycle (the DSS.DISPC\_DATA\_CYCLEk (k=1) register)
- Third cycle (the DSS.DISPC\_DATA\_CYCLEk (k=2) register)
- Enable (the DSS.DISPC\_CTRL[20] TDM\_EN bit)
- Parallel mode (the DSS.DISPC\_CTRL[22:21] TDM\_PARALLEL\_MODE field)
- Cycle format (the DSS.DISPC\_CTRL[24:23] TDM\_CYCLE\_FMT field)
- Unused bits (the DSS.DISPC\_CTRL[26:25] TDM\_UNUSED\_BITS field)

When all of these bit fields are set to the appropriate values, set the DSS.DISPC\_CTRL[5] GO\_LCD bit to indicate that all shadow registers of the pipelines connected to the LCD output are latched by the hardware (only if the DSS.DISPC\_CTRL[0] LCD\_EN bit is already set to 1). If the LCD output is disabled, the new values will be updated when the DSS.DISPC\_CTRL[0] LCD\_EN bit will be set to 1.

#### 13.4.3.4.5 LCD Spatial/Temporal Dithering

The following bit fields define the LCD spatial/temporal dithering configuration:

- Number of frames (the DSS.DISPC\_CTRL[31:30] SPATIAL\_TEMPORAL\_DITHER bit field) with:
  - 0x0 Spatial only (default value)
  - 0x1 Spatial + Temporal over two frames
  - 0x2 Spatial + Temporal over four frames
  - 0x3 Reserved
- Enable (the DSS.DISPC\_CTRL[7] ST\_DITHER\_EN bit)
  - 0x0 Disabled (default value)
  - 0x1 Enabled

When all of these bit fields are set to the appropriate values, set the DSS.DISPC\_CTRL[5] GO\_LCD bit to indicate that all shadow registers of the pipelines connected to the LCD output are latched by the hardware (only if the DSS.DISPC\_CTRL[0] LCD\_EN bit is already set to 1). If the LCD output is disabled, the new values will be updated when the DSS.DISPC\_CTRL[0] LCD\_EN bit will be set to 1.

#### 13.4.3.4.6 LCD Color Phase Rotation

The following bit fields define the color phase rotation configuration:

- Enable (the DSS.DISPC\_CFG[15] CPR bit)
  - 0x0 Disabled (default value)
  - 0x1 Enabled
- Red 10-bit signed coefficients used by the color phase rotation matrix (the DSS.DISPC\_CPR\_COEF\_R

register)

- Green 10-bit signed coefficients used by the color phase rotation matrix (the DSS.DISPC\_CPR\_COEF\_G register)
- Blue 10-bit signed coefficients used by the color phase rotation matrix (the DSS.DISPC\_CPR\_COEF\_B register)

The programmable color phase rotation block for the LCD output has nine 10-bit coefficients defined in the DSS.DISPC\_CPR\_COEF\_R, DSS.DISPC\_CPR\_COEF\_G, and DSS.DISPC\_CPR\_COEF\_B, as described in [Figure 13-60](#) through [Figure 13-63](#).

**Figure 13-60. Color Phase Rotation Matrix**

$$\begin{bmatrix} R_{out} \\ G_{out} \\ B_{out} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} RR & RG & RB \\ GR & GG & GB \\ BR & BG & BB \end{bmatrix} * \begin{bmatrix} R_{in} \\ G_{in} \\ B_{in} \end{bmatrix}$$

dss-E105

**Figure 13-61. Color Phase Rotation Matrix (R Component Only)**

$$R_{iout} = \frac{1}{256} * (RR * R_{in} + RG * G_{in} + RB * B_{in})$$

dss-E106

**Figure 13-62. Color Phase Rotation Matrix (G Component Only)**

$$G_{out} = \frac{1}{256} * (GR * R_{in} + GG * G_{in} + GB * B_{in})$$

dss-E107

**Figure 13-63. Color Phase Rotation Matrix (B Component Only)**

$$B_{out} = \frac{1}{256} * (BR * R_{in} + BG * G_{in} + BB * B_{in})$$

dss-E104

When all of these bit fields are set to the appropriate values, set the DSS.DISPC\_CTRL[5] GO\_LCD bit to indicate that all shadow registers of the pipelines connected to the LCD output are latched by the hardware (only if the DSS.DISPC\_CTRL[0] LCD\_EN bit is already set to 1). If the LCD output is disabled, the new values will be updated when the DSS.DISPC\_CTRL[0] LCD\_EN bit will be set to 1.

#### 13.4.3.4.6.1 Color Phase Rotation - Diagonal Matrix

The Color Phase Rotation feature is useful when using an LCD backlight that is not white. By using a correct configuration of the R, G and B coefficients of CPR, the color bias of the screen can be corrected. The following paragraphs give an example of configuration of the CPR feature.

The easiest example of CPR configuration is a diagonal matrix. This way, the output colors depends on one input color only. [Figure 13-64](#) gives the example of a diagonal matrix and the corresponding equation of the output components.

**Figure 13-64. Diagonal Matrix Configuration**

$$\begin{bmatrix} R_{out} \\ G_{out} \\ B_{out} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} RR & 0 & 0 \\ 0 & GG & 0 \\ 0 & 0 & BB \end{bmatrix} * \begin{bmatrix} R_{in} \\ G_{in} \\ B_{in} \end{bmatrix}$$

$$\rightarrow R_{out} = \frac{1}{256} * (RR * R_{in})$$

$$\rightarrow G_{out} = \frac{1}{256} * (GG * G_{in})$$

$$\rightarrow B_{out} = \frac{1}{256} * (BB * B_{in})$$

dss-200

According to these 3 new equations, each output component only depends on the corresponding input color. The coefficients can easily be used to reduce the impact of a non-white backlight.

Let's take the example of a "blue" backlight. In this case, users have the feeling that a blue film has been added on the screen, and then each color seems to be "too much blue". The goal is then to reduce the "Blue" component and to keep the "Red" and "Green" ones unchanged. The following matrix can be used for a reduction by a half of the blue component. [Figure 13-65](#) gives the corresponding matrix and equations for each component.

**Figure 13-65. Example - Diagonal Matrix Configuration**

$$\begin{bmatrix} R_{out} \\ G_{out} \\ B_{out} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} 256 & 0 & 0 \\ 0 & 256 & 0 \\ 0 & 0 & 128 \end{bmatrix} * \begin{bmatrix} R_{in} \\ G_{in} \\ B_{in} \end{bmatrix}$$

$$\rightarrow R_{out} = \frac{1}{256} * (256 * R_{in}) \Rightarrow R_{out} = R_{in}$$

$$\rightarrow G_{out} = \frac{1}{256} * (256 * G_{in}) \Rightarrow G_{out} = G_{in}$$

$$\rightarrow B_{out} = \frac{1}{256} * (128 * B_{in}) \Rightarrow B_{out} = 0.5 * B_{in}$$

dss-201

[Figure 13-66](#) shows the result of an image on a "blue" backlight screen with and without CPR.

**Figure 13-66. Image With and Without CPR (Diagonal Matrix)**

dss-202

A drawback of this diagonal matrix is that the color reduction is linear. The contrast is then different from the initial image. It is then necessary to use the 6 other coefficients of the CPR matrix to better correct a non-white backlight. The goal is to find the correct coefficients that remove the color offset added by the non-white backlight.

#### 13.4.3.4.6.2 Color Phase Rotation - Standard Matrix

In the following example, the LCD backlight adds an offset of 128 (B\_offset) to the Blue component. [Figure 13-67](#) shows an example of matrix that reduces the offset of the screen, the corresponding equations and the resulting output colors.

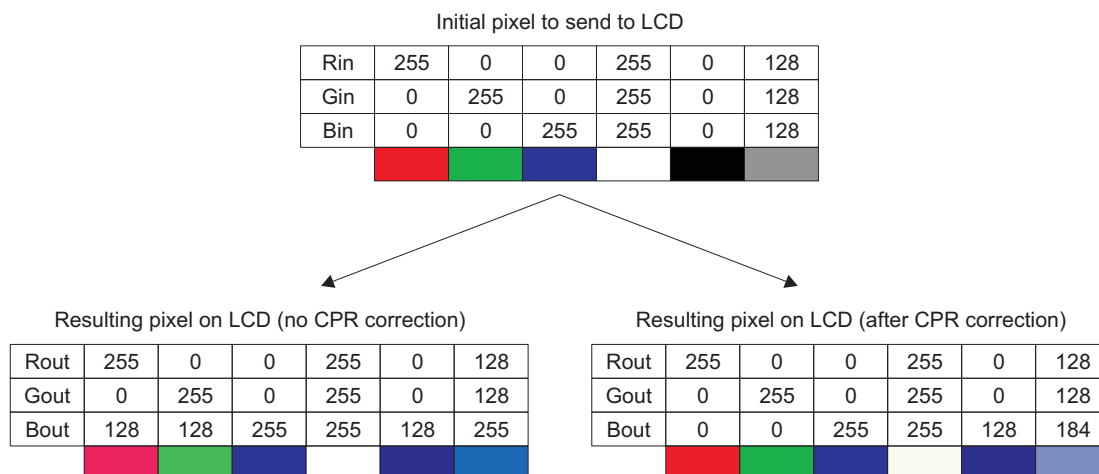

**Figure 13-67. Example - Image With and Without CPR (Standard Matrix)**

$$\begin{bmatrix} R_{out} \\ G_{out} \\ B_{out} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} 256 & 0 & 0 \\ 0 & 256 & 0 \\ -129 & -129 & 370 \end{bmatrix} * \begin{bmatrix} R_{in} \\ G_{in} \\ B_{in} \end{bmatrix}$$

$$\rightarrow R_{out} = \frac{1}{256} * (256 * R_{in})$$

$$\rightarrow G_{out} = \frac{1}{256} * (256 * G_{in})$$

$$\rightarrow B_{out} = \frac{1}{256} * (-129 * R_{in} - 129 * G_{in} + 370 * B_{in}) + B_{offset}$$

dss-203

This CPR matrix gives inputs and outputs very close. However, black cannot be corrected because of its zero-components. No matter which coefficients are used in the matrix, the result will always be equal to the offset added by the LCD backlight.

### 13.4.3.5 TV Set-Specific Control Registers

The following registers define the digital output configuration:

- DSS.DISPC\_CTRL
- DSS.DISPC\_CFG
- DSS.DISPC\_DEFAULT\_COLOR\_m (m=1)
- DSS.DISPC\_TRANS\_COLOR\_m (m=1)
- DSS.DISPC\_SIZE\_DIG

The digital output is enabled/disabled by setting/resetting the DSS.DISPC\_CTRL[1] DIGITAL\_EN bit. A valid configuration must be set before the digital output can be enabled.

Perform the initialization sequence as follows:

1. Initialize the video encoder and the display controller configuration registers.
2. Set the DSS.DISPC\_CTRL[6] GO\_DIGITAL bit and the DSS.DISPC\_CTRL[1] DIGITAL\_EN bit to 1.
3. Wait for the first VSYNC pulse signal.
4. Clear the SYNC\_LOST\_DIGITAL interrupt by setting the DSS.DISPC\_IRQSTS[15] SYNC\_LOST\_DIGITAL bit to 1.
5. Enable the SYNC\_LOST\_DIGITAL interrupt by setting the DSS.DISPC\_IRQEN[15] SYNC\_LOST\_DIGITAL bit to 1.

#### 13.4.3.5.1 Digital Timings

The following bit fields define the timing information:

- Data hold time (the DSS.DISPC\_CTRL[19:17] HT bit field)
- Logic clock divisor (the DSS.DISPC\_DIVISOR[23:16] LCD bit field)

The 8-bit pixel clock divider (DSS.DISPC\_DIVISOR[23:16]) bit field is used to select the logic clock frequency. The LCD generates a range of pixel clock frequencies from FCK/1 to FCK/255, where FCK is the input functional clock of the display controller.

#### 13.4.3.5.2 Digital Frame/Field Size

The following bit fields define the field size (frame if progressive mode):

- Number of lines per panel (the DSS.DISPC\_SIZE\_DIG[26:16] LPP bit field)
- Number of pixels per line (the DSS.DISPC\_SIZE\_DIG[10:0] PPL bit field)

#### 13.4.3.5.3 Digital Overlay

The following bit fields define the overlay attributes of the digital output:

- Transparency color key (the DSS.DISPC\_TRANS\_COLOR\_m register (m=1))
- Transparency color key enable (the DSS.DISPC\_CFG[12] TCK\_DIG\_EN bit)
- Transparency color key selection between the destination graphics transparency color key and the source video transparency color key (the DSS.DISPC\_CFG[13] TCK\_DIG\_SELECTION bit)
- The default solid background color is defined in the DSS.DISPC\_DEFAULT\_COLOR\_m[23:0] DEFAULT\_COLOR bit field (i=1).
- Alpha blender Enable (DSS.DISPC\_CFG[19] TV\_ALPHA\_BLDR\_EN)
- Global alpha blending values (DSS.DISPC\_GLOBAL\_ALPHA[23:16] VID2\_GLOBAL\_ALPHA and DSS.DISPC\_GLOBAL\_ALPHA[7:0] GFX\_GLOBAL\_ALPHA). The value 0xFF corresponds to 100% opaque and 0 to 100% transparent

---

**NOTE:** The destination graphics transparency color key is available only to the overlay with which the graphics pipeline is connected. The software must set the correct configuration of the LCD and digital overlays.

---

---

**NOTE:** When the alpha blender is enabled, the destination transparency color key is not available and the source transparency color key applies to the graphics pixels and not the video pixels.

---

When this bit field is set to the appropriate values, set the DSS.DISPC\_CTRL[6] GO\_DIGITAL bit to indicate that all shadow registers of the pipelines connected to the digital output are latched by the hardware (only if the DSS.DISPC\_CTRL[1] DIGITAL\_EN bit is already set to 1). If the digital output is disabled, the new values will be updated when the DSS.DISPC\_CTRL[1] DIGITAL\_EN bit will be set to 1.

### 13.4.4 RFBI Basic Programming Model

The RFBI programming model must be used for LCD display support only.

#### 13.4.4.1 DISPC Control Registers

The following DISPC registers are used in RFBI mode:

- The STALL mode is selected by setting the DSS.DISPC\_CTRL[11] STALL\_MODE bit. The DSS.DISPC\_CTRL[5] GO\_LCD bit must not be set to 1, but the display controller configuration (DMA engine, pipelines associated to the LCD output,...) must be set before enabling the LCD output by setting the DSS.DISPC\_CTRL[0] LCD\_EN bit to 1.
- To enable the hardware handcheck to avoid underflow, the DSS.DISPC\_CFG[16] FIFO\_HAND\_CHECK must be set to 1. The reset value of this bit is 0. The handcheck applies to the pipelines connected to the LCD output. It must be disabled before resetting the DSS.DISPC\_CTRL[11]

STALL\_MODE bit to 0. The new setting for the FIFO handcheck is used for the following frames.

**NOTE:** The LCD output is disabled at the end of the transfer of the frame. The software must reenale the LCD output to generate a new frame by setting the DSS.DISPC\_CTRL[0] LCD\_EN to 1. See [Figure 13-68](#).

#### 13.4.4.2 RFBI Control Registers

The following registers define the RFBI control registers:

- DSS.RFBI\_CTRL
- DSS.RFBI\_PIXEL\_CNT
- DSS.RFBI\_LINE\_NUMBER

##### 13.4.4.2.1 High Threshold

The DSS.RFBI\_CTRL[6:5] HIGH\_THR bit field is used to define the threshold to be used for the generation of the DMA request to receive data into the interconnect FIFO (24 x 32 FIFO depth) through the address of the register RFBI\_DATA. It must be the size of the burst. The supported values are 4x32, 8x32 and 16x32. The system DMA receives the DMA request and is in charge of providing the correct number of bytes. If the DSS.RFBI\_CTRL[7] DISABLE\_DMA\_REQ bit is reset, the DMA request is generated when there is enough room in the interconnect FIFO to accept the full burst. In case the RFBI receives writes L4 requests to the RFBI\_DATA location when the interconnect FIFO is full, the request is not accepted. The RFBI waits for a free entry in the interconnect FIFO to accept the L4 request.

If the DSS.RFBI\_CTRL[7] DISABLE\_DMA\_REQ bit is set, the DMA request is not generated. The threshold value is ignored.

**NOTE:** Software users can access the RFBI\_DATA location without using the DMA request and without programming the high threshold value (backward mode).

##### 13.4.4.2.2 Bypass Mode

Setting the DSS.RFBI\_CTRL[1] BYPASS\_MODE bit directly outputs the LCD controller output to the LCD panel. Resetting this bit directs the MPU module to send commands/parameters and data from the input video port FIFO.

##### 13.4.4.2.3 Enable

Setting/resetting the DSS.RFBI\_CTRL[0] EN bit enables/disables the RFBI module. The hardware resets the enable bit after all of the pixels are sent to the panel. The DSS.RFBI\_PIXEL\_CNT[31:0] PIXEL\_CNT bit field value defines the number of pixels to send to the LCD panel. When the transfer is finished, the configuration used can be modified.

**Table 13-29. RFBI Behavior**

RFBI_CTRL[1] BYPASS_MODE bit value	RFBI_CTRL[0] ENABLE bit value	RFBI Behavior
0	0	L4 interconnect can write command/param/data and read data/status from the Remote Frame Buffer (RFB). L4 interconnect access can only be done to the CSx actually active
0	1	The DISPC sends pixels to the RFB.

The stall signal is asserted when the module is disabled. Through the L4 port, pixels can be sent to the LCD panel only when the pixel count has reach the value 0x0

---

**NOTE:** The LCD output is disabled at the end of the transfer of the frame. The software must reenale the LCD output to generate a new frame by setting the DSS.DISPC\_CTRL[0] LCD\_EN to 1. See [Figure 13-68](#).

---

#### 13.4.4.2.4 Configuration Selection

Setting the DSS.RFBI\_CTRL[3:2] CONFIG\_SELECT bit field selects the configuration number (1 or 0 if bits are set or reset). The registers associated with the configuration output the data to the LCD panel.

If both chip-selects are selected, the configuration for the first chip-select is used (except for the polarity of the RFBI\_CS1 signal defined by the second configuration) and both devices connected to the CS signals are driven in parallel. In read mode, if both chip-selects are set, only RFBI\_CS0 is asserted to read data from the device connected on RFBI\_CS0. In write mode with two chip-selects selected, the RFBI can write to the two devices simultaneously.

#### 13.4.4.2.5 ITE Bit

Set the DSS.RFBI\_CTRL[4] ITE bit to start capturing the data from the display controller. This bit has no effect if the trigger mode is set to external. The display controller must be configured in the STALL mode to account for the RFBI\_DISPC\_STALL signal. Setting the trigger mode to external (DSS.RFBI\_CONFIG\_i[3:2] TRIGGER\_MODE bit field set to 0x1 or 0x2) causes the DSS.RFBI\_CTRL[4] ITE bit to be ignored. The corresponding chip-select must be selected when this bit is set by users.

The RFBI\_DISPC\_STALL signal is asserted when at least one of the following cases occur:

- Default status when no data to capture from the display controller
- High FIFO threshold reached
- End of the transfer (number of data to output)
- Reset of the RFBI module
- DSS.RFBI\_CTRL[0] EN bit reset to 0x0

The RFBI\_DISPC\_STALL signal is deasserted when the DSS.RFBI\_CTRL[0] EN bit is set to 0x1 and at least one of the following cases occur:

- Low FIFO threshold reached
- External TE occurs and the DSS.RFBI\_CONFIG\_i[3:2] TRIGGER\_MODE bit field is set to 0x1 or 0x2 for automatic external trigger (start of the transfer, the FIFO pointers are reset, the FIFO is empty).
- DSS.RFBI\_CTRL[4] ITE bit set to 0x1 by users (start of the transfer, the FIFO pointers are reset, the FIFO is empty).

#### 13.4.4.2.6 Number of Pixels to Transfer

Setting the DSS.RFBI\_PIXEL\_CNT[31:0] PIXEL\_CNT bit field value directs the application to indicate the number of pixels to be transferred to the LCD panel. The value can be changed only when the DSS.RFBI\_CTRL[0] EN is reset.

During the transfer, the hardware decrements the register when a pixel is sent to the remote frame buffer. When the DSS.RFBI\_CTRL[0] EN bit is set and a new value is written in the DSS.RFBI\_PIXEL\_CNT register when the current value in the register is a non-zero (the remaining number of pixels to transfer), the ongoing transfer is aborted.

From the L4 interconnect side, if the DSS.RFBI\_CONFIG\_i[10:9] CYCLE\_FMT bit field is equal to 0x3 and the DSS.RFBI\_CONFIG\_i[8:7] L4\_FMT bit field is equal to 0x0, an even number of write accesses to the data register must be performed before accessing any other register (CMD/PARAM/STATUS/READ).

When the DSS.RFBI\_CONFIG\_i[10:9] CYCLE\_FMT bit field is 0x3 (2 pixels are sent over 3 cycles), the number of pixels to be programmed in the DSS.RFBI\_PIXEL\_CNT[31:0] PIXEL\_CNT bit field must be a multiple of 2. If another CYCLE\_FMT is used, the value for PIXEL\_CNT can be odd or even. This constraint is valid for data provided on the L4 interconnect port and from the display controller.

If the DSS.RFBI\_CONFIG\_i[10:9] CYCLE\_FMT bit field is equal to 0x3, the DSS.RFBI\_CONFIG\_i[8:7] L4\_FMT bit field is equal to 0, and back-to-back register write is processed. The following registers should be written after the first data: RFBI\_CMD, RFBI\_PARAM, RFBI\_READ, and RFBI\_STS. The whole data transfer must first be performed before being able to write to any other registers (RFBI\_CMD, RFBI\_PARAM, RFBI\_READ, and RFBI\_STS).

#### 13.4.4.2.7 Programmable Line Number

When the trigger mode is set to external trigger mode with HSYNC and VSYNC or the TE, hardware resets the line counter when the VSYNC occurs and, after a programmable number of lines (the HSYNC pulse occurs for every line), the transfer to the LCD panel begins. When the programmable line number is 0, only the VSYNC pulse indicates the beginning of the transfer in both modes: HSYNC/VSYNC and TE (logical OR operation between HSYNC and VSYNC).

#### 13.4.4.3 RFBI Configuration

The following registers define the RFBI configuration:

- DSS.RFBI\_SYSCONFIG
- DSS.RFBI\_SYSSTS
- DSS.RFBI\_CONFIG\_0 (configuration 0) and DSS.RFBI\_CONFIG\_1 (configuration 1)
- DSS.RFBI\_VSYNC\_WIDTH
- DSS.RFBI\_HSYNC\_WIDTH

The configuration register for one configuration can be accessed only when the configuration is not in use (based on the value of the RFBI\_CTRL[3:2] CONFIG\_SELECT bit field).

##### 13.4.4.3.1 Parallel Mode

The DSS.RFBI\_CONFIG\_i[1:0] PARALLEL\_MODE bit field (where i = 0, 1) defines the width of the interface (8-, 9-, 12-, or 16-bit parallel).

##### 13.4.4.3.2 Trigger Mode

Setting the DSS.RFBI\_CONFIG\_i[3:2] TRIGGER\_MODE bit field configures the trigger on the external TE signal (RFBI\_TE\_VSYNC), or external with VSYNC/HSYNC with the programmable number of HSYNCs to begin the transfer in both cases or the internal programmable DSS.RFBI\_CTRL[4] ITE bit.

##### 13.4.4.3.3 VSYNC Pulse Width (Minimum Value)

The DSS.RFBI\_VSYNC\_WIDTH[15:0] MIN\_VSYNC\_PULSE\_WIDTH bit field defines the minimum number of L4 clock cycles of the VSYNC pulse for detection on VSYNC. It allows differentiation between VSYNC and HSYNC, which are ORed on the same signal and is also used in the VSYNC/HSYNC mode on the two separate input lines.

- The VSYNC pulse width must be at least equal to two L4 cycles when HSYNC is not present.
- The VSYNC pulse width must be at least equal to four L4 cycles when HSYNC is present.

##### 13.4.4.3.4 HSYNC Pulse Width (Minimum Value)

The DSS.RFBI\_HSYNC\_WIDTH[15:0] MIN\_HSYNC\_PULSE\_WIDTH bit field defines the minimum number of L4 clock cycles of the HSYNC pulse for detection on HSYNC. It allows differentiation between VSYNC and HSYNC, which are ORed on the same signal, and is also used in the VSYNC/HSYNC mode on the separate two input lines. The HSYNC pulse width must always be at least equal to two L4 cycles to be detected.

### 13.4.4.3.5 Cycle Format

Setting the DSS.RFBI\_CONFIG\_i[10:9] CYCLE\_FMT bit field (with i = 0, 1) defines which registers are used to format the data in the interconnect FIFO with the appropriate number of bits (starting from the LSB) and with the alignment on the interface as follows:

- DSS.RFBI\_DATA\_CYCLE\_i (if DSS.RFBI\_CONFIG\_i[10:9] CYCLE\_FMT bit field = 00) only  
or
- DSS.RFBI\_DATA\_CYCLE1\_i and DSS.RFBI\_DATA\_CYCLE2\_i (if DSS.RFBI\_CONFIG\_i[10:9] CYCLE\_FMT bit field = 01)  
or
- DSS.RFBI\_DATA\_CYCLE1\_i, DSS.RFBI\_DATA\_CYCLE2\_i, and DSS.RFBI\_DATA\_CYCLE3\_i (if DSS.RFBI\_CONFIG\_i[10:9] CYCLE\_FMT bit field = 10)

The data from the display controller and from the L4 interconnect are formatted based on the configuration of the DSS.RFBI\_DATA\_CYCLE\_i registers.

### 13.4.4.3.6 Unused Bits

Based on the configuration, the undefined bits for each cycle are defined with the previous values of the bits at the same position in the previous cycle, 0s, or 1s (the unused bits can be at any position). The DSS.RFBI\_CONFIG\_i[12:11] UNUSEDBITS bit field (with i = 0, 1) is used.

### 13.4.4.3.7 RFBI Timings

The timing registers for one configuration can be accessed only when the configuration is not in use (based on the value of the DSS.RFBI\_CTRL[3:2] CONFIG\_SELECT bit field). Granularity is defined using the DSS.RFBI\_CONFIG\_i[4] TIME\_GRANULARITY bit. This feature allows the extension of programmable ranges of timing parameters for the RFBI interface. Refer to [Table 13-30](#) for the bits configuration values.

- Chip-select assertion/deassertion time

RFBI\_A0 setup time to chip-select assertion is assured by the programmable chip-select assertion time from the start access time:

DSS.RFBI\_ONOFF\_TIMEi[3:0] CS\_ONTIME bit field (with i = 0, 1).

The chip-select deassertion time from the start access time is programmable:

DSS.RFBI\_ONOFF\_TIMEi[9:4] CS\_OFFTIME bit field (with i = 0, 1)

#### CAUTION

Configuring DSS.RFBI\_ONOFF\_TIMEi[3:0] CS\_ONTIME = DSS.RFBI\_ONOFF\_TIMEi[9:4] CS\_OFFTIME = 0 (with i = 0, 1) is not supported and must be avoided. This configuration creates contention on the bus and progressively damages the LCD panel.

- Chip-select pulse width

The total chip-select pulse width is the time when write cycle time or read cycle time has completed and is programmable:

DSS.RFBI\_CYCLE\_TIMEi[17:12] CS\_PULSE\_WIDTH bit field (with i = 0, 1)

It applies on the read-to-write, write-to-read, read-to-read, and write-to-write access based on:

- The DSS.RFBI\_CYCLE\_TIMEi[19] RR\_EN bit: Read-to-read access
- The DSS.RFBI\_CYCLE\_TIMEi[20] WW\_EN bit: Write-to-write access
- The DSS.RFBI\_CYCLE\_TIMEi[18] RW\_EN bit: Read-to-write access
- The DSS.RFBI\_CYCLE\_TIMEi[21] WR\_EN bit: Write-to-read access

By default, it applies to any access (read-to-read, read-to-write, write-to-read, write-to-write) when the chip-select changes.

- Access time

The total access time is the time from when A0 becomes valid until data are sampled before deasserting the RE signal; access time is programmable:

DSS.RFBI\_CYCLE\_TIMEi[27:22] ACCESS\_TIME bit field (with i = 0, 1)

When reading the data on the bus, the data are sampled at the end of the access time, which occurs before the end of the read off time (DSS.RFBI\_ONOFF\_TIMEi[29:24] RE\_OFFTIME, with i = 0, 1).

- Write enable cycle time

The total write enable cycle time is the time from when A0 becomes valid until write cycle completion; the write enable cycle time is programmable:

The DSS.RFBI\_CYCLE\_TIMEi[5:0] WE\_CYCLE\_TIME bit field (with i = 0, 1)

- Write enable assertion/deassertion time

The WE assertion delay time from start access time is programmable:

DSS.RFBI\_ONOFF\_TIMEi[13:10] WE\_ONTIME bit field (with i = 0, 1)

The WE deassertion delay time from the start access time is programmable:

DSS.RFBI\_ONOFF\_TIMEi[19:14] WE\_OFFTIME bit field (with i = 0, 1)

- Read enable cycle

The total read enable cycle time is the time when A0 becomes valid until read cycle completion; the read enable cycle time is programmable:

The DSS.RFBI\_CYCLE\_TIMEi[11:6] RECYCLE\_TIME bit field (with i = 0, 1)

- Read enable assertion/deassertion time

The RE assertion delay time from the start access time is programmable:

DSS.RFBI\_ONOFF\_TIMEi[23:20] RE\_ONTIME bit field (with i = 0, 1)

The RE deassertion delay time from the start access time is programmable:

DSS.RFBI\_ONOFF\_TIMEi[29:24] RE\_OFFTIME bit field (with i = 0, 1)

At cycle time completion (read access or write access) all control signals (RFBI\_CSi, RFBI\_WR, and RFBI\_RD, with i = 0, 1) are deasserted regardless of their deassertion time parameter values, if they are not deasserted already.

However, an exception to this forced deassertion exists when a pipelined request to the same chip-select or to a different chip-select is pending. Also, a control signal with deassertion time parameters equal to the cycle time parameter is not necessarily deasserted when a pipelined request to the same chip-select or different chip-select is pending. This prevents any unnecessary glitch transitions.

If no inactive cycles are required between successive accesses to the same chip-select (the DSS.RFBI\_CYCLE\_TIMEi[17:12] CS\_PULSE\_WIDTH bit field = 0, with i = 0, 1), and if assertion time parameters associated with the following access equal 0, the asserted control signals (RFBI\_CSi, RFBI\_WR, and RFBI\_RD, with i = 0, 1) stay asserted. This is applicable to any read/write-to-read/write access combination.

Table 13-30 summarizes the configurations values for each timing bit.

**Table 13-30. RFBI Timings Configuration**

Configuration bits <sup>(1)</sup>	Granularity <sup>(2)</sup>	
	one	two
DSS.RFBI_ONOFF_TIMEi[3:0] CS_ONTIME	0 to 15	0 to 30
DSS.RFBI_ONOFF_TIMEi[9:4] CS_OFFTIME	0 to 63	0 to 126
DSS.RFBI_CYCLE_TIMEi[17:12] CS_PULSE_WIDTH	0 to 63	0 to 126
DSS.RFBI_CYCLE_TIMEi[27:22] ACCESS_TIME	0 to 63	0 to 126
DSS.RFBI_CYCLE_TIMEi[5:0] WE_CYCLE_TIME	0 to 63	0 to 126
DSS.RFBI_ONOFF_TIMEi[13:10] WE_ONTIME	0 to 15	0 to 30
DSS.RFBI_ONOFF_TIMEi[19:14] WE_OFFTIME	0 to 63	0 to 126
DSS.RFBI_CYCLE_TIMEi[11:6] RECYCLE_TIME	0 to 63	0 to 126
DSS.RFBI_ONOFF_TIMEi[23:20] RE_ONTIME	0 to 15	0 to 30

<sup>(1)</sup> Where i = 0 or 1.

<sup>(2)</sup> Number of L4Clk cycles. The granularity can be configured using the DSS.RFBI\_CONFIG\_i[4] TIME\_GRANULARITY bit.

**Table 13-30. RFBI Timings Configuration (continued)**

Configuration bits <sup>(1)</sup>	Granularity <sup>(2)</sup>	
	one	two
DSS.RFBI_ONOFF_TIMEi[29:24] RE_OFFTIME	0 to 63	0 to 126

#### 13.4.4.3.8 RFBI State-Machine

Referring to [Table 13-18](#), the signals RFBI\_A0, RFBI\_RD, and RFBI\_WR are asserted/deasserted based on the register accessed (DSS.RFBI\_CMD, DSS.RFBI\_PARAM, DSS.RFBI\_DATA, DSS.RFBI\_READ, and DSS.RFBI\_STS). When the DSS.RFBI\_SYSSTS[8] BUSY bit is set by hardware, any access to the registers is stalled, except for the RFBI\_DATA register.

The DSS.RFBI\_SYSSTS[9] BUSY\_RFBI\_DATA bit indicates whether there are still pending data in the interconnect FIFO associated with the register RFBI\_DATA only.

- **Command register**  
Write a command at a time by writing in the DSS.RFBI\_CMD register. If the previous command is not processed, the DSS.RFBI\_SYSSTS[8] BUSY bit is set by hardware and the access to writing a new command is stalled.
- **Parameter register**  
Write a parameter at a time by writing in the DSS.RFBI\_PARAM register.  
If the previous parameter is not processed, the DSS.RFBI\_SYSSTS[8] BUSY bit is set by hardware and the access to writing a new parameter is stalled.
- **Data register**  
Write one or two pixels at a time by writing in the RFBI\_DATA register (when DSS.RFBI\_CONFIG\_i[10:9] CYCLE\_FMT = 0x3 with i = 0, 1, two pixels must be written contiguously, no other access to RFBI registers except DSS.RFBI\_DATA is allowed).  
The pixels are formatted based on the specified cycle format. If two pixels are written into the 32-data register, the DSS.RFBI\_CONFIG\_i[8:7] L4\_FMT bit field indicates the number of pixels for each L4 access to the register and the order of the pixels  
If the previous data are not processed, the DSS.RFBI\_SYSSTS[8] BUSY bit is set by hardware and any access for writing new data is stalled. When the DSS.RFBI\_SYSSTS[8] BUSY bit is reset by hardware, the access is not stalled.
- **Read/status register**  
Send through the command and parameter registers the correct information to receive data in the data or status register. The read data from the LCD panel is initiated by writing into the DSS.RFBI\_READ or DSS.RFBI\_STS registers. In this case, the DSS.RFBI\_SYSSTS[8] BUSY bit is set until the data are available in the register.  
When the DSS.RFBI\_SYSSTS[8] BUSY bit is set by hardware, the read or write access is stalled until the register is updated with a new value from the LCD panel. To avoid the stall, the software can poll the DSS.RFBI\_SYSSTS[8] BUSY bit until it is reset by hardware. To receive the data, send the appropriate command/parameters.

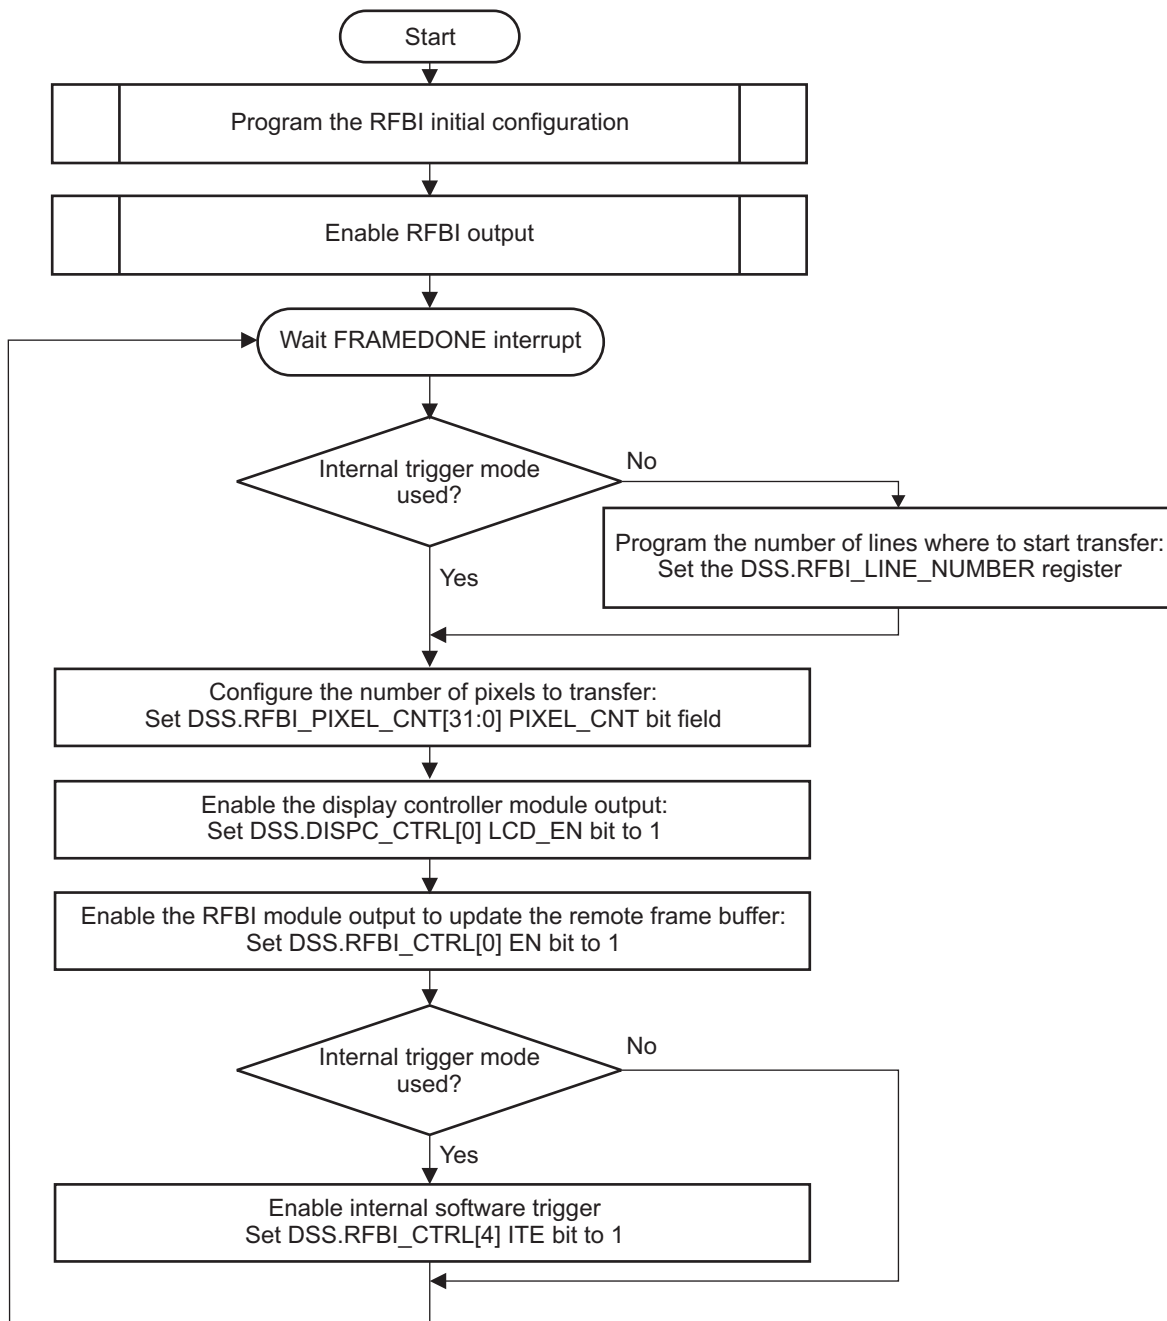

#### 13.4.4.3.9 RFBI Configuration Flow Charts

The RFBI configuration depends on the trigger mode used by the application. The available trigger modes are:

- Internal trigger mode when setting the DSS.RFBI\_CONFIG\_i[3:2] TRIGGER\_MODE bit field to 0x0
- External trigger mode:
  - TE external trigger mode when setting the DSS.RFBI\_CONFIG\_i[3:2] TRIGGER\_MODE bit field to 0x1
  - HSYNC/VSYNC external trigger mode when setting the DSS.RFBI\_CONFIG\_i[3:2] TRIGGER\_MODE bit field to 0x2

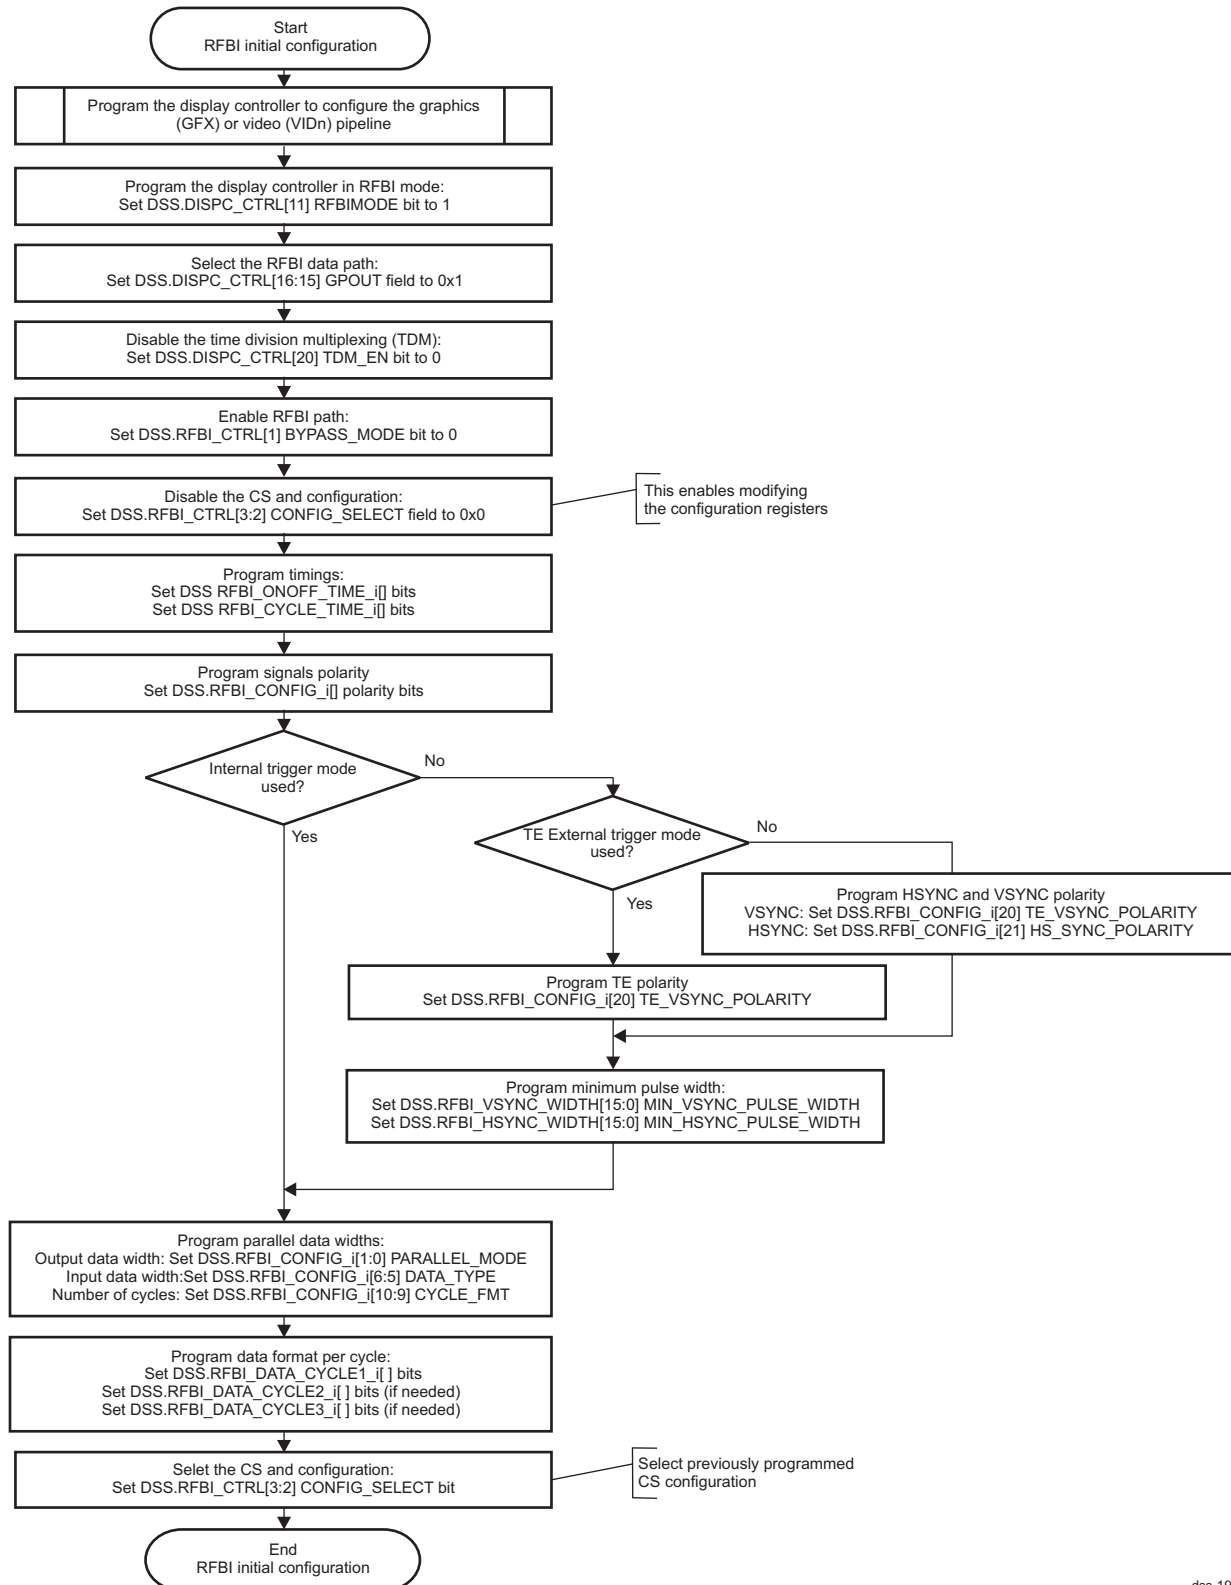

[Figure 13-68](#) gives an example of how to program and use the RFBI module:

**Figure 13-68. How to Use RFBI**

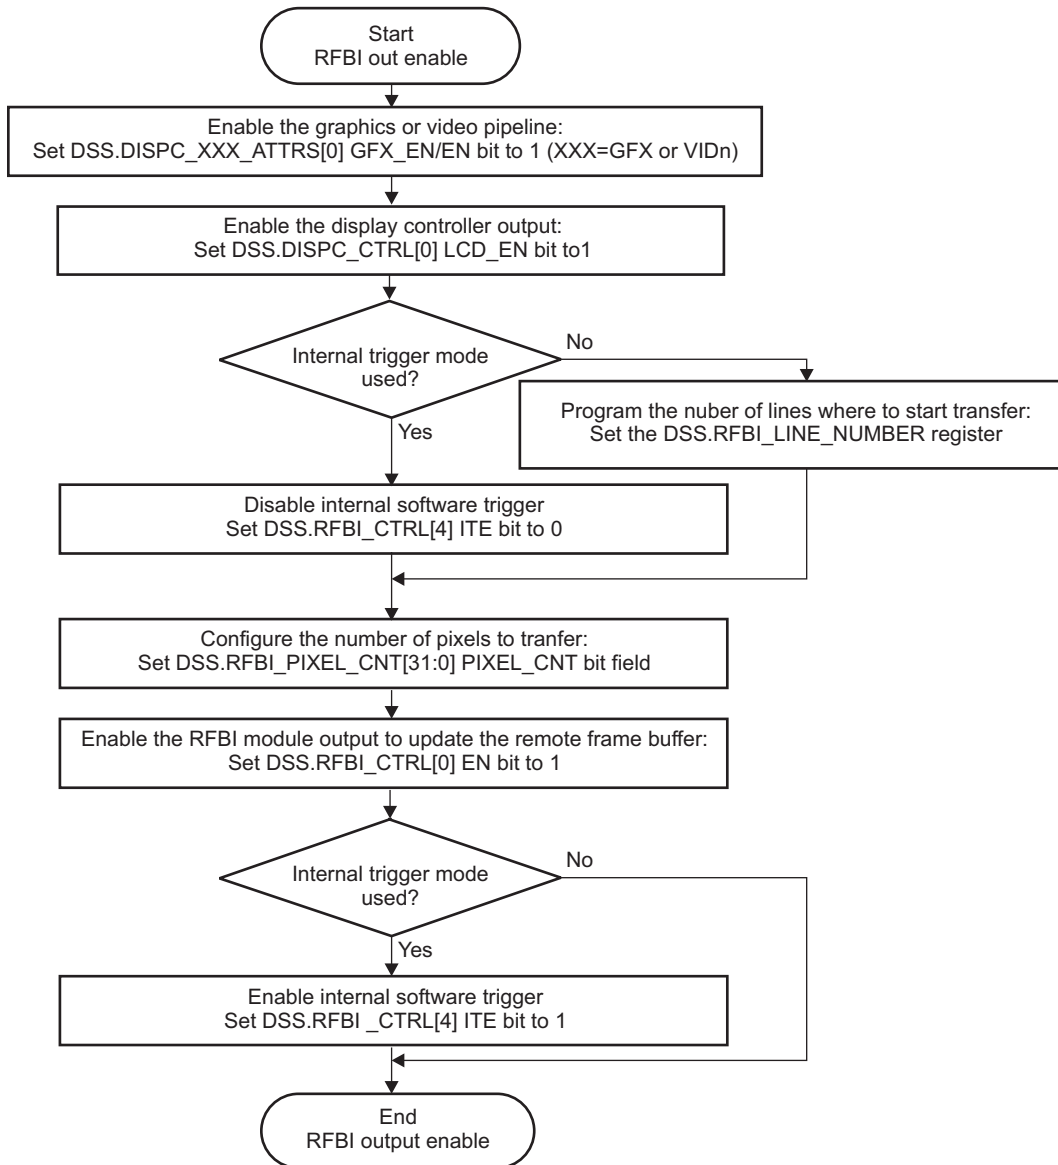

dss-192

Figure 13-69 details how to configure the RFBI registers:

**Figure 13-69. RFBI Initial Configuration**

dss-193

Figure 13-70 describes how to enable the RFBI module.

**Figure 13-70. RFBI Output Enable**

dss-324

## 13.5 Use Cases

This section gives some generic use cases and tips for setting the modules of the display subsystem.

### 13.5.1 How to Configure the Scaling Unit in the DISPC Module

This section describes the scaling capability of the display controller (DISPC). The scaling unit is a part of the video pipeline is used when transferring pixels from the system memory (SDRAM or on-chip SRAM) to the LCD panel or the TV set. The scaling unit consists of two scaling blocks: The vertical scaling block followed by the horizontal scaling block. The input pixel format is RGB24. In case the pixel format in system memory is not RGB, the color space conversion unit in front of the scaling unit converts the YUV pixels into RGB pixels. The two scaling units are independent: Neither of them, only one, or both can be used simultaneously

### 13.5.1.1 Filtering

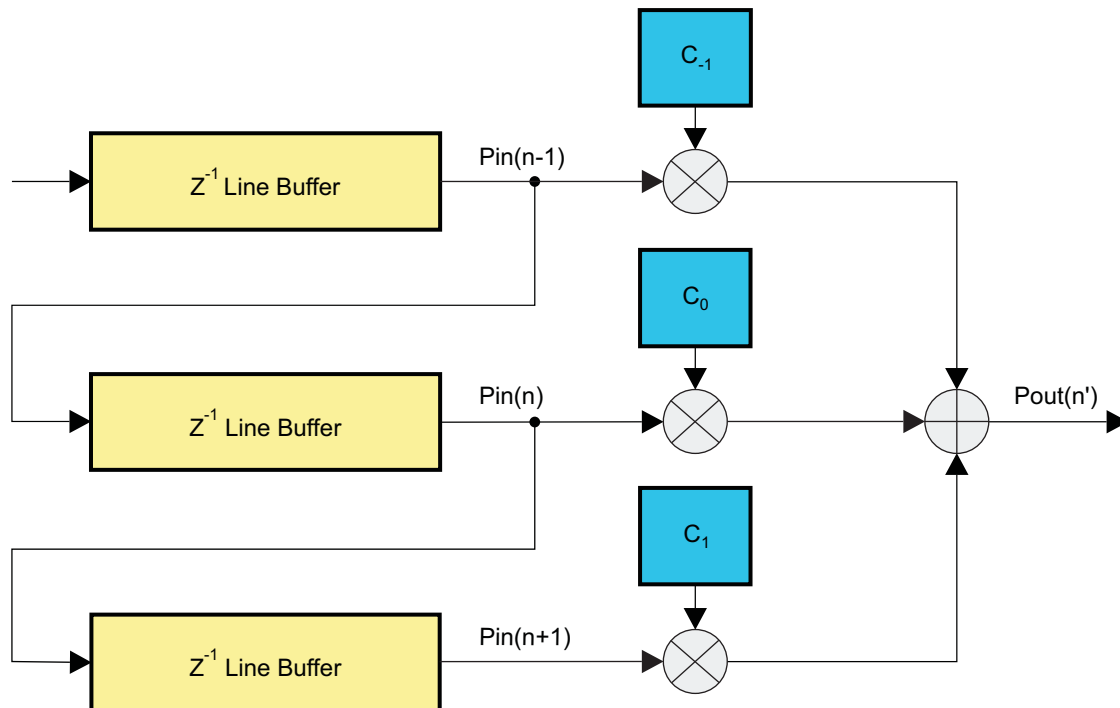

The scaling is used to down-scale, up-scale, or process the image while keeping the same size. It is applied independently horizontally and vertically. The same filtering applies for each color component (R, G, or B).

#### 13.5.1.1.1 Vertical Filtering

The vertical filtering unit is based on a poly-phase rotation architecture with eight phases and three taps. That means that 24 coefficients are programmable

The vertical 3-tap filtering macro architecture is shown in [Figure 13-71](#).

**Figure 13-71. Vertical Filtering Macro Architecture (Three Taps)**

dss-112

For the 3-tap vertical up/downsampling the equation is (with the example of R component):

$$R_{out}(n) = \left( \sum_{i=-1}^{i=1} C_i(\Phi) \times R_{in}(n+i) \right) \gg 7$$

dss-E067

(12)

Legend:

Rout: R component output  
 $C_i()$ : Vertical FIR coefficients  
 Rin: R component input  
 The line (n+1) is older than line (n).

**NOTE:** If the 5-tap resizer is used for RGB16 and YUV4:2:2 picture formats, the width of the input picture must be a multiple of 2 pixels and more than 5 pixels. This leads to the following register configuration:

```
DISPC_VIDn_ATTRS[21] VERTICAL_TAPS == 1
DISPC_VIDn_PICTURE_SIZE[10:0] VID_ORG_SIZE_X 4 and even
```

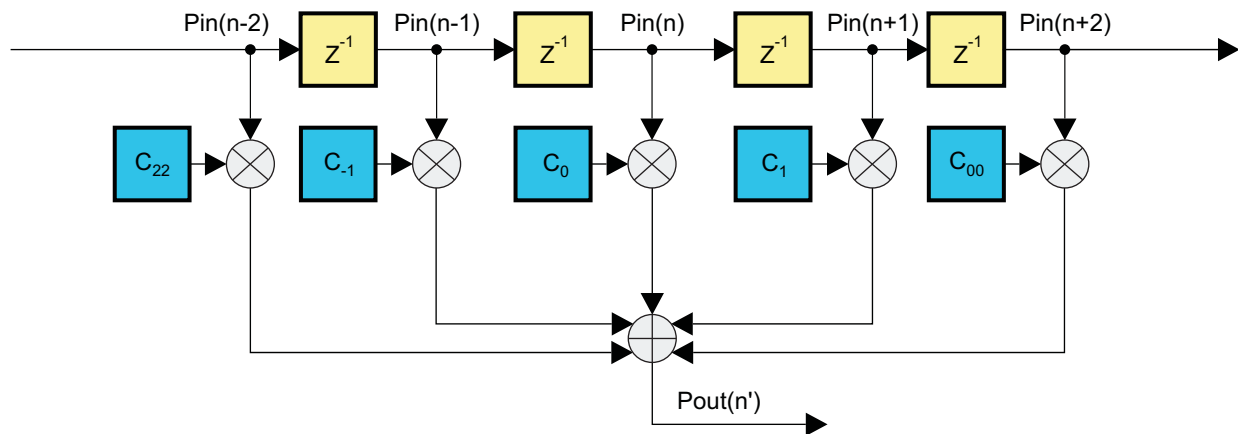

The programmable three coefficients of the poly-phase filters are signed 8-bit values (except for the central coefficient  $C_0()$ , which is unsigned).

The vertical filtering unit can be configured to support five taps.

The vertical 5-tap filtering macro architecture is shown in [Figure 13-72](#).

**Figure 13-72. Vertical Filtering Macro Architecture (Five Taps)**

dss-113

For the 5-tap vertical up/downsampling the equation is (with the example of R component):

$$R_{out}(n) = \left( \sum_{i=-2}^{i=2} C_i(\Phi) \times R_{in}(n+i) \right) \gg 7$$

dss-E066

(13)

Legend:

$R_{out}$ : R component output

$C_i()$ : Vertical FIR coefficients with  $C_{+2}()=C_{00}()$  and  $C_{-2}()=C_{22}()$

$R_{in}$ : R component input

The line (n+1) is older than line (n).

The programmable five coefficients of the poly-phase filters are signed 8-bit values (except for the central coefficient  $C_0()$ , which is unsigned).

In case of three taps, the memory lines are merged into three lines instead of six lines (one line is used as a cache line).

The first line is duplicated to fill up the two first lines (3-tap configuration) and the three first lines (5-tap configuration).

The last line is duplicated if the scaling logic requires loading of more lines and the last line has been reached

### 13.5.1.1.2 Horizontal Filtering

The horizontal filtering unit is based on a poly-phase rotation architecture with eight phases and five taps. That means that 40 coefficients are programmable.

The horizontal filtering macro architecture is shown in [Figure 13-73](#).

**Figure 13-73. Horizontal Filtering Macro Architecture (Five Taps)**

dss-114

For the 5-tap horizontal up/downsampling, the equation is (with the example of R component):

$$R_{out}(n) = \left( \sum_{i=-3}^{i=3} C_i(\Phi) \times R_{in}(n+i) \right) \gg 7$$

dss-E115

(14)

Legend:

- R<sub>out</sub>: R component output
- C<sub>i</sub>( $\Phi$ ): Vertical FIR coefficients
- R<sub>in</sub>: R component input
- The line (n+1) is older than line (n).

To horizontally and vertically filter the video layer, the phase is calculated separately. The programmable coefficients of the poly-phase filters are signed 8-bit values (except for the central coefficient C<sub>0</sub>( $\Phi$ ), which is unsigned).

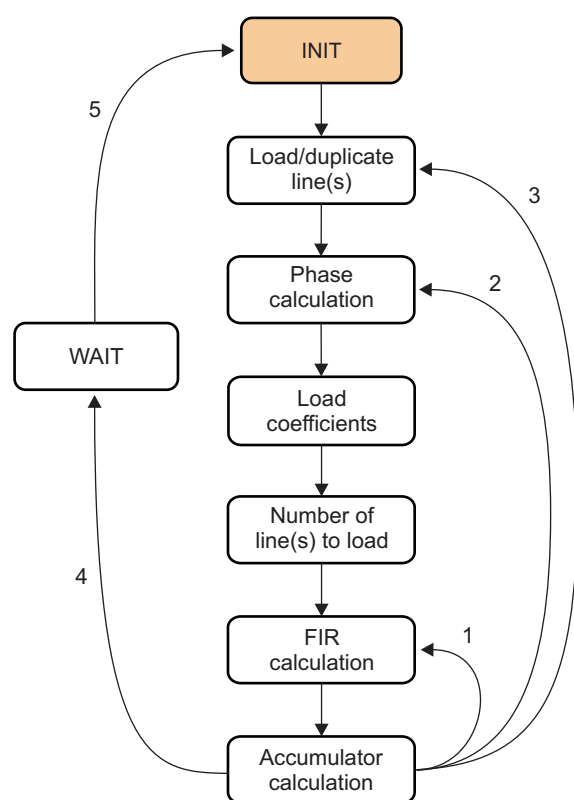

The first pixel is duplicated to fill up the three first pixel-buffers (5-tap configuration). The last pixel is duplicated if the scaling logic requires loading of more pixels and the last pixel has been reached

### 13.5.1.2 Scaling Algorithms

The up/downsampling finite state machines (FSM) below are detailed in this section.

[Figure 13-74](#) presents the vertical up/downsampling FSM.

**Figure 13-74. Vertical Up-/Down-Sampling Algorithm**

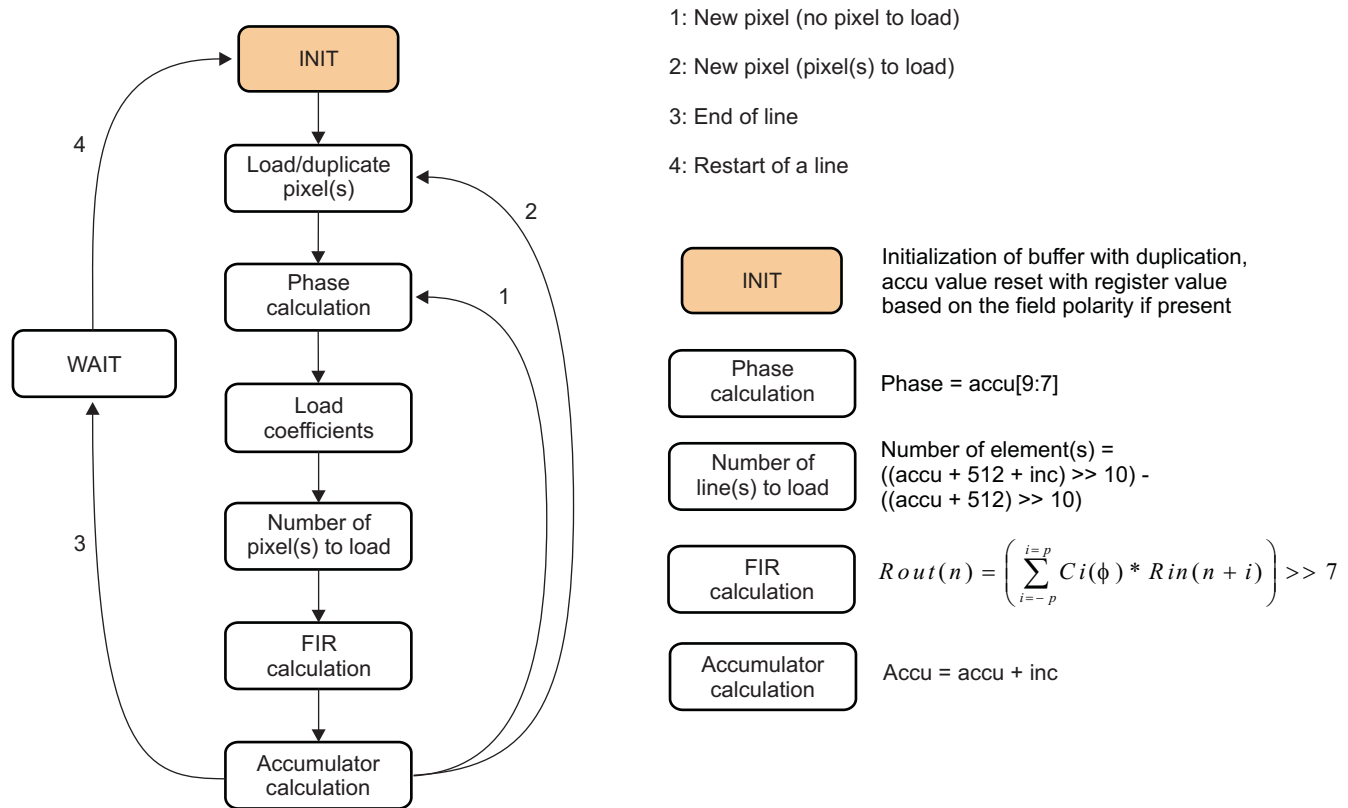

- 1: New pixel on the same line
- 2: New pixel on following line (no line to load)
- 3: New pixel on following line (line[s] to load)
- 4: End of frame
- 5: Restart of a new frame

INIT	Initialisation of buffer with duplication, accu value reset with register value based on the field polarity if present
Phase calculation	Phase = accu[9:7]
Number of line(s) to load	Number of element(s) = ((accu + 512 + inc) >> 10) - ((accu + 512) >> 10)
FIR calculation	$R_{out}(n) = \left( \sum_{i=-p}^{i=p} C_i(\phi) * R_{in}(n+i) \right) >> 7$
Accumulator calculation	Accu = accu + inc

dss-116

Figure 13-75 presents the horizontal up/downsampling FSM.

**Figure 13-75. Horizontal Up-/Down-Sampling Algorithm**

dss-117

### 13.5.1.3 Scaling Settings

**NOTE:**

- In this section, the screen word refers to LCD panel or TV set.
- n indicates pipeline 0 or 1 because there are two video pipelines in the DISPC.

#### 13.5.1.3.1 Register List

The following registers define the scaling registers for the video layer n configuration:

- DSS.DISPC\_VIDn\_BAj
- DSS.DISPC\_VIDn\_ATTRS
- DSS.DISPC\_VIDn\_FIR
- DSS.DISPC\_VIDn\_ACCUI
- DSS.DISPC\_VIDn\_FIR\_COEF\_H\_i
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV\_i
- DSS.DISPC\_VIDn\_FIR\_COEF\_Vi

Table 13-31 lists the registers for programming the vertical FIR coefficients (3-tap configuration).

**Table 13-31. Vertical FIR Coefficients Corresponding Table (3-Tap Configuration)**

C <sub>x</sub> ()	FIR_VC <sub>x</sub> ()
C <sub>-1</sub> ()	FIR_VC <sub>2</sub> ()
C <sub>0</sub> ()	FIR_VC <sub>1</sub> ()

**Table 13-31. Vertical FIR Coefficients Corresponding Table (3-Tap Configuration) (continued)**

$C_x()$	$FIR\_VC_x()$
$C_1()$	$FIR\_VC_0()$

The corresponding registers for programming the vertical FIR coefficients (3-tap configuration) are:

- $FIR\_VC_2() = DSS.DISPC\_VIDn\_FIR\_COEF\_HV\_i[31:24]$   $FIR\_VC2$
- $FIR\_VC_1() = DSS.DISPC\_VIDn\_FIR\_COEF\_HV\_i[23:16]$   $FIR\_VC1$
- $FIR\_VC_0() = DSS.DISPC\_VIDn\_FIR\_COEF\_HV\_i[15:8]$   $FIR\_VC0$

Table 13-32 lists the registers for programming the vertical FIR coefficients (5-tap configuration).

**Table 13-32. Vertical FIR Coefficients Corresponding Table (5-Tap Configuration)**

$C_x()$	$FIR\_VC_x()$
$C_{22}()$	$FIR\_VC_{22}()$
$C_{-1}()$	$FIR\_VC_2()$
$C_0()$	$FIR\_VC_1()$
$C_1()$	$FIR\_VC_0()$
$C_{00}()$	$FIR\_VC_{00}()$

The corresponding registers for programming the vertical FIR coefficients (5-tap configuration) are:

- $FIR\_VC_{22}() = DSS.DISPC\_VIDn\_FIR\_COEF\_Vi[15:8]$   $FIR\_VC22$
- $FIR\_VC_2() = DSS.DISPC\_VIDn\_FIR\_COEF\_HV\_i[31:24]$   $FIR\_VC2$
- $FIR\_VC_1() = DSS.DISPC\_VIDn\_FIR\_COEF\_HV\_i[23:16]$   $FIR\_VC1$
- $FIR\_VC_0() = DSS.DISPC\_VIDn\_FIR\_COEF\_HV\_i[15:8]$   $FIR\_VC0$
- $FIR\_VC_{00}() = DSS.DISPC\_VIDn\_FIR\_COEF\_Vi[7:0]$   $FIR\_VC00$

Table 13-33 lists the registers for programming the horizontal FIR coefficients (5-tap configuration).

**Table 13-33. Horizontal FIR Coefficients Corresponding Table (5-Tap Configuration)**

$C_x()$	$FIR\_HC_x()$
$C_{-2}()$	$FIR\_HC_4()$
$C_{-1}()$	$FIR\_HC_3()$
$C_0()$	$FIR\_HC_2()$
$C_1()$	$FIR\_HC_1()$
$C_2()$	$FIR\_HC_0()$

The corresponding registers for programming the vertical FIR coefficients (3-tap configuration) are:

- $FIR\_HC_4() = DSS.DISPC\_VIDn\_FIR\_COEF\_HV\_i[7:0]$   $FIR\_HC4$
- $FIR\_HC_3() = DSS.DISPC\_VIDn\_FIR\_COEF\_H\_i[31:24]$   $FIR\_HC3$
- $FIR\_HC_2() = DSS.DISPC\_VIDn\_FIR\_COEF\_H\_i[23:16]$   $FIR\_HC2$
- $FIR\_HC_1() = DSS.DISPC\_VIDn\_FIR\_COEF\_H\_i[15:8]$   $FIR\_HC1$
- $FIR\_HC_0() = DSS.DISPC\_VIDn\_FIR\_COEF\_H\_i[7:0]$   $FIR\_HC0$

### 13.5.1.3.2 Enabling

The video pipeline #n is enabled/disabled by setting/resetting the  $DSS.DISPC\_VIDn\_ATTRS[0].EN$  bit. While the video pipeline is enabled/disabled, the video layer is visible/not visible on the screen (LCD panel or TV set).

The video up/downsampling block for the video pipeline #n is programmed by setting the DSS.DISPC\_VIDn\_ATTRS[6:5] RESIZE\_EN bit field:

- When the RESIZE\_EN[1] bit is set to 1, the video vertical up/downsampling block is enabled. When set to 0, the vertical resize processing is disabled.
- When the RESIZE\_EN[0] bit is set to 1, the video horizontal up/downsampling block is enabled. When set to 0, the horizontal resize processing is disabled.
- When the RESIZE\_EN[1:0] is set to 0x3, both horizontal and vertical resize processing are enabled.

---

**NOTE:**

- Set a valid configuration before enabling the video up/downsampling block.
  - Vertical and horizontal downsampling are limited to a 0.25 resize factor. When processing a down-scaling with a vertical factor between 0.5 and 0.25, a 5-tap filter configuration must be used. See [Section 13.5.1.3.5](#) for more information concerning the filter coefficients.
- 

### 13.5.1.3.3 Factor

The following register bit fields define the increment value of the video up/downsampling block for video pipeline n:

- Vertical up/downsampling increment value (DSS.DISPC\_VIDn\_FIR[27:16] FIR\_V\_INC bit field, with n = 1 or 2): The unsigned integer value range is [1:4096]. The software calculates the value using the following equation:

$$\text{VIDFIRVINC}[11:0] = 1024 \times \frac{\text{VIDORGSIZEY}[10:0]}{\text{VIDSIZEY}[10:0]} \quad \text{dss-E118} \quad (15)$$

---

**NOTE:**

- If the FIR\_V\_INC[11:0] bit field value is greater than 4096, it is clipped to 4096. If VID\_SIZE\_Y[10:0] equals 0x1, VID\_SIZE\_Y[10:0] is replaced by 0x2 in the previous equation.
  - The VID\_ORG\_SIZE\_Y[10:0] and VID\_SIZE\_Y[10:0] bit field values must be programmed with the value desired minus 1.
- 
- Horizontal up/downsampling increment value (the DSS.DISPC\_VIDn\_FIR[11:0] FIR\_H\_INC bit field, with n = 1 or 2): The unsigned integer value range is [1:4096]. The software calculates the value using the following equation:

$$\text{VIDFIRHINC}[11:0] = 1024 \times \frac{\text{VIDORGSIZEX}[10:0]}{\text{VIDSIZEX}[10:0]} \quad \text{dss-E119} \quad (16)$$

---

**NOTE:**

- If the FIR\_H\_INC[11:0] bit field value is greater than 4096, it is clipped to 4096. If VID\_SIZE\_X[10:0] equals 1, VID\_SIZE\_X[10:0] is replaced by 2 in the previous equation.
  - The VID\_ORG\_SIZE\_X[10:0] and VID\_SIZE\_X[10:0] bit field values must be programmed with the value desired minus 1.
- 

### 13.5.1.3.4 Initial Phase

- Vertical up/downsampling accumulator value DSS.DISPC\_VIDn\_ACCUI[25:16] VERTICAL\_ACCU bit fields

The unsigned integer value range is [0:1023]. The accumulator value indicates on which phase the vertical filtering starts. The value 0 indicates that the phase 0 is the first phase used by the hardware to generate the first data.

- Vertical up/downsampling accumulator value DSS.DISPC\_VIDn\_ACCUI[9:0] VIDHORIZONTALACCUI

bit fields

The unsigned integer value range is [0:1023]. The accumulator value indicates on which phase the horizontal filtering starts. The value 0 indicates that the phase 0 is the first phase used by the hardware to generate the first data

Table 13-34 lists the vertical/horizontal accumulator values and phases

**Table 13-34. Vertical/Horizontal Accumulator Phase**

Accumulator Value	Phases
0	0
128	1
256	2
384	3
512	4
640	5
768	6
896	7

**NOTE:** For LCD output, the initial phase is always 0 (horizontal and vertical.) For TV output, the vertical phases (odd and even) can be nonzero values.

### 13.5.1.3.5 Coefficients

- **Vertical up/downsampling coefficients (DSS.DISPC\_VIDn\_FIR\_COEF\_HV\_i and DSS.DISPC\_VIDn\_FIR\_COEF\_V)**

The 3-tap vertical up/downsampling coefficients are defined in DSS.DISPC\_VIDn\_FIR\_COEF\_HV\_i registers. There are eight registers for the eight phases with three coefficients for each of them so a total of 24 programmable coefficients for the vertical up/downsampling block. Each register contains two 8-bit signed coefficients and one 8-bit unsigned coefficient (central one).

In addition, there are 2-tap vertical up/downsampling coefficients defined in DSS.DISPC\_VIDn\_FIR\_COEF\_Vi registers. There are eight registers for the eight phases with two coefficients for each of them so a total of 16 programmable coefficients for the vertical up/downsampling block used in addition of the 3-tap registers defined above. Each register contains two 8-bit signed coefficients ( $C_{22}()$  and  $C_{00}()$ ).

In case of 5-tap configuration, both sets of registers, DSS.DISPC\_VIDn\_FIR\_COEF\_HV\_i and DSS.DISPC\_VIDn\_FIR\_COEF\_V, are used. In case of 3-tap configuration, only one set of registers, DSS.DISPC\_VIDn\_FIR\_COEF\_HV, is used.

- **Horizontal up/downsampling coefficients (DSS.DISPC\_VIDn\_FIR\_COEF\_H\_i and DSS.DISPC\_VIDn\_FIR\_COEF\_HV)**

The 5-tap horizontal up/downsampling coefficients are defined in DSS.DISPC\_VIDn\_FIR\_COEF\_H\_i and DSS.DISPC\_VIDn\_FIR\_COEF\_HV\_i registers. There are eight registers for the eight phases with five coefficients for each register, for a total of 40 programmable coefficients for the horizontal up/downsampling block.

Each DSS.DISPC\_VIDn\_FIR\_COEF\_H\_i register contains three 8-bit signed coefficients and one 8-bit unsigned coefficient (central one), and each DSS.DISPC\_VIDn\_FIR\_COEF\_HV\_i contains one 8-bit signed coefficient.

Table 13-35 through Table 13-40 give the programmable coefficients for the FIR up/downsampling filters (Max-Fauque-Berthier method).

### 13.5.1.3.5.1 Up-Sampling

Table 13-35 gives the 24 coefficients to program the vertical upsampling (3-tap configuration).

**Table 13-35. Up-Sampling Vertical Filter Coefficients (Three Taps)**

Phases	FIR_VC <sub>2</sub> ()	FIR_VC <sub>1</sub> ()	FIR_VC <sub>0</sub> ()
0	0	128	0
1	3	123	2
2	12	111	5
3	32	89	7
4	0	64	64
5	7	89	32
6	5	111	12
7	2	123	3

Table 13-36 gives the 40 coefficients to program the vertical upsampling (5-tap configuration).

**Table 13-36. Up-Sampling Vertical Filter Coefficients (Five Taps)**

Phases	FIR_VC <sub>22</sub> ()	FIR_VC <sub>2</sub> ()	FIR_VC <sub>1</sub> ()	FIR_VC <sub>0</sub> ()	FIR_VC <sub>00</sub> ()
0	0	0	128	0	0
1	-1	13	124	-8	0
2	-2	30	112	-11	-1
3	-5	51	95	-11	-2
4	0	-9	73	73	-9
5	-2	-11	95	51	-5
6	-1	-11	112	30	-2
7	0	-8	124	13	-1

Table 13-37 gives the 40 coefficients to program the horizontal upsampling (5-tap configuration).

**Table 13-37. Up-Sampling Horizontal Filter Coefficients (Five Taps)**

Phases	FIR_HC <sub>4</sub> ()	FIR_HC <sub>3</sub> ()	FIR_HC <sub>2</sub> ()	FIR_HC <sub>1</sub> ()	FIR_HC <sub>0</sub> ()
0	0	0	128	0	0
1	-1	13	124	-8	0
2	-2	30	112	-11	-1
3	-5	51	95	-11	-2
4	0	-9	73	73	-9
5	-2	-11	95	51	-5
6	-1	-11	112	30	-2
7	0	-8	124	13	-1

The upsampling coefficients register configuration (vertical three taps and horizontal five taps) is the following:

- DSS.DISPC\_VIDn\_FIR\_COEF\_H\_0 = 0x00800000
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV\_0 = 0x00800000
- DSS.DISPC\_VIDn\_FIR\_COEF\_H\_1 = 0x0D7CF800
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV\_1 = 0x037B02FF
- DSS.DISPC\_VIDn\_FIR\_COEF\_H\_2 = 0x1E70F5FF
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV\_2 = 0x0C6F05FE
- DSS.DISPC\_VIDn\_FIR\_COEF\_H\_3 = 0x335FF5FE
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV\_3 = 0x205907FB
- DSS.DISPC\_VIDn\_FIR\_COEF\_H\_4 = 0xF74949F7
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV\_4 = 0x00404000

- DSS.DISPC\_VIDn\_FIR\_COEF\_H\_5 = 0xF55F33FB
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV\_5 = 0x075920FE
- DSS.DISPC\_VIDn\_FIR\_COEF\_H\_6 = 0xF5701EFE
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV\_6 = 0x056F0CFF
- DSS.DISPC\_VIDn\_FIR\_COEF\_H\_7 = 0xF87C0DFF
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV\_7 = 0x027B0300

**NOTE:** In this case, the DSS.DISPC\_VIDn\_FIR\_COEF\_Vi registers are not used.

The upsampling coefficients register configuration (both vertical and horizontal five taps) is the following:

- DSS.DISPC\_VIDn\_FIR\_COEF\_H\_0 = 0x00800000
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV\_0 = 0x00800000
- DSS.DISPC\_VIDn\_FIR\_COEF\_V0 = 0x00000000
- DSS.DISPC\_VIDn\_FIR\_COEF\_H\_1 = 0x0D7CF800
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV\_1 = 0x0D7CF8FF
- DSS.DISPC\_VIDn\_FIR\_COEF\_V1 = 0x0000FF00
- DSS.DISPC\_VIDn\_FIR\_COEF\_H\_2 = 0x1E70F5FF
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV\_2 = 0x1E70F5FE
- DSS.DISPC\_VIDn\_FIR\_COEF\_V2 = 0x0000FEFF
- DSS.DISPC\_VIDn\_FIR\_COEF\_H\_3 = 0x335FF5FE
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV\_3 = 0x335FF5FB
- DSS.DISPC\_VIDn\_FIR\_COEF\_V3 = 0x0000FBFE
- DSS.DISPC\_VIDn\_FIR\_COEF\_H\_4 = 0xF74949F7
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV\_4 = 0xF7404000
- DSS.DISPC\_VIDn\_FIR\_COEF\_V04 = 0x000000F7
- DSS.DISPC\_VIDn\_FIR\_COEF\_H\_5 = 0xF55F33FB
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV\_5 = 0xF55F33FE
- DSS.DISPC\_VIDn\_FIR\_COEF\_V5 = 0x0000FEFB
- DSS.DISPC\_VIDn\_FIR\_COEF\_H\_6 = 0xF5701EFE
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV\_6 = 0xF5701EFF
- DSS.DISPC\_VIDn\_FIR\_COEF\_V6 = 0x0000FFFE
- DSS.DISPC\_VIDn\_FIR\_COEF\_H\_7 = 0xF87C0DFF
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV\_7 = 0xF87C0D00
- DSS.DISPC\_VIDn\_FIR\_COEF\_V7 = 0x000000FF

### 13.5.1.3.5.2 Down-Sampling

Table 13-38 gives the 24 coefficients to program the vertical downsampling (3-tap configuration).

**Table 13-38. Down-Sampling Vertical Filter Coefficients (Three Taps)**

Phases	FIR_VC <sub>2</sub> ()	FIR_VC <sub>1</sub> ()	FIR_VC <sub>0</sub> ()
0	36	56	36
1	40	57	31
2	45	56	27
3	50	55	23
4	18	55	55
5	23	55	50
6	27	56	45

5	-7	22	53	48	12
6	-5	27	54	44	8
7	-2	31	55	40	4

The downsampling coefficients register configuration (vertical three taps and horizontal five taps) is the following:

- DSS.DISPC\_VIDn\_FIR\_COEF\_H\_0 = 0x24382400
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV\_0 = 0x24382400
- DSS.DISPC\_VIDn\_FIR\_COEF\_H\_1 = 0x28371FFE
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV\_1 = 0x28391F04
- DSS.DISPC\_VIDn\_FIR\_COEF\_H\_2 = 0x2C361BFB
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV\_2 = 0x2D381B08
- DSS.DISPC\_VIDn\_FIR\_COEF\_H\_3 = 0x303516F9
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV\_3 = 0x3237170C
- DSS.DISPC\_VIDn\_FIR\_COEF\_H\_4 = 0x11343311
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV\_4 = 0x123737F7
- DSS.DISPC\_VIDn\_FIR\_COEF\_H\_5 = 0x1635300C
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV\_5 = 0x173732F9
- DSS.DISPC\_VIDn\_FIR\_COEF\_H\_6 = 0x1B362C08
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV\_6 = 0x1B382DFB
- DSS.DISPC\_VIDn\_FIR\_COEF\_H\_7 = 0x1F372804
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV\_7 = 0x1F3928FE

---

**NOTE:**

- In this case, the DSS.DISPC\_VIDn\_FIR\_COEF\_Vi registers are not used.
  - In this case, the downsampling factor must be higher than 1/2.
- 

The downsampling coefficients register configuration (both the vertical and the horizontal five taps) is the following:

- DSS.DISPC\_VIDn\_FIR\_COEF\_H\_0 = 0x24382400
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV\_0 = 0x24382400
- DSS.DISPC\_VIDn\_FIR\_COEF\_V0 = 0x00000000
- DSS.DISPC\_VIDn\_FIR\_COEF\_H\_1 = 0x28371FFE
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV\_1 = 0x28371F04
- DSS.DISPC\_VIDn\_FIR\_COEF\_V1 = 0x000004FE
- DSS.DISPC\_VIDn\_FIR\_COEF\_H\_2 = 0x2C361BFB
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV\_2 = 0x2C361B08
- DSS.DISPC\_VIDn\_FIR\_COEF\_V2 = 0x000008FB
- DSS.DISPC\_VIDn\_FIR\_COEF\_H\_3 = 0x303516F9
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV\_3 = 0x3035160C
- DSS.DISPC\_VIDn\_FIR\_COEF\_V3 = 0x00000CF9
- DSS.DISPC\_VIDn\_FIR\_COEF\_H\_4 = 0x11343311
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV\_4 = 0x113433F7
- DSS.DISPC\_VIDn\_FIR\_COEF\_V4 = 0x0000F711
- DSS.DISPC\_VIDn\_FIR\_COEF\_H\_5 = 0x1635300C
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV\_5 = 0x163530F9
- DSS.DISPC\_VIDn\_FIR\_COEF\_V5 = 0x0000F90C
- DSS.DISPC\_VIDn\_FIR\_COEF\_H\_6 = 0x1B362C08
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV\_6 = 0x1B362CFB
- DSS.DISPC\_VIDn\_FIR\_COEF\_V6 = 0x0000FB08
- DSS.DISPC\_VIDn\_FIR\_COEF\_H\_7 = 0x1F372804
- DSS.DISPC\_VIDn\_FIR\_COEF\_HV\_7 = 0x1F3728FE
- DSS.DISPC\_VIDn\_FIR\_COEF\_V7 = 0x0000FE04

---

**NOTE:** This configuration must be used for vertical downsampling factors between 1/2 and 1/4

---

### 13.5.2 Display Low-Power Refresh Settings

This section describes the display low-power refresh application on the device. The display subsystem remains active while saving power by putting unused power domains and unused modules into idle mode. This process can be expanded to include the screen saver mode in which the MPU subsystem wakes up to update the frame buffer and then returns to idle mode. On the device platform, where power consumption is of high importance, the display modes must be configured properly to achieve optimal power savings

The display low-power refresh mode can be used in the following scenarios:

- During the period of time when there is no application running and the backlight turns off.
- Once the backlight turns off, the LCD display can be shut off or can be refreshed showing the time and date. The screen saver mode can be used to update the time every minute.

This section discusses the methodology for finding optimal power savings. These settings are detailed for a 16-bit, 240 x 320 pixel QVGA LCD.

### 13.5.2.1 Display Low-Power Refresh Overview

When the device is not in idle mode, meaning all clocks are on and the power is applied to all power domains, the following activity typically occurs with respect to the display subsystem:

- The MPU subsystem is processing
- The display subsystem DMA controller is moving data from the SDRAM frame buffer location to the display subsystem internal FIFO.
- The LCD data is being sent from the internal FIFO to the display panel.

When the MPU goes into idle mode, the following activity occurs:

- The display subsystem DMA controller remains active, moving data from the SDRAM frame buffer to the internal FIFO.
- The SDRAM will go in and out of self-refresh between transfers.
- The display subsystem internal FIFO will continue to send LCD data to the display panel.

This procedure is named as the display low-power refresh scenario.

---

**NOTE:** In the device, the display subsystem has its own power domain (the DSS power domain).

---

### 13.5.2.2 Display Subsystem Clock

#### 13.5.2.2.1 Display Subsystem Clock Configuration

The display subsystem contains one functional clock source, which is the DSS functional clock 1 (DSS1\_ALWON\_FCLK):

- DSS1\_ALWON\_FCLK is sourced from DPLL4 (DPLL4\_ALWON\_FCLK), with several multipliers available and is configured in the PRCM.CM\_CLKSEL\_DSS[4:0] CLKSEL\_DSS1 bit field.

The pixel clock is set as DSS1\_ALWON\_FCLK by configuring the DSS.DSS\_CONTROL[0] DISPC\_CLK\_SWITCH bit.

The LCD logic clock is determined by the DSS.DISPC\_DIVISOR[23:16] LCD bit field. This divisor is used on the DSS functional clock that is selected in the DSS\_CONTROL register (either DSS1\_ALWON\_FCLK or DSS2\_ALWON\_FCLK). This LCD divisor selects the logical clock frequency which is used to clock the logic in the display subsystem. For some applications there is a required minimum logical clock frequency. The lower the logical clock frequency then the lower the power consumption.

The pixel clock is determined by setting the DSS.DISPC\_DIVISOR[7:0] PCD bit field. This divisor is used on the LCD logic clock.

In the following example, the DPLL4 clock (DPLL4\_ALWON\_FCLK) is enabled and running at 266 MHz:

The PRCM.CM\_CLKSEL2\_PLL[19:8] PERIPH\_DPLL\_MULT bit field is set to 0x4 and the PRCM.CM\_CLKSEL2\_PLL[6:0] PERIPH\_DPLL\_DIV bit field is set to 0x1 (DPLL4 x 4/(1+1)):

$$DPLL4\_ALWON\_FCLKOUT = DPLL4\_ALWON\_FCLK(266MHz) \times 4/2 = 532 \text{ MHz}$$

---

**NOTE:** The DPLL4\_ALWON\_FCLKOUT clock is an internal clock in DPLL4 module after the DPLL\_MULT and DPLL\_DIV stages. The DPLL4\_M4\_CLK clock is one of the DPLL4 output clocks and is the clock source for DSS1\_ALWON\_FCLK.

---

The DSS.DSS\_CONTROL[0] DSS\_CLK\_SWITCH bit is set to 0x0 to select DSS1\_ALWON\_FCLK as the display subsystem functional clock:

$$DSS1\_ALWON\_FCLK = DPLL4\_M4\_CLK$$

The PRCM.CM\_CLKSEL\_DSS[4:0] CLKSEL\_DSS1 bit field is set to 0x08:

$$DSS1\_ALWON\_FCLK = \frac{DPLL4\_ALWON\_FCLKOUT(532MHz)}{8} = 66.5 \text{ MHz}$$

dss-E120

(17)

The DSS.DISPC\_DIVISOR[23:16] LCD bit field is set to 0x01:

$$\text{LogicClock} = \frac{\text{DSS1\_ALWON\_FCLK}(66.5\text{MHz})}{1} = 66.5 \text{ Mhz}$$

(18)

dss-E121

The DSS.DISPC\_DIVISOR[6:0] PCD bit field is set to 0x0C:

$$\text{PixelClock} = \frac{\text{LogicClock}(66.5\text{MHz})}{12} = 5.54 \text{ Mhz}$$

(19)

dss-E122

#### 13.5.2.2.1.1 Pixel Clock Frequency Settings to Reduce Power Consumption

Power consumption is reduced when a low pixel clock frequency is used. If the clock frequency is set too low, however, the frames-per-second (FPS) are reduced. This can result in visible flickering on the screen each time the screen is refreshed. To avoid electrical polarization problems, refer to the appropriate LCD panel datasheet to determine the maximum range of pixel clock frequency variation. To save power, therefore, the pixel clock frequency during low-power mode must be set as low as possible, but high enough to eliminate visible flickering

#### 13.5.2.2.1.2 Display Subsystem Divider Settings to Reduce Power Consumption

The pixel clock is determined by the DSS.DISPC\_DIVISOR[7:0] PCD and DSS.DISPC\_DIVISOR[23:16] LCD settings. In most cases, the LCD[7:0] bit field is set to 0x1 and the PCD[7:0] bit field is used as the main divider. To reduce power consumption, software users should investigate if the DSS.DISPC\_DIVISOR[23:16] LCD bit field can be set to a value other than 0x1 and then decrease DSS.DISPC\_DIVISOR[7:0] PCD bit field value. For example, if the desired pixel clock is 1.625 MHz with a 13-MHz functional clock, then this pixel clock can be achieved by setting DSS.DISPC\_DIVISOR[23:16] LCD to 0x1 and DSS.DISPC\_DIVISOR[7:0] PCD to 0x8. The same pixel clock can be achieved by setting DSS.DISPC\_DIVISOR[23:16] LCD to 0x2 and DSS.DISPC\_DIVISOR[7:0] PCD to 0x4.

#### 13.5.2.2.2 Display Subsystem Clock Enable

To take the DSS out of reset, all DSS-related clocks must be enabled, and the DPLL4 clock must be enabled. After taking the DSS out of reset, these clocks can be disabled if they are not used. The following clocks must be enabled before the DSS can come out of reset:

- PRCM.CM\_FCLKEN\_DSS[0] EN\_DSS1 = 0x1
- PRCM.CM\_FCLKEN\_DSS[1] EN\_DSS2 = 0x1
- PRCM.CM\_FCLKEN\_DSS[2] EN\_TV = 0x1
- PRCM.CM\_ICLKEN\_DSS[0] EN\_DSS = 0x1
- PRCM.CM\_CLKEN\_PLL[18:16] EN\_PERIPH\_DPLL = 0x7

Once these clocks are enabled, the display subsystem can be taken out of reset.

The following sections explain the display low-power mode configuration options, which are determined by product requirements (LCD panel type).

### 13.5.2.3 Autoidle and Smart Idle

#### 13.5.2.3.1 Autoidle

To further save power consumption, the autoidle feature at the module can be enabled for the active modules. For example, the PRCM and the system control modules are active during this mode. By enabling the autoidle feature, the clocks at the module level are gated when they are not needed.

The RFBI, display controller, and L4 interfaces can internally gate their clocks to decrease power consumption if no transaction is present on the related bus. The following bits must be set to enable this functionality:

- DSS.DSS\_SYSCONFIG[0] AUTOIDLE bit (1: Autoidle; 0: Clock free-running) for the display subsystem
- DSS.RFBI\_SYSCONFIG[0] AUTOIDLE bit (1: Autoidle; 0: Clock free-running) for the RFBI

- DSS.DISPC\_SYSCFG[0] AUTIDLE bit (1: Autoidle; 0: Clock free-running) for the display controller
- DSS.DISPC\_CFG[9] FUNC\_GATED bit (1: Functional clocks gated enabled, 0: Functional clocks gated disabled) for the display controller

### 13.5.2.3.2 Smart-Idle

The smart-idle feature can be enabled to allow the module to enter idle when the clocks are not needed. The smart-idle feature can be enabled for the display subsystem submodules to further save power consumption:

- Display controller: DSS.DISPC\_SYSCFG[4:3] SIDLEMODE
- RFBI: DSS.RFBI\_SYSCONFIG[4:3] SIDLEMODE

### 13.5.2.4 FIFO Thresholds

The display subsystem internal FIFO is used to move data to the LCD panel. This FIFO is filled by the display subsystem DMA controller. The DMA controller is triggered to start and stop based on two thresholds:

- DSS.DISPC\_GFX\_FIFO\_THR[11:0] GFX\_FIFO\_LOW\_THR
- DSS.DISPC\_GFX\_FIFO\_THR[27:16] GFX\_FIFO\_HIGH\_THR

When the level of the FIFO reaches the low threshold, the internal DMA controller begins to fill the FIFO With the data in the frame buffer. Once the amount of pixel data reaches the high threshold, the internal DMA controller stops.

#### 13.5.2.4.1 FIFO Threshold Settings to Reduce Power Consumption

Power consumption is reduced by increasing the difference between the high and low FIFO threshold levels, thereby leaving the SDRAM in self-refresh for a longer period of time. To perform this reduction, consider the following:

- The low FIFO threshold level must be as low as possible, but not low enough to cause any underflow.
- The high FIFO threshold level must not exceed the FIFO size minus one burst. A value above this limit results in the DMA controller trying to fill the FIFO to a level that cannot be reached, which will increase power consumption.
- The difference between high and low FIFO threshold levels must not be less than one burst size. These settings do not reduce power consumption because the SDRAM never goes into self-refresh, but they will avoid underflow.

### 13.5.2.5 Vertical and Horizontal Timings

The vertical and horizontal timings and the pixel clock speed determine the number of frames updated per second. [Figure 13-76](#) shows the timings for a 240 x 320 pixel QVGA LCD panel. If the pulse width (also called blanking) and the front porch parameters are increased, more setup time is added before the data is transferred. This additional time is beneficial for delaying the data transfer if the data is not ready because of bandwidth limitations. Care must be taken to determine the fps when modifying these parameters.

Use the following formula to determine the fps for a 240 x 320 QVGA LCD:

$$fps = \frac{1}{[(Hsw + 1) + (Hfp + 1) + 240 + (Hbp + 1)] \times [(Vsw + 1) + Vf p + 320 + Vbp]} \times (PCLK)$$

(20)

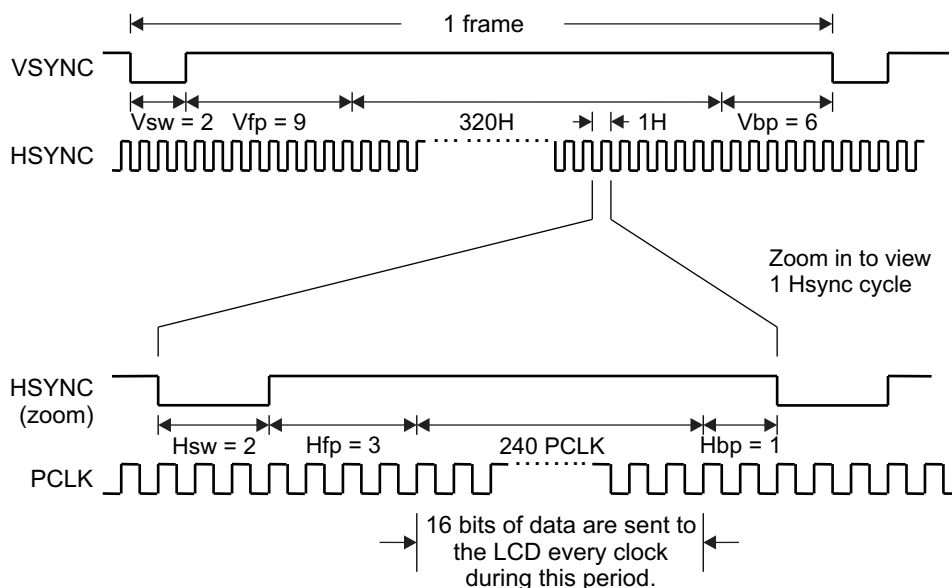

With:

- Hsw: DSS.DISPC\_TIMING\_H[7:0] HSW bit field value
- Hfp: DSS.DISPC\_TIMING\_H[19:8] HFP bit field value
- Hbp: DSS.DISPC\_TIMING\_H[31:20] HBP bit field value
- Vsw: DSS.DISPC\_TIMING\_V[7:0] VSW bit field value
- Vf p: DSS.DISPC\_TIMING\_V[19:8] VFP bit field value

- Vbp: DSS.DISPC\_TIMING\_V[31:20] VBP bit field value
- PCLK: Pixel clock period

The horizontal (Hsw) and vertical (Vsw) pulse widths and the horizontal front (Hfp) and back (Hbp) porches are increased by 1 because the value is programmed as the desired value minus 1.

### Figure 13-76. QVGA LCD Timings

dss-124

The fps for the example of 6-MHz pixel clock with the setting shown in [Figure 13-76](#) is as follows:

$$f_{ps} = \frac{1}{[(2 + 1) + 4 + 240 + 2] \times [(2 + 1) + 9 + 320 + 6] \times 166.67 \times 10^{-9}}$$

dss-E125

$$fps = 71.57 Hz \quad (21)$$

#### 13.5.2.5.1 Horizontal and Vertical Timing Settings to Reduce Power Consumption

The number of fps that the screen is refreshed is also determined by the vertical and horizontal timings. Consequently, longer timings between frames (blanking periods) reduce the fps and reduce average power consumption. Shorter blanking periods increase fps and increases power consumption. If the blanking between frames is too small, a FIFO underflow may occur.

## 13.6 Registers

### 13.6.1 DSS\_DISPC Registers

Table 13-41 lists the memory-mapped registers for the DSS\_DISPC. All register offset addresses not listed in Table 13-41 should be considered as reserved locations and the register contents should not be modified.

### Table 13-41. DSS\_DISPC Registers

Bit	Field	Type	Reset	Description
1	SOFTRESET	R/W	0h	Software reset. Set this bit to 1 to trigger a module reset. The bit is automatically reset by the hardware. During reads, it always returns 0h (R/W) = Normal mode 1h (R/W) = The module is reset.
0	AUTOIDLE	R/W	1h	Internal interface clock gating strategy 0h (R/W) = Interface clock is free-running 1h (R/W) = Automatic L3 and L4 interface clock gating strategy is applied based on interface activity

### 13.6.1.3 DISPC\_SYSSTS Register (offset = 14h) [reset = 1h]

DISPC\_SYSSTS is shown in [Figure 13-79](#) and described in [Table 13-44](#).

This register provides status information about the module, excluding interrupt status information.

### 13.6.1.4 DISPC\_IRQSTS Register (offset = 18h) [reset = 0h]

DISPC\_IRQSTS is shown in [Figure 13-80](#) and described in [Table 13-45](#).

This register regroups all the status of module internal events that generate an interrupt. A write of 1 to a given bit resets the bit

### 13.6.1.5 DISPC\_IRQEN Register (offset = 1Ch) [reset = 0h]

DISPC\_IRQEN is shown in [Figure 13-81](#) and described in [Table 13-46](#).

This register allows the masking/unmasking of module internal interrupt sources, on an event-by-event basis.

14	GPIN1	R	0h	General Purpose Input Signal 0h (R) = The GPin1 has been reset 1h (R) = The GPin1 has been set
13	GPIN0	R	0h	General Purpose Input Signal 0h (R) = The GPin0 has been reset 1h (R) = The GPin0 has been set
12	OVLY_OPT	R/W	0h	Overlay Optimization (available when graphics format is NOT 1, 2, and 4-BPP) 0h (R/W) = Graphics data below video1 window fetched from memory or no overlap between graphics and video1 windows 1h (R/W) = Graphics data below video1 window not fetched from memory.
11	STALL_MODE	R/W	0h	Stall mode for the LCD output 0h (R/W) = Normal mode selected 1h (R/W) = Stall mode selected. The Display Controller sends the data without considering the VSYNC/HSYNC. The LCD output is disabled at the end of the transfer of the frame. The S/W has to re-enable the LCD output to generate a new frame. The stall mode is used in RFBI command modes
10	RESERVED	R/W	0h	
9-8	TFT_DATA_LINES	R/W	0h	Number of lines of the LCD interface 0h (R/W) = 12-bit output aligned on the LSB of the pixel data interface 1h (R/W) = 16-bit output aligned on the LSB of the pixel data interface 2h (R/W) = 18-bit output aligned on the LSB of the pixel data interface 3h (R/W) = 24-bit output aligned on the LSB of the pixel data interface
7	ST_DITHER_EN	R/W	0h	Spatial temporal dithering enable 0h (R/W) = Spatial/temporal dithering logic disabled 1h (R/W) = Spatial/temporal dithering logic enabled

**Table 13-47. DISPC\_CTRL Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
6	GO_DIGITAL	R/W	0h	Digital GO Command 0h (R/W) = The hardware has finished updating the internal shadow registers of the pipeline(s) associated with the digital output using the user values. The hardware resets the bit when the update is completed 1h (R/W) = Users have finished programming the shadow registers of the pipeline(s) associated with the digital output and the hardware can update the internal registers at the external VSYNC
5	GO_LCD	R/W	0h	LCD GO Command 0h (R/W) = The hardware has finished updating the internal shadow registers of the pipeline(s) connected to the LCD output using the user values. The hardware resets the bit when the update is completed 1h (R/W) = Users have finished programming the shadow registers of the pipeline(s) associated with the LCD output and the hardware can update the internal registers at the VFP start period.
4	M8B	R/W	0h	Mono 8-bit mode 0h (R/W) = Pixel data [3:0] is used to output four pixel values to the panel at each pixel clock transition (only in Passive Mono 8-bit mode) 1h (R/W) = Pixel data [7:0] is used to output eight pixel values to the panel each pixel clock transition (only in Passive Mono 8-bit mode)
3	STNTFT	R/W	0h	LCD display type 0h (R/W) = Passive or Passive Matrix display operation enabled. Passive Matrix dither logic enabled 1h (R/W) = Active Matrix display operation enabled. Passive Matrix Dither logic and output FIFO bypassed
2	MONO_COLOR	R/W	0h	Monochrome/Color 0h (R/W) = Color operation enabled (Passive Matrix mode only) 1h (R/W) = Monochrome operation enabled (Passive Matrix mode only)
1	DIGITAL_EN	R/W	0h	Digital enable 0h (R/W) = Digital output disabled (at the end of the current field if interlace output when the bit is reset) 1h (R/W) = Digital output enabled
0	LCD_EN	R/W	0h	LCD enable 0h (R/W) = LCD output disabled (at the end of the frame when the bit is reset) 1h (R/W) = LCD output disabled (at the end of the frame when the bit is reset)

### 13.6.1.7 DISPC\_CFG Register (offset = 44h) [reset = 0h]

DISPC\_CFG is shown in [Figure 13-83](#) and described in [Table 13-48](#).

This control register configures the display controller module.  
Shadow register, updated on VFP start period or EVSYNC

**Figure 13-83. DISPC\_CFG Register**

**Table 13-48. DISPC\_CFG Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
3	PALETTEGAMMA_TBL	R/W	0h	Palette/Gamma Table selection 0h (R/W) = LUT used as palette (only if graphics format is BITMAP1, 2, 4, and 8) 1h (R/W) = LUT used as gamma table (only if graphics format is NOT BITMAP1, 2, 4, and 8 or no graphics window present)
2-1	LOAD_MODE	R/W	0h	Loading Mode for the Palette/Gamma Table 0h (R/W) = Palette/Gamma Table and data are loaded every frame 1h (R/W) = Palette/Gamma Table to be loaded. Users set the bit when the palette/gamma table has to be loaded. H/W resets the bit when table has been loaded. (DISPC_GFX_ATTRIBUTES. GfxEnable has to be set to 1) 2h (R/W) = Frame data only loaded every frame 3h (R/W) = Palette/Gamma Table and frame data loaded on first frame then switch to 10 (H/W)
0	PIXEL_GATED	R/W	0h	Pixel Gated Enable (only for Active Matrix Display) 0h (R/W) = Pixel Gated Enable (only for Active Matrix Display) 1h (R/W) = Pixel clock only toggles when there is valid data to display. (only in Active Matrix mode)

### 13.6.1.8 DISPC\_DEFAULT\_COLOR\_0 Register (offset = 4Ch + [i \* 4h]) [reset = 0h]

DISPC\_DEFAULT\_COLOR\_0 is shown in [Figure 13-84](#) and described in [Table 13-49](#).

The control register allows to configure the default solid background color for the LCD (DISPC\_DEFAULT\_COLOR\_0) and for 24-bit digital output (DISPC\_DEFAULT\_COLOR\_1). Shadow register, updated on VFP start period for DISPC\_DEFAULT\_COLOR\_0 and EVSYNC for DISPC\_DEFAULT\_COLOR\_1

**Figure 13-84. DISPC\_DEFAULT\_COLOR\_0 Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

31-24	RESERVED	R/W	0h	
23-0	DEFAULT_COLOR	R/W	0h	24-bit RGB color value to specify the default solid color to display RW 0x000000 when there is no data from the overlays

### 13.6.1.9 DISPC\_TRANS\_COLOR\_0 Register (offset = 54h + [i \* 4h]) [reset = 0h]

DISPC\_TRANS\_COLOR\_0 is shown in [Figure 13-85](#) and described in [Table 13-50](#).

The register sets the transparency color value for the video/graphics overlays for the LCD output (DISPC\_TRANS\_COLOR\_0) for 24-bit digital output (DISPC\_TRANS\_COLOR\_1).

Shadow register, updated on VFP start period for DISPC\_TRANS\_COLOR\_0 and EVSYNC for DISPC\_TRANS\_COLOR\_1

**Figure 13-85. DISPC\_TRANS\_COLOR\_0 Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### 13.6.1.10 DISPC\_LINE\_STS Register (offset = 5Ch) [reset = 7FFh]

DISPC\_LINE\_STS is shown in [Figure 13-86](#) and described in [Table 13-51](#).

The control register indicates the current LCD panel display line number

**Figure 13-86. DISPC\_LINE\_STS Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### 13.6.1.12 DISPC\_TIMING\_H Register (offset = 64h) [reset = 0h]

DISPC\_TIMING\_H is shown in [Figure 13-88](#) and described in [Table 13-53](#).

The register configures the timing logic for the HSYNC signal.  
Shadow register, updated on VFP start period

**Figure 13-88. DISPC\_TIMING\_H Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bit	Field	Type	Reset	Description
31-20	HBP	R/W	0h	Horizontal Back Porch. Encoded value (from 1 to 4096) to specify the number of pixel clock periods to add to the beginning of a line transmission before the first set of pixels is output to the display (program to value minus 1)
19-8	HFP	R/W	0h	Horizontal front porch. Encoded value (from 1 to 4096) to specify the number of pixel clock periods to add to the end of a line transmission before line clock is asserted (program to value minus 1)
7-0	HSW	R/W	0h	Horizontal synchronization pulse width Encoded value (from 1 to 256) to specify the number of pixel clock periods to pulse the line clock at the end of each line (program to value minus 1).

### 13.6.1.13 DISPC\_TIMING\_V Register (offset = 68h) [reset = 0h]

DISPC\_TIMING\_V is shown in [Figure 13-89](#) and described in [Table 13-54](#).

The register configures the timing logic for the VSYNC signal.  
Shadow register, updated on VFP start period

**Figure 13-89. DISPC\_TIMING\_V Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bit	Field	Type	Reset	Description
31-20	VBP	R/W	0h	Vertical back porch Encoded value (from 0 to 4095) to specify the number of line clock periods to add to the beginning of a frame before the first set of pixels is output to the display
19-8	VFP	R/W	0h	Vertical front porch Encoded value (from 0 to 4095) to specify the number of line clock periods to add to the end of each frame
7-0	VSW	R/W	0h	Vertical synchronization pulse width In active mode, encoded value (from 1 to 256) to specify the number of line clock periods (program to value minus one) to pulse the frame clock (VSYNC) pin at the end of each frame after the end of frame wait (VFP) period elapses. Frame clock uses as VSYNC signal in active mode. In passive mode, encoded value (from 1 to 256) to specify the number of extra line clock periods (program to value minus one) to insert after the vertical front porch (VFP) period has elapsed.

### 13.6.1.14 DISPC\_POL\_FREQ Register (offset = 6Ch) [reset = 0h]

DISPC\_POL\_FREQ is shown in [Figure 13-90](#) and described in [Table 13-55](#).

The register configures the signal configuration.  
Shadow register, updated on VFP start period

Bit	Field	Type	Reset	Description
11-8	ACBI	R/W	0h	AC-bias pin transitions per interrupt Value (from 0 to 15) used to specify the number of AC Bias pin transitions
7-0	ACB	R/W	0h	AC-bias pin frequency Value (from 0 to 255) used to specify the number of line clocks to count before transitioning the ac-bias pin. This pin is used to periodically invert the polarity of the power supply to prevent DC charge build-up within the display.

### 13.6.1.15 DISPC\_DIVISOR Register (offset = 70h) [reset = 00010002h]

DISPC\_DIVISOR is shown in [Figure 13-91](#) and described in [Table 13-56](#).

The register configures the divisors.

Shadow register, updated on VFP start period

**Figure 13-91. DISPC\_DIVISOR Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

15-8	RESERVED	R/W	0h	
7-0	PCD	R/W	2h	Pixel Clock Divisor Value (from 1 to 255) to specify the frequency of the pixel clock based on the Logic clock which is the functional clock divided by LCD. The values 0 and 1 are invalid.

### 13.6.1.16 DISPC\_GLOBAL\_ALPHA Register (offset = 74h) [reset = 0h]

DISPC\_GLOBAL\_ALPHA is shown in [Figure 13-92](#) and described in [Table 13-57](#).

The register defines the global alpha value for the graphics and video 2 pipelines. Shadow register, updated on VFP start period or EVSYNC for each bit field depending on the association of the each pipeline with the LCD or TV output.

**Figure 13-92. DISPC\_GLOBAL\_ALPHA Register**

### 13.6.1.17 DISPC\_SIZE\_DIG Register (offset = 78h) [reset = 0h]

DISPC\_SIZE\_DIG is shown in [Figure 13-93](#) and described in [Table 13-58](#).

The register configures the size of the digital output field (interlace), frame (progressive) (horizontal and vertical).

Shadow register, updated on EVSYNC

**Figure 13-93. DISPC\_SIZE\_DIG Register**

10-0	PPL	R/W	0h	Pixels per line Encoded value (from 1 to 2048) to specify the number of pixels contains within each line on the display (program to value minus one). When running in normal mode (stall mode is bypassed by setting DSS.DISPC_CONTROL[11] STALLMODE =0) the line width must be set to a value multiple of 8 pixels (ex: PPL=0x7)

### 13.6.1.19 DISPC\_GFX\_BA\_0 Register (offset = 80h + [i \* 4h]) [reset = 0h]

DISPC\_GFX\_BA\_0 is shown in [Figure 13-95](#) and described in [Table 13-60](#).

The register configures the base address of the graphics buffer displayed in the graphics window (0 1 :for ping-pong mechanism with external trigger, based on the field polarity, 0 only used when graphics pipeline on the LCD

output and 0 1 when on the 24-bit digital output).

Shadow register, updated on VFP start period or EVSYNC.

**Figure 13-95. DISPC\_GFX\_BA\_0 Register**

31-0	GFX_BA	R/W	0h	Graphics base address Base address of the graphics buffer (aligned on pixel size boundary) (in case 1-, 2-, and 4-BPP, byte alignment is required)

### 13.6.1.20 DISPC\_GFX\_POSITION Register (offset = 88h) [reset = 0h]

DISPC\_GFX\_POSITION is shown in [Figure 13-96](#) and described in [Table 13-61](#).

The register configures the position of the graphics window.  
Shadow register, updated on VFP start period or EVSYNC.

**Figure 13-96. DISPC\_GFX\_POSITION Register**

Bit	Field	Type	Reset	Description
31-27	RESERVED	R/W	0h	
26-16	GFX_POSY	R/W	0h	Y position of the graphics window. Encoded value (from 0 to 2047) to specify the Y position of the graphics window on the screen. The line at the top has the Y-position 0.
15-11	RESERVED	R/W	0h	
10-0	GFX_POSX	R/W	0h	X position of the graphics window. Encoded value (from 0 to 2047) to specify the X position of the graphics window on the screen. The first pixel on the left of the screen has the X-position 0.

### 13.6.1.21 DISPC\_GFX\_SIZE Register (offset = 8Ch) [reset = 0h]

DISPC\_GFX\_SIZE is shown in [Figure 13-97](#) and described in [Table 13-62](#).

The register configures the size of the graphics window.

Shadow register, updated on VFP start period or EVSYNC

**Figure 13-97. DISPC\_GFX\_SIZE Register**

Bit	Field	Type	Reset	Description
31-27	RESERVED	R/W	0h	
26-16	GFX_SIZEY	R/W	0h	Number of lines of the graphics window. Encoded value (from 1 to 2048) to specify the number of lines of the graphics window (program to value minus one)
15-11	RESERVED	R/W	0h	
10-0	GFX_SIZEX	R/W	0h	Number of pixels of the graphics window. Encoded value (from 1 to 2048) to specify the number of pixels per line of the graphics window (program to value minus one)

### 13.6.1.22 DISPC\_GFX\_ATTRS Register (offset = A0h) [reset = 0h]

DISPC\_GFX\_ATTRS is shown in [Figure 13-98](#) and described in [Table 13-63](#).

The register configures the graphics attributes.

Shadow register, updated on VFP start period or EVSYNC.

**Figure 13-98. DISPC\_GFX\_ATTRS Register**

### 13.6.1.23 DISPC\_GFX\_FIFO\_THR Register (offset = A4h) [reset = 3FF03C0h]

DISPC\_GFX\_FIFO\_THR is shown in [Figure 13-99](#) and described in [Table 13-64](#).

The register configures the graphics FIFO.

Shadow register, updated on VFP start period or EVSYNC.

**Figure 13-99. DISPC\_GFX\_FIFO\_THR Register**

### 13.6.1.25 DISPC\_GFX\_ROW\_INC Register (offset = ACh) [reset = 1h]

DISPC\_GFX\_ROW\_INC is shown in [Figure 13-101](#) and described in [Table 13-66](#).

The register configures the number of bytes to increment at the end of the row.  
Shadow register, updated on VFP start period or EVSYNC

**Figure 13-101. DISPC\_GFX\_ROW\_INC Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### 13.6.1.26 DISPC\_GFX\_PIXEL\_INC Register (offset = B0h) [reset = 0h]

DISPC\_GFX\_PIXEL\_INC is shown in [Figure 13-102](#) and described in [Table 13-67](#).

The register configures the number of bytes to increment between two pixels.  
Shadow register, updated on VFP start period or EVSYNC.

**Figure 13-102. DISPC\_GFX\_PIXEL\_INC Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### 13.6.1.27 DISPC\_GFX\_WINDOW\_SKIP Register (offset = B4h) [reset = 0h]

DISPC\_GFX\_WINDOW\_SKIP is shown in [Figure 13-103](#) and described in [Table 13-68](#).

The register configures the number of bytes to skip during video window display.  
Shadow register, updated on VFP start period or EVSYNC.

**Figure 13-103. DISPC\_GFX\_WINDOW\_SKIP Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

31-0	GFX_WINDOW_SKIP	R/W	0h	Number of bytes to skip during video window #1. Encoded signed value (from $(-2^{31})-1$ to $2^{31}$ ) to specify the number of bytes to skip in the graphics buffer when video window #1 is displayed on top of the graphics and no transparency color is enabled.

### 13.6.1.28 DISPC\_GFX\_TBL\_BA Register (offset = B8h) [reset = 0h]

DISPC\_GFX\_TBL\_BA is shown in [Figure 13-104](#) and described in [Table 13-69](#).

The register configures the base address of the palette buffer or the gamma table buffer. Shadow register, updated on VFP start period or EVSYNC.

**Figure 13-104. DISPC\_GFX\_TBL\_BA Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

31-0	GFX_TBL_BA	R/W	0h	Base address of the palette/gamma table buffer (24-bit entries in 32-bit containers, aligned on 32-bit boundary).

### 13.6.1.29 DISPC\_VID1\_BA\_0 to DISPC\_VID1\_BA\_1 Register (offset = BCh to C0h) [reset = 0h]

DISPC\_VID1\_BA\_0 to DISPC\_VID1\_BA\_1 is shown in [Figure 13-105](#) and described in [Table 13-70](#).

The register configures the base address of the video buffer for video window #n(#j for ping-pong mechanism with

external trigger, based on the field polarity: 0 for even field and 1 for odd field).

Shadow register, updated on VFP start period or EVSYNC.

**Figure 13-105. DISPC\_VID1\_BA\_0 to DISPC\_VID1\_BA\_1 Register**

### 13.6.1.30 DISPC\_VID1\_POSITION Register (offset = C4h) [reset = 0h]

DISPC\_VID1\_POSITION is shown in [Figure 13-106](#) and described in [Table 13-71](#).

The register configures the position of video window #n.

Shadow register, updated on VFP start period or EVSYNC.

**Figure 13-106. DISPC\_VID1\_POSITION Register**

### 13.6.1.33 DISPC\_VID1\_FIFO\_THR Register (offset = D0h) [reset = 3C003FFh]

DISPC\_VID1\_FIFO\_THR is shown in [Figure 13-109](#) and described in [Table 13-74](#).

The register configures the video FIFO associated with video pipeline #n.  
Shadow register, updated on VFP start period or EVSYNC.

**Figure 13-109. DISPC\_VID1\_FIFO\_THR Register**

15-12	RESERVED	R/W	0h	
11-0	FIFO_LOW_THR	R/W	3FFh	Video FIFO low threshold Number of bytes defining the threshold value

### 13.6.1.34 DISPC\_VID1\_FIFO\_SIZE\_STS Register (offset = D4h) [reset = 400h]

DISPC\_VID1\_FIFO\_SIZE\_STS is shown in [Figure 13-110](#) and described in [Table 13-75](#).

The register defines the video FIFO size for video pipeline #n.

**Figure 13-110. DISPC\_VID1\_FIFO\_SIZE\_STS Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

10-0	FIFO_SIZE	R/W	400h	Video FIFO Size Number of bytes defining the FIFO value

### 13.6.1.35 DISPC\_VID1\_ROW\_INC Register (offset = D8h) [reset = 1h]

DISPC\_VID1\_ROW\_INC is shown in [Figure 13-111](#) and described in [Table 13-76](#).

The register configures the number of bytes to increment at the end of the row for the buffer associated with video window #n.

Shadow register, updated on VFP start period or EVSYNC.

**Figure 13-111. DISPC\_VID1\_ROW\_INC Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### 13.6.1.36 DISPC\_VID1\_PIXEL\_INC Register (offset = DCh) [reset = 1h]

DISPC\_VID1\_PIXEL\_INC is shown in [Figure 13-112](#) and described in [Table 13-77](#).

The register configures the number of bytes to increment between two pixels for the buffer associated with video window #n.

Shadow register, updated on VFP start period or EVSYNC

**Figure 13-112. DISPC\_VID1\_PIXEL\_INC Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

15-0	PIXEL_INC	R/W	1h	Number of bytes to increment at the end of the row Encoded signed value (from $(-2^{15})-1$ to $2^{15}$ ) to specify the number of bytes between two pixels in the video buffer. The value 0 is invalid. The value 1 means next pixel. The value $1+n*BPP$ means increment of n pixels. The value $1-(n+1)*BPP$ means decrement of n pixels

### 13.6.1.37 DISPC\_VID1\_FIR Register (offset = E0h) [reset = 0h]

DISPC\_VID1\_FIR is shown in [Figure 13-113](#) and described in [Table 13-78](#).

The register configures the resize factors for horizontal and vertical up-/down-sampling of video window #n.

Shadow register, updated on VFP start period or EVSYNC

**Figure 13-113. DISPC\_VID1\_FIR Register**

15-13	RESERVED	R/W	0h	
12-0	FIR_H_INC	R/W	0h	Horizontal increment of the up-/down-sampling filter Encoded value (from 1 to 4096). The value 0 is invalid. Values greater than 4096 are invalid.

### 13.6.1.38 DISPC\_VID1\_PICTURE\_SIZE Register (offset = E4h) [reset = 0h]

DISPC\_VID1\_PICTURE\_SIZE is shown in [Figure 13-114](#) and described in [Table 13-79](#).

The register configures the size of the video picture associated with video layer #n before up-/down-scaling.

Shadow register, updated on VFP start period or EVSYNC.

**Figure 13-114. DISPC\_VID1\_PICTURE\_SIZE Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Field	Type	Reset	Description
31-27	RESERVED	R/W	0h	
26-16	VID_ORG_SIZE_Y	R/W	0h	Number of lines of the video picture Encoded value (from 1 to 2048) to specify the number of lines of the video picture in memory (program to value minus one)
15-11	RESERVED	R/W	0h	
10-0	VID_ORG_SIZE_X	R/W	0h	Number of pixels of the video picture Encoded value (from 1 to 2048) to specify the number of pixels of the video picture in memory (program to value minus one). The size is limited to the size of the line buffer of the vertical sampling block in case the video picture is processed by the vertical filtering unit.

### 13.6.1.39 DISPC\_VID1\_ACCU\_0 to DISPC\_VID1\_ACCU\_1 Register (offset = E8h to ECh) [reset = 0h]

DISPC\_VID1\_ACCU\_0 to DISPC\_VID1\_ACCU\_1 is shown in [Figure 13-115](#) and described in [Table 13-80](#).

The register configures the resize accumulator init values for horizontal and vertical up-/down-sampling of video

window #n (#l for ping-pong mechanism with external trigger, based on the field polarity)

Shadow register, updated on VFP start period or EVSYNC.

**Figure 13-115. DISPC\_VID1\_ACCU\_0 to DISPC\_VID1\_ACCU\_1 Register**

25-16	VERTICAL_ACCU	R/W	0h	Vertical initialization accu value. Encoded value (from 0 to 1023).
15-10	RESERVED	R/W	0h	
9-0	HORIZONTAL_ACCU	R/W	0h	Horizontal initialization accu value. Encoded value (from 0 to 1023).

### 13.6.1.40 DISPC\_VID1\_FIR\_COEF\_H\_0 Register (offset = F0h + [i \* 8h]) [reset = 0h]

DISPC\_VID1\_FIR\_COEF\_H\_0 is shown in [Figure 13-116](#) and described in [Table 13-81](#).

The bank of registers configure the up-/down-scaling coefficients for the vertical and horizontal resize of the video

picture associated with video window #n for the phases from 0 to 7.

Shadow register, updated on VFP start period or EVSYNC.

**Figure 13-116. DISPC\_VID1\_FIR\_COEF\_H\_0 Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

23-16	FIR_HC2	R/W	0h	Unsigned coefficient C2 for the horizontal up-/down-scaling with the phase n
15-8	FIR_HC1	R/W	0h	Signed coefficient C1 for the horizontal up-/down-scaling with the phase n
7-0	FIR_HC0	R/W	0h	Signed coefficient C0 for the horizontal up-/down-scaling with the phase

### 13.6.1.41 DISPC\_VID1\_FIR\_COEF\_HV\_0 Register (offset = F4h + [i \* 8h]) [reset = 0h]

DISPC\_VID1\_FIR\_COEF\_HV\_0 is shown in [Figure 13-117](#) and described in [Table 13-82](#).

The bank of registers configure the down/up-/down-scaling coefficients for the vertical and horizontal resize of the video picture associated with video window #n for the phases from 0 to 7.  
Shadow register, updated on VFP start period or EVSYNC

**Figure 13-117. DISPC\_VID1\_FIR\_COEF\_HV\_0 Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

23-16	FIR_VC1	R/W	0h	Unsigned coefficient C1 for the vertical up-/down-scaling with the phase n
15-8	FIR_VC0	R/W	0h	Signed coefficient C0 for the vertical up-/down-scaling with the phase n
7-0	FIR_HC4	R/W	0h	Signed coefficient C4 for the horizontal up-/down-scaling with the phase n

### 13.6.1.42 DISPC\_VID1\_CONV\_COEF0 Register (offset = 130h) [reset = 0h]

DISPC\_VID1\_CONV\_COEF0 is shown in [Figure 13-118](#) and described in [Table 13-83](#).

The register configures the color space conversion matrix coefficients for video pipeline #n.  
Shadow register, updated on VFP start period or EVSYNC.

**Figure 13-118. DISPC\_VID1\_CONV\_COEF0 Register**

### 13.6.1.43 DISPC\_VID1\_CONV\_COEF1 Register (offset = 134h) [reset = 0h]

DISPC\_VID1\_CONV\_COEF1 is shown in [Figure 13-119](#) and described in [Table 13-84](#).

The register configures the color space conversion matrix coefficients for video pipeline #n.  
Shadow register, updated on VFP start period or EVSYNC

**Figure 13-119. DISPC\_VID1\_CONV\_COEF1 Register**

### 13.6.1.44 DISPC\_VID1\_CONV\_COEF2 Register (offset = 138h) [reset = 0h]

DISPC\_VID1\_CONV\_COEF2 is shown in [Figure 13-120](#) and described in [Table 13-85](#).

The register configures the color space conversion matrix coefficients for video pipeline #n.  
Shadow register, updated on VFP start period or EVSYNC.

**Figure 13-120. DISPC\_VID1\_CONV\_COEF2 Register**

### 13.6.1.47 DISPC\_VID2\_BA\_0 to DISPC\_VID2\_BA\_1 Register (offset = 14Ch to 150h) [reset = 0h]

DISPC\_VID2\_BA\_0 to DISPC\_VID2\_BA\_1 is shown in [Figure 13-123](#) and described in [Table 13-88](#).

The register configures the base address of the video buffer for video window #n(#j for ping-pong mechanism with

external trigger, based on the field polarity: 0 for even field and 1 for odd field).

Shadow register, updated on VFP start period or EVSYNC.

**Figure 13-123. DISPC\_VID2\_BA\_0 to DISPC\_VID2\_BA\_1 Register**

**Table 13-91. DISPC\_VID2\_ATTRS Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-29	RESERVED	R/W	0h	
28	PRE_MULTIPLY_ALPHA	R/W	0h	The field configures the DISPC VID2 to process incoming data as pre-multiplied alpha data or non pre-multiplied alpha data. Default setting is non pre-multiplied alpha data. 0h (R/W) = Non pre-multiplyalpha data color component 1h (R/W) = Premultiplyalpha data color component
27-25	RESERVED	R/W	0h	
24	SELF_REFRESH	R/W	0h	Enables the self refresh of the video window from its own FIFO only. 0h (R/W) = The video pipeline accesses the interconnect to fetch data from the system memory 1h (R/W) = The video pipeline does not need anymore to fetch data from memory. Only the video FIFO is used. It takes effect after the frame has been loaded in the FIFO
23	ARBITRATION	R/W	0h	Determines the priority of the video pipeline. The video pipeline is one of the high priority pipeline. The arbitration wheel gives always the priority first to the high priority pipelines using round-robin between them. When there is only normal priority pipelines sending requests, the round-robin applies between them. 0h (R/W) = The video pipeline is one of the normal priority pipeline 1h (R/W) = The video pipeline is one of the high priority pipeline
22	LINE_BUFFER_SPLIT	R/W	0h	Video vertical line buffer split 0h (R/W) = Vertical line buffers are not split 1h (R/W) = Vertical line buffers are split into two
21	VERTICAL_TAPS	R/W	0h	Video vertical resize tap number 0h (R/W) = Three taps are used for the vertical filtering logic. The other two taps are not used 1h (R/W) = Five taps are used for the vertical filtering logic

**Table 13-91. DISPC\_VID2\_ATTRS Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
20	OPTIMIZATION	R/W	0h	Video optimization in case of 0h (R/W) = The DMA engine fetches one pixel for each 32-bit OCP request (RGB16 and YUV422) while doing 90- and 270-degree rotation (accessing on-chip memory and off-chip memory). 1h (R/W) = The DMA engine fetches two pixels for each 32-bit OCP request (RGB16 and YUV422) while doing 90- and 270-degree rotation (accessing on-chip memory and off-chip memory). The bit field [21] VIDVERTICALTAPS shall be set to 0x1, bit field [22] VIDLINEBUFFERSPLIT to 0x1, and all scaler registers shall be configured even for 1:1 ratio. Even width is required for the input picture when 5 taps are used.
19	FIFO_PRELOAD	R/W	0h	Video preload value 0h (R/W) = H/W prefetches pixels up to the preload value defined in the preload register 1h (R/W) = H/W prefetches pixels up to the high threshold value.
18	ROW_REPEAT_EN	R/W	0h	Video Row Repeat (YUV case only when rotating 90 or 270-degree) 0h (R/W) = Row of VIDn won't be read twice 1h (R/W) = The Row data are fetched twice to extract both the Y components
17	ENDIAN	R/W	0h	Video Endianness 0h (R/W) = Little endian operation is selected 1h (R/W) = Big endian operation is selected.
16	CHANNEL_OUT	R/W	0h	Video Channel Out configuration 0h (R/W) = LCD output selected 1h (R/W) = 24 bit output selected
15-14	BURST_SIZE	R/W	0h	Video DMA Burst Size 0h (R/W) = 4x32bit bursts 1h (R/W) = 8x32bit bursts 2h (R/W) = 16x32bit bursts 3h (R/W) = 3
13-12	ROTATION	R/W	0h	Video Rotation Flag 0h (R/W) = No rotation or VidFormat is RGB 1h (R/W) = Rotation by 90 degrees 2h (R/W) = Rotation by 180 degrees 3h (R/W) = Rotation by 270 degrees
11	FULL_RANGE	R/W	0h	VidFullRange 0h (R/W) = Limited range selected: 16 subtracted from Y before color space conversion 1h (R/W) = Full range selected: Y is not modified before the color space conversion
10	REPLICATION_EN	R/W	0h	VidReplicationEnable 0h (R/W) = Disable Video replication logic 1h (R/W) = Enable Video replication logic
9	COLOR_CONV_EN	R/W	0h	VidColorConvEnable 0h (R/W) = Disable Color Space Conversion CbYCr to RGB 1h (R/W) = Enable Color Space Conversion CbYCr to RGB

### 13.6.1.51 DISPC\_VID2\_FIFO\_THR Register (offset = 160h) [reset = 3C003FFh]

DISPC\_VID2\_FIFO\_THR is shown in [Figure 13-127](#) and described in [Table 13-92](#).

The register configures the video FIFO associated with video pipeline #n.  
Shadow register, updated on VFP start period or EVSYNC.

**Figure 13-127. DISPC\_VID2\_FIFO\_THR Register**

### 13.6.1.53 DISPC\_VID2\_ROW\_INC Register (offset = 168h) [reset = 1h]

DISPC\_VID2\_ROW\_INC is shown in [Figure 13-129](#) and described in [Table 13-94](#).

The register configures the number of bytes to increment at the end of the row for the buffer associated with video window #n.

Shadow register, updated on VFP start period or EVSYNC.

**Figure 13-129. DISPC\_VID2\_ROW\_INC Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**Table 13-94. DISPC\_VID2\_ROW\_INC Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	ROW_INC	R/W	1h	Number of bytes to increment at the end of the row Encoded signed value (from $(-2^{31})-1$ to $2^{31}$ ) to specify the number of bytes to increment at the end of the row in the video buffer. The value 0 is invalid. The value 1 means next pixel. The value $1+n*BPP$ means increment of n pixels. The value $1-(n+1)*BPP$ means decrement of n pixels.

### 13.6.1.54 DISPC\_VID2\_PIXEL\_INC Register (offset = 16Ch) [reset = 1h]

DISPC\_VID2\_PIXEL\_INC is shown in [Figure 13-130](#) and described in [Table 13-95](#).

The register configures the number of bytes to increment between two pixels for the buffer associated with video window #n.

Shadow register, updated on VFP start period or EVSYNC

**Figure 13-130. DISPC\_VID2\_PIXEL\_INC Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

The value 0 is invalid. The value 1 means next pixel. The value $1+n*BPP$ means increment of n pixels. The value $1-(n+1)*BPP$ means decrement of n pixels

### 13.6.1.55 DISPC\_VID2\_FIR Register (offset = 170h) [reset = 0h]

DISPC\_VID2\_FIR is shown in [Figure 13-131](#) and described in [Table 13-96](#).

The register configures the resize factors for horizontal and vertical up-/down-sampling of video window #n.

Shadow register, updated on VFP start period or EVSYNC

**Figure 13-131. DISPC\_VID2\_FIR Register**

15-13	RESERVED	R/W	0h	
12-0	FIR_H_INC	R/W	0h	Horizontal increment of the up-/down-sampling filter Encoded value (from 1 to 4096). The value 0 is invalid. Values greater than 4096 are invalid.

### 13.6.1.56 DISPC\_VID2\_PICTURE\_SIZE Register (offset = 174h) [reset = 0h]

DISPC\_VID2\_PICTURE\_SIZE is shown in [Figure 13-132](#) and described in [Table 13-97](#).

The register configures the size of the video picture associated with video layer #n before up-/down-scaling.

Shadow register, updated on VFP start period or EVSYNC.

**Figure 13-132. DISPC\_VID2\_PICTURE\_SIZE Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Field	Type	Reset	Description
31-27	RESERVED	R/W	0h	
26-16	VID_ORG_SIZE_Y	R/W	0h	Number of lines of the video picture Encoded value (from 1 to 2048) to specify the number of lines of the video picture in memory (program to value minus one)
15-11	RESERVED	R/W	0h	
10-0	VID_ORG_SIZE_X	R/W	0h	Number of pixels of the video picture Encoded value (from 1 to 2048) to specify the number of pixels of the video picture in memory (program to value minus one). The size is limited to the size of the line buffer of the vertical sampling block in case the video picture is processed by the vertical filtering unit.

### 13.6.1.57 DISPC\_VID2\_ACCU\_0 to DISPC\_VID2\_ACCU\_1 Register (offset = 178h to 17Ch) [reset = 0h]

DISPC\_VID2\_ACCU\_0 to DISPC\_VID2\_ACCU\_1 is shown in [Figure 13-133](#) and described in [Table 13-98](#).

The register configures the resize accumulator init values for horizontal and vertical up-/down-sampling of video

window #n (#l for ping-pong mechanism with external trigger, based on the field polarity)

Shadow register, updated on VFP start period or EVSYNC.

**Figure 13-133. DISPC\_VID2\_ACCU\_0 to DISPC\_VID2\_ACCU\_1 Register**

### 13.6.1.58 DISPC\_VID2\_FIR\_COEF\_H\_0 Register (offset = 180h + [i \* 8h]) [reset = 0h]

DISPC\_VID2\_FIR\_COEF\_H\_0 is shown in [Figure 13-134](#) and described in [Table 13-99](#).

The bank of registers configure the up-/down-scaling coefficients for the vertical and horizontal resize of the video

picture associated with video window #n for the phases from 0 to 7.

Shadow register, updated on VFP start period or EVSYNC

**Figure 13-134. DISPC\_VID2\_FIR\_COEF\_H\_0 Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

23-16	FIR_HC2	R/W	0h	Unsigned coefficient C2 for the horizontal up-/down-scaling with the phase n
15-8	FIR_HC1	R/W	0h	Signed coefficient C1 for the horizontal up-/down-scaling with the phase n
7-0	FIR_HC0	R/W	0h	Signed coefficient C0 for the horizontal up-/down-scaling with the phase n

### 13.6.1.59 DISPC\_VID2\_FIR\_COEF\_HV\_0 Register (offset = 184h + [i \* 8h]) [reset = 0h]

DISPC\_VID2\_FIR\_COEF\_HV\_0 is shown in [Figure 13-135](#) and described in [Table 13-100](#).

The bank of registers configure the down/up-/down-scaling coefficients for the vertical and horizontal resize of the

video picture associated with video window #n for the phases from 0 to 7.

Shadow register, updated on VFP start period or EVSYNC

**Figure 13-135. DISPC\_VID2\_FIR\_COEF\_HV\_0 Register**

15-8	FIR_VC0	R/W	0h	Signed coefficient C0 for the vertical up-/down-scaling with the phase n
7-0	FIR_HC4	R/W	0h	Signed coefficient C4 for the horizontal up-/down-scaling with the phase n

### 13.6.1.60 DISPC\_VID2\_CONV\_COEF0 Register (offset = 1C0h) [reset = 0h]

DISPC\_VID2\_CONV\_COEF0 is shown in [Figure 13-136](#) and described in [Table 13-101](#).

The register configures the color space conversion matrix coefficients for video pipeline #n.  
Shadow register, updated on VFP start period or EVSYNC.

**Figure 13-136. DISPC\_VID2\_CONV\_COEF0 Register**

### 13.6.1.64 DISPC\_VID2\_CONV\_COEF4 Register (offset = 1D0h) [reset = 0h]

DISPC\_VID2\_CONV\_COEF4 is shown in [Figure 13-140](#) and described in [Table 13-105](#).

The register configures the color space conversion matrix coefficients for video pipeline #n.  
Shadow register, updated on VFP start period or EVSYNC.

**Figure 13-140. DISPC\_VID2\_CONV\_COEF4 Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### 13.6.1.65 DISPC\_DATA\_CYCLE\_0 Register (offset = 1D4h + [i \* 4h]) [reset = 0h]

DISPC\_DATA\_CYCLE\_0 is shown in [Figure 13-141](#) and described in [Table 13-106](#).

The control register configures the output data format for ith (1st, 2nd or 3rd) cycle.  
Shadow register, updated on VFP start period.

### 13.6.1.66 DISPC\_VID1\_FIR\_COEF\_V\_0 to DISPC\_VID1\_FIR\_COEF\_V\_7 Register (offset = 1E0h to 1FCh) [reset = 0h]

DISPC\_VID1\_FIR\_COEF\_V\_0 to DISPC\_VID1\_FIR\_COEF\_V\_7 is shown in [Figure 13-142](#) and described in [Table 13-107](#).

This bank of registers configures the down/up/down-scaling coefficients for the vertical resize of the video picture associated with video window #n for phases 0 to 7. Shadow register, updated on VFP start period or EVSYNC.

**Figure 13-142. DISPC\_VID1\_FIR\_COEF\_V\_0 to DISPC\_VID1\_FIR\_COEF\_V\_7 Register**

### 13.6.1.68 DISPC\_CPR\_COEF\_R Register (offset = 220h) [reset = 0h]

DISPC\_CPR\_COEF\_R is shown in [Figure 13-144](#) and described in [Table 13-109](#).

This register configures the color phase rotation matrix coefficients for the red component. Shadow register, updated on VFP start period.

### 13.6.1.70 DISPC\_CPR\_COEF\_B Register (offset = 228h) [reset = 0h]

DISPC\_CPR\_COEF\_B is shown in [Figure 13-146](#) and described in [Table 13-111](#).

This register configures the color phase rotation matrix coefficients for the blue component. Shadow register, updated on VFP start period.

### 13.6.1.71 DISPC\_GFX\_PRELOAD Register (offset = 22Ch) [reset = 100h]

DISPC\_GFX\_PRELOAD is shown in [Figure 13-147](#) and described in [Table 13-112](#).

This register configures the graphics FIFO. Shadow register, updated on VFP start period or EVSYNC.

**Figure 13-147. DISPC\_GFX\_PRELOAD Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**Table 13-121. DSS\_CLK\_STS Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
1-0	LCD1_CLK_STS	R	1h	<p>LCD1_CLK clock selection status (mux #2) indicates which clock is used by the glitch free mux selecting the source of LCD1_CLK. It is required for the current clock and the new selected clock being running in order to be able to switch.</p> <p>Both clocks are used at the same time while the switch is on going.</p> <p>0h (R) = LCD1_CLK clock switching is ongoing</p> <p>1h (R) = DSS_CLK is used as LCD1_CLK</p> <p>2h (R) = PLI1_CLK1 is used by DISPC as LCD1_CLK</p>

### 13.6.3 DSS\_RFBI Registers

Table 13-122 lists the memory-mapped registers for the DSS\_RFBI. All register offset addresses not listed in Table 13-122 should be considered as reserved locations and the register contents should not be modified.

**Table 13-122. DSS\_RFBI REGISTERS**

Offset	Acronym	Register Name	Section
0h	RFBI_REVISION		<a href="#">Section 13.6.3.1</a>
10h	RFBI_SYSCONFIG		<a href="#">Section 13.6.3.2</a>
14h	RFBI_SYSSTS		<a href="#">Section 13.6.3.3</a>
40h	RFBI_CTRL		<a href="#">Section 13.6.3.4</a>
44h	RFBI_PIXEL_CNT		<a href="#">Section 13.6.3.5</a>
48h	RFBI_LINE_NUMBER		<a href="#">Section 13.6.3.6</a>
4Ch	RFBI_CMD		<a href="#">Section 13.6.3.7</a>
50h	RFBI_PARAM		<a href="#">Section 13.6.3.8</a>
54h	RFBI_DATA		<a href="#">Section 13.6.3.9</a>
58h	RFBI_READ		<a href="#">Section 13.6.3.10</a>
5Ch	RFBI_STS		<a href="#">Section 13.6.3.11</a>
60h	RFBI_CONFIG_0		<a href="#">Section 13.6.3.12</a>
64h	RFBI_ONOFF_TIME_0		<a href="#">Section 13.6.3.13</a>
68h	RFBI_CYCLE_TIME_0		<a href="#">Section 13.6.3.14</a>
6Ch	RFBI_DATA_CYCLE1_0		<a href="#">Section 13.6.3.15</a>
70h	RFBI_DATA_CYCLE2_0		<a href="#">Section 13.6.3.16</a>
74h	RFBI_DATA_CYCLE3_0		<a href="#">Section 13.6.3.17</a>
78h	RFBI_CONFIG_1		<a href="#">Section 13.6.3.12</a>
7Ch	RFBI_ONOFF_TIME_1		<a href="#">Section 13.6.3.13</a>
80h	RFBI_CYCLE_TIME_1		<a href="#">Section 13.6.3.14</a>
84h	RFBI_DATA_CYCLE1_1		<a href="#">Section 13.6.3.15</a>
88h	RFBI_DATA_CYCLE2_1		<a href="#">Section 13.6.3.16</a>
8Ch	RFBI_DATA_CYCLE3_1		<a href="#">Section 13.6.3.17</a>
90h	RFBI_VSYNC_WIDTH		<a href="#">Section 13.6.3.18</a>
94h	RFBI_HSYNC_WIDTH		<a href="#">Section 13.6.3.19</a>

### 13.6.3.1 RFBI\_REVISION Register (offset = 0h) [reset = 0h]

RFBI\_REVISION is shown in [Figure 13-156](#) and described in [Table 13-123](#).

This Register contains the IP revision code

**Figure 13-156. RFBI\_REVISION Register**

**Table 13-123. RFBI\_REVISION Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-8	RESERVED	R	0h	
7-0	REV	R	0h	IP Revision

### 13.6.3.2 RFBI\_SYSCONFIG Register (offset = 10h) [reset = 1h]

RFBI\_SYSCONFIG is shown in [Figure 13-157](#) and described in [Table 13-124](#).

This Register allows control of various parameters of the Interconnect Interface

**Figure 13-157. RFBI\_SYSCONFIG Register**

**Table 13-124. RFBI\_SYSCONFIG Register Field Descriptions**

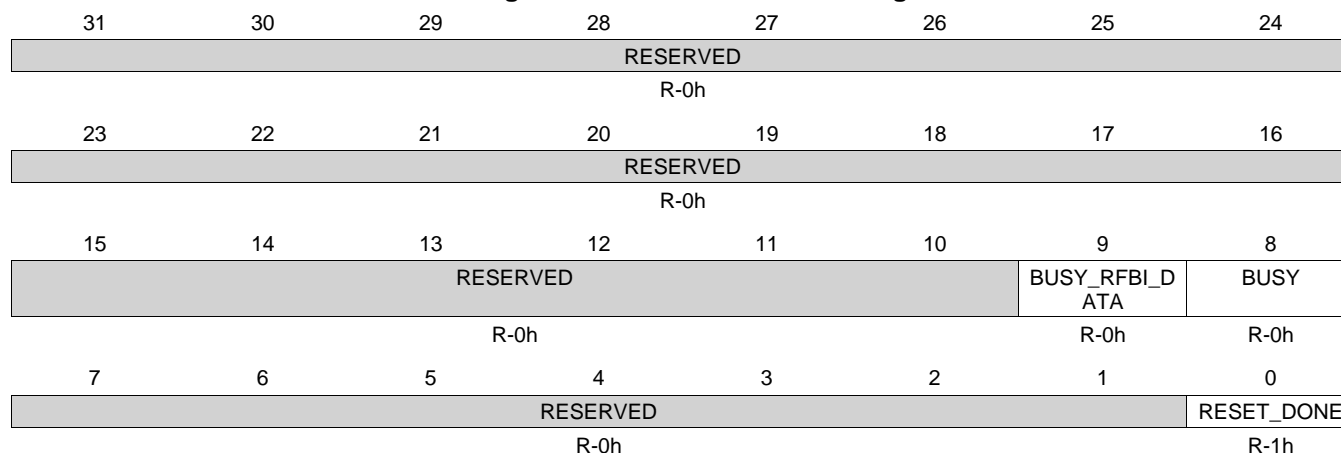

Bit	Field	Type	Reset	Description
31-5	RESERVED	R/W	0h	
4-3	SIDLE_MODE	R/W	0h	Slave interface power management, Idle req/ack control 0h (R/W) = Idle request is acknowledged unconditionally 1h (R/W) = An idle request is never acknowledged 2h (R/W) = Idle request is acknowledged based on the internal activity of the module 3h (R/W) = 3
2	RESERVED	R/W	0h	
1	SOFT_RESET	R/W	0h	Software reset Sets this bit to 1 to trigger a module reset. The bit is automatically reset by the hardware. During reads, it always returns 0 0h (R/W) = Normal mode 1h (R/W) = The module is reset
0	AUTO_IDLE	R/W	1h	Internal clock gating strategy (interconnectL4 and display controller clock) 0h (R/W) = Interconnect L4 clock and display controller clock are free-running. 1h (R/W) = Automatic clock gating strategy is applied for the interconnect L4 clock and display controller clock, based on the interconnect interface and internal activity

### 13.6.3.3 RFBI\_SYSSTS Register (offset = 14h) [reset = 1h]

RFBI\_SYSSTS is shown in [Figure 13-158](#) and described in [Table 13-125](#).

This register provides status information about the module, excluding the interrupt status information.

**Figure 13-158. RFBI\_SYSSTS Register**

**Table 13-125. RFBI\_SYSSTS Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-10	RESERVED	R	0h	
9	BUSY_RFBI_DATA	R	0h	Data are pending to be processed from interconnect FIFO. 0h (R/W) = No Data Pending 1h (R/W) = Data Pending
8	BUSY	R	0h	L4 Interface busy status bit 0h (R/W) = The access to the following register is not stalled: RFBI_CMD, RFBI_DATA, RFBI_STS, RFBI_PARAM, RFBI_READ 1h (R/W) = The access to any of the following registers is stalled: RFBI_CMD, RFBI_DATA, RFBI_STS, RFBI_PARAM, RFBI_READ.
7-1	RESERVED	R	0h	
0	RESET_DONE	R	1h	Internal reset monitoring 0h (R/W) = Internal module reset is on-going 1h (R/W) = Reset Completed

### 13.6.3.4 RFBI\_CTRL Register (offset = 40h) [reset = 2h]

RFBI\_CTRL is shown in [Figure 13-159](#) and described in [Table 13-126](#).

The control register allows configuration of the RFBI module

**Figure 13-159. RFBI\_CTRL Register**

31	30	29	28	27	26	25	24
RESERVED							
R/W-0h							
23	22	21	20	19	18	17	16
RESERVED							
R/W-0h							
15	14	13	12	11	10	9	8
RESERVED							SMART_DMA_REQ
R/W-0h							R/W-0h
7	6	5	4	3	2	1	0
DISABLE_DMA_REQ	HIGH_THR		ITE	CONFIG_SELECT		BYPASS_MODE	EN
R/W-0h	R/W-0h		R/W-0h	R/W-0h		R/W-1h	R/W-0h

**Table 13-126. RFBI\_CTRL Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-9	RESERVED	R/W	0h	
8	SMART_DMA_REQ	R/W	0h	Smart DMA request 0h (R/W) = The dmareq is asserted and de-asserted depending on the interconnect FIFO space even if Mldlreq is high in smart idle/no-idle mode and the entire burst gets error responses from the module. 1h (R/W) = The dmareq is de-asserted after 2 clk cycles if it has been asserted for more than or equal to 2 clk cycles and Mldlreq is high in smart idle or no idle mode. No more burst requests will be given even if the space is available in the interconnect FIFO.
7	DISABLE_DMA_REQ	R/W	0h	Disable DMA request 0h (R/W) = The dmareq is enabled and the signal is generated based on the space available and the request coming into the data register. 1h (R/W) = The dmareq is disabled and the signal is not generated at all based on space in the interconnect FIFO. It stays high until the DISABLE DMAREQ is high even if there is space in the interconnect FIFO to take requests.
6-5	HIGH_THR	R/W	0h	Defines the interconnect FIFO high threshold used by HW to assert DMA request. Used only if data written to RFBI_DATA are sent using system DMA 0h (R/W) = Size of the transfer of 4 words of 32-bit wide 1h (R/W) = Size of the transfer of 8 words of 32-bit wide 2h (R/W) = Size of the transfer of 16 words of 32-bit wide
4	ITE	R/W	0h	Internal Trigger 0h (R/W) = H/W waits for ITE bit to be set if in internal trigger mode for the configuration in use 1h (R/W) = User sets the ITE bit to start the transfer, when H/W takes into account the bit, the H/W resets it

**Table 13-126. RFBI\_CTRL Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
3-2	CONFIG_SELECT	R/W	0h	Select the CS and configuration 0h (R/W) = No CS selected 1h (R/W) = CS0 selected and Configuration #0 2h (R/W) = CS1 selected and configuration #1 3h (R/W) = CS0 and CS1 both selected (only the configuration for CS0 is used)
1	BYPASS_MODE	R/W	1h	Bypass Mode 0h (R/W) = The bypass mode is not selected 1h (R/W) = The bypass mode is selected
0	EN	R/W	0h	Enable/Disable flag 0h (R/W) = Disable RFBI 1h (R/W) = Enable RFBI

### 13.6.3.5 RFBI\_PIXEL\_CNT Register (offset = 44h) [reset = 0h]

RFBI\_PIXEL\_CNT is shown in [Figure 13-160](#) and described in [Table 13-127](#).

The control register configures the RFBI pixel count value.

**Figure 13-160. RFBI\_PIXEL\_CNT Register**

**Table 13-127. RFBI\_PIXEL\_CNT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	PIXEL_CNT	R/W	0h	Pixel counter value The S/W indicates the number of pixels to transfer to the LCD panel frame buffer. The value is set when the module is disabled. During the transfer the HW decrements the register when a pixel has been sent to the RFB.

### 13.6.3.6 RFBI\_LINE\_NUMBER Register (offset = 48h) [reset = 0h]

RFBI\_LINE\_NUMBER is shown in [Figure 13-161](#) and described in [Table 13-128](#).

The control register configures the number of lines to synchronize the beginning of the transfer.

**Figure 13-161. RFBI\_LINE\_NUMBER Register**

**Table 13-128. RFBI\_LINE\_NUMBER Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-11	RESERVED	R/W	0h	
10-0	LINE_NUMBER	R/W	0h	Programmable line number Line number from 0 to 2 <sup>11</sup> -1. Number of HSYNC after the VSYNC occurs before the beginning of the transfer.

### 13.6.3.7 RFBI\_CMD Register (offset = 4Ch) [reset = 0h]

RFBI\_CMD is shown in [Figure 13-162](#) and described in [Table 13-129](#).

The control register configures the RFBI command

**Figure 13-162. RFBI\_CMD Register**

**Table 13-129. RFBI\_CMD Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	RESERVED	R/W	0h	
15-0	CMD	R/W	0h	Command Value 8/9/12/16 bit value depending on the parallel mode

### 13.6.3.8 RFBI\_PARAM Register (offset = 50h) [reset = 0h]

RFBI\_PARAM is shown in [Figure 13-163](#) and described in [Table 13-130](#).

The control register configures the RFBI parameter.

**Figure 13-163. RFBI\_PARAM Register**

**Table 13-130. RFBI\_PARAM Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	RESERVED	R/W	0h	
15-0	PARAM	R/W	0h	Param Value 8/9/12/16 bit value depending on the parallel mode

### 13.6.3.9 RFBI\_DATA Register (offset = 54h) [reset = 0h]

RFBI\_DATA is shown in [Figure 13-164](#) and described in [Table 13-131](#).

The control register configures the RFBI data.

**Figure 13-164. RFBI\_DATA Register**

**Table 13-131. RFBI\_DATA Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	DATA	R/W	0h	Data value 12/16/18/24/2x16 bit value depending on the Data type

### 13.6.3.10 RFBI\_READ Register (offset = 58h) [reset = 0h]

RFBI\_READ is shown in [Figure 13-165](#) and described in [Table 13-132](#).

The control register configures the RFBI read

**Figure 13-165. RFBI\_READ Register**

**Table 13-132. RFBI\_READ Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	RESERVED	R/W	0h	
15-0	READ	R/W	0h	Read Value 8/9/12/16 bit value depending on the parallel mode

### 13.6.3.11 RFBI\_STS Register (offset = 5Ch) [reset = 0h]

RFBI\_STS is shown in [Figure 13-166](#) and described in [Table 13-133](#).

The control register configures the RFBI status.

**Figure 13-166. RFBI\_STS Register**

**Table 13-133. RFBI\_STS Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	RESERVED	R/W	0h	
15-0	STS	R/W	0h	Status value 8/9/12/16 bit value depending on the parallel mode

### 13.6.3.12 RFBI\_CONFIG\_0 Register (offset = 60h + [i \* 18h]) [reset = 310000h]

RFBI\_CONFIG\_0 is shown in [Figure 13-167](#) and described in [Table 13-134](#).

The control register allows configuration #I of the RFBI module

**Figure 13-167. RFBI\_CONFIG\_0 Register**

11-6	RECYCLE_TIME	R/W	0h	RE Cycle Time RW 0x00 Number of L4Clk cycles
5-0	WE_CYCLE_TIME	R/W	0h	WE Cycle Time Number of L4Clk cycles

### 13.6.3.15 RFBI\_DATA\_CYCLE1\_0 Register (offset = 6Ch + [i \* 18h]) [reset = 0h]

RFBI\_DATA\_CYCLE1\_0 is shown in [Figure 13-170](#) and described in [Table 13-137](#).

The control register configures the RFBI data format for 1st cycle.

**Figure 13-170. RFBI\_DATA\_CYCLE1\_0 Register**

**Table 13-137. RFBI\_DATA\_CYCLE1\_0 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-28	RESERVED	R/W	0h	
27-24	BIT_ALIGNMENT_PIXEL2	R/W	0h	Bit alignment Alignment of the bits from pixel#2 on the output interface
23-21	RESERVED	R/W	0h	
20-16	NB_BITS_PIXEL2	R/W	0h	Number of bits Number of bits from the pixel #2 (value from 0 to16 bits). The values from 17 to 31 are invalid.
15-12	RESERVED	R/W	0h	
11-8	BIT_ALIGNMENT_PIXEL1	R/W	0h	Bit alignment Alignment of the bits from pixel#1 on the output interface
7-5	RESERVED	R/W	0h	
4-0	NB_BITS_PIXEL1	R/W	0h	Number of bits Number of bits from the pixel #1 (value from 0 to16 bits). The values from 17 to 31 are invalid.

### 13.6.3.16 RFBI\_DATA\_CYCLE2\_0 Register (offset = 70h + [i \* 18h]) [reset = 0h]

RFBI\_DATA\_CYCLE2\_0 is shown in [Figure 13-171](#) and described in [Table 13-138](#).

The control register configures the RFBI data format for 2nd cycle.

**Figure 13-171. RFBI\_DATA\_CYCLE2\_0 Register**

**Table 13-138. RFBI\_DATA\_CYCLE2\_0 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-28	RESERVED	R/W	0h	
27-24	BIT_ALIGNMENT_PIXEL2	R/W	0h	Bit alignment Alignment of the bits from pixel#2 on the output interface
23-21	RESERVED	R/W	0h	
20-16	NB_BITS_PIXEL2	R/W	0h	Number of bits Number of bits from the pixel #2 (value from 0 to16 bits). The values from 17 to 31 are invalid.
15-12	RESERVED	R/W	0h	
11-8	BIT_ALIGNMENT_PIXEL1	R/W	0h	Bit alignment Alignment of the bits from pixel#1 on the output interface
7-5	RESERVED	R/W	0h	
4-0	NB_BITS_PIXEL1	R/W	0h	Number of bits Number of bits from the pixel #1 (value from 0 to16 bits). The values from 17 to 31 are invalid.

### 13.6.3.17 RFBI\_DATA\_CYCLE3\_0 Register (offset = 74h + [i \* 18h]) [reset = 0h]

RFBI\_DATA\_CYCLE3\_0 is shown in [Figure 13-172](#) and described in [Table 13-139](#).

The control register configures the RFBI data format for 3rd cycle.

**Figure 13-172. RFBI\_DATA\_CYCLE3\_0 Register**

**Table 13-139. RFBI\_DATA\_CYCLE3\_0 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-28	RESERVED	R/W	0h

11-8	BIT_ALIGNMENT_PIXEL1	R/W	0h	Bit alignment Alignment of the bits from pixel#1 on the output interface
7-5	RESERVED	R/W	0h	
4-0	NB_BITS_PIXEL1	R/W	0h	Number of bits Number of bits from the pixel #1 (value from 0 to16 bits). The values from 17 to 31 are invalid.

### 13.6.3.18 RFBI\_VSYNC\_WIDTH Register (offset = 90h) [reset = 0h]

RFBI\_VSYNC\_WIDTH is shown in [Figure 13-173](#) and described in [Table 13-140](#).

The control register configures the RFBI VSYNC minimum pulse width

**Figure 13-173. RFBI\_VSYNC\_WIDTH Register**

**Table 13-140. RFBI\_VSYNC\_WIDTH Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	RESERVED	R/W	0h	
15-0	MIN_VSYNC_PULSE_WIDTH	R/W	0h	Programmable min VSYNC pulse width Minimum VSYNC pulse width from 0 to 65535. Number of L4 clock cycles to determine when VSYNC pulse occurs. The values 0 and 1 are invalid.

### 13.6.3.19 RFBI\_HSYNC\_WIDTH Register (offset = 94h) [reset = 0h]

RFBI\_HSYNC\_WIDTH is shown in [Figure 13-174](#) and described in [Table 13-141](#).

The control register configures the RFBI HSYNC minimum pulse width.

**Figure 13-174. RFBI\_HSYNC\_WIDTH Register**

**Table 13-141. RFBI\_HSYNC\_WIDTH Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	RESERVED	R/W	0h	
15-0	MIN_HSYNC_PULSE_WIDTH	R/W	0h	Programmable min HSYNC pulse width Minimum HSYNC pulse width from 0 to 65535. Number of L4 clock cycles to determine when HSYNC pulse occurs. The values 0 and 1 are invalid.

## **Camera (VPFE)**

This chapter describes the camera (VPFE) of the device.

<b>Topic</b>	<b>Page</b>

## 14.1 Introduction

### 14.1.1 VPFE Features

The general features of the VPFE module include:

- A buffer memory for interfacing to the DMA at the chip level and preventing the CCDC module from overflowing.
- Support for conventional Bayer pattern and Foveon sensor formats
- Generates HD/VD timing signals and field ID to an external timing generator or can synchronize to the external timing generator
- Support for progressive and interlaced sensors (hardware support for up to 2 fields and firmware support for higher number of fields, typically 3-, 4-, and 5-field sensors)
- Support for up to the lesser of 75 MHz or 1/2 dma\_ocp\_clk sensor clock in the normal mode of operation
- Support for REC656/CCIR-656 standard (YCbCr 422 format, either 8- or 16-bit)
- Support for YCbCr 422 format, either 8- or 16-bit with discrete H and VSYNC signals.
- Support for up to 16-bit input
- Generates optical black clamping signals
- Support for digital clamping and black level compensation
- Support for 10-bit to 8-bit A-law compression
- Support for a low-pass filter prior to writing to SDRAM. If this filter is enabled, 2 pixels each in the left and right edges of each line are cropped from the output.
- Support for generating output to range from 16-bits to 8-bits wide (8-bits wide allows for 50% saving in storage area)
- Support for downsampling via programmable culling patterns
- Ability to control output to the SDRAM via an external write enable signal
- Support for up to 16K pixels (image size) in both the horizontal and vertical direction.

### 14.1.2 Unsupported Features

The VPFE module does not support the following features.

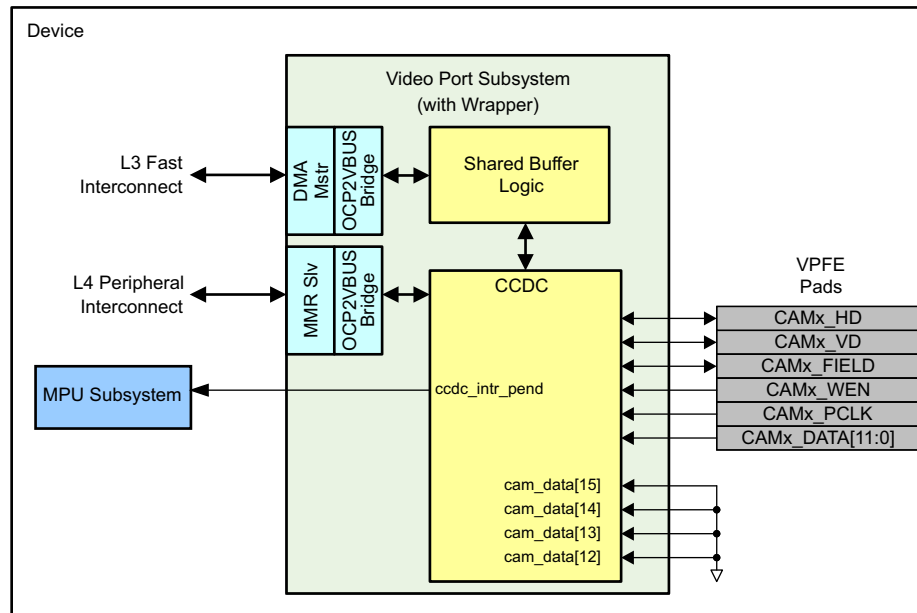

**Table 14-1. Unsupported VPFE Features**

Feature	Reason
VENC/VPBE Interface	There is no VENC on this device and therefore, Video Encoder direct interface is not connected.
16-bit Input	Only ccdc_data[11:0] pinned out

## 14.2 Integration

This device includes two instantiations of the Video Port Front End (VPFE) for connection to CCD cameras or BT.656 compliant video encoders.

**Figure 14-1. VPFE Integration**

### 14.2.1 VPFE Connectivity Attributes

The general connectivity attributes for the VPFE module are shown in [Table 14-2](#).

**Table 14-2. VPFE Connectivity Attributes**

Attributes	Type
Power Domain	Peripheral Domain
Clock Domain	PD_PER_L3_GCLK PD_PER_L3S_GCLK CCDCx_PCLK
Reset Signals	PER_DOM_RST_N
Idle/Wakeup Signals	Standby Smart Idle
Interrupt Requests	1 interrupt to MPU Subsystem (CCDCx_INT)
DMA Requests	None
Physical Address	L4 peripheral slave port L3 initiator port

## 14.2.2 VPFE Clock and Reset Management

The VPFE has separate functional and interface clocks. The pixel clock is supplied from an external pin and is restricted such that  $\text{ccd\_pclk\_clk} \leq \frac{1}{2} \text{dma\_ocp\_clk}$ .

**Table 14-3. VPFE Clock Signals**

Clock Signal	Maximum Frequency	Reference Source	Comments
mmr_ocp_clk MMR interface clock	100 MHz	CORE_CLKOUTM4	pd_per_l3_gclk from PRCM (divided down using mmr_ocp_clkdiv)
dma_ocp_clk L3 phase clock enable used to create L4 clock	200 MHz	CORE_CLKOUTM4	pd_per_l3_gclk from PRCM
ccd_pclk_clk Functional clock	The lesser of 75 MHz or $\frac{1}{2} \text{dma\_ocp\_clk}$	CCDCX_PCLK	From external pin

## 14.2.3 VPFE Pin List

The external pins for the VPFE module are shown in [Table 14-4](#).

**Table 14-4. VPFE Pin List**

Pin	Type	Description
cam_data[11:0]	I	Camera/VPFE data
cam_hd	I/O	Horizontal sync
cam_vd	I/O	Vertical sync
cam_field	I/O	Field indicator
cam_wen	I	Write enable
cam_pclk	I	Pixel clock

## 14.3 Functional Description

### 14.3.1 External IO Interface

The following subsections explain how to connect VPFE signal pins to various input devices.

#### 14.3.1.1 Summary

Table 14-5 summarizes the VPFE signal pins required by common input devices.

**Table 14-5. Summary of VPFE Signal Pins and Common Input Devices**

Signal Name	I/O	Description	Raw Data Mode 16-bit	Raw Data Mode 8-bit	Raw Data Mode, no Field or WEN 16-bit	Raw Data Mode, no Field or WEN 8-bit	BT.656 Mode 10-bit	BT.656 Mode 8-bit	Digital YCbCr Mode 16-bit	Digital YCbCr Mode 8-bit
cam_hd	I/O	Horizontal sync	+	+	+	+			+	+
cam_vd	I/O	Vertical sync	+	+	+	+			+	+
cam_field	I/O	Field indicator	+	+					+	+
cam_wen	I	Write enable	+	+					+	+
cam_pclk	I	Pixel clock	+	+	+	+	+	+	+	+
cam_data0	I	Camera/VPFE data (bit 0)	+	+	+	+	+	+	+	+
cam_data1	I	Camera/VPFE data (bit 1)	+	+	+	+	+	+	+	+
cam_data2	I	Camera/VPFE data (bit 2)	+	+	+	+	+	+	+	+
cam_data3	I	Camera/VPFE data (bit 3)	+	+	+	+	+	+	+	+
cam_data4	I	Camera/VPFE data (bit 4)	+	+	+	+	+	+	+	+
cam_data5	I	Camera/VPFE data (bit 5)	+	+	+	+	+	+	+	+
cam_data6	I	Camera/VPFE data (bit 6)	+	+	+	+	+	+	+	+
cam_data7	I	Camera/VPFE data (bit 7)	+	+	+	+	+	+	+	+
cam_data8	I	Camera/VPFE data (bit 8)	+		+		+		+	
cam_data9	I	Camera/VPFE data (bit 9)	+		+		+		+	
cam_data10	I	Camera/VPFE data (bit 10)	+		+				+	
cam_data11	I	Camera/VPFE data (bit 11)	+		+				+	

### 14.3.1.2 Raw Data Mode

Raw data mode is a generic parallel interface that supports up to a 16-bit data path to a CMOS or CCD sensor. The signal interface is described in [Table 14-6](#).

**Table 14-6. CCD Interface Signals**

Name	I/O	Function
CAM_D[15:0]	I	Image data – A mode set by INPMOD (not R656ON). <ul style="list-style-type: none"> <li>Bit width is configurable between 8 and 16 bits (DATSIZ).</li> <li>The polarity of the input image data is configurable (DATAPOL).</li> </ul>
CAM_VD	I	VSYNC - vertical sync signal
CAM_HD	I	HSYNC - horizontal sync signal
CAM_FIELD	I	Field identification signal (optional – FLDMODE) <ul style="list-style-type: none"> <li>This signal can be configured to be latched by the VD signal (FIDMD).</li> <li>The polarity of the field identification signal is configurable (FLDPOL).</li> </ul>
CAM_WEN	I	VPFE write enable signal (optional – EXWEN) <ul style="list-style-type: none"> <li>The EXWEN signal determines when data is captured, processed, and saved to memory or sent for further processing.</li> <li>If EXWEN is enabled, image data will be captured, processed, and saved to memory or sent for further processing, depending on the state of WENLOG.</li> <li>Data can be saved either when CAM_WEN is active and the pixels are within the internal frame (SPH, NPH, SLV, NLV) or when the pixels are within the internal frame (WENLOG).</li> </ul>
CAM_PCLK	I	Pixel clock <ul style="list-style-type: none"> <li>The PCLK signal is the signal used to latch input image data.</li> <li>The input image data can be captured on either the rising or on the falling edge of the PCLK signal which is configured by field PCLK_INV.</li> <li>The maximum pixel clock rate is 75 MHz.</li> </ul>

#### 14.3.1.2.1 Mode Information – Always Required

- INPMOD – input mode
- DATSIZ – size (bit width) of input data – always stored in LSBs
- DATAPOL – polarity of input data
- VDPOL – VD polarity
- HDPOL – HD polarity
- FLDMOD – field mode

#### 14.3.1.2.2 Timing Information – Optional, Depending on Control Signals and Sensor Mode

- If FLDMODE is enable
  - FLDPOL – CAM\_FIELD polarity
  - FIDMD – CAM\_FIELD latch information
- EXWEN – external CAM\_WEN signal
  - WENLOG – determines when data is valid along with frame settings

**Figure 14-2. CCD Controller Frame and Control Signal Definitions**

### 14.3.1.3 ITU-R BT.656 Interface

The BT.656 interface supports either 8-bit or 10-bit processing of input video YCbCr data. See [Section 14.4](#) for instructions on how to configure this mode.

Since the data synchronization information is carried along with the data lines, no synchronization signals (i.e., CAM\_HD, CAM\_VD, and CAM\_FIELD) are necessary in this mode.

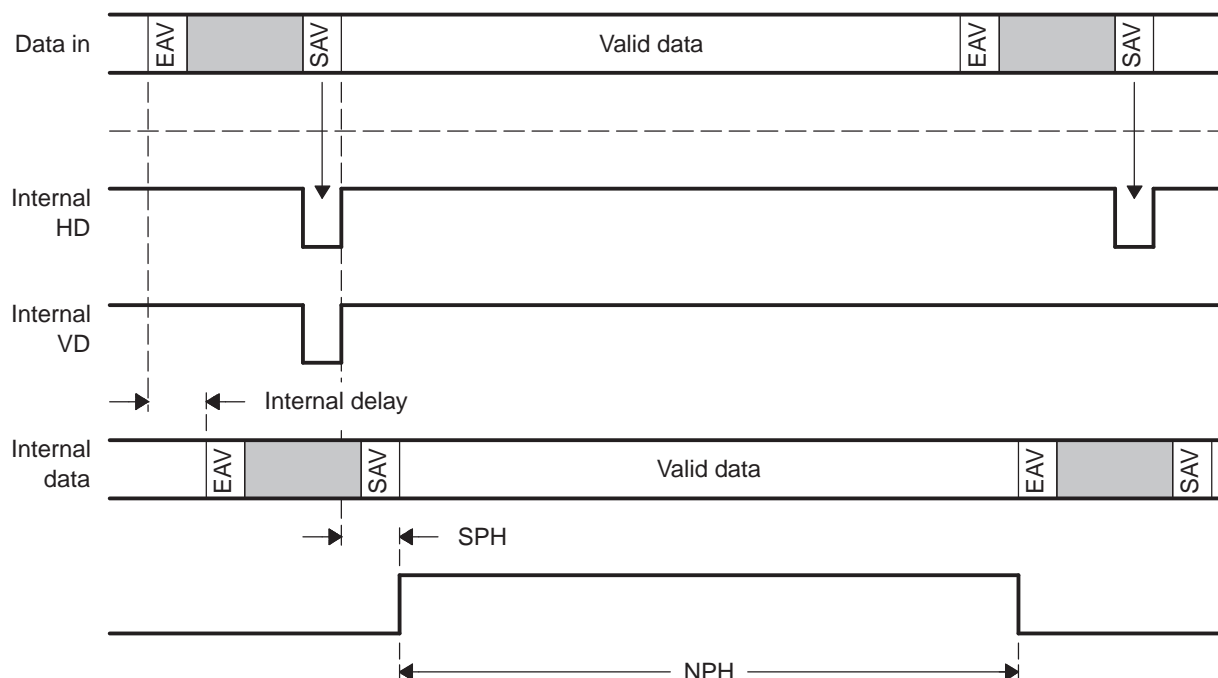

The signal interface is described in [Table 14-7](#).

**Table 14-7. ITU-R BT.656 Interface Signals**

Name	I/O	Function
CAM_D[9:0]	I	Image data – mode set by R656ON <ul style="list-style-type: none"> <li>Bit width is configurable to either eight or ten bits (BW656).</li> <li>The polarity of the input image data is configurable (DATAPOL).</li> </ul>
CAM_PCLK	I	Pixel clock <ul style="list-style-type: none"> <li>The PCLK signal is the signal used to latch input image data.</li> <li>The input image data can be captured on either the rising or on the falling edge of the PCLK signal which is configured by field PCLK_INV.</li> <li>The maximum pixel clock rate is 75 MHz.</li> </ul>

Two timing reference codes are transmitted as the synchronization signal. At the start and end of each video data block, two unique codes are sent, respectively. The start code is called the start of active video signal (SAV), and the end code is called the end of active video signal (EAV). The SAV and EAV codes proceed and follow valid data, as shown in [Figure 14-3](#). The VPFE controller internally bases on SAV and EAV codes to generate the necessary synchronization signals, i.e., horizontal sync, vertical synx, and field ID.

**Figure 14-3. BT.656 Signal Interface**

Both timing reference signals, SAV and EAV, consist of a four-word sequence in the following format: FF 00 00 XY, where FF 00 00 are a set preamble and the fourth word defines the field identification, the state of vertical field blanking, the state of horizontal line blanking, and protection (error correction) codes. The bit format of the fourth word is shown in [Table 14-8](#) and the definitions for bits, F, V, and H, are given in [Table 14-9](#). F, V, and H are used in place of the usual horizontal sync, vertical sync, and blank timing control signals. Bits P3, P2, P1, and P0 are protection (error correction) bits for F, V, and H. The relationship between F, V, and H and the protection (error correction) bits is given in [Table 14-10](#). To enable error correction, set the ECCFVH bit in the REC656IF register. The VPFE controller automatically detects and applies error correction when the ECCFVH bit is set.

**Table 14-8. Video Timing Reference Codes for SAV and EAV**

Data Bit Number	First Word (FF)	Second Word (00)	Third Word (00)	Fourth Word (XY)
9 (MSB)	1	0	0	1
8	1	0	0	F
7	1	0	0	V
6	1	0	0	H
5	1	0	0	P3
4	1	0	0	P2
3	1	0	0	P1
2	1	0	0	P0
1	1	0	0	0
0	1	0	0	0

**Table 14-9. F, V, H Signal Descriptions**

Signal	Value	Command
F	0	Field 1
	1	Field 2
V	0	0
	1	Vertical blank
H	0	SAV
	1	EAV

**Table 14-10. F, H, V Protection (error correction) Bits**

F	V	H	P3	P2	P1	P0
0	0	0	0	0	0	0
0	0	1	1	1	0	1
0	1	0	1	0	1	1
0	1	1	0	1	1	0
1	0	0	0	1	1	1
1	0	1	1	0	1	0
1	1	0	1	1	0	0
1	1	1	0	0	0	1

**NOTE:** The VPFE controller outputs the XY code in the SAV and EAV into the external memory. In order to eliminate this, set the SPH register field to +1. Also set the NPH register field to accurately represent the number of active pixels.

#### 14.3.1.4 Digital YCbCr Interface

The digital YCbCr interface supports either 8-bit or 16-bit devices. The signal interface is described in [Table 14-11](#).

Unlike the BT.656 mode, discrete horizontal sync (CAM\_HD) and vertical sync (CAM\_VD) signals are required. An NTSC/PAL decoder is an example device that can be connected to the YCbCr interface.

You can use data lines YI[7:0] or CI [7:0] for input in 8-bit mode. Alternately, you can connect two separate devices; however, only one can be active at any given time. Setting the YCINSWP bit in the CCDCFG register determines which set of 8-bit inputs are active.

Use data lines YI [7:0] and CI[7:0] for input in 16-bit mode. Use the YCINSWP bit in the CCDCFG register to swap the Y and Cr/Cb data lines.

**Table 14-11. CCD Interface Signals**

Name	I/O	Function
CAM_D [15:0] = YI [7:0] / CI [7:0]	I	Image data – mode set by INPMOD (not R656ON) <ul style="list-style-type: none"> <li>• Bit width is only configurable to either 8 bits or 16 bits (INPMOD).</li> <li>• The polarity of the input image data is reversible (DATAPOL).</li> <li>• When the 16-bit interface is used, you can swap the Y and C inputs (YCINSWP).</li> <li>• When the 8-bit interface is used, you can connect either half of the bus (YCINSWP).</li> <li>• When the 8-bit interface is used, you can set the position of the Y data to either the even or odd pixel (Y8POS).</li> </ul>
CAM_VD	I	VSYNC - vertical sync signal
CAM_HD	I	HSYNC - horizontal sync signal
CAM_FIELD	I	Field identification signal (optional – FLDMODE) <ul style="list-style-type: none"> <li>• This signal can be configured to be latched by the VD signal (FIDMD).</li> <li>• The polarity of the field identification signal is configurable (FLDPOL).</li> </ul>
CAM_PCLK	I	Pixel clock <ul style="list-style-type: none"> <li>• The PCLK signal is the signal used to latch input image data.</li> <li>• The input image data can be captured on either the rising or on the falling edge of the PCLK signal which is configured by field PCLK_INV.</li> <li>• The maximum pixel clock rate is 75 MHz.</li> </ul>

## 14.3.2 VPFE Data / Image Processing

This section describes the image/data processing of each module in the VPFE in more detail.

[Section 14.3.2.1](#) describes the raw data mode while [Section 14.3.2.2](#) explains the YCbCr and BT656 modes.

### 14.3.2.1 Raw Data Mode

Raw data mode is enabled by setting SYN\_MODE.INPMODE to 0 and setting REC656IF.REC656ON to 0.

[Figure 14-4](#) shows the corresponding data processing diagram.

**Figure 14-4. Data Processing in Raw Data Mode**

Typically, raw sensor data is one color per pixel in a color filter array (CFA). The color filter array applied is typically a Bayer pattern, as shown in [Figure 14-5](#) for RGB color space. Alternatively, the special Foveon X3-family sensors capture R, G, and B lights at each pixel location. Both Bayer and Foveon sensors are supported by the VPFE controller.

**Figure 14-5. Color Patterns**

Bayer format with R/Gr and Gb/B in alternate lines  
– Horizontal distance between same colors is 2.

Foveon sensor with R, G, and B in same line  
– Horizontal distance between same colors is 3.

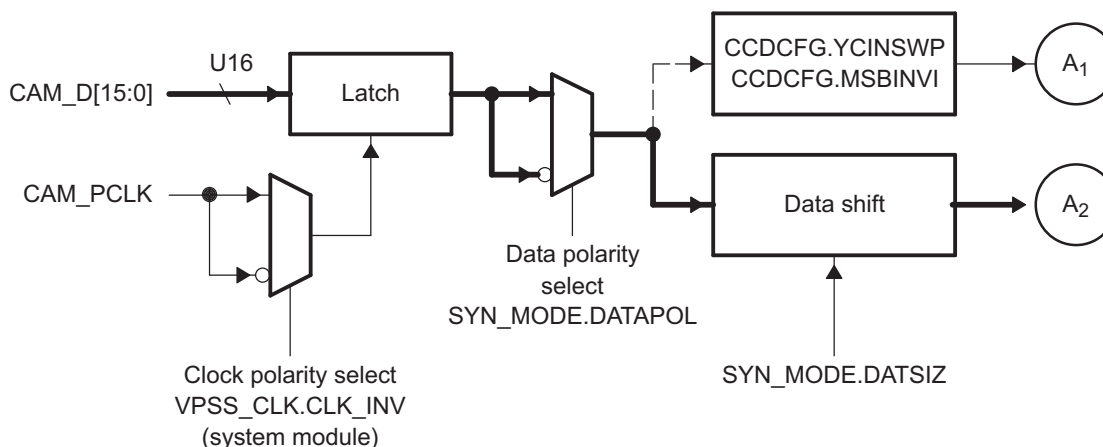

### 14.3.2.1.1 Input Sampling and Formatting

The data path of raw data mode is shown in the thicker lines in [Figure 14-6](#) (i.e., A2). Data path A1 is applicable to YUV input mode only.

- The pixel clock (CAM\_PCLK) latches the data.
- Pixel clock polarity can be either rising or falling edge and is set in VPSS clock control register (VPSS\_CLK).PCK\_INV).
- DATAPOL bit in the SYN\_MODE register affects the data representation.
- Data is right-shifted to align the data in the least significant bits of the data bus and provide the maximum dynamic range for the remainder of the processing (DATSIZ bit in the SYN\_MODE register). This also sets the maximum data size allowed in subsequent clipping/limiting operations and is the output data alignment when it is written to external memory.

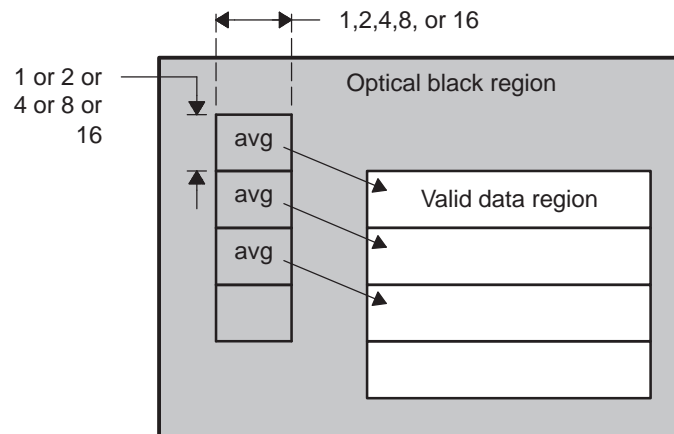

**Figure 14-6. Input Formatter**

### 14.3.2.1.2 Optical Black Clamping

Sensor manufacturers typically provide some optically masked pixels at the beginning/end of each line to allow you to determine the noise floor on any given frame of data. The optical black clamping function provides a means to average the optically black pixels and subtract that value from each input pixel as the first step in reducing the noise on the input pixels.

**Figure 14-7. Optical Black Averaging & Application**

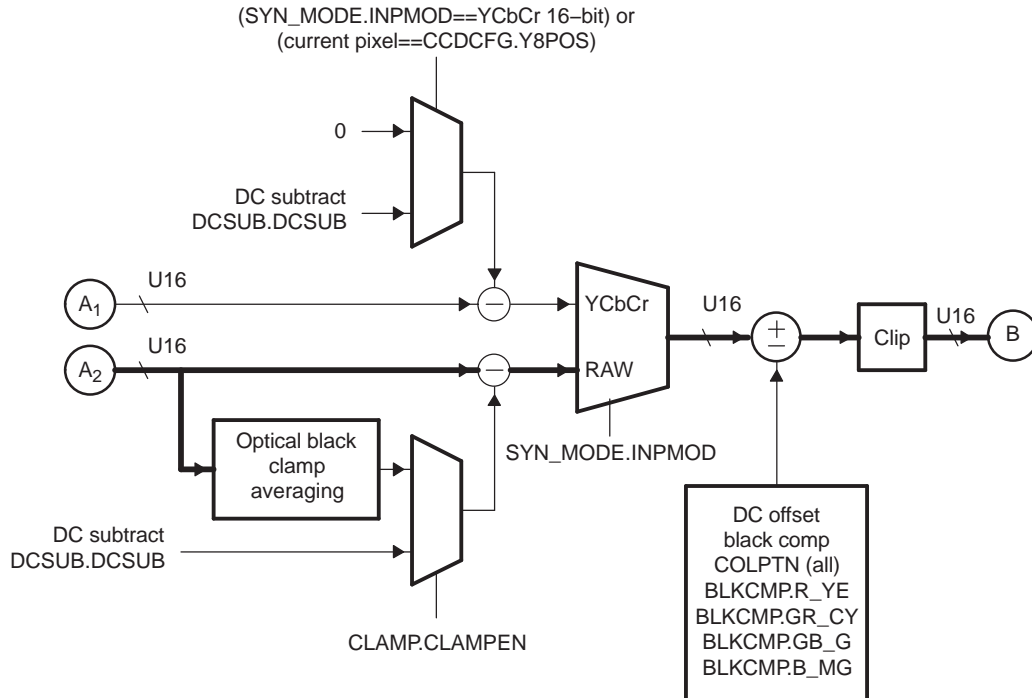

The averaging circuit takes an average of masked (black) pixel values from the image sensor, averaging pixels at the start (OBST bit in the CLAMP register) of each line (OBSLEN bit in the CLAMP register) and for the number of indicated lines (OBSLN bit in the CLAMP register), plus an optional gain adjustment (OBGAIN bit in the CLAMP register). The resultant value is subtracted from the image data at the succeeding line. You can control the position of the black pixels, the number of pixels (8 or 16) in each line that are averaged, and the number of lines (8 or 16) that are averaged.

Alternately, you can disable black clamp averaging (CLAMPEN bit in the CLAMP register) and select a constant black value for subtraction (DCSUB bit in the DCSUB register) instead of using the calculated average value.

The corresponding data path is shown in the thicker lines in [Figure 14-8](#).

**Figure 14-8. Black Clamping and Black Level Compensation**

#### 14.3.2.1.3 Black Level Compensation

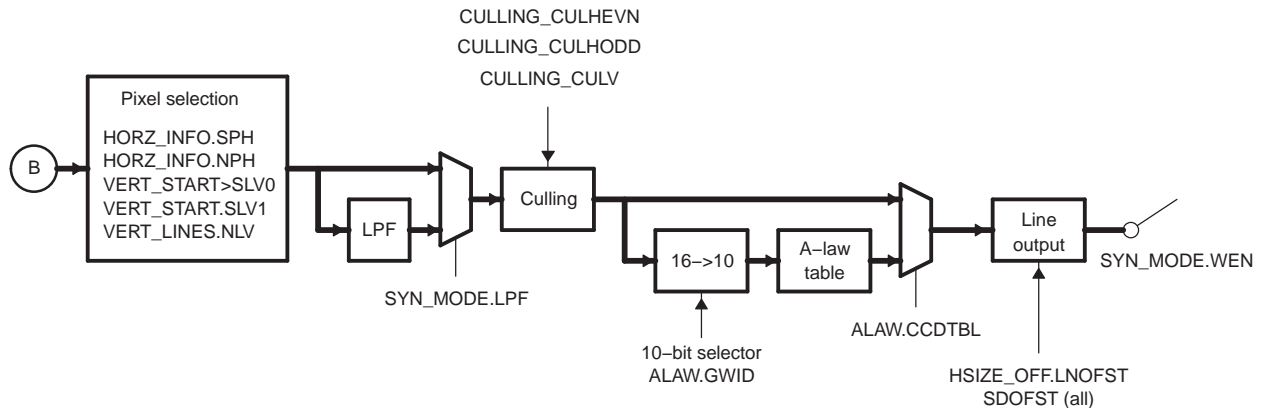

After the digital clamping is applied to the data, black level compensation is applied (Figure 14-8). In this operation, a fixed value is subtracted from the data depending on the color (i.e., R/Ye, Gr/Cy, Gb/G, and B/Mg). The offset (BLKCMP register, fields R\_YE, GR\_CY, GB\_G, B\_MG) that is applied to each data sample is selected according to the 0/1/2/3 phase and the color (0/1/2/3) specified for each phase (COLPTN). The color pattern definition is very flexible in order to accommodate many different capture devices, including normal Bayer CFA sampling, Foveon sensors, and VGA movie mode CCDs, whose VGA draft mode output does not follow the typical Bayer pattern.

#### 14.3.2.1.4 Output Formatter

The final stage of VPFE processing is the output formatter, as shown in Figure 14-9. A framing selection is applied to limit the processing area by the settings in the HORZ\_INFO, VERT\_START and VERT\_LINES registers.

**NOTE:** In addition to the framing applied at the beginning and end of the data formatter operation, you must apply a framing selection to limit the processing area. Please ensure that the settings are relative to that frame.

**Figure 14-9. Output Formatter**

#### 14.3.2.1.4.1 Low Pass Filter

Use the LPF bit in the SYN\_MODE register to apply an optional low-pass filter after the reframing. The low-pass filter consists of a simple 3-tap (  $\frac{1}{4}$ ,  $\frac{1}{2}$ ,  $\frac{1}{4}$  ) filter. Two pixels on the left and two pixels on the right of each line are cropped if the filter is enabled.

#### 14.3.2.1.4.2 Culling

Use the CULEVEN and CULODD bits in the CULLING register (8-bit repeating mask, one per field) to enable an optional culling operation, which culls (deletes) selected pixel data from a line. Use the CULV bit in the CULLING register to select lines from a frame.

Table 14-12 illustrates how the register values apply the decimation pattern to the data. The pixels in white will be saved to external memory and the shaded pixels are discarded.

In this case:

- CULLING = 0x59C40066, with
- CULHEVN = 0x59,
- CULHODD = 0xC4, and
- CULV = 0x66.

**Table 14-12. Example for Decimation Pattern**

		LSB							
		0	0	1	0	0	0	1	1
		1	0	0	1	1	0	1	0
0th line	CULHEVN								1
1st line	CULHODD								1
2nd line									0
3rd line									0
4th line									1
5th line									1
6th line									0
7th line									CULV

#### 14.3.2.1.4.3 A-Law Transformation

Use the CCDTBL bit in the ALAW register to apply an optional 10-to-8-bit A-Law transformation using a fixed A-Law table as the final processing stage. Using this causes the data width to reduce to 8 bits and allows packing to 8 bits/pixel when saving to external memory. Since the data resolution can be greater than 10 bits at this stage, you must select the 10 bits for input to the A-Law operation. Use the GWID bit in the ALAW register to select the 10 bits for input.

**Figure 14-10. A-Law Table**

**Table 14-13. A-Law Table – Part 1**

Inp ut	A- Law	Inp ut	A- Law	Inp ut	A- Law	Inp ut	A- Law	Inp ut	A- Law	Inp ut	A- Law	Inp ut	A- Law	Inp ut	A- Law

#### 14.3.2.1.4.4 Line Output Control

The final stage of the raw data mode is the line output control, which controls how the input sensor lines are written to external memory. The value of the ADR bit in the SDR\_ADDR register defines the starting address where the frame should be written in external memory. The value of the LNOFST bit in the HSIZE\_OFF register defines the distance between the beginning of output lines in bytes. Both the starting address and line offset must be aligned to 32-byte boundaries (i.e., either 16 or 32 pixels, depending on the PACK8 bit in the SYN\_MODE register). Use the SDOFST register to define additional offsets, depending on the field ID and the even/odd line numbers. Defining additional offsets provides a means to de-interlace an interlaced, two-field input and also inverts an input image vertically. See [Figure 14-11](#) and [Figure 14-12](#) for example usage.

**Figure 14-11. Image De-interfacing**

\*1 – SDOFST[13:12]=00b, +1 line for FID=1 lines

\*2 – SDOFST[11:9]=SDOFST[8:6]=SDOFST[5:3]=SDOFST[2:0]=001b, +2 lines

**Figure 14-12. Non-inversed vs Inversed Format**

#### 14.3.2.1.4.5 Output Format

The pixel data format in external memory is shown in [Table 14-16](#).

- If pixel data format is 8-bit, every 16-bit word in external memory stores two pixel data.
- If pixel data format is greater than 8-bit, every 16-bit word in external memory stores one pixel data, and the unused bits are MSB which are filled with 0.

**Table 14-15. Storage Format in external memory for Raw Data Mode**

	Upper Word		Lower Word	
	MSB (31)	LSB (16)	MSB (15)	LSB (0)
16-bit		Pixel1		Pixel0
15-bit	0	Pixel1	0	Pixel0
14-bit	0	Pixel1	0	Pixel0
13-bit	0	Pixel1	0	Pixel0
12-bit	0	Pixel1	0	Pixel0
11-bit	0	Pixel1	0	Pixel0
10-bit	0	Pixel1	0	Pixel0
9-bit	0	Pixel1	0	Pixel0
8-bit	0	Pixel1	0	Pixel0
8-bit pack	Pixel3	Pixel2	Pixel1	Pixel0

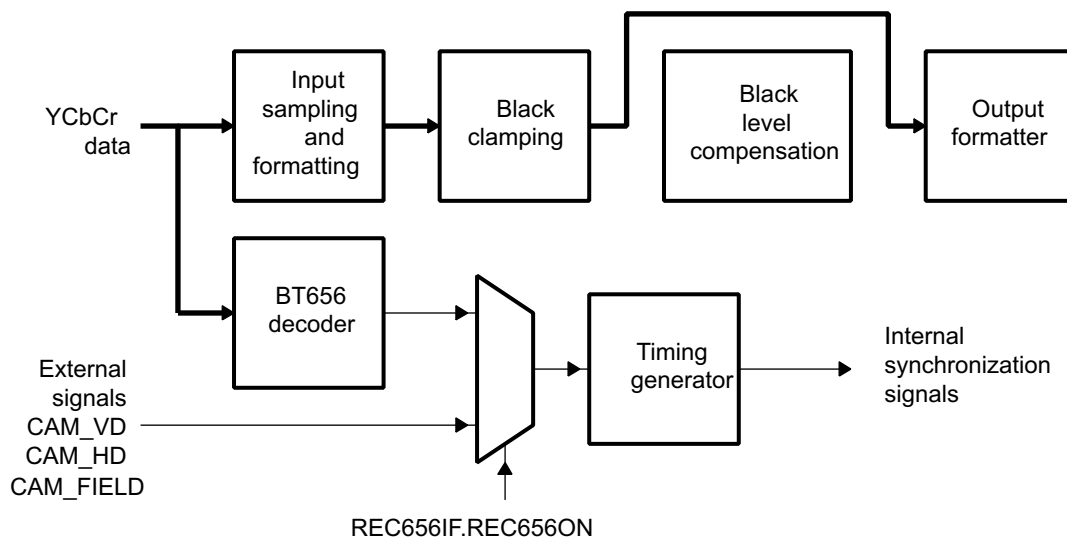

### 14.3.2.2 YCbCr and BT656 Modes

YCbCr mode and BT656 mode are similar in operation, as shown in [Figure 14-13](#). The additional logic used in BT656 mode is the CCIR656 decoder, which extracts synchronization information from input YCbCr data and regenerates the corresponding timing for internal operation.

- YCbCr mode is enabled by setting field INPMODE in register SYN\_MODE to 1 or 2 and clearing field REC656ON in register REC656IF.
- BT656 mode is enabled by setting REC656ON in register REC656IF to 1.

YCbCr mode typically has 8 bits per luma/chroma sample while BT656 mode has 8 bits or 10 bits per luma/chroma sample.

**Figure 14-13. Data Processing in YUV/BT656 Modes**

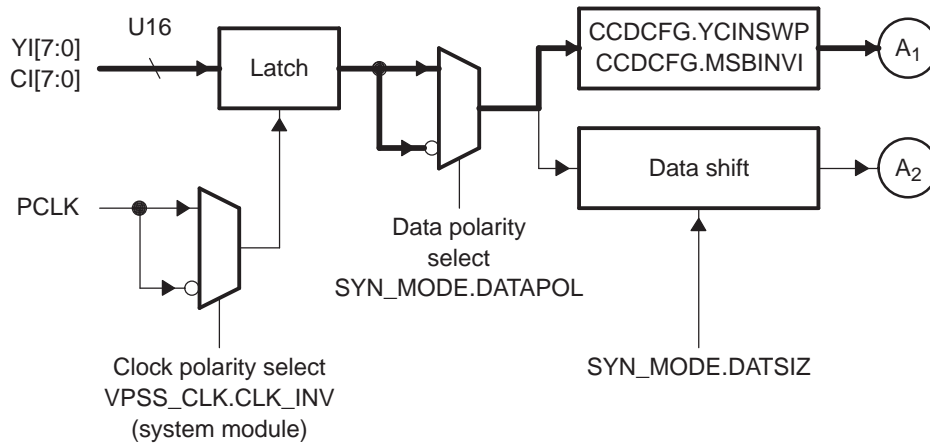

#### 14.3.2.2.1 Input Sampling and Formatting

The data path of YCbCr/BT656 modes is shown in thicker lines in [Figure 14-14](#) (i.e., A1). Data path A2 is applicable to raw data mode only.

- The pixel clock (CAM\_PCLK) latches data.
- Pixel clock polarity can be either rising or falling edge and is set in VPSS clock control register (VPSS\_CLK).PCLK\_INV).
- DATAPOL bit in the SYN\_MODE register affects the data representation.
- Bit YCINSWP in register CCDCFG can be used to swap the upper and lower portions of the 16-bit YCbCr data bus.
  - In 16-bit YCbCr mode, this swap bit determines which part of the bus luma and chroma samples occupy respectively.
  - In 8-bit mode, this swap bit determines which part of the bus is the effective 8-bit input. In other words, two external 8-bit YCbCr capture devices can be tied to VPFE module directly.
- Bit MSBINVI in register CCDCFG can be used to invert the MSB of the chroma signal.

**Figure 14-14. CCD Controller**

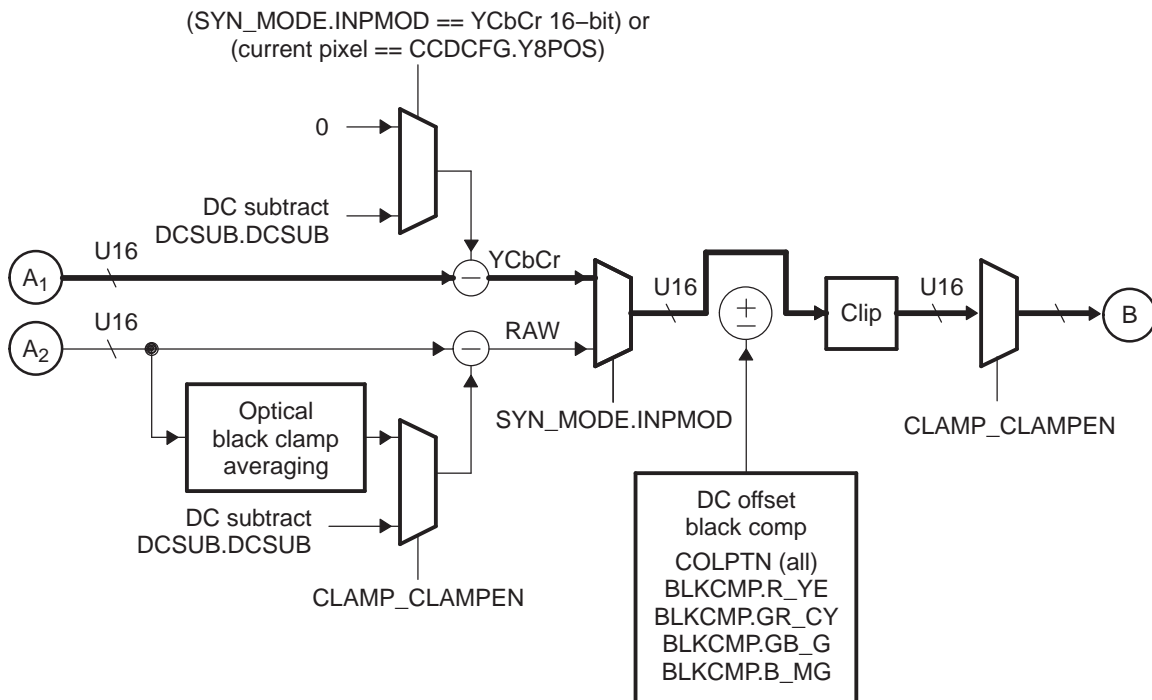

#### 14.3.2.2.2 Black Clamping

The second step in BT.656/YCbCr processing is black clamping

Use the DCSUB bit in the DCSUB register to subtract a fixed value from the luma sample for YUV data. Set the subtraction value to zero to disable the operation. See [Figure 14-15](#) for more details. You may notice that black compensation (BLKCMP) is not used in YCbCr and BT656 modes.

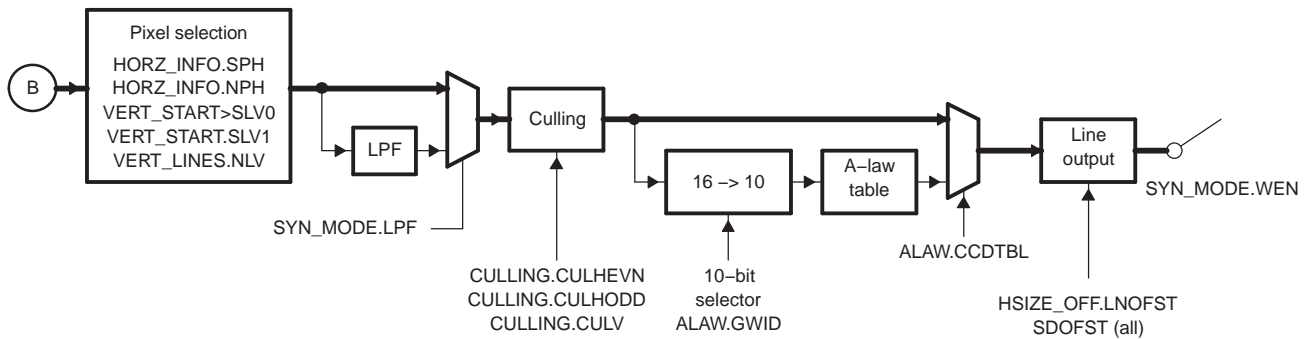

**Figure 14-15. Black Clamping and Block Level Compensation**

#### 14.3.2.2.3 Output Formatter

The output formatter is the final stage of VPFE processing (as shown as thicker lines in [Figure 14-16](#)).

Apply a framing selection to limit the processing area by the settings in the HORZ\_INFO, VERT\_START and VERT\_LINES registers.

**Figure 14-16. Output Formatter**

- Use the LFP bit in the SYN\_MODE register to disable the LPF by setting the LFP bit equal to 0.
- Culling can be used in YCbCr and BT656 modes; however, care must be taken to preserve the 422 output format.
- Do not use the A-Law transformation in YCbCr or BT.656 mode (the CCDTBL bit in the ALAW register = 0).

The pixel data in external memory is shown in [Table 14-16](#).

**Table 14-16. Storage Format in external memory for BT.656/YCbCr Modes**

external memory Address	Upper word		Lower word	
	MSB (31)	LSB (16)	MSB (15)	LSB (0)
N	Y1	Cr0	Y0	Cb0
N + 1	Y3	Cr2	Y2	Cb2
N + 2	Y5	Cr4	Y4	Cb4

## 14.4 Programming Model

The following programming procedures should be followed to enable the VPFE controller to receive video or image capture data.

1. Power-up the VPFE using the Power, Reset, and Clock Management (PRCM) module.
2. Disable the VPFE controller.
3. Configure the VPFE registers to match the system requirements, including interrupt setup.
4. Enable the VPFE controller.

Once the VPFE controller is enabled, it starts to process input data continuously. No user intervention is necessary to re-start the process. As a result, the VPFE interrupt must be set up correctly in order to operate properly. Users can terminate its operation by disabling the VPFE controller.

The remaining sections describe the programming procedure in more detail.

### 14.4.1 Enabling and Disabling the VPFE Controller

The following steps describe how to enable and disable the VPFE controller:

- Clearing the ENABLE bit in the VPFE\_PCR register disables the VPFE controller.
- Setting the ENABLE bit in the VPFE\_PCR register enables the VPFE controller.
  - The VPFE controller should be enabled prior to data transmission from the external device to avoid data loss.

### 14.4.2 Configuring VPFE Registers

#### 14.4.2.1 General Register Setup

Table 14-17 lists the minimum register fields that must be configured.

**Table 14-17. Basic Configuration of VPFE Registers**

Function	Register	Fields
External signal configuration (This includes signals CAM_VD, CAM_HD, CAM_FIELD, and CAM_WEN.)	SYN_MODE	VDHDEN VDPOL HDPOL FLDMODE FLDPOL EXWEN DATAPOL
	CCDCFG	VDLC
Input data mode	REC656	R656ON
	SYN_MODE	INPMOD
Color pattern	COLPTN	All
Black compensation	BLKCOMP	All
Data path configuration	SYN_MODE	WEN

Table 14-18 describes additional configuration requirements when certain conditions are met.

**Table 14-18. Conditional Configuration of VPFE Registers**

Category	If...	Then program...
Interlace mode	Field FLDMODE in register SYN_MODE is 1	Field FIDMD in register CCDCFG
External WEN	Field EXWEN in register SYN_MODE is 1	Field WENLOG bit in register CCDCFG
REC656 input	Field R656ON in register REC656 is 1	Field ECCFVH in register REC656 Field BW656 in register CCDCFG
RAW input	Field INPMOD in register SYN_MODE is 0 and Field R656ON in register REC656 is 1	Field DATSIZ in register SYN_MODE Field CLAMPEN in register CLAMP
16-bit YCC input	Field INPMOD in register SYN_MODE is 1 and Field R656ON in register REC656 is 1	Field YCINSWP in register CCDCFG Field MSBINVI in register CCDCFG Register DCSUB
8-bit YCC input	Field INPMOD in register SYN_MODE is 2 and Field R656ON in register REC656 is 1	Field Y8POS in register CCDCFG
Optical black clamp enabled	Field CLAMPEN in register CLAMP is 1 and Field INPMOD in register SYN_MODE is 0	Field OBGAIN in register CLAMP Field OBST in register CLAMP Field OBSLN in register CLAMP Field OBSLEN in register CLAMP
Optical black clamp disabled	Field CLAMPEN in register CLAMP is 0 and Field INPMOD in register SYN_MODE is 0	Register DCSUB
Write to external memory	Field WEN in register SYN_MODE is 1	Field LPF in register SYN_MODE Field PACK8 in register SYN_MODE Field CCDTBL in register ALAW Field BSWD in register CCDCFG Register HORZ_INFO Register VERT_START Register VERT_LINES Register CULLING Register SDR_ADDR Register HSIZE_OFF Register SDOFST
A-law	Field CCDTBL in register ALAW is 1	Field GWID in register ALAW
Interrupt	Interrupts CCDC_VD0_INT and CCDC_VD1_INT are to be used	Register VDINT

#### 14.4.2.2 Interrupts

The VPFE controller can generate three interrupts: CCDC\_VD0\_INT, CCDC\_VD1\_INT, and CCDC\_VD2\_INT.

**NOTE:** Enable the VDHDEN field in register SYN\_MODE to receive any of these VPFE controller interrupts.

The CCDC\_VD0\_INT and CCDC\_VD1\_INT interrupts occur relative to the VD pulse, as shown in Figure 14-17 and Figure 14-18. Please note that field VDPOL in register SYN\_MODE changes the trigger timing.

- If field VDPOL is 1, the VDINT0 and VDINT1 counters begin counting CAM\_HD pulses from the falling edge of signal CAM\_VD.
- If field VDPOL is 0, the VDINT0 and VDINT1 counters begin counting CAM\_HD pulses from the rising edge of signal CAM\_VD.

- Interrupts CCDC\_VD0\_INT and CCDC\_VD1\_INT occur after receiving the number of horizontal lines (CAM\_HD pulse signals) set in the VDINT0 bit in the VDINT register and the VDINT1 bit in the VDINT register, respectively.

**Figure 14-17. VDPOL is 0**

**Figure 14-18. VDPOL is 1**

The CCDC\_VD2\_INT interrupt always occurs at the falling edge of the CAM\_WEN signal (via an external pin), as shown in Figure 14-19. There are no registers in the VPFE module to configure this interrupt.

**Figure 14-19. CCDC\_VD2\_INT Interrupt**

#### 14.4.2.3 Status

The BUSY status bit in the VPFE\_PCR register is set when the start of frame occurs (if the ENABLE bit in the VPFE\_PCR register is 1 at that time). It automatically resets to 0 at the end of a frame.

#### 14.4.2.4 CAM\_VD latched Registers

The VDLC field in register CCDCFG affects the access of the following registers and register fields.

##### Registers

VPFE\_PCR  
HORZ\_INFO  
VERT\_START  
VERT\_LINES  
CULLING  
HSIZE\_OFF  
SDOFST  
SDR\_ADDR

##### Register Fields

WEN in SYN\_MODE  
LPF in SYN\_MODE

**Registers**

CLAMPEN in CLAMP  
YCINSWP in CCDCFG

**NOTE:**

1. If the VDLC field is 0, changes to the above registers/register fields will take effect immediately.
2. If the VDLC field is 1, changes to the above registers/register fields will take effect at the start of a new frame (i.e., the changes are latched by the CAM\_VD signal). Reads from these registers/register fields will return the most recent write value (even though these values may not take effect).

Be careful to avoid undesired effects when using the first approach.

#### 14.4.2.5 Inter-frame Operations

As described in the previous section, the VPFE\_PCR and SDR\_ADDR registers will be latched by the CAM\_VD signal if the VDLC field in the CCDCFG register is 0. This important feature provides a reliable way for programmers to enable/disable the VPFE module and/or modify the memory pointers in-between frames. For example, the VPFE interrupt service routine (ISR) can program the SDR\_ADDR register to a new value before the end of the current frame. By doing so, the current frame is received without any interruption and the new external memory address (SDR\_ADDR register) will be used for receiving the next frame.

#### 14.4.3 VPFE Limitations

The major limitations of the VPFE module are summarized as follows:

- The CAM\_PCLK (pixel clock) signal cannot be higher than 75 MHz.
- The SDR\_ADDR and HSIZE\_OFF registers should be programmed to values with 5 LBS bits as 0; namely, the memory space they point to should be on a 32-byte boundary.
- The COLPTN register should be set to 0 in YCbCr and BT.656 modes.
- The BLKCMP register should be set to 0 in YCbCr and BT.656 modes.
- Low-pass filter (LPF field in SYN\_MODE register) should be disabled in YCbCr and BT.656 modes.
- A-LAW should be disabled in YCbCr and BT.656 modes.

### 14.5 Registers

#### 14.5.1 VPFE Registers

[Table 14-19](#) lists the memory-mapped registers for the VPFE. All register offset addresses not listed in [Table 14-19](#) should be considered as reserved locations and the register contents should not be modified.

**Table 14-19. VPFE Registers**

Offset	Acronym	Register Name	Section
0h	VPFE_REVISION		<a href="#">Section 14.5.1.1</a>

**Table 14-26. VPFE\_VERT\_START Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	RESERVED	R	0h	
30-16	SLV0	R/W	0h	Start line, vertical (field 0). SLV0 sets line at which data output to external memory will begin, measured from the start of VD. This bit field is latched by VD.
15	RESERVED	R	0h	
14-0	SLV1	R/W	0h	Start line, vertical (field 1). SLV1 sets line at which data output to external memory will begin, measured from the start of VD. For a progressive sensor this field is ignored. This bit field is latched by VD.

### 14.5.1.8 VPFE\_VERT\_LINES Register (offset = 1Ch) [reset = 0h]

VPFE\_VERT\_LINES is shown in [Figure 14-27](#) and described in [Table 14-27](#).

Number of Vertical Lines Register

**Figure 14-27. VPFE\_VERT\_LINES Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																	NLV														
R-0h																	R/W-0h														

**Table 14-27. VPFE\_VERT\_LINES Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-15	RESERVED	R	0h	
14-0	NLV	R/W	0h	Number of lines, vertical. NLV sets the number of vertical lines that will be output to external memory. The number of lines output to external memory = (NLV + 1). This bit field is latched by VD.

### 14.5.1.9 VPFE\_CULLING Register (offset = 20h) [reset = FFFF00FFh]

VPFE\_CULLING is shown in [Figure 14-28](#) and described in [Table 14-28](#).

Culling Information in Horizontal and Vertical Directions Register

**Figure 14-28. VPFE\_CULLING Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**Table 14-28. VPFE\_CULLING Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-24	CULHEVN	R/W	FFh	Horizontal Culling Pattern for Even Line, 8-bit mask. LSB is first pixel, MSB is 8th pixel, then pattern repeats. This bit field is latched by VD. 0h (R/W) = CULLING (deletion) 1h (R/W) = Retain (to be saved to external memory)
23-16	CULHODD	R/W	FFh	Horizontal Culling Pattern for Odd Line, 8-bit mask. LSB is first pixel, MSB is 8th pixel, then pattern repeats. This bit field is latched by VD. 0h (R/W) = CULLING (deletion) 1h (R/W) = Retain (to be saved to external memory)
15-8	RESERVED	R	0h	
7-0	CULV	R/W	FFh	Vertical Culling Pattern, 8-bit mask. LSB is first line, MSB is 8th line, then pattern repeats. This bit field is latched by VD. 0h (R/W) = CULLING (deletion) 1h (R/W) = Retain (to be saved to external memory)

#### 14.5.1.10 VPFE\_HSIZE\_OFF Register (offset = 24h) [reset = 0h]

VPFE\_HSIZE\_OFF is shown in [Figure 14-29](#) and described in [Table 14-29](#).

Horizontal Size Register

**Figure 14-29. VPFE\_HSIZE\_OFF Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																LNOFST															
R-0h																R/W-0h															

**Table 14-29. VPFE\_HSIZE\_OFF Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	
15-0	LNOFST	R/W	0h	Address offset for each line. LNOFST Sets offset for each output line in external memory Either 16 or 32 pixels depending on setting of PACK8. The 5 LSB are ignored, and a zero is returned when read the offset will be on a 32-byte boundary. For optimal performance in the system, the address offset should be on a 256-byte boundary. This bit field is latched by VD.

### 14.5.1.11 VPFE\_SDOFST Register (offset = 28h) [reset = 0h]

VPFE\_SDOFST is shown in [Figure 14-30](#) and described in [Table 14-30](#).

## ***Ethernet Subsystem***

---

---

---

This chapter describes the ethernet subsystem of the device.

<b>Topic</b>	<b>Page</b>
<b>15.1 Introduction .....</b>	<b>2205</b>
<b>15.2 Integration .....</b>	<b>2207</b>
<b>15.3 Functional Description .....</b>	<b>2217</b>
<b>15.4 Software Operation .....</b>	<b>2276</b>
<b>15.5 Ethernet Subsystem Registers .....</b>	<b>2281</b>

## 15.1 Introduction

Described in the following sections is the Layer 2 3-port switch (3PSW) Ethernet subsystem. The 3-port switch gigabit ethernet subsystem provides ethernet packet communication and can be configured as an ethernet switch. It provides the gigabit media independent interface (GMII), reduced gigabit media independent interface (RGMI), reduced media independent interface (RMII), the management data input output (MDIO) for physical layer device (PHY) management.

As a Layer 2 switch, this device is capable of supporting all higher layers and various protocols, such as IPV4, IPV6, and 802.3x, in software.

### 15.1.1 Features

The general features of the ethernet switch subsystem are:

- Two 10/100/1000 Ethernet ports with GMII, RMII and RGMII interfaces
- Wire rate switching (802.1d)
- Non Blocking switch fabric
- Flexible logical FIFO based packet buffer structure
- Four priority level QOS support (802.1p)
- CPPI 3.1 compliant DMA controllers
- Support for IEEE 1588v2 Clock Synchronization (2008 Annex D, E, and F)
  - Timing FIFO and time stamping logic inside the SS
- Device Level Ring (DLR) Support
- Address Lookup Engine
  - 1024 addresses plus VLANs
  - Wire rate lookup
  - VLAN support
  - Host controlled time-based aging
  - Spanning tree support
  - L2 address lock and L2 filtering support
  - MAC authentication (802.1x)
  - Receive or destination based Multicast and Broadcast limits
  - MAC address blocking
  - Source port locking
  - OUI host accept/deny feature
- Flow Control Support (802.3x)
- EtherStats and 802.3Stats RMON statistics gathering (shared)
- Support for external packet dropping engine
- CPGMAC\_SL transmit to CPGMAC\_SL receive Loopback mode (digital loopback) supported
- CPGMAC\_SL receive to CPGMAC\_SL transmit Loopback mode (FIFO loopback) supported
- Maximum frame size 2016 bytes (2020 with VLAN)
- 8k (2048 x 32) internal CPPI buffer descriptor memory
- MDIO module for PHY Management
- Programmable interrupt control with selected interrupt pacing
- Emulation Support.
- Programmable transmit Inter-Packet Gap (IPG)
- Reset isolation

### 15.1.2 Unsupported Features

There are 18 level interrupts from the CPGMAC module and 2 (used) level interrupts from the MDIO module. The CPSW\_3GSS includes an interrupt combiner/pacer to combine these interrupts together to produce 4 interrupt outputs (per processing core). This device does not split processing among multiple cores but allows servicing of the Core0 interrupts by the Cortex-A9 or the PRU-ICSS.

The unsupported CPGMAC features in the device are shown in the following table.

**Table 15-1. Unsupported CPGMAC Features**

Feature	Reason
GMII	Only 4 Rx/Tx data pins are pinned out for each port. The device supports MII (on GMII interface), RGMII, and RMII interfaces only
Phy link status	The MLINK inputs are not pinned out. Phy link status outputs can be connected to device GPIOs.
Internal Delay mode for RGMII	RGMII Internal Delay mode is not supported.

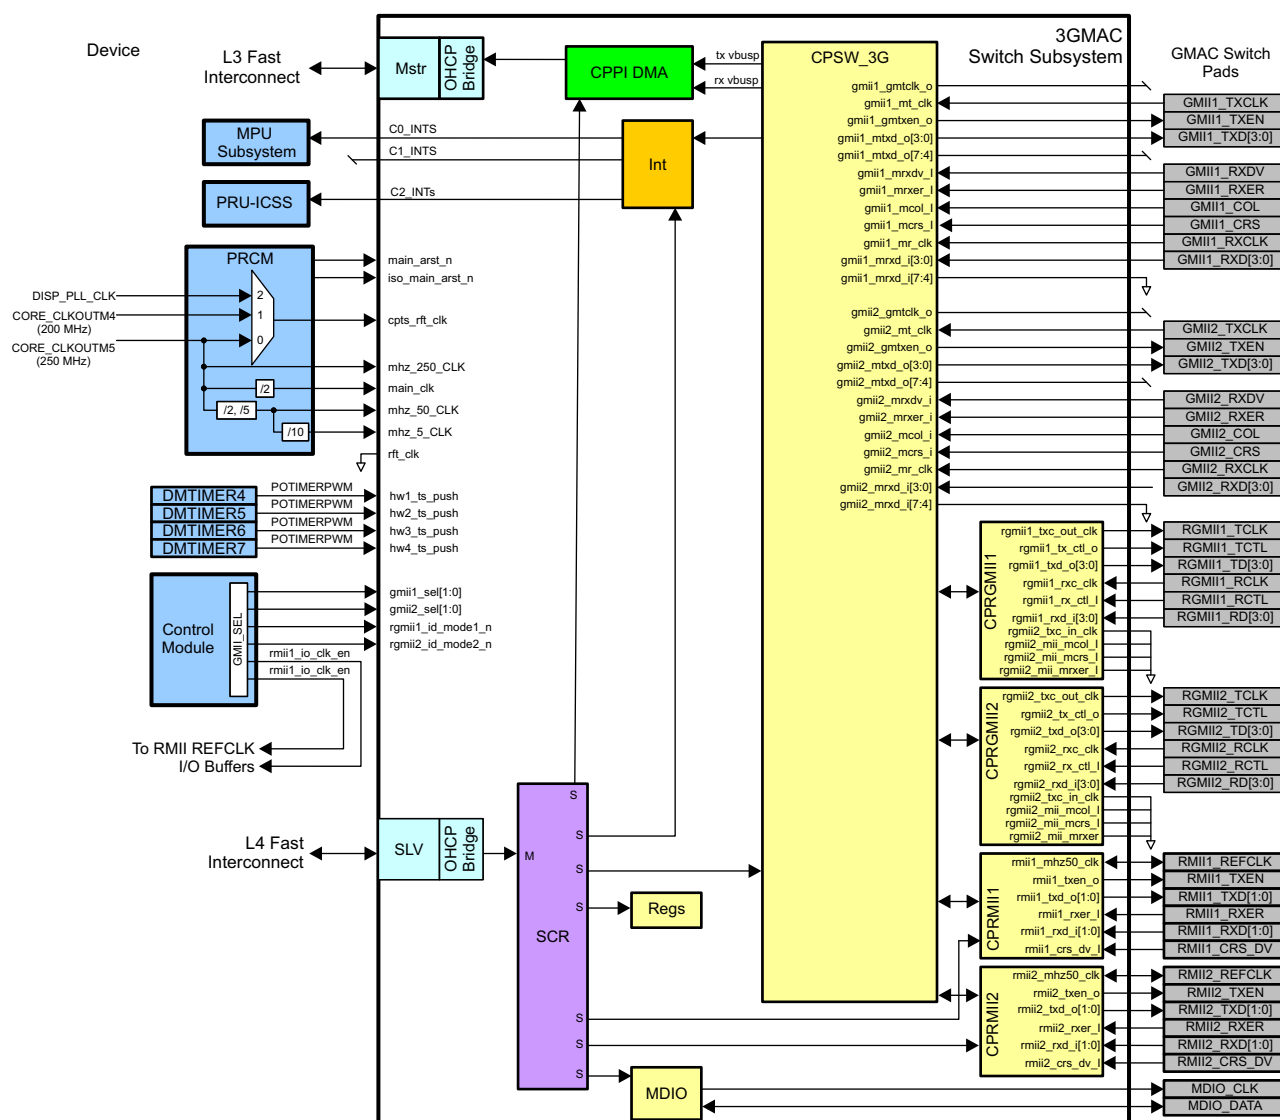

## 15.2 Integration

This device includes a single instantiation of the three-port Gigabit Ethernet Switch Subsystem (CPSW\_3GSS\_RG). The switch provides 2 external ethernet ports (ports 1 and 2) and an internal CPPI interface port (port 0) with IEEE 1588v2 and 802.1ae support. The subsystem consists of:

- One instance of the 3-port Gigabit switch CPSW-3G, which contains:
  - 2 CPGMAC\_SL 10/100/1000 ethernet port modules with GMII interface
- Two RGMII interface modules
- Two RMII interface modules
- One MDIO interface module
- One Interrupt Controller module
- Local CPPI memory of size 8K Bytes

The integration of the Ethernet Switch is shown in [Figure 15-1](#)

**Figure 15-1. Ethernet Switch Integration**

### 15.2.1 Ethernet Switch Connectivity Attributes

The general connectivity attributes for the Ethernet Switch module are shown in [Table 15-2](#).

**Table 15-2. Ethernet Switch Connectivity Attributes**

Attributes	Type
Power Domain	Peripheral Domain
Clock Domain	PD_PER_CPSW_125MHZ_GCLK (Main) PD_PER_CPSW_250MHZ_GCLK (MHZ_250_CLK) PD_PER_CPSW_50MHZ_GCLK (MHZ_50_CLK) PD_PER_CPSW_5MHZ_GCLK (MHZ_5_CLK) PD_PER_CPSW_CPTS_RFT_CLK (CPTS_RFT_CLK)
Reset Signals	CPSW_MAIN_ARST_N CPSW_ISO_MAIN_ARST_N
Idle/Wakeup Signals	Smart Idle Standby
Interrupt Requests	Three sets of 4 Interrupts RX_THRESH (3PGSWRXTHR0) – Receive Threshold interrupt (nonpaced) RX (3PGSWRXINT0) – Receive interrupt (paced) TX (3PGSWTXINT0) – Transmit interrupt (paced) Misc (3PGSWMISC0) – Other interrupts  The Subsystem contains 3 sets of interrupts—C0, C1, and C2—to allow for split core processing of packets. On this device, the C0 version of the interrupts is used for the MPU Subsystem, the C1 version is unused, and the C2 version is used for PRU-ICSS.
DMA Requests	None
Physical Address	L4 Fast slave port L3 Fast initiator port

## 15.2.2 Ethernet Switch Clock and Reset Management

The ethernet switch controller operates in its own clock domain and its initiator and target interfaces are connected to the L3/L4 through asynchronous bridges. The OCP interfaces are driven by the MAIN clock input. Additional reference clock inputs are provided for operating the various ethernet ports at different rates.

**Table 15-3. Ethernet Switch Clock Signals**

Clock Signal	Max Freq	Reference / Source	Comments
rft_clk Gigabit GMII Tx Reference clock	125 MHz	Tied low	not supported
main_clk Logic/Interface clock	125 MHz	CORE_CLKOUTM5 / 2	pd_per_cpsw_125mhz_gclk from PRCM

rmii2_mhz_50_clk RMII Port 2 Reference clock	50 MHz	External Pin	rmii2_refclk_in from RMII2_REFCLK pad

### 15.2.3 Ethernet Switch Pin List

The external signals for the Ethernet Switch module are shown in the following table.

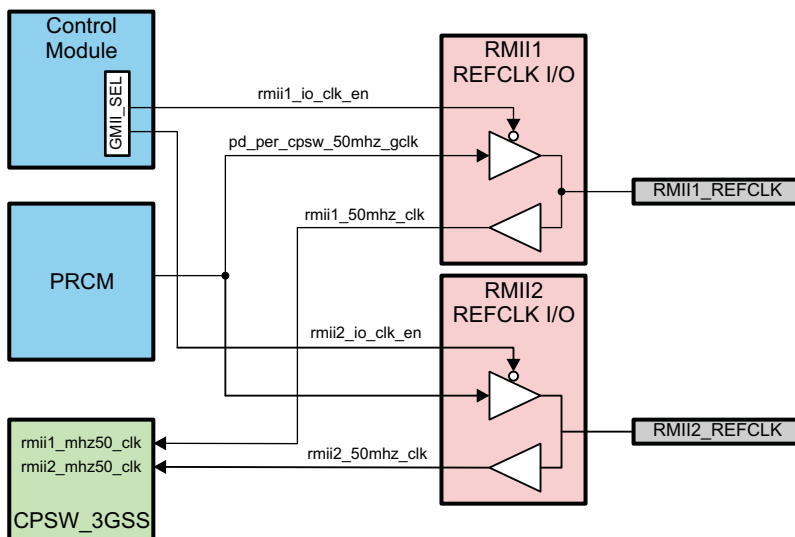

**Table 15-4. Ethernet Switch Pin List**

Pin	Type*	Description
GMIIx_RXCLK	I	GMII/MII Receive clock
GMIIx_RXD[3:0]	I	GMII/MII Receive data
GMIIx_RXDV	I	GMII/MII Receive data valid
GMIIx_RXER	I	GMII/MII Receive error
GMIIx_COL	I	GMII/MII Collision detect
GMIIx_CRS	I	GMII/MII Carrier sense
GMIIx_TXCLK	I	GMII/MII Transmit clock
GMII_TXD[3:0]	O	GMII/MII Transmit data
GMIIx_TXEN	O	GMII/MII Transmit enable
RGMIIx_RCLK	I	RGMII Receive clock
RGMIIx_RCTL	I	RGMII Receive control
RGMIIx_RD[3:0]	I	RGMII Receive data
RGMIIx_TCLK	O	RGMII Transmit clock
RGMIIx_TCTL	O	RGMII Transmit control
RGMIIx_TD[3:0]	O	RGMII Transmit data
RMIIx_RXD[1:0]	I	RMII Receiver data
RMIIx_RXER	I	RMII Receiver error
RMIIx_CRS_DV	I	RMII Carrier sense / Data valid
RMIIx_TXEN	O	RMII Transmit enable
RMIIx_REFCLK	I/O	RMII Reference clock
RMIIx_TXD[1:0]	O	RMII Transmit data
MDIO_CLK	O	MDIO Serial clock
MDIO_DATA	I/O	MDIO Serial data

### 15.2.4 Ethernet Switch RMII Clocking Details

The RMII interface reference clock pin operates as an input. When used as an input, the clock is driven by the I/O pad. The operation is controlled by the GMII\_SEL[RMIIx\_IO\_CLK\_EN] fields in the Control Module, as shown in [Figure 15-2](#), and defaults to input mode.

**Figure 15-2. Ethernet Switch RMII Clock Detail**

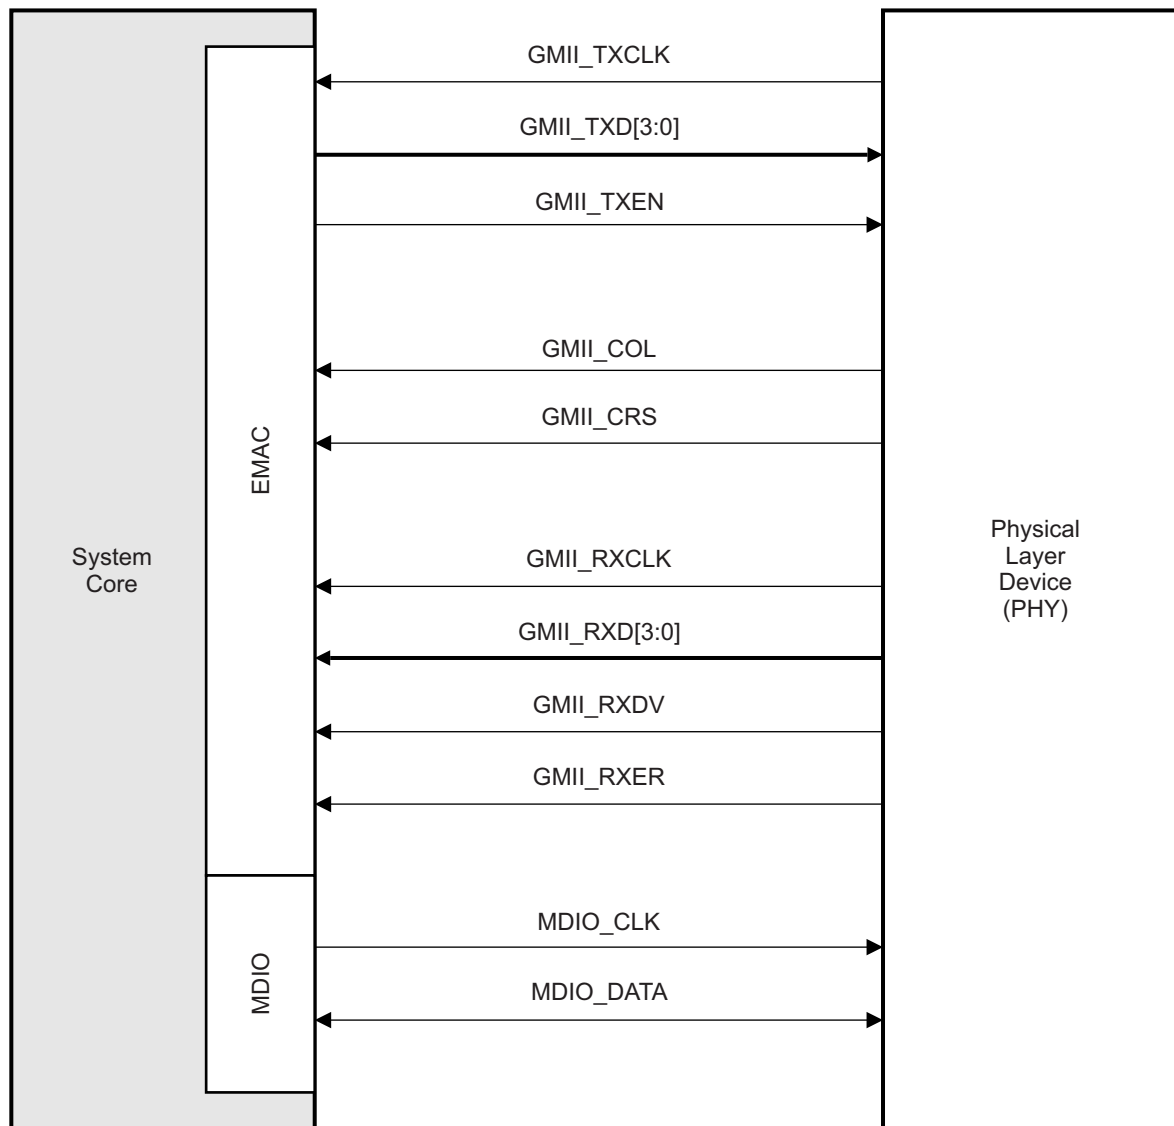

### 15.2.5 GMII Interface Signal Connections and Descriptions

GMII Interface can operate in MII Mode.

In MII Mode(100/10 Mbps) 3PSW operates in Full duplex and Half Duplex.

The pin connections of the GMII Interface are shown in [Figure 15-3](#).

**Figure 15-3. MII Interface Connections**

The detailed description of the signals in MII Mode are explained in the following sections.

**Table 15-5. GMII Interface Signal Descriptions in MII (100/10Mbps) Mode**

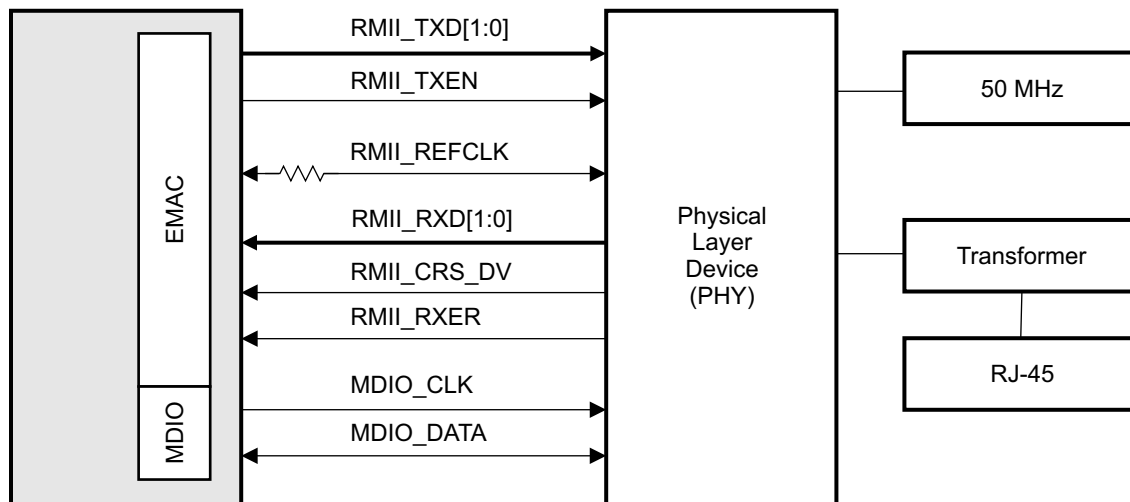

Signal	Type	Description
GMII_TXCLK	I	The transmit clock is a continuous clock that provides the timing reference for transmit operations. The GMII_TXD and GMII_TXEN signals are tied to this clock. The clock is generated by the PHY and is 2.5 MHz at 10 Mbps operation and 25 MHz at 100 Mbps operation.
GMII_TXD[3:0]	O	The transmit data pins are a collection of 4 data signals GMII_TXD[3:0] comprising 4 bits of data. GMII_TXD[0] is the least-significant bit (LSB). The signals are synchronized by GMII_TXCLK and valid only when GMII_TXEN is asserted.
GMII_TXEN	O	The transmit enable signal indicates that the GMII_TXD[3:0] pins are generating 4-bit data for use by the PHY. It is driven synchronously by GMII_TXCLK
GMII_COL	I	In half-duplex operation, the GMII_COL pin is asserted by the PHY when it detects a collision on the network. It remains asserted while the collision condition persists. This signal is not necessarily synchronous to GMII_TXCLK nor GMII_RXCLK In full-duplex operation, the GMII_COL pin is used for hardware transmit flow control. Asserting the GMII_COL pin stops packet transmissions; packets transmitting when MCOL is asserted will complete transmission. The GMII_COL pin should be held low if hardware transmit flow control is not used
GMII_CRD	I	In half-duplex operation, the GMII_CRD pin is asserted by the PHY when the network is not idle in either transmit or receive. The pin is deasserted when both transmit and receive are idle. This signal is not necessarily synchronous to GMII_TXCLK nor GMII_RXCLK. In full-duplex operation, the GMII_CRD pin should be held low.
GMII_RXCLK	I	The receive clock is a continuous clock that provides the timing reference for receive operations. The GMII_RXD, GMII_RXDV, and MRXER signals are tied to this clock. The clock is generated by the PHY and is 2.5 MHz at 10 Mbps operation and 25 MHz at 100 Mbps operation.
GMII_RXD[3:0]	I	The receive data pins are a collection of 4 data signals comprising 4 bits of data. GMII_RXD[0] is the least-significant bit (LSB). The signals are synchronized by GMII_RXCLK and valid only when GMII_RXDV is asserted.
GMII_RXDV	I	The receive data valid signal indicates that the GMII_RXD pins are generating nibble data for use by the 3PSW. It is driven synchronously to GMII_RXCLK
MDIO_CLK	O	Management data clock (MDIO_CLK). The MDIO data clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MDIO_DATA pin.
MDIO_DATA	I/O	The MDIO_DATA pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication, PHY address, register address, and data bit cycles. The MDIO_DATA pin acts as an output for all but the data bit cycles at which time it is an input for read operations.

### 15.2.6 RMII Signal Connections and Descriptions

Figure 15-4 shows a device with integrated 3PSW and MDIO interfaced via a RMII connection in a typical system.

The individual CPSW and MDIO signals for the RMII interface are summarized in Table 15-6.

For more information, see either the IEEE 802.3 standard or ISO/IEC 8802-3:2000(E).

**Figure 15-4. RMII Interface Connections**

**Table 15-6. RMII Interface Signal Descriptions**

Signal	Type	Description
RMII_TXD[1-0]	O	Transmit data. The transmit data pins are a collection of 2 bits of data. RMII_TXD0 is the least-significant bit (LSB). The signals are synchronized by RMII_REFCLK and valid only when RMII_TXEN is asserted.
RMII_TXEN	O	Transmit enable. The transmit enable signal indicates that the RMII_TXD pins are generating data for use by the PHY. RMII_TXEN is synchronous to RMII_MHZ_50_CLK.
RMII_REFCLK	I	RMII reference clock. The reference clock is used to synchronize all RMII signals. RMII_REFCLK must be continuous and fixed at 50 MHz.
RMII_RXD[1-0]	I	Receive data. The receive data pins are a collection of 2 bits of data. RMII_RXD0 is the least-significant bit (LSB). The signals are synchronized by RMII_REFCLK and valid only when RM_CRS_DV is asserted and RMII_RXER is deasserted.
RMII_CRS_DV	I	Carrier sense/receive data valid. Multiplexed signal between carrier sense and receive data valid.
RMII_RXER	I	Receive error. The receive error signal is asserted to indicate that an error was detected in the received frame.
MDIO_CLK	O	Management data clock. The MDIO data clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MDIO pin.
MDIO_DATA	I/O	MDIO DATA. MDIO data pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication, PHY address, register address, and data bit cycles. The MDIO_DATA signal acts as an output for all but the data bit cycles at which time it is an input for read operations.

## 15.2.7 RGMII Signal Connections and Descriptions

Figure 15-5 shows a device with integrated CPSW and MDIO interfaced via a RGMII connection in a typical system.

**Figure 15-5. RGMII Interface Connections**

**Table 15-7. RGMII Interface Signal Descriptions**

Signal	Type	Description
RGMII_TD[3-0]	O	The transmit data pins are a collection of 4 bits of data. RGMII_RD0 is the least-significant bit (LSB). The signals are valid only when RGMII_TCTL is asserted.
RGMII_TCTL	O	Transmit Control/enable .The transmit enable signal indicates that the RGMII_TD pins are generating data for use by the PHY.
RGMII_TCLK	O	The transmit reference clock will be 125Mhz, 25Mhz, or 2.5Mhz depending on speed of operation.
RGMII_RD[3-0]	I	The receive data pins are a collection of 4 bits of data. RGMII_RD is the least-significant bit (LSB). The signals are valid only when RGMII_RCTL is asserted.

**Table 15-7. RGMII Interface Signal Descriptions (continued)**

Signal	Type	Description
RGMII_RCTL	I	The receive data valid/control signal indicates that the RGMII_RD pins are nibble data for use by the 3PSW.
RGMII_RCLK	I	The receive clock is a continuous clock that provides the timing reference for receive operations. The clock is generated by the PHY and is 2.5 MHz at 10 Mbps operation and 25 MHz at 100 Mbps operation, 125 MHz at 1000Mbps of operation.
MDIO_CLK	O	Management data clock. The MDIO data clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MDIO pin.
MDIO_DATA	I/O	MDIO DATA. MDIO data pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication, PHY address, register address, and data bit cycles. The MDIO_DATA pin acts as an output for all but the data bit cycles at which time it is an input for read operations.

## 15.3 Functional Description

The 3 port switch (3PSW) Ethernet Subsystem peripheral are compliant to the IEEE Std 802.3 Specification. The 3PSW Ethernet Subsystem contains two RGMII/RMII interfaces, one CPPI 3.0 interface, Interrupt Controller, MDIO and CPSW\_3G which contains two GMII interfaces as shown in [Figure 15-6](#).

The subsystem modules are discussed in detail in the following sections.

### 15.3.1 CPSW\_3G Subsystem

#### 15.3.1.1 Interrupt Pacing

The receive and transmit pulse interrupts can be paced. The receive threshold and miscellaneous interrupts are not paced. The Interrupt pacing feature limits the number of interrupts that occur during a given period of time. For heavily loaded systems in which interrupts can occur at a very high rate (e.g. 148,800 packets per second for Ethernet), the performance benefit is significant due to minimizing the overhead associated with servicing each interrupt. Interrupt pacing increases the CPU cache hit ratio by minimizing the number of times that large interrupt service routines are moved to and from the CPU instruction cache.

Each CPU receive and transmit pulse interrupt contains an interrupt pacing sub-block (six total). Each sub-block is disabled by default allowing the selected interrupt inputs to pass through unaffected. The interrupt pacing module counts the number of interrupts that occur over a 1ms interval of time. At the end of each 1ms interval, the current number of interrupts is compared with a target number of interrupts (specified by the associated maximum number of interrupts register).

Based on the results of the comparison, the length of time during which interrupts are blocked is dynamically adjusted. The 1ms interval is derived from a 4us pulse that is created from a prescale counter whose value is set in the int\_prescale value in the Int\_Ctrl register. The int\_prescale value should be written with the number of VBUSP\_CLK periods in 4us. The pacing timer determines the interval during which interrupts are blocked and decrements every 4us. It is reloaded each time a zero count is reached. The value loaded into the pacing timer is calculated by hardware every 1ms according to the following algorithm:

```
if (intr_count > 2*intr_max)
    pace_timer = 255;
else if (intr_count > 1.5*intr_max)
    pace_timer = last_pace_timer*2 + 1;
else if (intr_count > 1.0*intr_max)
    pace_timer = last_pace_timer + 1;
else if (intr_count > 0.5*intr_max)
    pace_timer = last_pace_timer - 1;
else if (intr_count != 0)
    pace_timer = last_pace_timer/2;
else
    pace_timer = 0;
```

If the rate of interrupt inputs is much less than the target interrupt rate specified in the associated maximum interrupts register, then the interrupt is not blocked. If the interrupt rate is greater than the target rate, the interrupt will be “paced” at the rate specified in the interrupt maximum register. The interrupt maximum register should be written with a value between 2 and 63 inclusive indicating the target number of interrupts per milli-second.

#### 15.3.1.2 Reset Isolation

Reset isolation for the Ethernet switch on Device is that the switch function of the ethernet IP remains active even in case of all device resets except for POR pin reset and ICEPICK COLD reset. Packet traffic to/from the 3PSW host will be flushed/dropped, but the ethernet switch will remain operational for all traffic between external devices on the switch even though the device is under-going a device reset. Pin mux configuration for ethernet related IO and reference clocks needed by the Ethernet switch IP to be active is controlled by a protected control module bit. If reset isolation is enabled, then only a POR pin or ICEPICK COLD reset event should fully reset the Ethernet switch IP including the actual switch and also the reference clocks and pin mux control specifically associated with the Ethernet IP.

#### 15.3.1.2.1 Modes of Operation

The device has two modes of operation concerning the reset of the 3PSW Ethernet switch.

The mode is controlled by the CPSW\_ISO\_CTRL bit in **RESET\_ISO** register of the **device control module**. This bit should default to '0'. Writes to the CPSW\_ISO\_CTRL bit must be supervisor mode writes.

Mode 1: CPSW\_ISO\_CTRL=0 (reset isolation disabled)

- This mode is selected when CPSW\_ISO\_CTRL bit of control module is = 0. This should be the default state of the bit after control module reset.
- Upon any device level resets, the entire CPSW\_3GSS\_R IP, L3/L4, control module (including all pin mux control and the CPSW\_ISO\_CTRL bit) is immediately reset.

Mode 2: CPSW\_ISO\_CTRL=1 (reset isolation enabled)

- This mode is selected when CPSW\_ISO\_CTRL bit of control module is = 1.
- Upon any device reset source other than POR pin or ICEPICK cold (so this includes SW global cold, any watchdog reset, warm RESETn pin, ICEPICK warm, SW global warm), the following should be true:
  - The CPSW\_3GSS\_R is put into 'isolate' mode and non-switch related portions of the IP are reset.
  - The 50-MHz and 125-MHz reference clocks to the 3PSW Ethernet Subsystem remains active throughout the entire reset condition.
  - The control for pin multiplexing for all of the signals should maintain their current configuration throughout the entire reset condition.
  - The reset isolated logic inside 3PSW Ethernet Subsystem IP which maintains the switch functionality
  -
- Upon any cold reset sources, the entire 3PSW Ethernet Subsystem, control module (including all pin mux control and the CPSW\_ISO\_CTRL bit itself) is reset.

### 15.3.1.3 Interrupts

The 3 Port Switch Ethernet Subsystem generates four interrupt events.

#### 15.3.1.3.1 Receive Packet Completion Pulse Interrupt (RX\_PULSE)

The RX\_PULSE interrupt is a paced pulse interrupt selected from the 3PSW RX\_PEND [7:0] interrupts. The receive DMA controller has eight channels with each channel having a corresponding (RX\_PEND[7:0]).

The following steps will enable the receive packet completion interrupt.

- Enable the required channel interrupts of the DMA engine by setting 1 to the appropriate bit in the RX\_INTMASK\_SET register.
- The receive completion interrupt(s) to be routed to RX\_PULSE is selected by setting one or more bits in the receive interrupt enable register Cn\_RX\_EN. The masked interrupt status can be read in the Receive Interrupt Masked Interrupt Status (Cn\_RX\_STAT) register.

When the 3PSW completes a packet reception, the subsystem issues an interrupt to the CPU by writing the packet's last buffer descriptor address to the appropriate channel queue's receive completion pointer located in the state RAM block. The interrupt is generated by the write when enabled by the interrupt mask, regardless of the value written.

Upon interrupt reception, the CPU processes one or more packets from the buffer chain and then acknowledges one or more interrupt(s) by writing the address of the last buffer descriptor processed to the queue's associated receive completion pointer (RXn\_CP) in the receive DMA state RAM.

Upon reception of an interrupt, software should perform the following:

- Read the RX\_STAT register to determine which channel(s) caused the interrupt.
- Process received packets for the interrupting channel(s).
- Write the 3PSW completion pointer(s) (RXn\_CP). The data written by the host (buffer descriptor address of the last processed buffer) is compared to the data in the register written by the subsystem (address of last buffer descriptor used by the subsystem). If the two values are not equal (which means that the 3PSW has received more packets than the CPU has processed), the receive packet completion interrupt signal remains asserted. If the two values are equal (which means that the host has processed all packets that the system has received), the pending interrupt is de-asserted. The value that the 3PSW is expecting is found by reading the receive channeln completion pointer register (RXn\_CP).
- Write the value 1h to the CPDMA\_EOI\_VECTOR register.

To disable the interrupt:

- The eight channel interrupts may be individually disabled by writing to 1 the appropriate bit in the RX\_INTMASK\_CLR
- The receive completion pulse interrupt could be disabled by clearing to 0 all the bits of the RX\_EN.

The software could still poll for the RX\_INTSTAT\_RAW and RX\_INTSTAT\_MASKED registers if the corresponding interrupts are enabled.

#### 15.3.1.3.2 Transmit Packet Completion Pulse Interrupt (TX\_PULSE)

The TX\_PULSE interrupt is a paced pulse interrupt selected from the 3PSW TX\_PEND [7:0] interrupts. The transmit DMA controller has eight channels with each channel having a corresponding (TX\_PEND[7:0]).

To enable the transmit packet completion interrupt:

- Enable the required channel interrupts of the DMA engine by setting 1 to the appropriate bit in the TX\_INTMASK\_SET register.
- The transmit completion interrupt(s) to be routed to TX\_PULSE is selected by setting one or more bits in the transmit interrupt enable register Cn\_TX\_EN. The masked interrupt status can be read in the Transmit Interrupt Masked Interrupt Status (Cn\_TX\_STAT) register.

When the 3PSW completes the transmission of a packet, the 3PSW subsystem issues an interrupt to the CPU by writing the packet's last buffer descriptor address to the appropriate channel queue's transmit completion pointer located in the state RAM block. The interrupt is generated by the write when enabled by the interrupt mask, regardless of the value written.

Upon receiving an interrupt, software should perform the following:

- Read the TX\_STAT register to determine which channel(s) caused the interrupt
- Process received packets for the interrupting channel(s).
- Write the 3PSW completion pointer(s) (TX<sub>n</sub>\_CP). The data written by the host (buffer descriptor address of the last processed buffer) is compared to the data in the register written by the 3PSW (address of last buffer descriptor used by the 3PSW). If the two values are not equal (which means that the 3PSW has transmitted more packets than the CPU has processed), the transmit packet completion interrupt signal remains asserted. If the two values are equal (which means that the host has processed all packets that the subsystem has transferred), the pending interrupt is cleared. The value that the 3PSW is expecting is found by reading the transmit channel<sub>n</sub> completion pointer register (TX<sub>n</sub>\_CP).
- Write the 2h to the CPDMA\_EOI\_VECTOR register.

To disable the interrupt:

- The eight channel interrupts may be individually disabled by writing to 1 the appropriate bit in the TX\_INTMASK\_CLR.
- The receive completion pulse interrupt could be disabled by clearing to 0 all the bits of the TX\_EN. The software could still poll for the TX\_INTSTAT\_RAW and TX\_INTSTAT\_MASKED registers if the corresponding interrupts are enabled.

#### 15.3.1.3.3 Receive Threshold Pulse Interrupt (RX\_THRESH\_PULSE)

The RX\_THRESH\_PULSE interrupt is an immediate (non-paced) pulse interrupt selected from the CPSW\_3G RX\_THRESH\_PEND[7:0] interrupts. The receive DMA controller has eight channels with each channel having a corresponding threshold pulse interrupt (RX\_THRESH\_PEND [7:0]).

To enable the receive threshold pulse Interrupt:

- Enable the required channel interrupts of the DMA engine by setting 1 to the appropriate bit in the RX\_INTMASK\_SET register.
- The receive threshold interrupt(s) to be routed to RX\_THRESH\_PULSE is selected by setting one or more bits in the receive threshold interrupt enable register RX\_THRESH\_EN. The masked interrupt status can be read in the Receive Threshold Masked Interrupt Status (C<sub>n</sub>\_RX\_THRESH\_STAT) register.

The RX\_THRESH\_PULSE is asserted when enabled when the channel's associated free buffer count RX\_FREEBUFFER<sub>n</sub> is less than or equal to the corresponding RX\_PENDTHRESH<sub>n</sub> register.

Upon receiving an interrupt, software should perform the following:

- Read the C<sub>n</sub>\_RX\_THRESH\_STAT bit address location to determine which channel(s) caused the interrupt.
- Process the received packets in order to add more buffers to any channel that is below the threshold value.
- Write the CPSW\_3G completion pointer(s).
- Write the value 0h to the CPDMA\_EOI\_VECTOR register.

The threshold pulse interrupt is an immediate interrupt intended to indicate that software should immediately process packets to preclude an overrun condition from occurring for the particular channels.

To disable the interrupt:

- The eight channel receive threshold interrupts may be individually disabled by writing to 1 the appropriate bit in the RX\_INTMASK\_CLR register.
- The receive threshold pulse interrupt could be disabled by clearing to Zero the corresponding bits of the RX\_THRESH\_EN. The software could still poll for the RX\_INTSTAT\_RAW and INTSTAT\_MASKED registers if the corresponding interrupts are enabled.

#### 15.3.1.3.4 Miscellaneous Pulse Interrupt (MISC\_PULSE)

The MISC\_PULSE interrupt is an immediate, non-paced, pulse interrupt selected from the miscellaneous interrupts (EVNT\_PEND, STAT\_PEND, HOST\_PEND, MDIO\_LINKINT, MDIO\_USERINT). The miscellaneous interrupt(s) is selected by setting one or more bits in the *Cn\_MISC\_EN*[4:0] register. The masked interrupt status can be read in the *Cn\_MISC\_STAT*[4:0] register. Upon reception of an interrupt, software should perform the following:

- Read the *Misc\_Stat*[4:0] register to determine which caused the interrupt.
- Process the interrupt.
- Write the appropriate value (0x3) to the *CPDMA\_EOI\_VECTOR* register.
- Write a 1 to the appropriate bit in the *MDIOLINKINTRAW* register.

This device does not support multiple link interrupts. Only *MDIO\_LINKINT*[0] and *MDIO\_USERINT*[0] are used. *MDIO\_LINKINT*[1] and *MDIO\_USERINT*[1] are not used.

##### 15.3.1.3.4.1 EVNT\_PEND (CPTS\_PEND) Interrupt

See [Section 15.3.7](#), *Common Platform Time Sync (CPTS)*, for information on the time sync event interrupt.

##### 15.3.1.3.4.2 Statistics Interrupt

The statistics level interrupt (STAT\_PEND) will be asserted if enabled when any statistics value is greater than or equal to 0x80000000. The statistics interrupt is cleared by writing to decrement all statistics values greater than 0x80000000 (such that their new values are less than 0x80000000). The statistics interrupt is enabled by setting to one the appropriate bit in the *INTMASK\_SET* register in the *CPDMA* submodule.

The statistics interrupt is disabled by writing one to the appropriate bit in the *INTMASK\_CLR* register. The raw and masked statistics interrupt status may be read by reading the *TX\_IntStat\_Raw* and *TX\_IntStat\_Masked* registers, respectively

##### 15.3.1.3.4.3 Host Error Interrupt

The host error interrupt (HOST\_PEND) will be asserted if enabled when a host error is detected during transmit or receive *CPDMA* transactions. The host error interrupt is intended for software debug, and is cleared by a warm reset or a system reset. The raw and masked statistics interrupt status can be read by reading the *TX\_INTSTAT\_RAW* and *TXINTSTAT\_MASKED* registers, respectively.

The following list shows the transmit host error conditions:

- SOP error
- OWNERSHIP bit not set in SOP buffer
- next buffer descriptor pointer without EOP set to 0
- buffer pointer set to 0
- buffer length set to 0
- packet length error

The receive host error conditions are show in the following list:

- Ownership bit not set in input buffer.
- Zero buffer pointer.
- Zero buffer Length on non-SOP descriptor.
- SOP buffer length not greater than offset.

The host error interrupt is disabled by clearing to 0 the appropriate bit in the *CPDMA\_INTMASK\_CLR* register.

#### 15.3.1.3.4.4 MDIO Interrupts

MDIO\_LINKINT is set if there is a change in the link state of the PHY corresponding to the address in the PHYADDRMON field of the MDIOUSERPHYSEL<sub>n</sub> register and the corresponding LINKINTENB bit is set. The MDIO\_LINKINT event is also captured in the MDIOLINKINTMASKED register. When the GO bit in the MDIOUSERACCESS<sub>n</sub> registers transitions from 1 to 0, indicating the completion of a user access, and the corresponding USERINTMASKSET bit in the MDIOUSERINTMASKSET register is set, the MDIO\_USERINT signal is asserted 1. The MDIO\_USERINT event is also captured in the MDIOUSERINTMASKED register.

To enable the miscellaneous pulse interrupt:

The miscellaneous interrupt(s) is selected by setting one or more bits in the miscellaneous interrupt enable register (MISC\_EN).

- The Statistics interrupt is enabled by setting to 1 the STAT\_INT\_MASK bit in the DMA\_INTMASK\_SET register.
- The HOST\_PEND is enabled by setting to 1 the HOST\_ERR\_INT\_MASK in the DMA\_INTMASK\_SET register.

Upon receiving of an interrupt, software should perform the following:

- Read the C<sub>n</sub>\_MISC\_STAT register to determine the source of the interrupt.
- Process the interrupt.
- Write the value 3h to the CPDMA\_EOI\_VECTOR register.

#### 15.3.1.4 Embedded Memories

Memory Type Description	Number of Instances
Single port 2560 by 64 RAM	3 (Packet FIFOs)
Single port 64-word by 1152-bit RAM	1 (ALE)
Single port 2048-word by 32-bit RAM	1 (CPPI)

### 15.3.2 CPSW\_3G

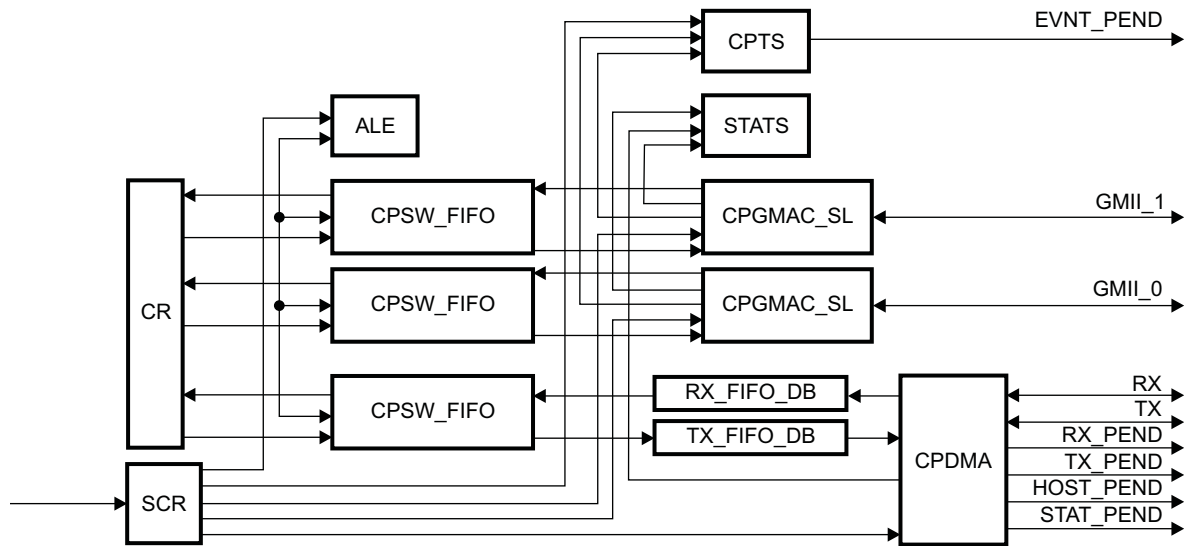

The CPSW\_3G GMII interfaces are compliant to the IEEE Std 802.3 Specification.

The CPSW\_3G contains two CPGMAC\_SL interfaces (ports 1 and 2), one CPPI 3.0 interface Host Port (port 0), Common Platform Time Sync (CPTS), ALE Engine and CPDMA.

The top level block diagram of CPSW\_3G is shown below:

Figure 15-6. CPSW\_3G Block Diagram

### 15.3.2.1 Media Independent Interface (GMII)

The CPSW\_3G contains two CPGMAC\_SL submodules. Each CPGMAC\_SL has a single GMII interface. The CPGMAC\_SL submodules are ports 1 and 2. For more details, see [Section 15.3.3, Ethernet Mac Sliver \(CPGMAC\\_SL\)](#).

### 15.3.2.2 IEEE 1588v2 Clock Synchronization Support

The CPSW\_3G supports IEEE 1588v2 clock synchronization. Ethernet GMII Transmit (egress) and receive (ingress) time sync operation are also supported.

#### 15.3.2.2.1 IEEE 1588v2 Receive Packet Operation

There are two CPSW\_3G receive time sync interfaces for each ethernet port. The first is the TS\_RX\_MII interface and the second is the TS\_RX\_DEC interface. Both interfaces are generated in the switch and are input to the CPTS module. There are register bits in the CPSW\_3G that control time sync operations in addition to the registers in the CPTS module. The pX\_ts\_rx\_en bit in the switch Px\_Ctrl register must be set for receive time sync operation to be enabled (TS\_RX\_MII).

The TS\_RX\_MII interface issues a record signal (pX\_ts\_rx\_mii\_rec) along with a handle (pX\_ts\_rx\_mii\_hndl[3:0]) to the CPTS controller for each packet that is received. The record signal is a single clock pulse indicating that a receive packet has been detected at the associated port MII interface.

The handle value is incremented with each packet and rolls over to zero after 15. There are 16 possible handle values so there can be a maximum of 16 packets "in flight" from the TS\_RX\_MII to the TS\_RX\_DEC block (through the CPGMAC\_SL) at any given time. A handle value is reused (not incremented) for any received packet that is shorter than about 31 octets (including preamble). Handle reuse on short packets prevents any possible overrun condition if multiple fragments are consecutively received.

The TS\_RX\_MII logic is in the receive wireside clock domain. There is no decode logic in the TS\_RX\_MII to determine if the packet is a time sync event packet or not. Each received packet generates a record signal and new handle. The handle is sent to the CPTS controller with the record pulse and the handle is also sent to the TS\_RX\_DEC block along with the packet. The packet decode is performed in the TS\_RX\_DEC block. The decode function is separated from the record function because in some systems the incoming packet can be encrypted. The decode function would be after packet decryption in those systems.

The TS\_RX\_DEC function decodes each received packet and determines if the packet meets the time sync event packet criteria. If the packet is determined to be a time sync event packet, then the time sync event packet is signaled to the CPTS controller via the TS\_RX\_DEC interface (pX\_ts\_rx\_dec\_evt, pX\_ts\_rx\_dec\_hdl[3:0], pX\_ts\_rx\_dec\_msg\_type, pX\_ts\_rx\_dec\_seq\_id). The event signal is a single clock pulse indicating that the packet matched the time sync event packet criteria and that the associated packet handle, message type, and sequence ID are valid. No indication is given for received packets that do not meet the time sync event criteria. The 16-bit sequence ID is found in the time sync event packet at the sequence ID offset into the PTP message header (pX\_ts\_seq\_id\_offset). A packet is determined to be a receive event packet under the following conditions:

#### 15.3.2.2.1.1 Annex F

1. Receive time sync is enabled (pX\_ts\_rx\_en is set in the switch Px\_Ctrl register).
2. One of the following sequences is true:
 

Where the first packet ltype matches:

  - ts\_ltype1 and pX\_ts\_ltype1\_en is set
  - ts\_ltype2 and pX\_ts\_ltype2\_en is set
  - vlan\_ltype1 and pX\_vlan\_ltype1\_en is set and the second packet ltype matches ts\_ltype1 and pX\_ts\_ltype1\_en is set
  - vlan\_ltype1 and pX\_vlan\_ltype1\_en is set and the second packet ltype matches ts\_ltype2 and pX\_ts\_ltype2\_en is set
  - vlan\_ltype2 and pX\_vlan\_ltype2\_en is set and the second packet ltype matches ts\_ltype1 and pX\_ts\_ltype1\_en is set
  - vlan\_ltype2 and pX\_vlan\_ltype2\_en is set and the second packet ltype matches ts\_ltype2 and pX\_ts\_ltype2\_en is set
  - vlan\_ltype1 and pX\_vlan\_ltype1\_en is set and the second packet ltype matches vlan\_ltype2 and pX\_vlan\_ltype2\_en is set and the third packet ltype matches ts\_ltype1 and pX\_ts\_ltype1\_en is set
  - vlan\_ltype1 and pX\_vlan\_ltype1\_en is set and the second packet ltype matches vlan\_ltype2 and pX\_vlan\_ltype2\_en is set and the third packet ltype matches ts\_ltype2 and pX\_ts\_ltype2\_en is set
3. The PTP message begins in the byte after the LTYPE.
4. The packet message type is enabled in the pX\_ts\_msg\_type\_en field in the Px\_TS\_SEQ\_MTYPE register.
5. The packet was received without error (not long/short/mac\_ctl/crc/code/align).
6. The ALE determined that the packet is to be sent only to the host (port 0).

#### 15.3.2.2.1.2 Annex D

1. Receive time sync is enabled (pX\_ts\_rx\_en is set in the switch Px\_Ctrl register).
2. One of the following sequences is true:
 

Where the first packet ltype matches:

  - 0x0800 and pX\_ts\_annex\_d\_en is set
  - vlan\_ltype1 and pX\_vlan\_ltype1\_en is set and the second packet ltype matches 0x0800 and pX\_ts\_annex\_d\_en is set
  - vlan\_ltype2 and pX\_vlan\_ltype2\_en is set and the second packet ltype matches 0x0800 and pX\_ts\_annex\_d\_en is set
  - vlan\_ltype1 and pX\_vlan\_ltype1\_en is set and the second packet ltype matches vlan\_ltype2 and pX\_vlan\_ltype2\_en is set and the third packet ltype matches 0x0800 and pX\_ts\_annex\_d\_en is set
3. Byte 14 (the byte after the LTYPE) contains 0x45 (IP\_VERSION).
 

**Note:** The byte numbering assumes that there are no vlans. The byte number is intended to show the relative order of the bytes.
4. Byte 22 contains 0x00 if the pX\_ts\_ttl\_nonzero bit in the switch Px\_Ctrl register is zero or byte 22 contains any value if pX\_ts\_ttl\_nonzero is set. Byte 22 is the time to live field.

5. Byte 23 contains 0x11 (UDP Fixed).
6. Byte 30 contains decimal 224 (0xe0).
7. Byte 31 contains 0x00.
8. Byte 32 contains 0x01.
9. Byte 33 contains one of the following:
  - Decimal 129 and the pX\_ts\_129 bit in the switch Px\_Ctrl register is set
  - Decimal 130 and the pX\_ts\_130 bit in the switch Px\_Ctrl register is set
  - Decimal 131 and the pX\_ts\_131 bit in the switch Px\_Ctrl register is set
  - Decimal 129 and the pX\_ts\_132 bit in the switch Px\_Ctrl register is set
10. Bytes 36 and 37 contain one of the following:
  - Decimal 0x01 and 0x3f respectively and the pX\_ts\_319 bit in the switch Px\_Ctrl register is set.
  - Decimal 0x01 and 0x40 respectively and the pX\_ts\_320 bit in the switch Px\_Ctrl register is set.
11. The PTP message begins in byte 42.
12. The packet message type is enabled in the pX\_ts\_msg\_type\_en field in Px\_Ctrl.
13. The packet was received without error (not long/short/mac\_ctl/crc/code/align).
14. The ALE determined that the packet is to be sent only to the host (port 0).

#### 15.3.2.2.2 IEEE 1588v2 Transmit Packet Operation

There are two CPSW\_3G transmit time sync interfaces for each ethernet port. The first is the TS\_TX\_DEC interface and the second is the TS\_TX\_MII interface. Both interfaces are generated in the switch and are input to the CPTS module. The pX\_ts\_tx\_en bit in the Px\_Ctrl register must be set for transmit time sync operation to be enabled.

The TS\_TX\_DEC function decodes each packet to be transmitted and determines if the packet meets the time sync event packet criteria. If the packet is determined to be a time sync event packet, then the time sync event is signaled to the CPTS controller via the TS\_TX\_DEC interface (pX\_ts\_tx\_dec\_evnt, pX\_ts\_tx\_dec\_hdl[3:0], pX\_ts\_tx\_dec\_msg\_type, pX\_ts\_tx\_dec\_seq\_id). The event signal is a single clock pulse indicating that the packet matched the time sync event packet criteria and that the associated packet handle, message type, and sequence ID are valid.

The 16-bit sequence ID is found in the time sync event packet at the sequence ID offset into the message header (pX\_ts\_seq\_id\_offset). No indication is given for transmit packets that do not meet the time sync event criteria. The time sync event packet handle is also passed along with the packet to the TS\_TX\_MII with an indication that the packet is a time sync event packet. Unlike receive, only transmit event packets increment the handle value. The decode function is separated from the record function because some systems may encrypt the packet. The encryption is after the decode function on transmit (egress). A packet is determined to be a transmit event packet if the following is met:

##### 15.3.2.2.2.1 Annex F

1. Transmit time sync is enabled (pX\_ts\_tx\_en is set in the switch Px\_Ctrl register).
2. One of the following sequences is true:
  - The first packet ltype matches ts\_ltype1 and pX\_ts\_ltype1\_en is set
  - The first packet ltype matches ts\_ltype2 and pX\_ts\_ltype2\_en is set
  - The first packet ltype matches vlan\_ltype1 and pX\_vlan\_ltype1\_en is set and the second packet matches ts\_ltype1 and pX\_ts\_ltype1\_en is set
  - The first packet ltype matches vlan\_ltype1 and pX\_vlan\_ltype1\_en is set and the second packet ltype matches ts\_ltype2 and pX\_ts\_ltype2\_en is set
  - The first packet ltype matches vlan\_ltype2 and pX\_vlan\_ltype2\_en is set and the second packet ltype matches ts\_ltype1 and pX\_ts\_ltype1\_en is set
  - The first packet ltype matches vlan\_ltype2 and pX\_vlan\_ltype2\_en is set and the second packet ltype matches ts\_ltype2 and pX\_ts\_ltype2\_en is set

- The first packet ltype matches vlan\_ltype1 and pX\_vlan\_ltype1\_en is set and the second packet ltype matches vlan\_ltype2 and pX\_vlan\_ltype2\_en is set and the third packet ltype matches ts\_ltype1 and pX\_ts\_ltype1\_en is set
  - The first packet ltype matches vlan\_ltype1 and pX\_vlan\_ltype1\_en is set and the second packet ltype matches vlan\_ltype2 and pX\_vlan\_ltype2\_en is set and the third packet ltype matches ts\_ltype2 and pX\_ts\_ltype2\_en is set
3. The packet message type is enabled in pX\_ts\_msg\_type\_en.
  4. The packet was received by the host (port 0).

### 15.3.2.2.2 Annex D

1. Transmit time sync is enabled (pX\_ts\_tx\_en is set in the switch Px\_Ctrl register).
2. One of the following sequences is true:
  - The first packet ltype matches 0x0800 and pX\_ts\_annex\_d\_en is set
  - The first packet ltype matches vlan\_ltype1 and pX\_vlan\_ltype1\_en is set and the second packet ltype matches 0x0800 and pX\_ts\_annex\_d\_en is set
  - The first packet ltype matches vlan\_ltype2 and pX\_vlan\_ltype2\_en is set and the second packet ltype matches 0x0800 and pX\_ts\_annex\_d\_en is set
  - The first packet ltype matches vlan\_ltype1 and pX\_vlan\_ltype1\_en is set and the second packet ltype matches vlan\_ltype2 and pX\_vlan\_ltype2\_en is set and the third packet ltype matches 0x0800 and pX\_ts\_annex\_d\_en is set
3. Byte 14 (the byte after the LTYPE) contains 0x45 (IP\_VERSION).
 

**Note:** The byte numbering assumes that there are no vlans. The byte number is intended to show the relative order of the bytes. If VLAN(s) are present, then the byte numbers push down.
4. Byte 22 contains 0x00 if the pX\_ts\_ttl\_nonzero bit in the switch Px\_Ctrl register is zero or byte 22 contains any value if pX\_ts\_ttl\_nonzero is set. Byte 22 is the time to live field.
5. Byte 23 contains 0x11 (UDP Fixed).
6. Byte 30 contains decimal 224 (0xe0)
7. Byte 31 contains 0x00
8. Byte 32 contains 0x01
9. Byte 33 contains one of the following:
  - Decimal 129 and the pX\_ts\_129 bit in the switch Px\_Ctrl register is set
  - Decimal 130 and the pX\_ts\_130 bit in the switch Px\_Ctrl register is set
  - Decimal 131 and the pX\_ts\_131 bit in the switch Px\_Ctrl register is set
  - Decimal 132 and the pX\_ts\_132 bit in the switch Px\_Ctrl register is set
10. Bytes 36 and 37 contain either of the following:
  - Decimal 1 (hex 0x01) and decimal 63 (hex 0x3f) respectively and the pX\_ts\_319 bit in the switch Px\_Ctrl register is set
  - Decimal 1 (hex 0x01) and decimal 64 (hex 0x40) respectively and the pX\_ts\_320 bit in the switch Px\_Ctrl register is set
11. The PTP message begins in byte 42 (this is offset 0).
12. The packet message type is enabled in pX\_ts\_msg\_type\_en.
13. The packet was received by the host (port 0).

The TS\_TX\_MII interface issues a single clock record signal (pX\_ts\_tx\_mii\_rec) at the beginning of each transmitted packet. If the packet is a time sync event packet then a single clock event signal (pX\_ts\_tx\_mii\_evnt) along with a handle (pX\_ts\_rx\_mii\_hdl[2:0]) will be issued before the next record signal for the next packet. The event signal will not be issued for packets that did not meet the time sync event criteria in the TS\_TX\_DEC function. If consecutive record indications occur without an interleaving event indication, then the packet associated with the first record was not a time sync event packet.

The record signal is a single clock pulse indicating that a transmit packet egress has been detected at the associated port MII interface. The handle value is incremented with each time sync event packet and rolls over to zero after 7. There are 8 possible handle values so there can be a maximum of eight time sync event packets “in flight” from the TS\_TX\_DEC to the TS\_TX\_MII block at any given time. The handle value increments only on time sync event packets. The TS\_TX\_MII logic is in the transmit wireside clock domain.

### 15.3.2.3 Device Level Ring (DLR) Support

Device Level Ring (DLR) support is enabled by setting the `dlr_en` bit in the `CPSW_Ctrl` register. When enabled, incoming received DLR packets are detected and sent to queue 3 (highest priority) of the egress port(s). If the host port is the egress port for a DLR packet then the packet is sent on the CPDMA Rx channel selected by the `p0_dlr_cpdma_ch` field in the `P0_Ctrl` register. The supervisor node MAC address feature is supported with the `dlr_unicast` bit in the unicast address table entry.

When set, the `dlr_unicast` bit causes a packet with the matching destination address to be flooded to the `vlan_member_list` minus the receive port and minus the host port (the `port_number` field in the unicast address table entry is a don't care). Matching `dlr_unicast` packets are flooded regardless of whether the packet is a DLR packet or not. The `en_p0_uni_flood` bit in the `ALE_Ctrl` register has no effect on DLR unicast packets. Packets are determined to be DLR packets, as shown:

1. DLR is enabled (`dlr_en` is set in the switch `CPSW_Ctrl` register).
2. One of the following sequences is true:
  - The first packet ltype matches `vlan_ltype1` and `pX_vlan_ltype1_en` is set and the second packet ltype matches `dlr_ltype`.
  - The first packet ltype matches `vlan_ltype2` and `pX_vlan_ltype2_en` is set and the second packet ltype matches `dlr_ltype`.
  - The first packet ltype matches `vlan_ltype1` and `pX_vlan_ltype1_en` is set and the second packet ltype matches `vlan_ltype2` and `pX_vlan_ltype2_en` is set and the third packet ltype matches `dlr_ltype`.

### 15.3.2.4 CPDMA RX and TX Interfaces

The CPDMA submodule is a CPPI 3.0 compliant packet DMA transfer controller. The CPPI 3.0 interface is port 0.

After reset, initialization, and configuration the host may initiate transmit operations. Transmit operations are initiated by host writes to the appropriate transmit channel head descriptor pointer contained in the STATERAM block. The transmit DMA controller then fetches the first packet in the packet chain from memory in accordance with CPPI 3.0 protocol. The DMA controller writes the packet into the external transmit FIFO in 64-byte bursts (maximum).

Receive operations are initiated by host writes to the appropriate receive channel head descriptor pointer after host initialization and configuration. The receive DMA controller writes the receive packet data to external memory in accordance with CPPI 3.0 protocol. See the CPPI Buffer Descriptors section for detailed description of Buffer Descriptors

### 15.3.2.4.1 CPPI Buffer Descriptors

The buffer descriptor is a central part of the 3PSW Ethernet Subsystem and is how the application software describes Ethernet packets to be sent and empty buffers to be filled with incoming packet data.

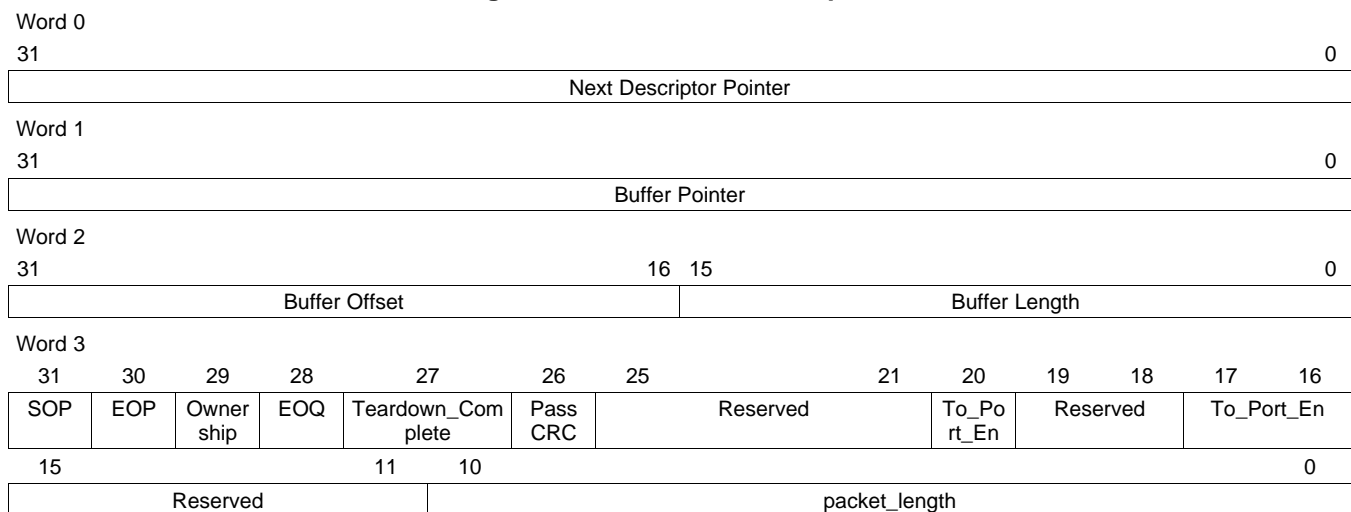

Host Software sends and receives network frames via the CPPI 3.0 compliant host interface. The host interface includes module registers and host memory data structures. The host memory data structures are buffer descriptors and data buffers. Buffer descriptors are data structures that contain information about a single data buffer. Buffer descriptors may be linked together to describe frames or queues of frames for transmission of data and free buffer queues available for received data.

Note: The 8k bytes of Ethernet Subsystem CPPI RAM begin at address 0x4a102000 and end at 0x4a103FFF from the 3PSW perspective. The buffer descriptors programmed to access the CPPI RAM memory should use the address range from 0x4a102000.

#### 15.3.2.4.1.1 TX Buffer Descriptors

A TX buffer descriptor is a contiguous block of four 32-bit data words aligned on a 32-bit word boundary.

**Figure 15-7. Tx Buffer Descriptor Format**

#### 15.3.2.4.1.1.1 CPPI Tx Data Word – 0

##### Next Descriptor Pointer

The next descriptor pointer points to the 32-bit word aligned memory address of the next buffer descriptor in the transmit queue. This pointer is used to create a linked list of buffer descriptors. If the value of this pointer is zero, then the current buffer is the last buffer in the queue. The software application must set this value prior to adding the descriptor to the active transmit list. This pointer is not altered by the EMAC. The value of pNext should never be altered once the descriptor is in an active transmit queue, unless its current value is NULL.

If the pNext pointer is initially NULL, and more packets need to be queued for transmit, the software application may alter this pointer to point to a newly appended descriptor. The EMAC will use the new pointer value and proceed to the next descriptor unless the pNext value has already been read. In this latter case, the transmitter will halt on the transmit channel in question, and the software application may restart it at that time. The software can detect this case by checking for an end of queue (EOQ) condition flag on the updated packet descriptor when it is returned by the EMAC.

#### 15.3.2.4.1.1.2 CPPI Tx Data Word – 1

##### Buffer Pointer

The byte aligned memory address of the buffer associated with the buffer descriptor. The host sets the **buffer\_pointer**. The software application must set this value prior to adding the descriptor to the active transmit list. This pointer is not altered by the EMAC.

#### 15.3.2.4.1.1.3 CPPI Tx Data Word – 2

##### Buffer \_Offset

Buffer Offset – Indicates how many unused bytes are at the start of the buffer. A value of 0x0000 indicates that no unused bytes are at the start of the buffer and that valid data begins on the first byte of the buffer. A value of 0x000F (decimal 15) indicates that the first 15 bytes of the buffer are to be ignored by the port and that valid buffer data starts on byte 16 of the buffer. The host sets the buffer\_offset value (which may be zero to the buffer length minus 1). Valid only on sop.

##### Buffer \_Length

Buffer Length – Indicates how many valid data bytes are in the buffer. Unused or protocol specific bytes at the beginning of the buffer are not counted in the Buffer Length field. The host sets the buffer\_length. The buffer\_length must be greater than zero.

#### 15.3.2.4.1.1.4 CPPI Tx Data Word – 3

##### Start of Packet (SOP) Flag

When set, this flag indicates that the descriptor points to a packet buffer that is the start of a new packet. In the case of a single fragment packet, both the SOP and end of packet (EOP) flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet sets the EOP flag. This bit is set by the software application and is not altered by the EMAC.

0 - Not start of packet buffer

1 - Start of packet buffer

##### End of Packet (EOP) Flag

When set, this flag indicates that the descriptor points to a packet buffer that is last for a given packet. In the case of a single fragment packet, both the start of packet (SOP) and EOP flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet sets the EOP flag. This bit is set by the software application and is not altered by the EMAC.

0 - Not end of packet buffer.

1 - End of packet buffer.

##### Ownership

When set this flag indicates that all the descriptors for the given packet (from SOP to EOP) are currently owned by the EMAC. This flag is set by the software application on the SOP packet descriptor before adding the descriptor to the transmit descriptor queue. For a single fragment packet, the SOP, EOP, and OWNER flags are all set. The OWNER flag is cleared by the EMAC once it is finished with all the descriptors for the given packet. Note that this flag is valid on SOP descriptors only.

0 - The packet is owned by the host

1 - The packet is owned by the port

##### EOQ

When set, this flag indicates that the descriptor in question was the last descriptor in the transmit queue for a given transmit channel, and that the transmitter has halted. This flag is initially cleared by the software application prior to adding the descriptor to the transmit queue. This bit is set by the EMAC when the EMAC identifies that a descriptor is the last for a given packet (the EOP flag is set), and there are no more descriptors in the transmit list (next descriptor pointer is NULL).

The software application can use this bit to detect when the EMAC transmitter for the corresponding channel has halted. This is useful when the application appends additional packet descriptors to a transmit queue list that is already owned by the EMAC. Note that this flag is valid on EOP descriptors only.

0 - The Tx queue has more packets to transfer.

- 1 - The Descriptor buffer is the last buffer in the last packet in the queue.

#### **teardown\_Complete**

This flag is used when a transmit queue is being torn down, or aborted, instead of allowing it to be transmitted. This would happen under device driver reset or shutdown conditions. The EMAC sets this bit in the SOP descriptor of each packet as it is aborted from transmission. Note that this flag is valid on SOP descriptors only. Also note that only the first packet in an unsent list has the TDOWNCMPLT flag set. Subsequent descriptors are not processed by the EMAC.

- 0 - The port has not completed the teardown process.
- 1 - The port has completed the commanded teardown process.

#### **pass\_crc**

This flag is set by the software application in the SOP packet descriptor before it adds the descriptor to the transmit queue. Setting this bit indicates to the EMAC that the 4 byte Ethernet CRC is already present in the packet data, and that the EMAC should not generate its own version of the CRC. When the CRC flag is cleared, the EMAC generates and appends the 4-byte CRC. The buffer length and packet length fields do not include the CRC bytes. When the CRC flag is set, the 4-byte CRC is supplied by the software application and is already appended to the end of the packet data. The buffer length and packet length fields include the CRC bytes, as they are part of the valid packet data. Note that this flag is valid on SOP descriptors only.

- 0 – The CRC is not included with the packet data and packet length.
- 1 – The CRC is included with the packet data and packet length.

#### **to\_port**

To Port – Port number to send the directed packet to. This field is set by the host. This field is valid on SOP. Directed packets go to the directed port, but an ALE lookup is performed to determine untagged egress in VLAN\_AWARE mode.

- 1 – Send the packet to port 1 if to\_port\_en is asserted.
- 2 – Send the packet to port 2 if to\_port\_en is asserted.

#### **To\_port\_enable**

To Port Enable – Indicates when set that the packet is a directed packet to be sent to the to\_port field port number. This field is set by the host. The packet is sent to one port only (index not mask). This bit is valid on SOP.

- 0 – not a directed packet
- 1 – directed packet

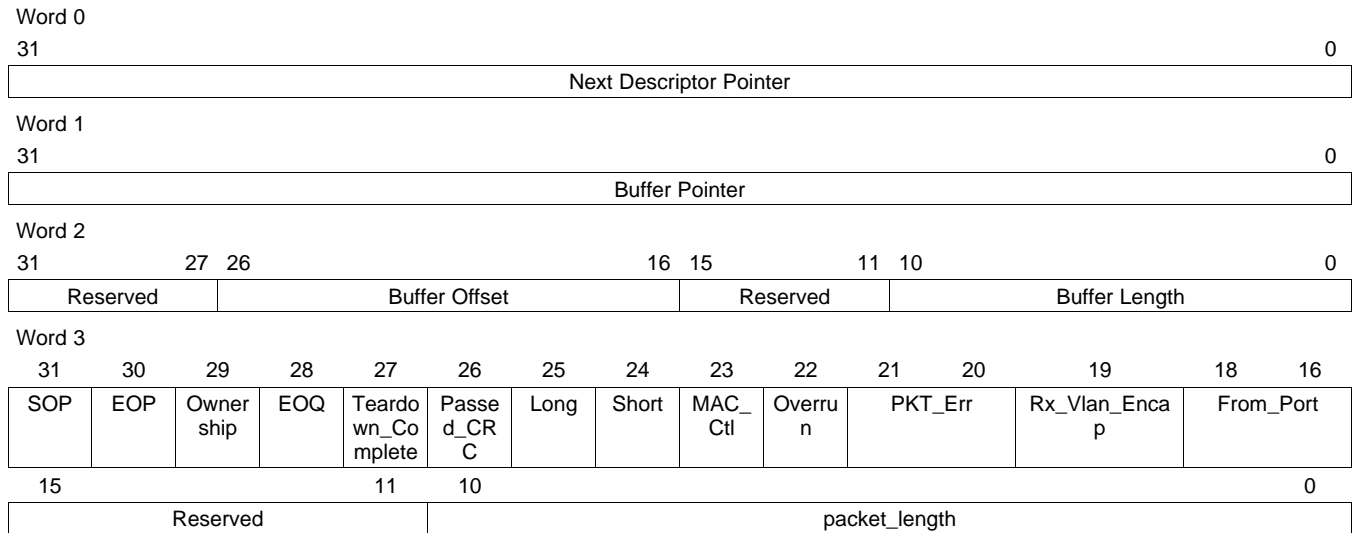

#### **Packet Length**

Specifies the number of bytes in the entire packet. Offset bytes are not included. The sum of the buffer\_length fields should equal the packet\_length. Valid only on SOP. The packet length must be greater than zero. The packet data will be truncated to the packet length if the packet length is shorter than the sum of the packet buffer descriptor buffer lengths. A host error occurs if the packet length is greater than the sum of the packet buffer descriptor buffer lengths

### **15.3.2.4.1.2 RX Buffer Descriptors**

An RX buffer descriptor is a contiguous block of four 32-bit data words aligned on a 32-bit word boundary.

**Figure 15-8. Rx Buffer Descriptor Format**

#### 15.3.2.4.1.2.1 CPPI Rx Data Word – 0

##### next\_descriptor\_pointer

The 32-bit word aligned memory address of the next buffer descriptor in the RX queue. This is the mechanism used to reference the next buffer descriptor from the current buffer descriptor. If the value of this pointer is zero then the current buffer is the last buffer in the queue. The host sets the **next\_descriptor\_pointer**.

#### 15.3.2.4.1.2.2 CPPI Rx Data Word – 1

##### buffer\_pointer

The byte aligned memory address of the buffer associated with the buffer descriptor. The host sets the **buffer\_pointer**.

#### 15.3.2.4.1.2.3 CPPI Rx Data Word – 2

##### Buffer \_Offset

Buffer Offset – Indicates how many unused bytes are at the start of the buffer. A value of 0x0000 indicates that there are no unused bytes at the start of the buffer and that valid data begins on the first byte of the buffer. A value of 0x000F (decimal 15) indicates that the first 15 bytes of the buffer are to be ignored by the port and that valid buffer data starts on byte 16 of the buffer. The port writes the **buffer\_offset** with the value from the **rx\_buffer\_offset** register value. The host initializes the **buffer\_offset** to zero for free buffers. The **buffer\_length** must be greater than the **rx\_buffer\_offset** value. The buffer offset is valid only on **sop**.

##### Buffer \_Length

Buffer Length – Indicates how many valid data bytes are in the buffer. Unused or protocol specific bytes at the beginning of the buffer are not counted in the Buffer Length field. The host initializes the **buffer\_length**, but the port may overwrite the host initiated value with the actual buffer length value on SOP and/or EOP buffer descriptors. SOP buffer length values will be overwritten if the packet size is less than the size of the buffer or if the offset is nonzero. EOP buffer length values will be overwritten if the entire buffer is not filled up with data. The **buffer\_length** must be greater than zero.

**15.3.2.4.1.2.4 CPPI Rx Data Word – 3****Start of Packet (SOP) Flag**

When set, this flag indicates that the descriptor points to a packet buffer that is the start of a new packet. In the case of a single fragment packet, both the SOP and end of packet (EOP) flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet has the EOP flag set. This flag is initially cleared by the software application before adding the descriptor to the receive queue. This bit is set by the EMAC on SOP descriptors.

**End of Packet (EOP) Flag**

When set, this flag indicates that the descriptor points to a packet buffer that is last for a given packet. In the case of a single fragment packet, both the start of packet (SOP) and EOP flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet has the EOP flag set. This flag is initially cleared by the software application before adding the descriptor to the receive queue. This bit is set by the EMAC on EOP descriptors.

**Ownership (OWNER) Flag**

When set, this flag indicates that the descriptor is currently owned by the EMAC. This flag is set by the software application before adding the descriptor to the receive descriptor queue. This flag is cleared by the EMAC once it is finished with a given set of descriptors, associated with a received packet. The flag is updated by the EMAC on SOP descriptor only. So when the application identifies that the OWNER flag is cleared on an SOP descriptor, it may assume that all descriptors up to and including the first with the EOP flag set have been released by the EMAC. (Note that in the case of single buffer packets, the same descriptor will have both the SOP and EOP flags set.)

**End of Queue (EOQ) Flag**

When set, this flag indicates that the descriptor in question was the last descriptor in the receive queue for a given receive channel, and that the corresponding receiver channel has halted. This flag is initially cleared by the software application prior to adding the descriptor to the receive queue. This bit is set by the EMAC when the EMAC identifies that a descriptor is the last for a given packet received (also sets the EOP flag), and there are no more descriptors in the receive list (next descriptor pointer is NULL). The software application can use this bit to detect when the EMAC receiver for the corresponding channel has halted. This is useful when the application appends additional free buffer descriptors to an active receive queue. Note that this flag is valid on EOP descriptors only.

**Tardown Complete (TDOWNCMPLT) Flag**

This flag is used when a receive queue is being torn down, or aborted, instead of being filled with received data. This would happen under device driver reset or shutdown conditions. The EMAC sets this bit in the descriptor of the first free buffer when the tear down occurs. No additional queue processing is performed.

**Pass CRC (PASSCRC) Flag**

This flag is set by the EMAC in the SOP buffer descriptor if the received packet includes the 4-byte CRC. This flag should be cleared by the software application before submitting the descriptor to the receive queue.

**Long (Jabber) Flag**

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is a jabber frame and was not discarded because the RX\_CEF\_EN bit was set in the MACCTRL. Jabber frames are frames that exceed the RXMAXLEN in length, and have CRC, code, or alignment errors.

**Short (Fragment) Flag**

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is only a packet fragment and was not discarded because the RX\_CSF\_EN bit was set in the MACCTRL.

**Control Flag**

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is an EMAC control frame and was not discarded because the RX\_CMF\_EN bit was set in the MACCTRL.

**Overrun Flag**

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet was aborted due to a receive overrun.

#### **Pkt\_error Flag**

Packet Contained Error on Ingress –

00 – no error

01 – CRC error on ingress

10 – Code error on ingress

11 – Align error on ingress

#### **rx\_vlan\_encap**

VLAN Encapsulated Packet – Indicates when set that the packet data contains a 32-bit VLAN header word that is included in the packet byte count. This field is set by the port to be the value of the CPSW control register rx\_vlan\_encap bit

#### **from\_port**

From Port – Indicates the port number that the packet was received on (ingress to the switch).

#### **Packet Length**

Specifies the number of bytes in the entire packet. The packet length is reduced to 12-bits. Offset bytes are not included. The sum of the buffer\_length fields should equal the packet\_length. Valid only on SOP.

### **15.3.2.4.2 Receive DMA Interface**

The Receive DMA is an eight channel CPPI 3.0 compliant interface. Each channel has a single queue for frame reception.

#### **15.3.2.4.2.1 Receive DMA Host Configuration**

To configure the Rx DMA for operation the host must perform the following:

- Initialize the receive addresses.
- Initialize the Rx\_HDP Registers to zero.
- Enable the desired receive interrupts in the IntMask register.
- Write the rx\_buffer\_offset register value.
- Setup the receive channel(s) buffer descriptors in host memory as required by CPPI 3.0.
- Enable the RX DMA controller by setting the rx\_en bit in the Rx\_Ctrl register.

#### **15.3.2.4.2.2 Receive Channel Teardown**

The host commands a receive channel teardown by writing the channel number to the Rx\_Teardown register. When a teardown command is issued to an enabled receive channel the following will occur:

- Any current frame in reception will complete normally.
- The teardown\_complete bit will be set in the next buffer descriptor in the chain

if there is one.

- The channel head descriptor pointer will be cleared to zero
- A receive interrupt for the channel will be issued to the host.
- The host should acknowledge a teardown interrupt with a 0xffffffff acknowledge value.

Channel teardown may be commanded on any channel at any time. The host is informed of the teardown completion by the set teardown complete buffer descriptor bit. The port does not clear any channel enables due to a teardown command. A teardown command to an inactive channel issues an interrupt that software should acknowledge with a 0xffffffff acknowledge value (note that there is no buffer descriptor in this case). Software may read the interrupt acknowledge location to determine if the interrupt was due to a commanded teardown. The read value will be 0xffffffff if the interrupt was due to a teardown command.

#### 15.3.2.4.3 Transmit DMA Interface

The Transmit DMA is an eight channel CPPI 3.0 compliant interface. Priority between the eight queues may be either fixed or round robin as selected by tx\_ptype in the DMA\_Ctrl register. If the priority type is fixed, then channel 7 has the highest priority and channel 0 has the lowest priority. Round robin priority proceeds from channel 0 to channel 7. Packet Data transfers occur on the TX\_VBUSP interface in 64-byte maximum burst transfers

##### 15.3.2.4.3.1 Transmit DMA Host Configuration

To configure the TX DMA for operation the host must do the following:

- Initialize the Tx\_HDP registers to a zero value.
- Enable the desired transmit interrupts in the IntMask register.
- Setup the transmit channel(s) buffer descriptors in host memory as defined in CPPI 3.0.
- Configure and enable the transmit operation as desired in the Tx\_Ctrl register.
- Write the appropriate Tx\_HDP registers with the appropriate values to start transmit operations.

##### 15.3.2.4.3.2 Transmit Channel Teardown

The host commands a transmit channel teardown by writing the channel number to the Tx\_Teardown register. When a teardown command is issued to an enabled transmit channel the following will occur:

- Any frame currently in transmission will complete normally
- The teardown complete bit will be set in the next sop buffer descriptor (if there is one).
- The channel head descriptor pointer will be set to zero.
- An interrupt will be issued to inform the host of the channel teardown.
- The host should acknowledge a teardown interrupt with a 0xffffffff acknowledge value

Channel teardown may be commanded on any channel at any time. The host is informed of the teardown completion by the set teardown complete buffer descriptor bit. The port does not clear any channel enables due to a teardown command. A teardown command to an inactive channel issues an interrupt that software should acknowledge with a 0xffffffff acknowledge value (note that there is no buffer descriptor in this case). Software may read the interrupt acknowledge location to determine if the interrupt was due to a commanded teardown. The read value will be 0xffffffff if the interrupt was due to a teardown command.

##### 15.3.2.4.4 Transmit Rate Limiting

Transmit operations can be configured to rate limit the transmit data for each transmit priority. Rate limiting is enabled for a channel when the tx\_rlim[7:0] bit associated with that channel is set in the DMA\_Ctrl register. Rate limited channels must be the highest priority channels. For example, if two rate limited channels are required then tx\_rlim[7:0] should be set to 11000000 with the msb corresponding to channel 7.

When any channels are configured to be rate-limiting, the priority type must be fixed for transmit. Round-robin priority type is not allowed when rate-limiting. Each of the eight transmit priorities has an associated register to control the rate at which the priority is allowed to send data (Tx\_Pri(7..0)\_Rate) when the channel is rate-limiting. Each priority has a send count (pri(7..0)\_send\_cnt[13:0]) and an idle count (pri(7..0)\_idle\_cnt[13:0]). The transfer rate includes the inter-packet gap (12 bytes) and the preamble (8 bytes). The rate in Mbits/second that each priority is allowed to send is controlled by the below equation.

Priority Transfer rate in Mbit/s = ((priN\_idle\_cnt/(priN\_idle\_cnt + priN\_send\_cnt)) \* frequency \* 32

Where the frequency is the CLK frequency.

#### 15.3.2.4.5 Command IDLE

The `cmd_idle` bit in the `DMA_Ctrl` register allows CPDMA operation to be suspended. When the idle state is commanded, the CPDMA will stop processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission will be completed normally without suspension. For transmission, any complete or partial frame in the tx cell fifo will be transmitted. For receive, frames that are detected by the CPDMA after the suspend state is entered are ignored. No statistics will be kept for ignored frames. Commanded idle is similar in operation to emulation control and clock stop.

### 15.3.2.5 VLAN Aware Mode

The CPSW\_3G is in VLAN aware mode when the CPSW Control register `vlan_aware` bit is set. In VLAN aware mode ports 0 receive packets (out of the CPSW\_3G) may or may not be VLAN encapsulated depending on the CPSW Control register `rx_vlan_encap` bit. The header packet VLAN is generated as described in [Section 15.3.3, Ethernet Mac Sliver \(CPGMAC\\_SL\)](#). Port 0 receive packet data is never modified. VLAN is not removed regardless of the force untagged egress bit for Port 0. VLAN encapsulated receive packets have a 32-bit VLAN header encapsulation word added to the packet data. VLAN encapsulated packets are specified by a set `rx_vlan_encap` bit in the packet buffer descriptor.

Port 0 transmit packets are never VLAN encapsulated (encapsulation is not allowed).

In VLAN aware mode, transmitted packet data is changed depending on the packet type (pkt\_type), packet priority (pkt\_pri), and VLAN information as shown in the below tables:

### Figure 15-9. VLAN Header Encapsulation Word

31	29	28	27										16
HDR_PKT_Priority		HDR_PKT_CFI	HDR_PKT_Vid										
15			10	9	8	7	6	5	4	3	2	1	0
Reserved			PKT_Type		Reserved								

### Table 15-8. VLAN Header Encapsulation Word Field Descriptions

Field	Description
HDR_PKT_Priority	Header Packet VLAN priority (Highest priority: 7)
HDR_PKT_CFI	Header Packet VLAN CFI bit.
HDR_PKT_Vid	Header Packet VLAN ID
PKT_Type	Packet Type. Indicates whether the packet is VLAN-tagged, priority-tagged, or non-tagged. 00: VLAN-tagged packet 01: Reserved 10: Priority-tagged packet 11: Non-tagged packet

### 15.3.2.6 VLAN Unaware Mode

The CPSW\_3G is in VLAN unaware mode when the CPSW Control register `vlan_aware` bit is cleared. Port 0 receive packets (out of the CPSW\_3G) may or may not be VLAN encapsulated depending on the CPSW Control register `rx_vlan_encap` bit. Port 0 transmit packets are never VLAN encapsulated.

### 15.3.2.7 Address Lookup Engine (ALE)

The address lookup engine (ALE) processes all received packets to determine which port(s) if any that the packet should be forwarded to. The ALE uses the incoming packet received port number, destination address, source address, length/type, and VLAN information to determine how the packet should be forwarded. The ALE outputs the port mask to the switch fabric that indicates the port(s) the packet should be forwarded to. The ALE is enabled when the ale\_enable bit in the ALE\_Ctrl register is set. All packets are dropped when the ale\_enable bit is cleared to zero.

In normal operation, the CPGMAC\_SL modules are configured to issue an abort, instead of an end of packet, at the end of a packet that contains an error (runt, frag, oversize, jabber, crc, alignment, code etc.) or at the end of a mac control packet. However, when the CPGMAC\_SL configuration bit(s) cef, csf, or cmf are set, error frames, short frames or mac control frames have a normal end of packet instead of an abort at the end of the packet. When the ALE receives a packet that contains errors (due to a set header error bit), or a mac control frame and does not receive an abort, the packet will be forwarded only to the host port (port 0). No ALE learning occurs on packets with errors or mac control frames. Learning is based on source address and lookup is based on destination address.

The ALE may be configured to operate in bypass mode by setting the ale\_bypass bit in the ALE\_Ctrl register. When in bypass mode, all CPGMAC\_SL received packets are forwarded only to the host port (port 0). Packets from the two ports can be on separate Rx DMA channels by configuring the CPDMA\_Rx\_Ch\_Map register. In bypass mode, the ALE processes host port transmit packets the same as in normal mode. In general, packets would be directed by the host in bypass mode.

The ALE may be configured to operate in OUI deny mode by setting the enable\_oui\_deny bit in the ALE\_Ctrl register. When in OUI deny mode, a packet with a non-matching OUI source address will be dropped unless the destination address matches a multicast table entry with the super bit set. Broadcast packets will be dropped unless the broadcast address is entered into the table with the super bit set. Unicast packets will be dropped unless the unicast address is in the table with block and secure both set (supervisory unicast packet).

Multicast supervisory packets are designated by the super bit in the table entry. Unicast supervisory packets are indicated when block and secure are both set. Supervisory packets are not dropped due to rate limiting, OUI, or VLAN processing.

#### 15.3.2.7.1 Address Table Entry

The ALE table contains 1024 entries. Each table entry represents a free entry, an address, a VLAN, an address/VLAN pair, or an OUI address. Software should ensure that there are not double address entries in the table. The double entry used would be indeterminate. Reserved table bits must be written with zeroes.

Source Address learning occurs for packets with a unicast, multicast or broadcast destination address and a unicast or multicast (including broadcast) source address. Multicast source addresses have the group bit (bit 40) cleared before ALE processing begins, changing the multicast source address to a unicast source address. A multicast address of all ones is the broadcast address which may be added to the table. A learned unicast source address is added to the table with the following control bits:

**Table 15-9. Learned Address Control Bits**

unicast_type	11
Block	0
Secure	0

If a received packet has a source address that is equal to the destination address then the following occurs:

- The address is learned if the address is not found in the table.
- The address is updated if the address is found.
- The packet is dropped.

##### 15.3.2.7.1.1 Free Table Entry

**Table 15-10. Free (Unused) Address Table Entry Bit Values**

71:62	61:60	59:0
Reserved	Entry Type (00)	Reserved

### 15.3.2.7.1.2 Multicast Address Table Entry

**Table 15-11. Multicast Address Table Entry Bit Values**

71:70	68:66	65	64	63:62	61:60	59:48	47:0
Reserved	Port Mask	Super	Reserved	Mcast Fwd State	Entry Type (01)	Reserved	Multicast Address

#### Table Entry Type

00: Free Entry

01: Address Entry : unicast or multicast determined by dest **address bit 40** .

10: VLAN entry

11: VLAN Address Entry : unicast or multicast determined by **address bit 40**.

#### Supervisory Packet (SUPER)

When set, this field indicates that the packet with a matching multicast destination address is a supervisory packet.

0: Non-supervisory packet

1: Supervisory packet

#### Port Mask(2:0) (PORT\_MASK)

This three bit field is the port bit mask that is returned with a found multicast destination address. There may be multiple bits set indicating that the multicast packet may be forwarded to multiple ports (but not the receiving port).

#### Multicast Forward State (MCAST\_FWD\_STATE)

Multicast Forward State – Indicates the port state(s) required for the received port on a destination address lookup in order for the multicast packet to be forwarded to the transmit port(s). A transmit port must be in the Forwarding state in order to forward the packet. If the transmit port\_mask has multiple set bits then each forward decision is independent of the other transmit port(s) forward decision.

00: Forwarding

01: Blocking/Forwarding/Learning

10: Forwarding/Learning

11: Forwarding

The forward state test returns a true value if both the Rx and Tx ports are in the required state.

#### Table Entry Type (ENTRY\_TYPE)

Address entry type. Unicast or multicast determined by address bit 40.

01: Address entry. Unicast or multicast determined by address bit 40.

#### Packet Address (MULTICAST\_ADDRESS)

This is the 48-bit packet MAC address. For an OUI address, only the upper 24-bits of the address are used in the source or destination address lookup. Otherwise, all 48-bits are used in the lookup.

### 15.3.2.7.1.3 VLAN/Multicast Address Table Entry

**Table 15-12. VLAN/Multicast Address Table Entry Bit Values**

71:69	68:66	65	64	63:62	61:60	59:48	47:0
Reserved	Port Mask	Super	Reserved	Mcast Fwd State	Entry Type (11)	vlan_id	Multicast Address

### Supervisory Packet (SUPER)

When set, this field indicates that the packet with a matching multicast destination address is a supervisory packet.

0: Non-supervisory packet

1: Supervisory packet

### Port Mask(2:0) (PORT\_MASK)

This three bit field is the port bit mask that is returned with a found multicast destination address. There may be multiple bits set indicating that the multicast packet may be forwarded to multiple ports (but not the receiving port).

### Multicast Forward State (MCAST\_FWD\_STATE)

Multicast Forward State – Indicates the port state(s) required for the received port on a destination address lookup in order for the multicast packet to be forwarded to the transmit port(s). A transmit port must be in the Forwarding state in order to forward the packet. If the transmit port\_mask has multiple set bits then each forward decision is independent of the other transmit port(s) forward decision.

00 – Forwarding

01 – Blocking/Forwarding/Learning

10 – Forwarding/Learning

11 – Forwarding

The forward state test returns a true value if both the Rx and Tx ports are in the required state.

### Table Entry Type (ENTRY\_TYPE)

Address entry type. Unicast or multicast determined by address bit 40.

11: VLAN address entry. Unicast or multicast determined by address bit 40.

### VLAN ID (VLAN\_ID)

The unique identifier for VLAN identification. This is the 12-bit VLAN ID.

### Packet Address (MULTICAST\_ADDRESS)

This is the 48-bit packet MAC address. For an OUI address, only the upper 24-bits of the address are used in the source or destination address lookup. Otherwise, all 48-bits are used in the lookup.

#### 15.3.2.7.1.4 Unicast Address Table Entry

**Table 15-13. Unicast Address Table Entry Bit Values**

71:70	69	68	67:66	65	64	63:62	61:60	59:48	47:0
Reserved	DLR Unicast	Reserved	Port Number	Block	Secure	Unicast Type (00) or (X1)	Entry Type (01)	Reserved	Unicast Address

### DLR Unicast

DLR Unicast – When set, this bit indicates that the address is a Device Level Ring (DLR) unicast address. Received packets with a matching destination address will be flooded to the vlan\_member\_list (minus the receive port and the host port). The port\_number field is a don't care when this bit is set. Matching packets received on port 1 egress on port 2. Matching packets received on port 2 egress on port 1. Matching packets received on port 0 egress on ports 1 and 2.

### Port Number (PORT\_NUMBER)

Port Number – This field indicates the port number (not port mask) that the packet with a unicast destination address may be forwarded to. Packets with unicast destination addresses are forwarded only to a single port (but not the receiving port).

### Block (BLOCK)

Block – The block bit indicates that a packet with a matching source or destination address should be dropped (block the address).

0 – Address is not blocked.

1 – Drop a packet with a matching source or destination address (secure must be zero)

If block and secure are both set, then they no longer mean block and secure. When both are set, the block and secure bits indicate that the packet is a unicast supervisory (super) packet and they determine the unicast forward state test criteria. If both bits are set then the packet is forwarded if the receive port is in the Forwarding/Blocking/Learning state. If both bits are not set then the packet is forwarded if the receive port is in the Forwarding state.

### Secure (SECURE)

Secure – This bit indicates that a packet with a matching source address should be dropped if the received port number is not equal to the table entry port\_number.

0 – Received port number is a don't care.

1 – Drop the packet if the received port is not the secure port for the source address and do not update the address (block must be zero)

### Unicast Type (UNICAST\_TYPE)

Unicast Type – This field indicates the type of unicast address the table entry contains.

00 – Unicast address that is not ageable.

01 – Ageable unicast address that has not been touched.

10 – OUI address - lower 24-bits are don't cares (not ageable).

11 – Ageable unicast address that has been touched.

### Table Entry Type (ENTRY\_TYPE)

Address entry. Unicast or multicast determined by address bit 40.

01: Address entry. Unicast or multicast determined by address bit 40.

### Packet Address (UNICAST\_ADDRESS)

This is the 48-bit packet MAC address. All 48-bits are used in the lookup.

#### 15.3.2.7.1.5 OUI Unicast Address Table Entry

**Table 15-14. OUI Unicast Address Table Entry Bit Values**

71:64	63:62	61:60	59:48	47:24	23:0
Reserved	Unicast Type (10)	Entry Type (01)	Reserved	Unicast OUI	Reserved

### Unicast Type (UNICAST\_TYPE)

Unicast Type – This field indicates the type of unicast address the table entry contains.

00 – Unicast address that is not ageable.

01 – Ageable unicast address that has not been touched.

10 – OUI address - lower 24-bits are don't cares (not ageable).

11 – Ageable unicast address that has been touched.

### Table Entry Type (ENTRY\_TYPE)

Address entry. Unicast or multicast determined by address bit 40.

01: Address entry. Unicast or multicast determined by address bit 40.

### Packet Address (UNICAST\_OUI)

For an OUI address, only the upper 24-bits of the address are used in the source or destination address lookup.

#### 15.3.2.7.1.6 VLAN/Unicast Address Table Entry

**Table 15-15. Unicast Address Table Entry Bit Values**

71:68	67:66	65	64	63:62	61:60	59:48	47:0
Reserved	Port Number	Block	Secure	Unicast Type (00) or (X1)	Entry Type (11)	vlan_id	Unicast Address

### Port Number (PORT\_NUMBER)

Port Number – This field indicates the port number (not port mask) that the packet with a unicast destination address may be forwarded to. Packets with unicast destination addresses are forwarded only to a single port (but not the receiving port).]

### Block (BLOCK)

Block – The block bit indicates that a packet with a matching source or destination address should be dropped (block the address).

0 – Address is not blocked.

1 – Drop a packet with a matching source or destination address (secure must be zero)

If block and secure are both set, then they no longer mean block and secure. When both are set, the block and secure bits indicate that the packet is a unicast supervisory (super) packet and they determine the unicast forward state test criteria. If both bits are set then the packet is forwarded if the receive port is in the Forwarding/Blocking/Learning state. If both bits are not set then the packet is forwarded if the receive port is in the Forwarding state.

### Secure (SECURE)

Secure – This bit indicates that a packet with a matching source address should be dropped if the received port number is not equal to the table entry port\_number.

0 – Received port number is a don't care.

1 – Drop the packet if the received port is not the secure port for the source address and do not update the address (block must be zero)

### Unicast Type (UNICAST\_TYPE)

Unicast Type – This field indicates the type of unicast address the table entry contains.

00 – Unicast address that is not ageable.

01 – Ageable unicast address that has not been touched.

10 – OUI address - lower 24-bits are don't cares (not ageable).

11 – Ageable unicast address that has been touched.

### Table Entry Type (ENTRY\_TYPE)

Address entry. Unicast or multicast determined by address bit 40.

11 – VLAN address entry. Unicast or multicast determined by address bit 40.

### VLAN ID (VLAN\_ID)

The unique identifier for VLAN identification. This is the 12-bit VLAN ID.

## Packet Address (UNICAST\_ADDRESS)

This is the 48-bit packet MAC address. All 48-bits are used in the lookup.

### 15.3.2.7.1.7 VLAN Table Entry

**Table 15-16. VLAN Table Entry**

71:62	61:60	59:48	47:27	26:24	23:19	18:16	15:11	10:8	7:3	2:0
Reserved	Entry Type (10)	vlan_id	Reserved	Force Untagged Egress	Reserved	Reg Mcast Flood Mask	Reserved	Unreg Mcast Flood Mask	Reserved	Vlan Member List

## Table Entry Type (ENTRY\_TYPE)

10: VLAN entry

## VLAN ID (VLAN\_ID)

The unique identifier for VLAN identification. This is the 12-bit VLAN ID.

## Force Untagged Packet Egress (FORCE\_UNTAGGED\_EGRESS)

This field causes the packet VLAN tag to be removed on egress (except on port 0).

## Registered Multicast Flood Mask (REG\_MCAST\_FLOOD\_MASK)

Mask used for multicast when the multicast address is found

## Unregistered Multicast Flood Mask (UNREG\_MCAST\_FLOOD\_MASK)

Mask used for multicast when the multicast address is not found

## VLAN Member List (VLAN\_MEMBER\_LIST)

This three bit field indicates which port(s) are members of the associated VLAN.

### 15.3.2.7.2 Packet Forwarding Processes

There are four processes that an incoming received packet may go through to determine packet forwarding. The processes are Ingress Filtering, VLAN\_Aware Lookup, VLAN\_Unaware Lookup, and Egress.

Packet processing begins in the Ingress Filtering process. Each port has an associated packet forwarding state that can be one of four values (Disabled, Blocked, Learning, or Forwarding). The default state for all ports is disabled. The host sets the packet forwarding state for each port. The receive packet processes are described in the following sections.

In the packet ingress process (receive packet process), there is a forward state test for unicast destination addresses and a forward state test for multicast addresses. The multicast forward state test indicates the port states required for the receiving port in order for the multicast packet to be forwarded to the transmit port(s). A transmit port must be in the Forwarding state for the packet to be forwarded for transmission. The mcast\_fwd\_state indicates the required port state for the receiving port as indicated in [Table 15-12](#).

The unicast forward state test indicates the port state required for the receiving port in order to forward the unicast packet. The transmit port must be in the Forwarding state in order to forward the packet. The block and secure bits determine the unicast forward state test criteria. If both bits are set then the packet is forwarded if the receive port is in the Forwarding/Blocking/Learning state. If both bits are not set then the packet is forwarded if the receive port is in the Forwarding state. The transmit port must be in the Forwarding state regardless. The forward state test used in the ingress process is determined by the destination address packet type (multicast/unicast).

In general, packets received with errors are dropped by the address lookup engine without learning, updating, or touching the address. The error condition and the abort are indicated by the CPGMAC\_SL to the ALE. Packets with errors may be passed to the host (not aborted) by a CPGMAC\_SL port if the port has a set rx\_cmf\_en, rx\_cef\_en, or rx\_csf\_en bit(s).

Error packets that are passed to the host by the CPGMAC\_SL are considered to be bypass packets by the ALE and are sent only to the host. Error packets do not learn, update, or touch addresses regardless of whether they are aborted or sent to the host. Packets with errors received by the host are forwarded as normal.

The following control bits are in the CPGMAC\_SL1/2\_MACCTRL register.

**rx\_cef\_en:** This CPGMAC\_SL control bit enables frames that are fragments, long, jabber, CRC, code, and alignment errors to be forwarded.

**rx\_csf\_en:** This CPGMAC\_SL bit enables short frames to be forwarded.

**rx\_cmf\_en:** This CPGMAC\_SL control bit enables mac control frames to be forwarded.

### 15.3.2.7.2.1 Ingress Filtering Process

If (Rx port_state is Disabled) then discard the packet
if (directed packet) then use directed port number and go to Egress process
if ((ale_bypass or error packet) and (host port is not the receive port)) then use host portmask and go to Egress process
if (((block) and (unicast source address found)) or ((block) and (unicast destination address found))) then discard the packet
if ((enable_rate_limit) and (rate limit exceeded) and (not rate_limit_tx)) then if (((mcast/bcast destination address found) and (not super)) or (mcast/bcast destination address not found)) then discard the packet
if ((not forward state test valid) and (destination address found)) then discard the packet to any port not meeting the requirements <ul style="list-style-type: none"> <li>Unicast destination addresses use the unicast forward state test and multicast destination addresses use the multicast forward state test.</li> </ul>
if ((destination address not found) and ((not transmit port forwarding) or (not receive port forwarding))) then discard the packet to any ports not meeting the above requirements
if (source address found) and (secure) and (receive port number != port_number)) then discard the packet
if ((not super) and (drop_untagged) and ((non-tagged packet) or ((priority tagged) and not(en_vid0_mode))) then discard the packet
If (VLAN_Unaware) force_untagged_egress = "000000" reg_mcast_flood_mask = "111111" unreg_mcast_flood_mask = "111111" vlan_member_list = "111111" else if (VLAN not found) force_untagged_egress = unknown_force_untagged_egress reg_mcast_flood_mask = unknown_reg_mcast_flood_mask unreg_mcast_flood_mask = unknown_unreg_mcast_flood_mask vlan_member_list = unknown_vlan_member_list else force_untagged_egress = found_force_untagged_egress reg_mcast_flood_mask = found_reg_mcast_flood_mask unreg_mcast_flood_mask = found_unreg_mcast_flood_mask vlan_member_list = found_vlan_member_list
if ((not super) and (vid_ingress_check) and (Rx port is not VLAN member)) then discard the packet
if ((enable_auth_mode) and (source address not found) and not(destination address found and (super))) then discard the packet

if (destination address equals source address) then discard the packet
if (vlan_aware) goto VLAN_Aware_Lookup process else goto VLAN_Unaware_Lookup process

#### 15.3.2.7.2.2 VLAN\_Aware Lookup Process

if ((unicast packet) and (destination address found with or without VLAN) and dlr_unicast) then portmask is the vlan_member_list less the host port and goto Egress process
if ((unicast packet) and (destination address found with or without VLAN) and (not super)) then portmask is the logical "AND" of the port_number and the vlan_member_list and goto Egress process
if ((unicast packet) and (destination address found with or without VLAN) and (super)) then portmask is the port_number and goto Egress process
if (Unicast packet) # destination address not found then portmask is vlan_member_list less host port and goto Egress process
if ((Multicast packet) and (destination address found with or without VLAN) and (not super)) then portmask is the logical "AND" of reg_mcast_flood_mask and found destination address/VLAN portmask (port_mask) and vlan_member_list and goto Egress process
if ((Multicast packet) and (destination address found with or without VLAN) and (super)) then portmask is the port_mask and goto Egress process
if (Multicast packet) # destination address not found then portmask is the logical "AND" of unreg_mcast_flood_mask and vlan_member_list then goto Egress process
if (Broadcast packet) then use found vlan_member_list and goto Egress process

#### 15.3.2.7.2.3 VLAN\_Unaware Lookup Process

if ((unicast packet) and (destination address found with or without VLAN) and dlr_unicast) then portmask is the vlan_member_list less the host port and goto Egress process
if ((unicast packet) and (destination address found with or without VLAN) and (not super)) then portmask is the logical "AND" of the port_number and the vlan_member_list and goto Egress process
if ((unicast packet) and (destination address found with or without VLAN) and (super)) then portmask is the port_number and goto Egress process
if (Unicast packet) # destination address not found then portmask is vlan_member_list less host port and goto Egress process
if ((Multicast packet) and (destination address found with or without VLAN) and (not super)) then portmask is the logical "AND" of reg_mcast_flood_mask and found destination address/VLAN portmask (port_mask) and vlan_member_list and goto Egress process
if ((Multicast packet) and (destination address found with or without VLAN) and (super)) then portmask is the port_mask and goto Egress process
if (Multicast packet) # destination address not found then portmask is the logical "AND" of unreg_mcast_flood_mask and vlan_member_list then goto Egress process
if (Broadcast packet) then use found vlan_member_list and goto Egress process

#### 15.3.2.7.2.4 Egress Process

Clear Rx port from portmask (don't send packet to Rx port).
Clear disabled ports from portmask.
if ((enable_oui_deny) and (OUI source address not found) and (not ale_bypass) and (not error packet) and not ((mcast destination address) and (super))) then Clear host port from portmask
if ((enable_rate_limit) and (rate_limit_tx)) then if (not super) and (rate limit exceeded on any tx port) then clear rate limited tx port from portmask If address not found then super cannot be set.
If portmask is zero then discard packet
Send packet to portmask ports.

#### 15.3.2.7.3 Learning/Updating/Touching Processes

The learning, updating, and touching processes are applied to each receive packet that is not aborted. The processes are concurrent with the packet forwarding process. In addition to the following, a packet must be received without error in order to learn/update/touch an address.

##### 15.3.2.7.3.1 Learning Process

If (not(Learning or Forwarding) or (enable_auth_mode) or (packet error) or (no_learn)) then do not learn address
if ((Non-tagged packet) and (drop_untagged)) then do not learn address
if ((vlan_aware) and (VLAN not found) and (unknown_vlan_member_list = "000")) then do not learn address
if ((vid_ingress_check) and (Rx port is not VLAN member) and (VLAN found)) then do not learn address
if ((source address not found) and (vlan_aware) and not(learn_no_vid)) then learn address with VLAN
if ((source address not found) and ((not vlan_aware) or (vlan_aware and learn_no_vid))) then learn address without VLAN

##### 15.3.2.7.3.2 Updating Process

if (dlr_unicast) then do not update address
If (not(Learning or Forwarding) or (enable_auth_mode) or (packet error) or (no_sa_update)) then do not update address
if ((Non-tagged packet) and (drop_untagged)) then do not update address
if ((vlan_aware) and (VLAN not found) and (unknown_vlan_member_list = "000")) then do not update address
if ((vid_ingress_check) and (Rx port is not VLAN member) and (VLAN found)) then do not update address
if ((source address found) and (receive port number != port_number) and (secure or block)) then do not update address

```
if ((source address found) and (receive port number != port_number))
then update address
```

### 15.3.2.7.3.3 Touching Process

```
if ((source address found) and (ageable) and (not touched))
then set touched
```

### 15.3.2.8 Packet Priority Handling

Packets are received on three ports, two of which are CPGMAC\_SL Ethernet ports and the third port is the CPPI host port. Received packets have a received packet priority (0 to 7 with 7 being the highest priority). The received packet priority is determined as shown:

1. If the first packet LTYPE = 0x8100 then the received packet priority is the packet priority (VLAN tagged and priority tagged packets).
2. If the first packet LTYPE = 0x0800 and byte 14 (following the LTYPE) is equal to 0x45 then the received packet priority is the 6-bit TOS field in byte 15 (upper 6-bits) mapped through the port's DSCP priority mapping register (IPV4 packet).
3. The received packet priority is the source (ingress) port priority (untagged non-IPV4 packet).

The received packet priority is mapped through the receive ports associated "packet priority to header packet priority mapping register" to obtain the header packet priority (the CPDMA Rx and Tx nomenclature is reversed from the CPGMAC\_SL nomenclature for legacy reasons). The header packet priority is mapped through the "header priority to switch priority mapping register" to obtain the hardware switch priority (0 to 3 with 3 being the highest priority). The header packet priority is then used as the actual transmit packet priority if the VLAN information is to be sent on egress.

### 15.3.2.9 FIFO Memory Control

Each of the three CPSW\_3G ports has an identical associated FIFO. Each FIFO contains a single logical receive (ingress) queue and four logical transmit queues (priority 0 through 3). Each FIFO memory contains 20,480 bytes (20k) total organized as 2560 by 64-bit words contained in a single memory instance. The FIFO memory is used for the associated port transmit and receive queues. The tx\_max\_blks field in the FIFO's associated Max\_Blks register determines the maximum number of 1k FIFO memory blocks to be allocated to the four logical transmit queues (transmit total).

The rx\_max\_blks field in the FIFO's associated Max\_Blks register determines the maximum number of 1k memory blocks to be allocated to the logical receive queue. The tx\_max\_blks value plus the rx\_max\_blks value must sum to 20 (the total number of blocks in the FIFO). If the sum were less than 20 then some memory blocks would be unused. The default is 17 (decimal) transmit blocks and three receive blocks. The FIFO's follow the naming convention of the Ethernet ports. Host Port is Port0 and External Ports are Port1,2

### 15.3.2.10 FIFO Transmit Queue Control

There are four transmit queues in each transmit FIFO. Software has some flexibility in determining how packets are loaded into the queues and on how packet priorities are selected for transmission (how packets are removed and transmitted from queues). All ports on the switch have identical FIFO's. For the purposes of the below the transmit FIFO is switch egress even though the port 0 transmit FIFO is connected to the CPDMA receive (also switch egress). The CPDMA nomenclature is reversed from the CPGMAC\_SL nomenclature due to legacy reasons.

### 15.3.2.10.1 Normal Priority Mode

When operating in normal mode, lower priority frames are dropped before higher priority frames. The intention is to give preference to higher priority frames. Priority 3 is the highest priority and is allowed to fill the FIFO. Priority 2 will drop packets if the packet is going to take space in the last 2k available. Priority 1 will drop packets if the packet is going to take space in the last 4k available. Priority 0 will drop packets if the packet is going to take space in the last 6k available. If fewer than 4 priorities are to be implemented then the priorities should be mapped such that the highest priorities are used.

For example, if two priorities are going to be used then all packets should be mapped to priorities 3 and 2 and priorities 1 and 0 should be unused. Priority escalation may be used in normal priority mode if desired. Normal priority mode is configured as described below:

- Select normal priority mode by setting tx\_in\_sel[1:0] = 00 for all ports (default value in P0/1/2\_Tx\_In\_Ctl)
- Configure priority mapping to use only the highest priorities if less than 4 priorities are used. Refer to the Packet Priority Handling section of this chapter.

### 15.3.2.10.2 Dual Mac Mode

When operating in dual mac mode the intention is to transfer packets between ports 0 and 1 and ports 0 and 2, but not between ports 1 and 2. Each CPGMAC\_SL appears as a single MAC with no bridging between MAC's. Each CPGMAC\_SL has at least one unique (not the same) mac address.

Dual mac mode is configured as described below:

- Set the ale\_vlan\_aware bit in the ALE\_Ctrl register. This bit configures the ALE to process in vlan aware mode. The CPSW\_3G vlan aware bit (vlan\_aware in CPSW\_Ctrl) determines how packets VLAN's are processed on CPGMAC\_SL egress and does not affect how the ALE processes packets or the packet destination. The CPSW\_3G vlan aware bit may be set or not as required (must be set if VLAN's are to exit the switch).

- **Configure the Port 1 to Port 0 VLAN**

Add a VLAN Table Entry with ports 0 and 1 as members (clear the flood masks).

Add a VLAN/Unicast Address Table Entry with the Port1/0 VLAN and a port number of 0. Packets received on port 1 with this unicast address will be sent only to port 0 (egress). If multiple mac addresses are desired for this port then multiple entries of this type may be configured.

- **Configure the Port 2 to Port 0 VLAN**

Add a VLAN Table Entry with ports 0 and 2 as members (clear the flood masks).

Add a VLAN/Unicast Address Table Entry with the Port2/0 VLAN and a port number of 0. Packets received on port 2 with this unicast address will be sent only to port 0 (egress). If multiple mac addresses are desired for this port then multiple entries of this type may be configured.

- Packets from the host (port 0) to ports 1 and 2 should be directed. If directed packets are not desired then VLAN with addresses can be added for both destination ports.
- Select the dual mac mode on the port 0 FIFO by setting tx\_in\_sel[1:0] = 01 in P0\_Tx\_In\_Ctl. The intention of this mode is to allow packets from both ethernet ports to be written into the FIFO without one port starving the other port.
- The priority levels may be configured such that packets received on port 1 egress on one CPDMA RX channel while packets received on port 2 egress on a different CPDMA RX channel.

### 15.3.2.10.3 Rate Limit Mode

Rate-limit mode is intended to allow some CPDMA transmit (switch ingress) channels and some CPGMAC\_SL FIFO priorities (switch egress) to be rate-limited. Non rate-limited traffic (bulk traffic) is allowed on non rate-limited channels and FIFO priorities. The bulk traffic does not impact the rate-limited traffic. Rate-limited traffic must be configured to be sent to rate-limited queues (via packet priority handling).

The allocated rates for rate-limited traffic must not be oversubscribed. For example, if port 1 is sending 15% rate limited traffic to port 2 priority 3, and port 0 is also sending 10% rate-limited traffic to port 2 priority 3, then the port 2 priority 3 egress rate must be configured to be 25% plus a percent or two for margin. The switch must be configured to allow some percentage of non rate-limited traffic. Non-rate-limited traffic must be configured to be sent to non rate-limited queues. No packets from the host should be dropped, but non rate-limited traffic received on an ethernet port can be dropped. Rate-limited mode is configured as shown:

- Set tx\_in\_sel[1:0] = 10 in P1/2\_Tx\_In\_Ctl to enable ports 1 and 2 transmit FIFO inputs to be configured for rate-limiting queues. Enabling a queue to be rate-limiting with this field affects only the packet being loaded into the FIFO, it does not configure the transmit for queue shaping.
- Configure the number of rate-limited queues for port 1 and 2 transmit FIFO's by setting the tx\_rate\_en[3:0] field in P1/2\_Tx\_In\_Ctl. Rate limited queues must be the highest number. For example, if there are two rate limited queues then 1100 would be written to this field for priorities 3 and 2. This field enables the FIFO to allow rate-limited traffic into rate-limited queues while discriminating against non rate-limited queues.
- Set p1\_priN\_shape\_en and p2\_priN\_shape\_en in the CPSW\_3G PTYPE register. These bits determine which queues actually shape the output data stream. In general, the same priorities that are set in tx\_rate\_en are set in these bits as well, but the FIFO input and output enable bits are separate to allow rate-limiting from the host to non shaped channels if desired.  
When queue shaping is not enabled for a queue then packets are selected for egress based on priority. When queue shaping is enabled then packets are selected for egress based on queue percentages. If shaping is required on a single queue then it must be priority 3 (priorities 2, 1 and 0 are strict priority). If shaping is required on two queues then it must be on priorities 2 and 3 (priorities 1 and 0 are strict priority). If shaping is required on three queues then it must be priorities 3, 2, and 1 (priority 0 would then get the leftovers). Priority shaping follows the requirements in the IEEE P802.1Qav/D6.0 specification. Priority shaping is not compatible with priority escalation (escalation must be disabled).
- P0\_Tx\_In\_Ctl[1:0] should remain at the default 00 value. Port 0 egress (CPDMA RX) should not be rate-limited.
- The CPDMA is configured for rate-limited transmit (switch ingress) channels by setting the highest bits of the tx\_rlim[7:0] field in the CPDMA DMA\_Ctrl register. If there are two rate limited channels then tx\_rlim[7:0] = 11000000 (the rate limited channels must be the highest priorities). Also, tx\_ptype in the DMA\_Ctrl register must be set (fixed priority mode). Rate limited channels must go to rate-limited FIFO queues, and the FIFO queue rate must not be oversubscribed.

### 15.3.2.11 Packet Padding

VLAN tagged ingress packets of 64 to 67-bytes will be padded to 64-bytes on egress (all ports) if the VLAN is removed on egress.

### 15.3.2.12 Flow Control

There are two types of switch flow control – CPPI port flow control and Ethernet port flow control. The CPPI and Ethernet port naming conventions for data flow into and out of the switch are reversed. For the CPPI port (port 0), transmit operations move packets from external memory into the switch and then out to either or both Ethernet transmit ports (ports 1 and 2). CPPI receive operations move packets that were received on either or both Ethernet receive ports to external memory.

#### 15.3.2.12.1 CPPI Port Flow Control

The CPPI port has flow control available for transmit (switch ingress). CPPI receive operations (switch egress) do not require flow control. CPPI Transmit flow control is initiated when enabled and triggered. CPPI transmit flow control is enabled by setting the p0\_flow\_en bit in the **CPSW\_Flow\_Ctrl** register. CPPI transmit flow control is enabled by default on reset because host packets should not be dropped in any mode of operation.

### 15.3.2.12.2 Ethernet Port Flow Control

The Ethernet ports have flow control available for transmit and receive. Transmit flow control stops the Ethernet port from transmitting packets to the wire (switch egress) in response to a received pause frame. Transmit flow control does not depend on FIFO usage.

The ethernet ports have flow control available for receive operations (packet ingress). Ethernet port receive flow control is initiated when enabled and triggered. Packets received on an ethernet port can be sent to the other ethernet port or the CPPI port (or both). Each destination port can trigger the receive ethernet port flow control. An ethernet destination port triggers another ethernet receive flow control when the destination port is full.

When a packet is received on an ethernet port interface with enabled flow control the below occurs:

- The packet will be sent to all ports that currently have room to take the entire packet.
- The packet will be retried until successful to all ports that indicate they don't have room for the packet.

The flow control trigger to the CPGMAC\_SL will be asserted until the packet has been sent, and there is room in the logical receive FIFO for packet runout from another flow control trigger (**rx\_pkt\_cnt** = 0). Ethernet port receive flow control is disabled by default on reset. Ethernet port receive flow control requires that the **rx\_flow\_en** bit in the associated CPGMAC\_SL be set to one.

When receive flow control is enabled on a port, the port's associated FIFO block allocation must be adjusted. The port RX allocation must increase from the default three blocks to accommodate the flow control runout. A corresponding decrease in the TX block allocation is required. If a sending port ignores a pause frame then packets may overrun on receive (and be dropped) but will not be dropped on transmit. If flow control is disabled for gmii ports, then any packets that are dropped are dropped on transmit and not on receive.

#### 15.3.2.12.2.1 Receive Flow Control

When enabled and triggered, receive flow control is initiated to limit the CPGMAC\_SL from further frame reception. Half-duplex mode receive flow control is collision based while full duplex mode issues 802.3X pause frames. In either case, receive flow control prevents frame reception by issuing the flow control appropriate for the current mode of operation. Receive flow control is enabled by the **rx\_flow\_en** bit in the **MACCTRL** register. Receive flow control is triggered (when enabled) when the **RX\_FLOW\_TRIGGER** input is asserted. The CPGMAC\_SL is configured for collision or IEEE 802.3X flow control via the **fullduplex** bit in the **MACCTRL** register.

##### 15.3.2.12.2.1.1 Collision Based Receive Buffer Flow Control

Collision-based receive buffer flow control provides a means of preventing frame reception when the port is operating in half-duplex mode (**fullduplex** is cleared in **MACCTRL**). When receive flow control is enabled and triggered, the port will generate collisions for received frames. The jam sequence transmitted will be the twelve byte sequence C3.C3.C3.C3.C3.C3.C3.C3.C3.C3.C3.C3 (hex). The jam sequence will begin no later than approximately as the source address starts to be received. Note that these forced collisions will not be limited to a maximum of 16 consecutive collisions, and are independent of the normal back-off algorithm. Receive flow control does not depend on the value of the incoming frame destination address. A collision will be generated for any incoming packet, regardless of the destination address.

##### 15.3.2.12.2.1.2 IEEE 802.3X Based Receive Flow Control

IEEE 802.3x based receive flow control provides a means of preventing frame reception when the port is operating in full-duplex mode (**fullduplex** is set in **MACCTRL**). When receive flow control is enabled and triggered, the port will transmit a pause frame to request that the sending station stop transmitting for the period indicated within the transmitted pause frame.

The CPGMAC\_SL will transmit a pause frame to the reserved multicast address at the first available opportunity (immediately if currently idle, or following the completion of the frame currently being transmitted). The pause frame will contain the maximum possible value for the pause time (0xFFFF). The MAC will count the receive pause frame time (decrements 0xFF00 down to zero) and retransmit an outgoing pause frame if the count reaches zero. When the flow control request is removed, the MAC will transmit a pause frame with a zero pause time to cancel the pause request.

Note that transmitted pause frames are only a request to the other end station to stop transmitting. Frames that are received during the pause interval will be received normally (provided the Rx FIFO is not full).

Pause frames will be transmitted if enabled and triggered regardless of whether or not the port is observing the pause time period from an incoming pause frame.

The CPGMAC\_SL will transmit pause frames as described below:

- The 48-bit reserved multicast destination address 01.80.C2.00.00.01.
- The 48-bit source address — SL\_SA(47:0).
- The 16-bit length/type field containing the value 88.08
- The 16-bit pause opcode equal to 00.01
- The 16-bit pause time value FF.FF. A pause-quantum is 512 bit-times. Pause frames sent to cancel a pause request will have a pause time value of 00.00.
- Zero padding to 64-byte data length (The CPGMAC\_SL will transmit only 64 byte pause frames).
- The 32-bit frame-check sequence (CRC word).

All quantities above are hexadecimal and are transmitted most-significant byte first. The least-significant bit is transferred first in each byte.

If **rx\_flow\_en** is cleared to zero while the pause time is nonzero, then the pause time will be cleared to zero and a zero count pause frame will be sent.

#### 15.3.2.12.2.2 Transmit Flow Control

Incoming pause frames are acted upon, when enabled, to prevent the CPGMAC\_SL from transmitting any further frames. Incoming pause frames are only acted upon when the **fullduplex** and **tx\_flow\_en** bits in the **MACCTRL** register are set. Pause frames are not acted upon in half-duplex mode. Pause frame action will be taken if enabled, but normally the frame will be filtered and not transferred to memory.

MAC control frames will be transferred to memory if the **rx\_cmf\_en** (Copy MAC Frames) bit in the **MACCTRL** register is set. The **tx\_flow\_en** and **fullduplex** bits effect whether or not MAC control frames are acted upon, but they have no effect upon whether or not MAC control frames are transferred to memory or filtered.

Pause frames are a subset of MACCTRL Frames with an opcode field=0x0001. Incoming pause frames will only be acted upon by the port if:

- **tx\_flow\_en** is set in **MACCTRL**, and
- the frame's length is 64 to **rx\_maxlen** bytes inclusive, and
- the frame contains no crc error or align/code errors.

The pause time value from valid frames will be extracted from the two bytes following the opcode. The pause time will be loaded into the port's transmit pause timer and the transmit pause time period will begin.

If a valid pause frame is received during the transmit pause time period of a previous transmit pause frame then:

- if the destination address is not equal to the reserved multicast address or any enabled or disabled unicast address, then the transmit pause timer will immediately expire, or
- if the new pause time value is zero then the transmit pause timer will immediately expire, else
- the port transmit pause timer will immediately be set to the new pause frame pause time value. (Any remaining pause time from the previous pause frame will be discarded).

If **tx\_flow\_en** in **MACCTRL** is cleared, then the pause-timer will immediately expire.

The port will not start the transmission of a new data frame any sooner than 512-bit times after a pause frame with a non-zero pause time has finished being received (**GMII\_RXDV** going inactive). No transmission will begin until the pause timer has expired (the port may transmit pause frames in order to initiate outgoing flow control). Any frame already in transmission when a pause frame is received will be completed and unaffected.

Incoming pause frames consist of the below:

- A 48-bit destination address equal to:
- The reserved multicast destination address 01.80.C2.00.00.01, or
- The SL\_SA(47:0) input mac source address.
- The 48-bit source address of the transmitting device.
- The 16-bit length/type field containing the value 88.08
- The 16-bit pause opcode equal to 00.01
- The 16-bit pause\_time. A pause-quantum is 512 bit-times.
- Padding to 64-byte data length.
- The 32-bit frame-check sequence (CRC word).

All quantities above are hexadecimal and are transmitted most-significant byte first. The least-significant bit is transferred first in each byte.

The padding is required to make up the frame to a minimum of 64 bytes. The standard allows pause frames longer than 64 bytes to be discarded or interpreted as valid pause frames. The CPGMAC\_SL will recognize any pause frame between 64 bytes and **rx\_maxlen** bytes in length.

### 15.3.2.13 Packet Drop Interface

The packet drop interface supports an external packet drop engine. The port 1 (and port 2) CPGMAC\_SL receive FIFO VBUSP interface signals are CPSW\_3G outputs. The receive packet interface has an associated packet drop input P1\_RFIFO\_DROP (P2\_RFIFO\_DROP). An external packet drop engine may “snoop” the received packet header and data to determine whether or not the packet should be dropped.

If the packet is to be dropped the external logic must assert the drop signal by no later than the second clock after the end of packet (or abort) indication from the CPGMAC\_SL. The drop signal should remain asserted until the second clock after the end of packet (or abort) indication. If the packet is not to be dropped then the drop signal should remain deasserted. The CPGMAC\_SL section contains more information on the receive FIFO VBUSP interface signals and end of packet indication.

### 15.3.2.14 Short Gap

The port 1 (and port 2) transmit inter-packet gap (IPG) may be shortened by eight bit times when enabled and triggered. The **tx\_short\_gap\_en** bit in the **SL1\_MACCTRL (SL2\_MACCTRL)** register enables the gap to be shortened when triggered. The condition is triggered when the port 1 (port 2) transmit FIFO has a user defined number of FIFO blocks used. The port 1 transmit FIFO blocks used determines if the port 1 gap is shortened, and the port 2 transmit FIFO blocks used determines if the port 2 gap is shortened. The **CPSW\_Gap\_Thresh** register value determines the port 1 short gap threshold, and the **CPSW\_Gap\_Thresh** register value determines the port 2 short gap threshold.

### 15.3.2.15 Switch Latency

The CPSW\_3G is a store and forward switch. The switch latency is defined as the amount of time between the end of packet reception of the received packet to the start of the output packet transmit.

Mode	Latency
Gig (1000)	880ns
100	1.3us
10	6.5us

### 15.3.2.16 Emulation Control

The emulation control input (EMUSUSP) and submodule emulation control registers allow CPSW\_3G operation to be completely or partially suspended. There are three CPSW\_3G submodules that contain emulation control registers (CPGMAC\_SL1, CPGMAC\_SL2, and CPDMA). The submodule emulation control registers must be accessed to facilitate CPSW\_3G emulation control. The CPSW\_3G module enters the emulation suspend state if all three submodules are configured for emulation suspend and the emulation suspend input is asserted.

A partial emulation suspend state is entered if one or two submodules is configured for emulation suspend and the emulation suspend input is asserted. Emulation suspend occurs at packet boundaries. The emulation control feature is implemented for compatibility with other peripherals.

#### CPGMAC\_SL Emulation Control

The emulation control input (**TBEMUSUP**) and register bits (**soft** and **free** in the **EMCTRL** register) allow CPGMAC\_SL operation to be suspended. When the emulation suspend state is entered, the CPGMAC\_SL will stop processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission will be completed normally without suspension. For receive, frames that are detected by the CPGMAC\_SL after the suspend state is entered are ignored. Emulation control is implemented for compatibility with other peripherals.

#### CPDMA Emulation Control

The emulation control input (**TBEMUSUP**) and register bits (**soft** and **free** in the **EMCTRL** register) allow CPDMA operation to be suspended. When the emulation suspend state is entered, the CPDMA will stop processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission will be completed normally without suspension. For transmission, any complete or partial frame in the tx cell fifo will be transmitted. For receive, frames that are detected by the CPDMA after the suspend state is entered are ignored. No statistics will be kept for ignored frames. Emulation control is implemented for compatibility with other peripherals.

The following table shows the operations of the emulation control input and register bits:

**Table 15-17. Operations of Emulation Control Input and Register Bits**

EMUSUSP	soft	free	Description
0	X	X	Normal Operation
1	0	0	Normal Operation
1	1	0	Emulation Suspend
1	X	1	Normal Operation

#### Emulation Suspend Input

The emulation suspend input described above comes from the Debug Subsystem. See [Chapter 31, Debug Subsystem](#), to enable an emulation suspend event input for the Ethernet Subsystem (EMAC).

### 15.3.2.17 Software IDLE

The submodule software idle register bits enable CPSW\_3G operation to be completely or partially suspended by software control. There are three CPSW\_3G submodules that contain software idle register bits (CPGMAC\_SL1, CPGMAC\_SL2, and CPDMA). Each of the three submodules may be individually commanded to enter the idle state. The idle state is entered at packet boundaries, and no further packet operations will occur on an idled submodule until the idle command is removed. The CPSW\_3G module enters the idle state when all three submodules are commanded to enter and have entered the idle state. Idle status is determined by reading or polling the three submodule idle bits. The CPSW\_3G is in the idle state when all three submodules are in the idle state. The **CPSW\_Soft\_Idle** bit may be set if desired after the submodules are in the idle state. The **CPSW\_Soft\_Idle** bit causes packets to not be transferred from one FIFO to another FIFO internal to the switch.

### 15.3.2.18 Software Reset

The CPSW\_3G software reset register, CPSW\_3GSS software reset register and the three submodule software reset registers enable the CPSW\_3GSS to be reset by software. There are three CPSW\_3G submodules that contain software reset registers (CPGMAC\_SL1, CPGMAC\_SL2, and CPDMA). Each of the three submodules may be individually commanded to be reset by software.

For the CPDMA, the reset state is entered at packet boundaries, at which time the CPDMA reset occurs. The CPGMAC\_SL soft reset is immediate. Submodule reset status is determined by reading or polling the submodule reset bit. If the submodule reset bit is read as a one, then the reset process has not yet completed. The submodule soft reset process could take up to 2ms each. The reset has completed if the submodule reset bit is read as a zero.

After all three submodules (in any order) have been reset and a read of each submodule reset bit indicates that the reset process is complete, the CPSW\_3G software reset register bit may be written to complete the CPSW\_3G module software reset operation. The CPSW\_3G software reset bit controls the reset of the FIFO's, the statistics submodule, and the address lookup engine (ALE). The CPSW\_3G software reset is immediate and will be indicated by reading a zero from the soft reset bit.

The CPSW\_3GSS software reset bit controls the reset of the INT, REGS and CPPI. The CPSW\_3GSS software reset is immediate and will be indicated by reading a zero from the soft reset bit.

### 15.3.2.19 FIFO Loopback

FIFO loopback mode is entered when the fifo\_loopback bit in the CPSW\_Ctrl register is set. FIFO loopback mode causes packets received on a port to be turned around and transmitted back on the same port. Port 0 receive is fixed on channel zero in FIFO loopback mode. The RXSOFOVERRUN statistic is incremented for each packet sent in FIFO loopback mode. Packets sent in with errors are returned with errors (they are not dropped). FIFO loopback is intended as a simple mechanism for test purposes. FIFO loopback should be performed in full duplex mode only.

### 15.3.2.20 CPSW\_3G Network Statistics

The CPSW\_3G has a set of statistics that record events associated with frame traffic on selected switch ports. The statistics values are cleared to zero 38 clocks after the rising edge of VBUSP\_RST\_N. When one or more port enable bits (stat\_port\_en[2:0]) are set, all statistics registers are write to decrement. The value written will be subtracted from the register value with the result being stored in the register. If a value greater than the statistics value is written, then zero will be written to the register (writing 0xffffffff will clear a statistics location).

When all port enable bits are cleared to zero, all statistics registers are read/write (normal write direct, so writing 0x00000000 will clear a statistics location). All write accesses must be 32-bit accesses. In the below statistics descriptions, "the port" refers to any enabled port (with a corresponding set stat\_port\_en[2:0] bit).

The statistics interrupt (STAT\_PEND) will be issued if enabled when any statistics value is greater than or equal to 0x80000000. The statistics interrupt is removed by writing to decrement any statistics value greater than 0x80000000. The statistics are mapped into internal memory space and are 32-bits wide. All statistics rollover from 0xffffffff to 0x00000000.

#### 15.3.2.20.1 Rx-only Statistics Descriptions

##### 15.3.2.20.1.1 Good Rx Frames (Offset = 0h)

The total number of good frames received on the port. A good frame is defined to be:

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Had a length of 64 to rx\_maxlen bytes inclusive
- Had no CRC error, alignment error or code error.

For definitions of alignment, code and CRC errors, see [Section 15.3.2.20.1.5, Rx CRC Errors](#) and [Section 15.3.2.20.1.6, Rx Align/Code Errors](#). Overruns have no effect upon this statistic.

#### 15.3.2.20.1.2 Broadcast Rx Frames (Offset = 4h)

The total number of good broadcast frames received on the port. A good broadcast frame is defined to be:

- Any data or MAC control frame which was destined for only address 0xFFFFFFFFFFFF
- Had a length of 64 to rx\_maxlen bytes inclusive
- Had no CRC error, alignment error or code error.

See the Rx Align/Code Errors and Rx CRC errors statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

#### 15.3.2.20.1.3 Multicast Rx Frames (Offset = 8h)

The total number of good multicast frames received on the port. A good multicast frame is defined to be:

- Any data or MAC control frame which was destined for any multicast address other than 0xFFFFFFFFFFFF
- Had a length of 64 to rx\_maxlen bytes inclusive
- Had no CRC error, alignment error or code error

See the Rx Align/Code Errors and Rx CRC errors statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

#### 15.3.2.20.1.4 Pause Rx Frames (Offset = Ch)

The total number of IEEE 802.3X pause frames received by the port (whether acted upon or not). Such a frame:

- Contained any unicast, broadcast, or multicast address
- Contained the length/type field value 88.08 (hex) and the opcode 0x0001
- Was of length 64 to rx\_maxlen bytes inclusive
- Had no CRC error, alignment error or code error
- Pause-frames had been enabled on the port (tx\_flow\_en = 1).

The port could have been in either half or full-duplex mode.

See the Rx Align/Code Errors and Rx CRC errors statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

#### 15.3.2.20.1.5 Rx CRC Errors (Offset = 10h)

The total number of frames received on the port that experienced a CRC error. Such a frame:

- Was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Was of length 64 to rx\_maxlen bytes inclusive
- Had no code/align error,
- Had a CRC error

Overruns have no effect upon this statistic.

A CRC error is defined to be:

- A frame containing an even number of nibbles
- Failing the Frame Check Sequence test

#### 15.3.2.20.1.6 Rx Align/Code Errors (Offset = 14h)

The total number of frames received on the port that experienced an alignment error or code error. Such a frame:

- Was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode

- Was of length 64 to rx\_maxlen bytes inclusive
- Had either an alignment error or a code error

Overruns have no effect upon this statistic.

An alignment error is defined to be:

- A frame containing an odd number of nibbles
- Failing the Frame Check Sequence test if the final nibble is ignored

A code error is defined to be a frame which has been discarded because the port's MRXER pin driven with a one for at least one bit-time's duration at any point during the frame's reception.

Note: RFC 1757 etherStatsCRCAAlignErrors Ref. 1.5 can be calculated by summing Rx Align/Code Errors and Rx CRC errors.

#### **15.3.2.20.1.7 Oversize Rx Frames (Offset = 18h)**

The total number of oversized frames received on the port. An oversized frame is defined to be:

- Was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Was greater than rx\_maxlen in bytes
- Had no CRC error, alignment error or code error

See the Rx Align/Code Errors and Rx CRC errors statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

#### **15.3.2.20.1.8 Rx Jabbers (Offset = 1Ch)**

The total number of jabber frames received on the port. A jabber frame:

- Was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Was greater than rx\_maxlen in bytes
- Had no CRC error, alignment error or code error

See the Rx Align/Code Errors and Rx CRC errors statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

#### **15.3.2.20.1.9 Undersize (Short) Rx Frames (Offset = 20h)**

The total number of undersized frames received on the port. An undersized frame is defined to be:

- Was any data frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Was greater than rx\_maxlen in bytes
- Had no CRC error, alignment error or code error

See the Rx Align/Code Errors and Rx CRC errors statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

#### **15.3.2.20.1.10 Rx Fragments (Offset = 24h)**

The total number of frame fragments received on the port. A frame fragment is defined to be:

- Any data frame (address matching does not matter)
- Less than 64 bytes long
- Having a CRC error, an alignment error, or a code error
- Not the result of a collision caused by half duplex, collision based flow control

See the Rx Align/Code Errors and Rx CRC errors statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

#### 15.3.2.20.1.11 Rx Start of Frame Overruns (Offset = 84h)

The total number of frames received on the port that had a CPDMA start of frame (SOF) overrun or were dropped by due to FIFO resource limitations. SOF overrun frame is defined to be:

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Any length (including less than 64 bytes and greater than rx\_maxlen bytes)
- The CPDMA had a start of frame overrun or the packet was dropped due to FIFO resource limitations

#### 15.3.2.20.1.12 Rx Middle of Frame Overruns (Offset = 88h)

The total number of frames received on the port that had a CPDMA middle of frame (MOF) overrun. MOF overrun frame is defined to be:

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Any length (including less than 64 bytes and greater than rx\_maxlen bytes)
- The CPDMA had a middle of frame overrun

#### 15.3.2.20.1.13 Rx DMA Overruns (Offset = 8Ch)

The total number of frames received on the port that had either a DMA start of frame (SOF) overrun or a DMA MOF overrun. An Rx DMA overrun frame is defined to be:

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Any length (including less than 64 bytes and greater than rx\_maxlen bytes)
- The CPGMAC\_SL was unable to receive it because it did not have the DMA buffer resources to receive it (zero head descriptor pointer at the start or during the middle of the frame reception)

CRC errors, alignment errors and code errors have no effect upon this statistic.

#### 15.3.2.20.1.14 Rx Octets (Offset = 30h)

The total number of bytes in all good frames received on the port. A good frame is defined to be:

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Of length 64 to rx\_maxlen bytes inclusive
- Had no CRC error, alignment error or code error

See the Rx Align/Code Errors and Rx CRC errors statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

#### 15.3.2.20.1.15 Net Octets (Offset = 80h)

The total number of bytes of frame data received and transmitted on the port. Each frame counted:

- was any data or MAC control frame destined for any unicast, broadcast or multicast address (address match does not matter)
- Any length (including less than 64 bytes and greater than rx\_maxlen bytes)

Also counted in this statistic is:

- Every byte transmitted before a carrier-loss was experienced
- Every byte transmitted before each collision was experienced, (i.e. multiple retries are counted each time)
- Every byte received if the port is in half-duplex mode until a jam sequence was transmitted to initiate flow control. (The jam sequence was not counted to prevent double-counting)

Error conditions such as alignment errors, CRC errors, code errors, overruns and underruns do not affect the recording of bytes by this statistic.

The objective of this statistic is to give a reasonable indication of ethernet utilization

### **15.3.2.20.2 Tx-only Statistics Descriptions**

The maximum and minimum transmit frame size is software controllable.

#### **15.3.2.20.2.1 Good Tx Frames (Offset = 34h)**

The total number of good frames received on the port. A good frame is defined to be:

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Any length
- Had no late or excessive collisions, no carrier loss and no underrun

#### **15.3.2.20.2.2 Broadcast Tx Frames (Offset = 38h)**

The total number of good broadcast frames received on the port. A good broadcast frame is defined to be:

- Any data or MAC control frame which was destined for only address 0xFFFFFFFFFFFF
- Any length
- Had no late or excessive collisions, no carrier loss and no underrun

#### **15.3.2.20.2.3 Multicast Tx Frames (Offset = 3Ch)**

The total number of good multicast frames received on the port. A good multicast frame is defined to be:

- Any data or MAC control frame which was destined for any multicast address other than 0xFFFFFFFFFFFF
- Any length
- Had no late or excessive collisions, no carrier loss and no underrun

#### **15.3.2.20.2.4 Pause Tx Frames (Offset = 40h)**

This statistic indicates the number of IEEE 802.3X pause frames transmitted by the port.

Pause frames cannot underrun or contain a CRC error because they are created in the transmitting MAC, so these error conditions have no effect upon the statistic. Pause frames sent by software will not be included in this count.

Since pause frames are only transmitted in full duplex carrier loss and collisions have no effect upon this statistic.

Transmitted pause frames are always 64 byte multicast frames so will appear in the Tx Multicast Frames and 64octet Frames statistics.

#### **15.3.2.20.2.5 Collisions (Offset = 48h)**

This statistic records the total number of times that the port experienced a collision. Collisions occur under two circumstances.

1. When a transmit data or MAC control frame:

- Was destined for any unicast, broadcast or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced a collision. A jam sequence is sent for every non-late collision, so this statistic will increment on each occasion if a frame experiences multiple collisions (and increments on late collisions)

CRC errors have no effect upon this statistic.

2. When the port is in half-duplex mode, flow control is active, and a frame reception begins.

**15.3.2.20.2.6 Single Collision Tx Frames (Offset = 4Ch)**

The total number of frames transmitted on the port that experienced exactly one collision. Such a frame:

- Was any data or MAC control frame destined for any unicast, broadcast or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced one collision before successful transmission. The collision was not late.

CRC errors have no effect upon this statistic.

**15.3.2.20.2.7 Multiple Collision Tx Frames (Offset = 50h)**

The total number of frames transmitted on the port that experienced multiple collisions. Such a frame:

- Was any data or MAC control frame destined for any unicast, broadcast or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced 2 to 15 collisions before being successfully transmitted. None of the collisions were late.

CRC errors have no effect upon this statistic.

**15.3.2.20.2.8 Excessive Collisions (Offset = 54h)**

The total number of frames for which transmission was abandoned due to excessive collisions. Such a frame:

- Was any data or MAC control frame destined for any unicast, broadcast or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced 16 collisions before abandoning all attempts at transmitting the frame. None of the collisions were late.

CRC errors have no effect upon this statistic.

**15.3.2.20.2.9 Late Collisions (Offset = 58h)**

The total number of frames on the port for which transmission was abandoned because they experienced a late collision. Such a frame:

- Was any data or MAC control frame destined for any unicast, broadcast or multicast address
- Was any size
- Experienced a collision later than 512 bit-times into the transmission. There may have been up to 15 previous (non-late) collisions which had previously required the transmission to be re-attempted. The Late Collisions statistic dominates over the single, multiple and excessive Collisions statistics - if a late collision occurs the frame will not be counted in any of these other three statistics.

CRC errors have no effect upon this statistic.

**15.3.2.20.2.10 Tx Underrun (Offset = 5Ch)**

There should be no transmitted frames that experience underrun.

**15.3.2.20.2.11 Deferred Tx Frames (Offset = 44h)**

The total number of frames transmitted on the port that first experienced deferment. Such a frame:

- Was any data or MAC control frame destined for any unicast, broadcast or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced no collisions before being successfully transmitted

- Found the medium busy when transmission was first attempted, so had to wait.
- CRC errors have no effect upon this statistic.

#### **15.3.2.20.2.12 Carrier Sense Errors (Offset = 60h)**

The total number of frames received on the port that had a CPDMA middle of frame (MOF) overrun. MOF overrun frame is defined to be:

- Was any data or MAC control frame destined for any unicast, broadcast or multicast address
- Was any size
- The carrier sense condition was lost or never asserted when transmitting the frame (the frame is not retransmitted). This is a transmit only statistic. Carrier Sense is a don't care for received frames. Transmit frames with carrier sense errors are sent until completion and are not aborted.

CRC errors have no effect upon this statistic.

#### **15.3.2.20.2.13 Tx Octets (Offset = 64h)**

The total number of bytes in all good frames transmitted on the port. A good frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Was any size
- Had no late or excessive collisions, no carrier loss and no underrun.

### **15.3.2.20.3 Rx- and Tx-Shared Statistics Descriptions**

#### **15.3.2.20.3.1 Rx + Tx 64 Octet Frames (Offset = 68h)**

The total number of 64-byte frames received and transmitted on the port. Such a frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Did not experience late collisions, excessive collisions, or carrier sense error
- Was exactly 64 bytes long. (If the frame was being transmitted and experienced carrier loss that resulted in a frame of this size being transmitted, then the frame will be recorded in this statistic).

CRC errors, code/align errors and overruns do not affect the recording of frames in this statistic.

#### **15.3.2.20.3.2 Rx + Tx 65–127 Octet Frames (Offset = 6Ch)**

The total number of frames of size 65 to 127 bytes received and transmitted on the port. Such a frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Did not experience late collisions, excessive collisions, or carrier sense error
- Was 65 to 127 bytes long

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

#### **15.3.2.20.3.3 Rx + Tx 128–255 Octet Frames (Offset = 70h)**

The total number of frames of size 128 to 255 bytes received and transmitted on the port. Such a frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Did not experience late collisions, excessive collisions, or carrier sense error
- Was 128 to 255 bytes long

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

**15.3.2.20.3.4 Rx + Tx 256–511 Octet Frames (Offset = 74h)**

The total number of frames of size 256 to 511 bytes received and transmitted on the port. Such a frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Did not experience late collisions, excessive collisions, or carrier sense error
- Was 256 to 511 bytes long

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

**15.3.2.20.3.5 Rx + Tx 512–1023 Octet Frames (Offset = 78h)**

The total number of frames of size 512 to 1023 bytes received and transmitted on the port. Such a frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Did not experience late collisions, excessive collisions, or carrier sense error
- Was 512 to 1023 bytes long

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

**15.3.2.20.3.6 Rx + Tx 1024\_Up Octet Frames (Offset = 7Ch)**

The total number of frames of size 1024 to rx\_maxlen bytes for receive or 1024 up for transmit on the port. Such a frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Did not experience late collisions, excessive collisions, or carrier sense error
- Was 1024 to rx\_maxlen bytes long on receive, or any size on transmit

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

**Table 15-18. Rx Statistics Summary**

Rx Statistic	Frame/ Oct	Rx/ Rx+T x	Frame Type					Frame Size (bytes)								Event				
			MAC control		Data			<64	64	65- 127	128- 255	256- 511	512- 1023	1024- rx_ maxlen	>rx_ maxlen	Flow Coll.	CRC Error	Align/ Code	Over- run	Addr. Disc.
			Pause frame	Non- pause	Multi- cast	Broad- cast	Uni- cast													
Good Rx Frames	F	Rx	(y	y	y	y	y)	n	(y	y	y	y	y	y)	n	-	n	n	-	n
Broadcast Rx Frames	F	Rx	(%	%	n	y)	n	n	(y	y	y	y	y	y)	n	-	n	n	-	n
Multicast Rx Frames	F	Rx	(%	%	y)	n	n	n	(y	y	y	y	y	y)	n	-	n	n	-	n
Pause Rx Frames	F	Rx	y	n	n	n	n	n	(y	y	y	y	y	y)	n	-	n	n	-	-
Rx CRC Errors	F	Rx	(y	y	y	y	y)	n	(y	y	y	y	y	y)	n	-	y	n	-	n
Rx Align/Code Errors	F	Rx	(y	y	y	y	y)	n	(y	y	y	y	y	y)	n	-	-	y	-	n
Oversized Rx Frames	F	Rx	(y	y	y	y	y)	n	n	n	n	n	n	n	y	-	n	n	-	n
Rx Jabbers	F	Rx	(y	y	y	y	y)	n	n	n	n	n	n	n	y	-	(y	y)	-	n
Undersized Rx Frames	F	Rx	n	n	(y	y	y)	y	n	n	n	n	n	n	n	-	n	n	-	n
Rx Fragments	F	Rx	n	n	(y	y	y)	y^	n	n	n	n	n	n	n	-	(y	y)	-	-
Rx Overruns	F	Rx	(y	y	y	y	y)	(y	y	y	y	y	y	y)	y)	-	-	-	y	n
64octet Frames	F	Rx+T x	(y	y	y	y	y)	n	y	n	n	n	n	n	n	-	-	-	-	n
65-127octet Frames	F	Rx+T x	(y	y	y	y	y)	n	n	y	n	n	n	n	n	-	-	-	-	n
128-255octet Frames	F	Rx+T x	(y	y	y	y	y)	n	n		y	n	n	n	n	-	-	-	-	n
256-511octet Frames	F	Rx+T x	(y	y	y	y	y)	n	n	n	n	y	n	n	n	-	-	-	-	n
512-1023octet Frames	F	Rx+T x	(y	y	y	y	y)	n	n	n	n	n	y	n	n	-	-	-	-	n
1024-UPoctet Frames	F	Rx+T x	(y	y	y	y	y)	n	n	n	n	n	n	y	n	-	-	-	-	n
Rx Octets	O	Rx	(y	y	y	y	y)	n	(y	y	y	y	y	y)	n	-	n	n	-	n
Net Octets	O	Rx+T x	(y	y	y	y	y)	(y	y	y	y	y	y	y	y	y)	-	-	-	-

**Notes for the Rx Statistics Summary:**

1. "AND" is assumed horizontally across the table between all conditions which form the statistic (marked y or n) except where (y|y), meaning "OR" is indicated. Parentheses are significant.
2. "-" indicates conditions which are ignored in the formations of the statistic.
3. Statistics marked "Rx+Tx" are formed by summing the Rx and Tx statistics, each of which is formed independently.
4. The non-pause column refers to all MAC control frames (i.e. frames with length/type=88.08) with opcodes other than 0x0001. The pauseframe column refers to MAC frames with the opcode=0x0001.
5. The multicast, broadcast and unicast columns in the table refer to non-MACCTRL/non-pause frames (i.e. data frames).
6. "%" If either a MAC control frame or pause frame has a multicast or broadcast destination address then the appropriate statistics will be updated.
7. "y^" Frame fragments are not counted if less than 8 bytes.
8. flow coll. are half-duplex collisions forced by the MAC to achieve flow-control. A collision will be forced during the first 8 bytes so should not show in frame fragments. Some of the '-'s in this column might in reality be 'n's.
9. The rx\_overruns stat show above is for rx\_mof\_overruns and rx\_sof\_overruns added together.

**Table 15-19. Tx Statistics Summary**

Tx Statistic	Frame/ Oct	Tx/ Rx+ Tx	Frame Type					Frame Size (bytes)							Event									
			MAC control		Data			64	65- 127	128- 255	256- 511	512- 1023	1024 - 1535	> 1535	CRC Error	Collision Type					No Carrier	Que ued	Defer red	Und er- run
			Pause e (MA C)	Any (CP U)	Multi - cast	Broad- cast	Uni- cast									Flow	1	2- 15	16	Late				
Good Tx Frames	F	Tx	(y	y	y	y	y)	(y	y	y	y	y	y	y)	-	-	-	-	n	n	n	-	-	n
Broadcast Tx Frames	F	Tx	n	(%	n	y)	n	(y	y	y	y	y	y	y)	-	-	-	-	n	n	n	-	-	n
Multicast Tx Frames	F	Tx	(y	%	y)	n	n	y	y	y	y	y	y	y)	-	-	-	-	n	n	n	-	-	n
Pause Tx Frames	F	Tx	y	n	n	n	n	y	n	n	n	n	n	n	-	-	-	-	-	-	-	-	-	-
Collisions	F	Tx	n	(y	y	y	y)	(y	y	y	y	y	y	y)	-	(+	+	+	+	+	n	-	-	-
Single Collision Tx Frames	F	Tx	n	(y	y	y	y)	(y	y	y	y	y	y	y)	-	-	y	n	n	n	n	-	-	-
Multiple Collision Tx Frames	F	Tx	n	(y	y	y	y)	(y	y	y	y	y	y	y)	-	-	n	y	n	n	n	-	-	-
Excessive Collisions	F	Tx	n	(y	y	y	y)	(y	y	y	y	y	y	y)	-	-	n	n	y	n	n	-	-	-
Late Collisions	F	Tx	n	(y	y	y	y)	n	(y	y	y	y	y	y)	-	-	-	-	-	y	-	-	-	-
Deferred Tx Frames	F	Tx	n	(y	y	y	y)	(y	y	y	y	y	y	y)	-	-	n	n	n	n	n	-	y	n
Carrier Sense Errors	F	Tx	(y	y	y	y	y)	(y	y	y	y	y	y	y)	-	-	-	-	-	-	y	-	-	-
64octet Frames	F	Rx+ Tx	(y	y	y	y	y)	y	n	n	n	n	n	n	-	-	-	-	n	n	n	-	-	-
65-127octet Frames	F	Rx+ Tx	(y	y	y	y	y)	n	y	n	n	n	n	n	-	-	-	-	n	n	n	-	-	-
128-255octet Frames	F	Rx+ Tx	(y	y	y	y	y)	n	n	y	n	n	n	n	-	-	-	-	n	n	n	-	-	-
256-511octet Frames	F	Rx+ Tx	(y	y	y	y	y)	n	n	n	y	n	n	n	-	-	-	-	n	n	n	-	-	-
512-1023octet Frames	F	Rx+ Tx	(y	y	y	y	y)	n	n	n	n	y	n	n	-	-	-	-	n	n	n	-	-	-
1024-UPoctet Frames	F	Rx+ Tx	(y	y	y	y	y)	n	n	n	n	n	y	y	-	-	-	-	n	n	n	-	-	-
Tx Octets	O	Tx	(y	y	y	y	y)	(y	y	y	y	y	y	y)	-	-	-	-	n	n	n	-	-	n
Net Octets	O	Rx+ Tx	(y	y	y	y	y)	(y	y	y	y	y	y	y)	-	-	\$	\$	\$	\$	\$	-	-	-

**Notes for the Tx Statistics Summary:**

1. "AND" is assumed horizontally across the table between all conditions which form the statistic (marked y or n) except where (y|y), meaning "OR" is indicated. Parentheses are significant.
2. "-" indicates conditions which are ignored in the formations of the statistic.
3. Statistics marked "Rx+Tx" are formed by summing the Rx and Tx statistics, each of which is formed independently.
4. Pause (MAC) frames are issued in the MAC as perfect (no CRC error) 64 byte frames in full duplex only, so they cannot collide.
5. "%" If a CPU sourced MAC control frame has a multicast or broadcast destination address then the appropriate statistics will be updated.
6. "+" indicates collisions which are "summed" (i.e. every collision is counted in the Collisions statistic). Jam sequences used for halfduplex flow control are also counted.
7. "\$" Every byte written on the wire during each retry attempt is also counted in addition to frames which experience no collisions or carrier loss.
8. The flow collision type is for half-duplex collisions forced by the MAC to achieve flow control. Some of the '-'s in this column might in reality be 'n's. To prevent double-counting, Net Octets are unaffected by the jam sequence – the 'received' bytes, however, are counted. (See [Table 15-18](#).)
9. When the transmit Tx FIFO is drained due to the MAC being disabled or link being lost, then the frames being purged will not appear in the Tx statistics.

### 15.3.3 Ethernet Mac Sliver (CPGMAC\_SL)

The CPGMAC\_SL peripheral shall be compliant to the IEEE Std 802.3 Specification. Half duplex mode is supported in 10/100 Mbps mode, but not in 1000 Mbps (gigabit) mode.

Features:

- Synchronous 10/100/1000 Mbit operation.
- G/MII Interface.
- Hardware Error handling including CRC.
- Full Duplex Gigabit operation (half duplex gigabit is not supported).
- EtherStats and 802.3Stats RMON statistics gathering support for external statistics collection module.
- Transmit CRC generation selectable on a per channel basis.
- Emulation Support.
- VLAN Aware Mode Support.
- Hardware flow control.
- Programmable Inter Packet Gap (IPG)

#### 15.3.3.1 GMII/MII Media Independent Interface

The following sections cover operation of the Media Independent Interface in 10/100/1000 Mbps modes. An IEEE 802.3 compliant Ethernet MAC controls the interface.

##### 15.3.3.1.1 Data Reception

###### 15.3.3.1.1.1 Receive Control

Data received from the PHY is interpreted and output. Interpretation involves detection and removal of the preamble and start of frame delimiter, extraction of the address and frame length, data handling, error checking and reporting, cyclic redundancy checking (CRC), and statistics control signal generation.

###### 15.3.3.1.1.2 Receive Inter-Frame Interval

The 802.3 required inter-packet gap (IPG) is 24 GMII clocks (96 bit times) for 10/100 Mbit modes, and 12 GMII clocks (96 bit times) for 1000 Mbit mode. However, the MAC can tolerate a reduced IPG (2 GMII clocks in 10/100 mode and 5 GMII clocks in 1000 mode) with a correct preamble and start frame delimiter.

This interval between frames must comprise (in the following order):

- An Inter-Packet Gap (IPG).
- A seven octet preamble (all octets 0x55).
- A one octet start frame delimiter (0x5D).

###### 15.3.3.1.2 Data Transmission

The Gigabit Ethernet Mac Sliver (GMII) passes data to the PHY when enabled. Data is synchronized to the transmit clock rate. The smallest frame that can be sent is two bytes of data with four bytes of CRC (6 byte frame).

###### 15.3.3.1.2.1 Transmit Control

A jam sequence is output if a collision is detected on a transmit packet. If the collision was late (after the first 64 bytes have been transmitted) the collision is ignored. If the collision is not late, the controller will back off before retrying the frame transmission. When operating in full duplex mode the carrier sense (CRS) and collision sensing modes are disabled.

### 15.3.3.1.2.2 CRC Insertion

The MAC generates and appends a 32-bit Ethernet CRC onto the transmitted data if the transmit packet header **pass\_crc** bit is zero. For the CPMAC\_SL generated CRC case, a CRC at the end of the input packet data is not allowed.

If the header word **pass\_crc** bit is set, then the last four bytes of the TX data are transmitted as the frame CRC. The four CRC data bytes should be the last four bytes of the frame and should be included in the packet byte count value. The MAC performs no error checking on the outgoing CRC when the **pass\_crc** bit is set.

### 15.3.3.1.2.3 TXER

The GMII\_TXER signal is not used. If an underflow condition occurs on a transmitted frame, the frame CRC will be inverted to indicate the error to the network. Underflow is a hardware error.

### 15.3.3.1.2.4 Adaptive Performance Optimization (APO)

The Ethernet MAC port incorporates Adaptive Performance Optimization (APO) logic that may be enabled by setting the **tx\_pace** bit in the **MACCTRL** register. Transmission pacing to enhance performance is enabled when set. Adaptive performance pacing introduces delays into the normal transmission of frames, delaying transmission attempts between stations, reducing the probability of collisions occurring during heavy traffic (as indicated by frame deferrals and collisions) thereby increasing the chance of successful transmission.

When a frame is deferred, suffers a single collision, multiple collisions or excessive collisions, the pacing counter is loaded with an initial value of 31. When a frame is transmitted successfully (without experiencing a deferral, single collision, multiple collision or excessive collision) the pacing counter is decremented by one, down to zero.

With pacing enabled, a new frame is permitted to immediately (after one IPG) attempt transmission only if the pacing counter is zero. If the pacing counter is non zero, the frame is delayed by the pacing delay, a delay of approximately four inter-packet gap delays. APO only affects the IPG preceding the first attempt at transmitting a frame. It does not affect the back-off algorithm for retransmitted frames.

### 15.3.3.1.2.5 Inter-Packet-Gap Enforcement

The measurement reference for the IPG of 96 bit times is changed depending on frame traffic conditions. If a frame is successfully transmitted without collision, and **GMII\_CRS** is de-asserted within approximately 48 bit times of **GMII\_TXEN** being de-asserted, then 96 bit times is measured from **GMII\_TXEN**. If the frame suffered a collision, or if **GMII\_CRS** is not de-asserted until more than approximately 48 bit times after **GMII\_TXEN** is de-asserted, then 96 bit times (approximately, but not less) is measured from **GMII\_CRS**.

The transmit IPG can be shortened by eight bit times when enabled and triggered. The **tx\_short\_gap\_en** bit in the **MACCTRL** register enables the **TX\_SHORT\_GAP** input to determine whether the transmit IPG is shortened by eight bit times.

### 15.3.3.1.2.6 Back Off

The Gigabit Ethernet Mac Sliver (GMII) implements the 802.3 binary exponential back-off algorithm.

### 15.3.3.1.2.7 Programmable Transmit Inter-Packet Gap

The transmit inter-packet gap (IPG) is programmable through the **Tx\_Gap** register. The default value is decimal 12. The transmit IPG may be increased to the maximum value of 0x1ff. Increasing the IPG is not compatible with transmit pacing. The short gap feature will override the increased gap value, so the short gap feature may not be compatible with an increased IPG.

### 15.3.3.1.2.8 Speed, Duplex, and Pause Frame Support Negotiation

The CPMAC\_SL can operate in half duplex or full duplex in 10/100 Mbit modes, and can operate in full duplex only in 1000 Mbit mode. Pause frame support is included in 10/100/1000 Mbit modes as configured by the host.

### 15.3.3.2 Frame Classification

Received frames are proper (good) frames if they are between 64 and **rx\_maxlen** in length (inclusive) and contain no errors (code/align/CRC).

Received frames are long frames if their frame count exceeds the value in the **rx\_maxlen** register. The **rx\_maxlen** register reset (default) value is 1518 (dec). Long received frames are either oversized or jabber frames. Long frames with no errors are oversized frames. Long frames with CRC, code, or alignment errors are jabber frames.

Received frames are short frames if their frame count is less than 64 bytes. Short frames that contain no errors are undersized frames. Short frames with CRC, code, or alignment errors are fragment frames.

A received long packet will always contain **rx\_maxlen** number of bytes transferred to memory (if **rx\_csf\_en** = 1). An example with **rx\_maxlen** = 1518 is below:

- If the frame length is 1518, then the packet is not a long packet and there will be 1518 bytes transferred to memory.
- If the frame length is 1519, there will be 1518 bytes transferred to memory. The last three bytes will be the first three CRC bytes.
- If the frame length is 1520, there will be 1518 bytes transferred to memory. The last two bytes will be the first two CRC bytes.
- If the frame length is 1521, there will be 1518 bytes transferred to memory. The last byte will be the first CRC byte.

If the frame length is 1522, there will be 1518 bytes transferred to memory. The last byte will be the last data byte.

### 15.3.4 Command IDLE

The **cmd\_idle** bit in the MACCTRL register allows CPGMAC\_SL operation to be suspended. When the idle state is commanded, the CPGMAC\_SL will stop processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission will be completed normally without suspension. Received frames that are detected after the suspend state is entered are ignored. Commanded idle is similar in operation to emulation control and clock stop.

### 15.3.5 RMII Interface

The CPRMII peripheral shall be compliant to the RMII specification document.

Features:

- Source Synchronous 10/100 Mbit operation.
- Full and Half Duplex support.

#### 15.3.5.1 RMII Receive (RX)

The CPRMII receive (RX) interface converts the input data from the external RMII PHY (or switch) into the required MII (CPGMAC) signals. The carrier sense and collision signals are determined from the RMII input data stream and transmit inputs as defined in the RMII specification.

An asserted **RMII\_RXER** on any di-bit in the received packet will cause an **MII\_RXER** assertion to the CPGMAC during the packet. In 10Mbps mode, the error is not required to be duplicated on 10 successive clocks. Any di-bit which has an asserted **RMII\_RXER** during any of the 10 replications of the data will cause the error to be propagated.

Any received packet that ends with an improper nibble boundary aligned RMII\_CRS\_DV toggle will issue an MII\_RXER during the packet to the CPGMAC. Also, a change in speed or duplex mode during packet operations will cause packet corruption.

The CPRMII can accept receive packets with shortened preambles, but 0x55 followed by a 0x5d is the shortest preamble that will be recognized (1 preamble byte with the start of frame byte). At least one byte of preamble with the start of frame indicator is required to begin a packet. An asserted RMII\_CRS\_DV without at least a single correct preamble byte followed by the start of frame indicator will be ignored.

### 15.3.5.2 RMII Transmit (TX)

The CPRMII transmit (TX) interface converts the 3PSW MII input data into the RMII transmit format. The data is then output to the external RMII PHY.

The 3PSW does not source the transmit error (MII\_TXERR) signal. Any transmit frame from the CPGMAC with an error (ie. underrun) will be indicated as an error by an error CRC. Transmit error is assumed to be deasserted at all times and is not an input into the CPRMII module. Zeroes are output on RMII\_TXD[1:0] for each clock that RMII\_TXEN is deasserted.

### 15.3.6 RGMII Interface

The CPRGMII peripheral shall be compliant to the RGMII specification document.

Features:

- Supports 1000/100/10 Mbps Speed.
- MII mode is not supported.

If RGMII is used, and a 10Mbit operation is desired, in-band mode must be used and an ethernet PHY that supports in-band status signaling must be selected.

#### 15.3.6.1 RGMII Receive (RX)

The CPRGMII receive (RX) interface converts the source synchronous DDR input data from the external RGMII PHY into the required G/MII (CPGMAC) signals.

#### 15.3.6.2 In-Band Mode of Operation

The CPRGMII is operating in the in-band mode of operation when the **RGMIIRX\_INBAND** input is asserted. **RGMIIRX\_INPUT** is asserted by configuring the ext\_en bit to 1 of the MACCTRL register. The link status, duplexity, and speed are determined from the RGMII input data stream as defined in the RGMII specification. The link speed is indicated as shown in the following table:

RGMIISPEED(1:0)	Link Speed
00	10 Mbs mode
01	100 Mbs mode
10	1000 Mbs mode
11	reserved

#### 15.3.6.3 Forced Mode of Operation

The CPRGMII is operating in the forced mode of operation when the **RGMIIRX\_INBAND** input is deasserted by setting MACCTRL.EXT\_EN to 0. In the forced mode of operation, the in-band data is ignored if present. In this mode, the contents of RGMII\_CTL are meaningless. Link status, duplexity, and speed status should be determined from the external ethernet PHY via MDIO transactions.

#### 15.3.6.4 RGMII Transmit (TX)

The CPRGMII transmit (TX) interface converts the CPGMAC G/MII input data into the DDR RGMII format. The DDR data is then output to the external PHY.

The CPGMAC does not source the transmit error (MTXERR) signal. Any transmit frame from the CPGMAC with an error (that is, underrun) will be indicated as an error by an error CRC. Transmit error is assumed to be deasserted at all times and is not an input into the CPRGMII module.

The RGMII0/1\_ID\_MODE bit value in the GMII\_SEL register should only be set to 1 for 'no internal delay'. The device does not support internal delay mode for RGMII.

### 15.3.7 Common Platform Time Sync (CPTS)

The CPTS module is used to facilitate host control of time sync operations. It enables compliance with the IEEE 1588-2008(v2) standard for a precision clock synchronization protocol.

#### 15.3.7.1 Architecture

**Figure 15-10. CPTS Block Diagram**

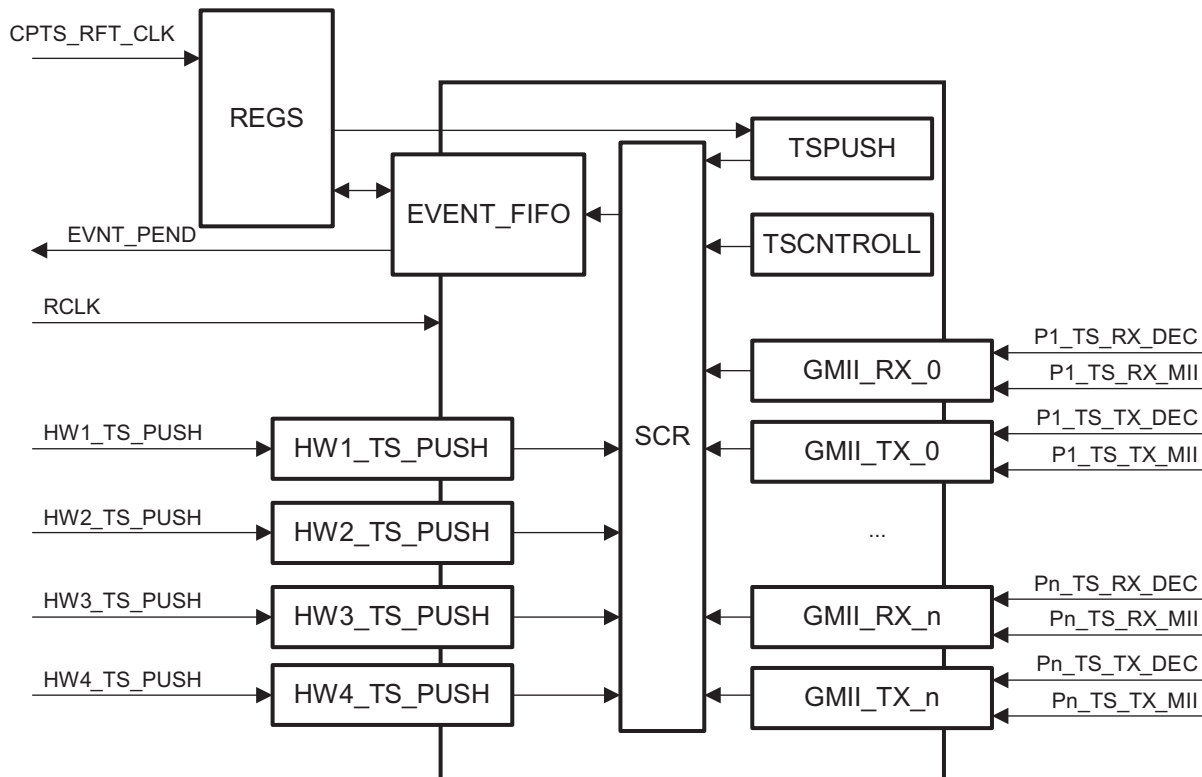

Figure 15-10 shows the architecture of the CPTS module inside the 3PSW Ethernet Subsystem. Time stamp values for every packet transmitted or received on either port of the 3PSW are recorded. At the same time, each packet is decoded to determine if it is a valid time sync event. If so, an event is loaded into the Event FIFO for processing containing the recorded time stamp value when the packet was transmitted or received.

In addition, both hardware (HWx\_TS\_PUSH) and software (TS\_PUSH) can be used to read the current time stamp value through the Event FIFO

The reference clock used for the time stamp (RCLK) is sourced from one of the two sources, as shown in Figure 15-10. The source can be selected by configuring the CM\_CPTS\_RFT\_CLKSEL register in the Control Module. For more details, see [Chapter 7, Control Module](#).

### 15.3.7.2 Time Sync Overview

The CPTS module is used to facilitate host control of time sync operations. The CPTS collects time sync events and then presents them to the host for processing. There are five types of time sync events (ethernet receive event, ethernet transmit event, time stamp push event, time stamp rollover event, and time stamp half-rollover event). Each ethernet port can cause transmit and receive events. The time stamp push is initiated by software.

#### 15.3.7.2.1 Time Sync Initialization

The CPTS module should be configured as shown:

- Complete the reset sequence (VBUSP\_RST\_N) to reset the module.
- Write the rftclk\_sel[4:0] value in the RFTCLK\_Sel register with the desired reference clock multiplexor value. This value is allowed to be written only when the cpts\_en bit is cleared to zero.
- Write a one to the cpts\_en bit in the TS\_Ctrl register. The RCLK domain is in reset while this bit is low.
- Enable the interrupt by writing a one to the ts\_pend\_en bit in the TS\_Int\_En register (if using interrupts and not polling).

#### 15.3.7.2.2 Time Stamp Value

The time stamp value is a 32-bit value that increments on each RCLK rising edge when CPTS\_EN is set to one. When CPTS\_EN is cleared to zero the time stamp value is reset to zero. If more than 32-bits of time stamp are required by the application, the host software must maintain the necessary number of upper bits. The upper time stamp value should be incremented by the host when the rollover event is detected.

For test purposes, the time stamp can be written via the time stamp load function (CPTS\_LOAD\_VAL and CPTS\_LOAD\_EN registers).

#### 15.3.7.2.3 Event FIFO

All time sync events are pushed onto the Event FIFO. There are 16 locations in the event FIFO with no overrun indication supported. Software must service the event FIFO in a timely manner to prevent FIFO overrun.

#### 15.3.7.2.4 Time Sync Events

Time Sync events are 64-bit values that are pushed onto the event FIFO and read in two 32-bit reads. CPTS\_EVT\_LOW and CPTS\_EVT\_HIGH are defined in and , respectively.

There are six types of sync events

- Time stamp push event
- Hardware time stamp push event
- Time stamp counter rollover event
- Time stamp counter half-rollover event
- Ethernet receive event
- Ethernet transmit event

##### 15.3.7.2.4.1 Time Stamp Push Event

Software can obtain the current time stamp value (at the time of the write) by initiating a time stamp push event. The push event is initiated by setting the TS\_PUSH bit of the CPTS\_TS\_PUSH register. The time stamp value is returned in the event, along with a time stamp push event code. Software should not push a second time stamp event on to the FIFO until the first time stamp value has been read from the event FIFO.

#### 15.3.7.2.4.2 Time Stamp Counter Rollover Event

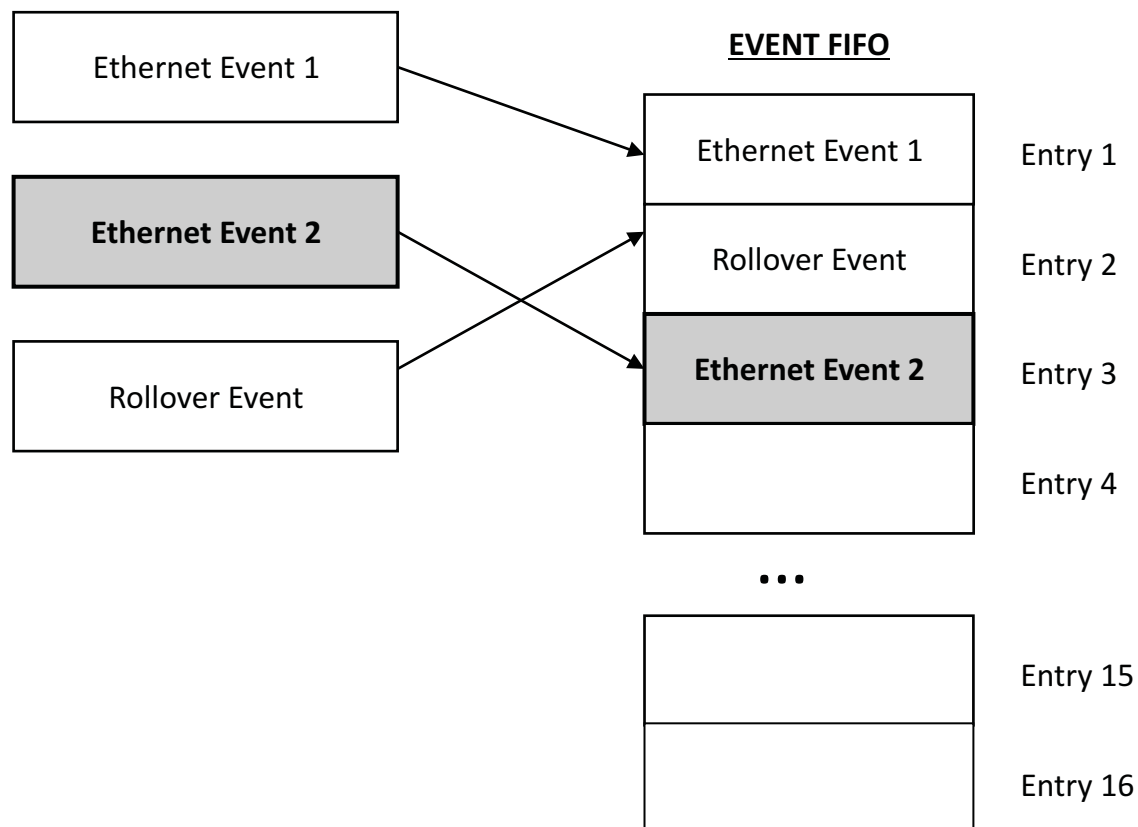

The CPTS module contains a 32-bit time stamp value. The counter upper bits are maintained by host software. The rollover event indicates to software that the time stamp counter has rolled over from 0xFFFF\_FFFF to 0x0000\_0000, and the software maintained upper count value should be incremented.

#### 15.3.7.2.4.3 Time Stamp Counter Half-Rollover Event

The CPTS includes a time stamp counter half-rollover event. The half-rollover event indicates to software that the time stamp value has incremented from 0x7FFF\_FFFF to 0x8000\_0000. The half-rollover event is included to enable software to correct a misaligned event condition. The half-rollover event is included to enable software to determine the correct time for each event that contains a valid time stamp value – such as an Ethernet event. If an Ethernet event occurs around a counter rollover (full rollover), the rollover event could possibly be loaded into the event FIFO before the Ethernet event, even though the Ethernet event time was actually taken before the rollover. Figure 3 below shows a misalignment condition.

This misaligned event condition arises because an ethernet event time stamp occurs at the beginning of a packet and time passes before the packet is determined to be a valid synchronization packet. The misaligned event condition occurs if the rollover occurs in the middle, after the packet time stamp has been taken, but before the packet has been determined to be a valid time sync packet.

**Figure 15-11. Event FIFO Misalignment Condition**

Host software must detect and correct for misaligned event conditions. For every event after a rollover and before a half-rollover, software must examine the time stamp most significant bit. If bit 31 of the time stamp value is low (0x0000\_0000 through 0x7FFF\_FFFF), then the event time stamp was taken after the rollover and no correction is required.

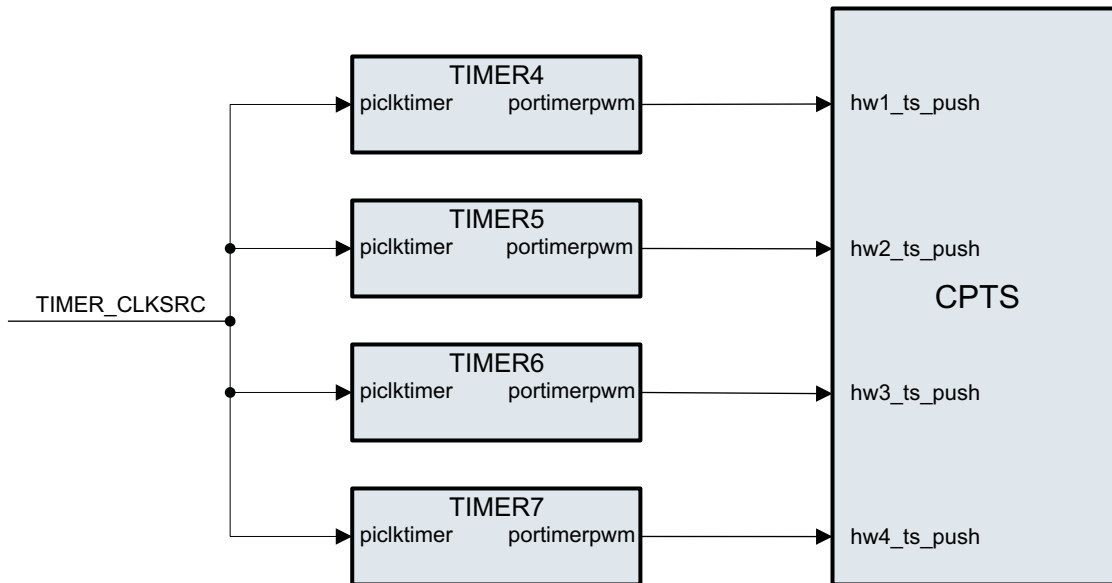

If the value is high (0x8000\_0000 through 0xFFFF\_FFFF), the time stamp value was taken before the rollover and a misalignment is detected. The misaligned case indicates to software that it must subtract one from the upper count value stored in software to calculate the correct time for the misaligned event. The misaligned event occurs only on the rollover boundary and not on the half-rollover boundary. Software only needs to check for misalignment from a rollover event to a half-rollover event.

#### 15.3.7.2.4.4 Hardware Time Stamp Push Event

There are four hardware time stamp inputs (HW1/4\_TS\_PUSH) that can cause hardware time stamp push events to be loaded into the Event FIFO. Each hardware time stamp input is internally connected to the PORTIMERPWM output of each timer as shown in Figure 4.

Figure 15-12. HW1/4\_TSP\_PUSH Connection

The event is loaded into the event FIFO on the rising edge of the timer, and the PORT\_NUMBER field in the EVT\_HIGH register indicates the hardware time stamp input that caused the event.

Each hardware time stamp input must be asserted for at least 10 periods of the selected RCLK clock. Each input can be enabled or disabled by setting the respective bits in the **CONTROL** register.

Hardware time stamps are intended to be an extremely low frequency signals, such that the event FIFO does not overrun. Software must keep up with the event FIFO and ensure that there is no overrun, or events will be lost.

#### 15.3.7.2.4.5 Ethernet Port Events

##### 15.3.7.2.4.5.1 Ethernet Port Receive Event

Each ethernet port can generate a receive ethernet event. Receive ethernet events are generated for valid received time sync packets. There are two CPTS interfaces for each ethernet receive port. The first is the Px\_TS\_RX\_MII interface and the second is the Px\_TS\_RX\_DEC interface. Information from these interfaces is used to generate an ethernet receive event for each ethernet time sync packet received on the associated port.

The Px\_TS\_RX\_MII interface issues a record signal (pX\_ts\_rx\_mii\_rec) along with a handle (pX\_ts\_rx\_mii\_hndl) for each packet (every packet) that is received on the associated ethernet port. The record signal is a single clock pulse indicating that a receive packet has been detected at the associated port MII interface. The handle value is incremented with each packet and rolls over to zero after 15.

There are 16 possible handle values so there can be a maximum of 16 packets "in flight" from the TS\_RX\_MII to the TS\_RX\_DEC block at any given time. A handle value is reused (not incremented) for any received packet that is shorter than about 31 octets (including preamble). Handle reuse on short packets prevents any possible overrun condition (more than 16 "in flight" packets) if multiple fragments are consecutively received.

Valid receive ethernet time sync events are signaled to the CPTS via the Px\_TS\_RX\_DEC interface. When the pX\_ts\_rx\_dec\_evnt is asserted, a valid event is detected and will be loaded into the event FIFO. Only valid receive time sync packets are indicated on the Px\_TS\_RX\_DEC interface. The pX\_ts\_rx\_dec\_hdl, pX\_ts\_rx\_dec\_msg\_type, and pX\_ts\_rx\_dec\_seq\_id signals are registered on an asserted pX\_ts\_rx\_dec\_evnt. When a Tx\_TS\_RX\_DEC event is asserted, the handle value is used to retrieve the time stamp that was loaded with the same handle value from the Px\_TS\_RX\_MII interface.

#### 15.3.7.2.4.5.2 Ethernet Port Transmit Event

Each ethernet port can generate a transmit ethernet event. Transmit ethernet events are generated for valid transmitted time sync packets. There are two CPTS interfaces for each ethernet transmit port. The first is the Px\_TS\_TX\_DEC interface and the second is the Px\_TS\_TX\_MII interface. Information from these interfaces is used to generate an ethernet transmit event for each ethernet time sync packet transmitted on the associated port.

Valid ethernet transmit time sync events are signaled to the CPTS via the Px\_TS\_TX\_DEC interface. When the pX\_ts\_tx\_dec\_evnt signal is asserted, a valid time sync event has been detected and will be loaded into the event FIFO. Only valid transmit time sync packets are indicated on the Px\_TS\_TX\_DEC interface. The pX\_ts\_tx\_dec\_hdl, pX\_ts\_tx\_dec\_msg\_type, pX\_ts\_tx\_dec\_seq\_id signals are registered on an asserted pX\_ts\_tx\_dec\_evnt.

The time stamp for the event will be generated and signaled from the Px\_TS\_TX\_MII interface when the packet is actually transmitted. The event will be loaded into the event FIFO when the time stamp is recorded as controlled by the Px\_TS\_TX\_MII interface. The handle value is incremented with each time sync event packet and rolls over to zero after 7. There are 8 possible handle values so there can be a maximum of 8 time sync event packets “in flight” from the TS\_TX\_DEC to the TS\_TX\_MII block at any given time. The handle value increments only on time sync event packets.

The Px\_TS\_TX\_MII interface issues a single clock record signal (pX\_ts\_tx\_mii\_rec) at the beginning of each transmitted packet. If the packet is a time sync event packet then a single clock event signal (pX\_ts\_tx\_mii\_evnt) along with a handle (pX\_ts\_tx\_mii\_hdl) will be issued before the next record signal for the next transmitted packet. The event signal will not be issued for packets that were not indicated as valid time sync event packets on the Px\_TS\_TX\_DEC interface. If consecutive record indications occur without an interleaving event indication, then the packet associated with the first record was not a time sync event packet. The record signal is a single clock pulse indicating that a transmit packet egress has been detected at the associated port MII interface.

**Table 15-20. Values of messageType field**

Message Type	Value (hex)
Sync	0
Delay_Req	1
Pdelay_Req	2
Pdelay_Resp	3
Reserved	4-7
Follow_Up	8
Delay_Resp	9
Pdelay_Resp_Follow_Up	A
Announce	B
Signaling	C
Management	D
Reserved	E-F

### 15.3.7.3 Interrupt Handling

When an event is push onto the Event FIFO, an interrupt can be generated to indicate to software that a time sync event occurred. The following steps should be taken to process time sync events using interrupts:

- Enable the TS\_PEND interrupt by setting the TS\_PEND\_EN bit of the CPTS\_INT\_EN register.
- Upon interrupt, read the CPTS\_EVT\_LOW and CPTS\_EVT\_HIGH register values.
- Set the EVT\_POP field (bit zero) of the CPTS\_EVT\_POP register to pop the previously read value off of the event FIFO.
- Process the interrupt as required by the application software

Software has the option of processing more than a single event from the event FIFO in the interrupt service routine in the following way:

1. Enable the TS\_PEND interrupt by setting the TS\_PEND\_EN bit of the CPTS\_INT\_EN register.
2. Upon interrupt enter the CPTS service routine.
3. Read the CPTS\_EVT\_LOW and CPTS\_EVT\_HIGH register values.
4. Set the EVT\_POP bit of the CPTS\_EVT\_POP register to pop the previously read value off of the event FIFO.
5. Wait for an amount of time greater than eight CPTS\_RFT\_CLK periods
6. Read the ts\_pend\_raw bit in the CPTS\_INTSTAT\_RAW register to determine if another valid event is in the event FIFO. If it is asserted then goto step 3. Otherwise goto step 7.
7. Process the interrupt(s) as required by the application software

Software also has the option of disabling the interrupt and polling the ts\_pend\_raw bit of the CPTS\_INTSTAT\_RAW register to determine if a valid event is on the event FIFO.

### 15.3.8 MDIO

The MII Management I/F module implements the 802.3 serial management interface to interrogate and control two Ethernet PHYs simultaneously using a shared two-wire bus. Two user access registers to control and monitor up to two PHYs simultaneously.

#### 15.3.8.1 MII Management Interface Frame Formats

The following tables show the read and write format of the 32-bit MII Management interface frames, respectively.

**Table 15-21. MDIO Read Frame Format**

Preamble	Start Delimiter	Operation Code	PHY Address	Register Address	Turnaround	Data
0xFFFF FFFF	01	10	AAAAA	RRRRR	Z0	DDDD.DDDD. DDDD.DDDD

**Table 15-22. MDIO Write Frame Format**

Preamble	Start Delimiter	Operation Code	PHY Address	Register Address	Turnaround	Data
0xFFFF FFFF	01	01	AAAAA	RRRRR	10	DDDD.DDDD. DDDD.DDDD

The default or idle state of the two wire serial interface is a logic one. All tri-state drivers should be disabled and the PHY's pull-up resistor will pull the **MDIO\_DATA** line to a logic one. Prior to initiating any other transaction, the station management entity shall send a preamble sequence of 32 contiguous logic one bits on the **MDIO\_DATA** line with 32 corresponding cycles on **MDIO\_CLK** to provide the PHY with a pattern that it can use to establish synchronization. A PHY shall observe a sequence of 32 contiguous logic one bits on **MDIO\_DATA** with 32 corresponding **MDIO\_CLK** cycles before it responds to any other transaction.

**Preamble**

The start of a frame is indicated by a preamble, which consists of a sequence of 32 contiguous bits all of which are a “1”. This sequence provides the PHY a pattern to use to establish synchronization.

**Start Delimiter**

The preamble is followed by the start delimiter which is indicated by a “01” pattern. The pattern assures transitions from the default logic one state to zero and back to one.

**Operation Code**

The operation code for a read is “10”, while the operation code for a write is a “01”.

**PHY Address**

The PHY address is 5 bits allowing 32 unique values. The first bit transmitted is the MSB of the PHY address.

**Register Address**

The Register address is 5 bits allowing 32 registers to be addressed within each PHY. Refer to the 10/100 PHY address map for addresses of individual registers.

**Turnaround**

An idle bit time during which no device actively drives the MDIO\_DATA signal shall be inserted between the register address field and the data field of a read frame in order to avoid contention. During a read frame, the PHY shall drive a zero bit onto MDIO\_DATA for the first bit time following the idle bit and preceding the Data field. During a write frame, this field shall consist of a one bit followed by a zero bit.

**Data**

The Data field is 16 bits. The first bit transmitted and received is the MSB of the data word.

### 15.3.8.2 Functional Description

The MII Management I/F will remain idle until enabled by setting the enable bit in the MDIOCTRL register. The MII Management I/F will then continuously poll the link status from within the Generic Status Register of all possible 32 PHY addresses in turn recording the results in the MDIO link register.

The linksel bit in the MDIOUserPhySel register determines the status input that is used. A change in the link status of the two PHYs being monitored will set the appropriate bit in the MDIOLinkIntRaw register and the MDIOLinkIntMasked register, if enabled by the linkint\_enable bit in the MDIOUserPhySel register.

The MDIO Alive register is updated by the MII Management I/F module if the PHY acknowledged the read of the generic status register. In addition, any PHY register read transactions initiated by the host also cause the MDIOAlive register to be updated.

At any time, the host can define a transaction for the MII Management interface module to undertake using the data, phyadr, regadr, and write fields in a MDIOUserAccess register. When the host sets the go bit in this register, the MII Management interface module will begin the transaction without any further intervention from the host. Upon completion, the MII Management interface will clear the go bit and set the userintraw bit in the MDIOUserIntRaw register corresponding to the MDIOUserAccess register being used.

The corresponding bit in the MDIOUserIntMasked register may also be set depending on the mask setting in the MDIOUserIntMaskSet and MDIOUserIntMaskClr registers. A round-robin arbitration scheme is used to schedule transactions which may be queued by the host in different MDIOUserAccess registers. The host should check the status of the go bit in the MDIOUserAccess register before initiating a new transaction to ensure that the previous transaction has completed. The host can use the ack bit in the MDIOUserAccess register to determine the status of a read transaction.

It is necessary for software to use the MII Management interface module to setup the auto-negotiation parameters of each PHY attached to a MAC port, retrieve the negotiation results, and setup the MACCTRL register in the corresponding MAC.

## 15.4 Software Operation

### 15.4.1 Transmit Operation

After reset the host must write zeroes to all Tx DMA State head descriptor pointers. The Tx port may then be enabled. To initiate packet transmission the host constructs transmit queues in memory (one or more packets for transmission) and then writes the appropriate Tx DMA state head descriptor pointers. For each buffer added to a transmit queue, the host must initialize the Tx buffer descriptor values as follows:

1. Write the Next Descriptor Pointer with the 32-bit aligned address of the next descriptor in the queue (zero if last descriptor).
2. Write the Buffer Pointer with the byte aligned address of the buffer data.
3. Write the Buffer Length with the number of bytes in the buffer.
4. Write the Buffer Offset with the number of bytes in the offset to the data (nonzero with SOP only).
5. Set the SOP, EOP, and Ownership bits as appropriate.
6. Clear the End Of Queue bit.

The port begins Tx packet transmission on a given channel when the host writes the channel's Tx queue head descriptor pointer with the address of the first buffer descriptor in the queue (nonzero value). Each channel may have one or more queues, so each channel may have one or more head descriptor pointers. The first buffer descriptor for each Tx packet must have the Start of Packet (SOP) bit and the Ownership bit set to one by the host. The last buffer descriptor for each Tx packet must have the End of Packet (EOP) bit set to one by the host.

The port will transmit packets until all queued packets have been transmitted and the queue(s) are empty. When each packet transmission is complete, the port will clear the Ownership bit in the packet's SOP buffer descriptor and issue an interrupt to the host by writing the packet's last buffer descriptor address to the queue's Tx DMA State Completion Pointer. The interrupt is generated by the write, regardless of the value written.

When the last packet in a queue has been transmitted, the port sets the End Of Queue bit in the EOP buffer descriptor, clears the Ownership bit in the SOP Descriptor, zeroes the appropriate DMA state head descriptor pointer, and then issues a Tx interrupt to the host by writing to the queue's associated Tx completion pointer (address of the last buffer descriptor processed by the port). The port issues a maskable level interrupt (which may then be routed through external interrupt control logic to the host).

On interrupt from the port, the host processes the buffer queue, detecting transmitted packets by the status of the Ownership bit in the SOP buffer descriptor. If the Ownership bit is cleared to zero, then the packet has been transmitted and the host may reclaim the buffers associated with the packet. The host continues queue processing until the end of the queue or until a SOP buffer descriptor is read that contains a set Ownership bit indicating that the packet transmission is not complete.

The host determines that all packets in the queue have been transmitted when the last packet in the queue has a cleared Ownership bit in the SOP buffer descriptor, the End of Queue bit is set in the last packet EOP buffer descriptor, and the Next Descriptor Pointer of the last packet EOP buffer descriptor is zero. The host acknowledges an interrupt by writing the address of the last buffer descriptor to the queue's associated Tx Completion Pointer in the Tx DMA State.

If the host written buffer address value is different from the buffer address written by the port, then the level interrupt remains asserted. If the host written buffer address value is equal to the port written value, then the level interrupt is deasserted. The port write to the completion pointer actually stores the value in the state register (ram). The host written value is actually not written to the register location. The host written value is compared to the register contents (which was written by the port) and if the two values are equal, the interrupt is removed, otherwise the interrupt remains asserted. The host may process multiple packets previous to acknowledging an interrupt, or the host may acknowledge interrupts for every packet.

A misqueued packet condition may occur when the host adds a packet to a queue for transmission as the port finishes transmitting the previous last packet in the queue. The misqueued packet is detected by the host when queue processing detects a cleared Ownership bit in the SOP buffer descriptor, a set End of Queue bit in the EOP buffer descriptor, and a nonzero Next Descriptor Pointer in the EOP buffer descriptor.

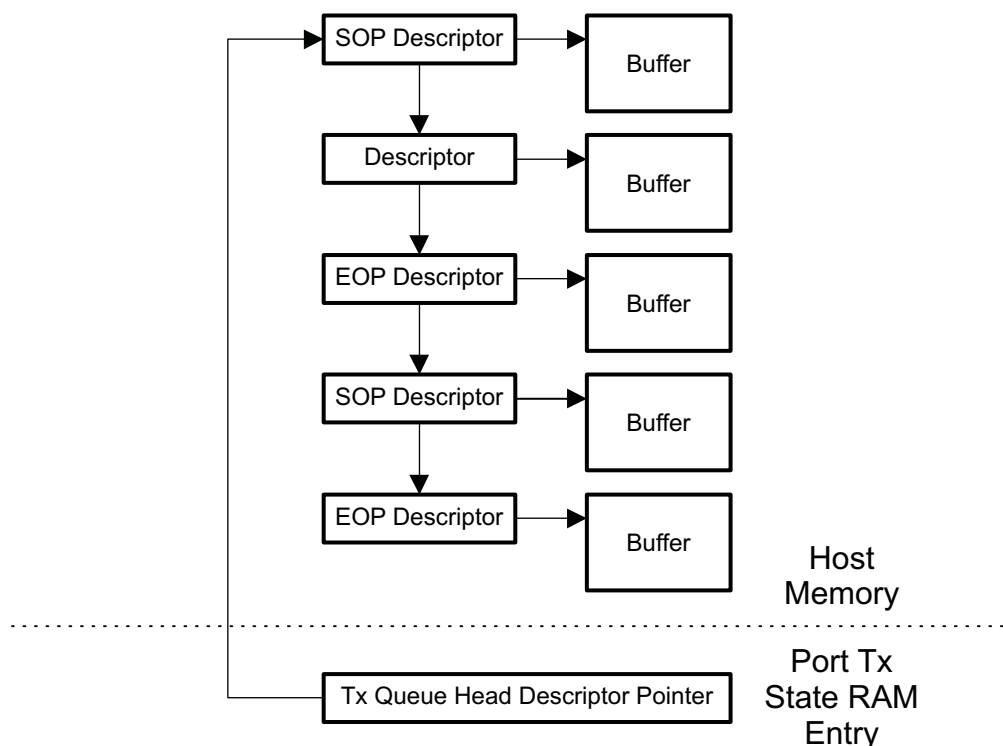

A misqueued packet means that the port read the last EOP buffer descriptor before the host added the new last packet to the queue, so the port determined queue empty just before the last packet was added. The host corrects the misqueued packet condition by initiating a new packet transfer for the misqueued packet by writing the misqueued packet's SOP buffer descriptor address to the appropriate DMA State Tx Queue head Descriptor Pointer.

The host may add packets to the tail end of an active Tx queue at any time by writing the Next Descriptor Pointer to the current last descriptor in the queue. If a Tx queue is empty (inactive), the host may initiate packet transmission at any time by writing the appropriate Tx DMA State head descriptor pointer.

The host software should always check for and reinitiate transmission for misqueued packets during queue processing on interrupt from the port. In order to preclude software underrun, the host should avoid adding buffers to an active queue for any Tx packet that is not complete and ready for transmission.

The port determines that a packet is the last packet in the queue by detecting the End of Packet bit set with a zero Next Descriptor Pointer in the packet buffer descriptor. If the End of Packet bit is set and the Next Descriptor Pointer is nonzero, then the queue still contains one or more packets to be transmitted. If the EOP bit is set with a zero Next Descriptor Pointer, then the port will set the EOQ bit in the packet's EOP buffer descriptor and then zero the appropriate head descriptor pointer previous to interrupting the port (by writing the completion pointer) when the packet transmission is complete.

**Figure 15-13. Port TX State RAM Entry**

## 15.4.2 Receive Operation

**Figure 15-14. Port RX DMA State**

After reset the host must write zeroes to all Rx DMA State head descriptor pointers. The Rx port may then be enabled. To initiate packet reception, the host constructs receive queues in memory and then writes the appropriate Rx DMA state head descriptor pointer. For each Rx buffer descriptor added to the queue, the host must initialize the Rx buffer descriptor values as follows:

- Write the Next Descriptor Pointer with the 32-bit aligned address of the next descriptor in the queue (zero if last descriptor)
- Write the Buffer Pointer with the byte aligned address of the buffer data
- Clear the Offset field
- Write the Buffer Length with the number of bytes in the buffer
- Clear the SOP, EOP, and EOQ bits
- Set the Ownership bit

The host enables packet reception on a given channel by writing the address of the first buffer descriptor in the queue (nonzero value) to the channel's head descriptor pointer in the channel's Rx DMA state. When packet reception begins on a given channel, the port fills each Rx buffer with data in order starting with the first buffer and proceeding through the Rx queue. If the Buffer Offset in the Rx DMA State is nonzero, then the port will begin writing data after the offset number of bytes in the SOP buffer. The port performs the following operations at the end of each packet reception:

- Overwrite the buffer length in the packet's EOP buffer descriptor with the number of bytes actually received in the packet's last buffer. The host initialized value is the buffer size. The overwritten value will be less than or equal to the host initialized value.
- Set the EOP bit in the packet's EOP buffer descriptor.
- Set the EOQ bit in the packet's EOP buffer descriptor if the current packet is the last packet in the queue.
- Overwrite the packet's SOP buffer descriptor Buffer Offset with the Rx DMA state value (the host initialized the buffer descriptor Buffer Offset value to zero). All non SOP buffer descriptors must have a zero Buffer Offset initialized by the host.

- Overwrite the packet's SOP buffer descriptor buffer length with the number of valid data bytes in the buffer. If the buffer is filled up, the buffer length will be the buffer size minus buffer offset.
- Set the SOP bit in the packet's SOP buffer descriptor.
- Write the SOP buffer descriptor Packet Length field.
- Clear the Ownership bit in the packet's SOP buffer descriptor.
- Issue an Rx host interrupt by writing the address of the packet's last buffer descriptor to the queue's Rx DMA State Completion Pointer. The interrupt is generated by the write to the Rx DMA State Completion Pointer address location, regardless of the value written.

On interrupt the host processes the Rx buffer queue detecting received packets by the status of the Ownership bit in each packet's SOP buffer descriptor. If the Ownership bit is cleared then the packet has been completely received and is available to be processed by the host.

The host may continue Rx queue processing until the end of the queue or until a buffer descriptor is read that contains a set Ownership bit indicating that the next packet's reception is not complete. The host determines that the Rx queue is empty when the last packet in the queue has a cleared Ownership bit in the SOP buffer descriptor, a set End of Queue bit in the EOP buffer descriptor, and the Next Descriptor Pointer in the EOP buffer descriptor is zero.

A misqueued buffer may occur when the host adds buffers to a queue as the port finishes the reception of the previous last packet in the queue. The misqueued buffer is detected by the host when queue processing detects a cleared Ownership bit in the SOP buffer descriptor, a set End of Queue bit in the EOP buffer descriptor, and a nonzero Next Descriptor Pointer in the EOP buffer descriptor.

A misqueued buffer means that the port read the last EOP buffer descriptor before the host added buffer descriptor(s) to the queue, so the port determined queue empty just before the host added more buffer descriptor(s). In the transmit case, the packet transmission is delayed by the time required for the host to determine the condition and reinitiate the transaction, but the packet is not actually lost. In the receive case, receive overrun condition may occur in the misqueued buffer case.

If a new packet reception is begun during the time that the port has determined the end of queue condition, then the received packet will overrun (start of packet overrun). If the misqueued buffer occurs during the middle of a packet reception then middle of packet overrun may occur. If the misqueued buffer occurs after the last packet has completed, and is corrected before the next packet reception begins, then overrun will not occur. The host acts on the misqueued buffer condition by writing the added buffer descriptor address to the appropriate Rx DMA State Head Descriptor Pointer.

### 15.4.3 Initializing the MDIO Module

The following steps are performed by the application software or device driver to initialize the MDIO device:

1. Configure the PREAMBLE and CLKDIV bits in the MDIO control register (MDIOCTRL).
  2. Enable the MDIO module by setting the EN bit in MDIOCTRL.
  3. The MDIO PHY alive status register (MDIOALIVE) can be read in polling fashion until a PHY connected to the system responded, and the MDIO PHY link status register (MDIOLINK) can determine whether this PHY already has a link.
  4. Setup the appropriate PHY addresses in the MDIO user PHY select register (MDIOUSERPHYSEL<sub>n</sub>), and set the LINKINTENB bit to enable a link change event interrupt if desirable.
- If an interrupt on general MDIO register access is desired, set the corresponding bit in the MDIO user command complete interrupt mask set register (MDIOUSERINTMASKSET) to use the MDIO user access register (MDIOUSERACCESS<sub>n</sub>). Since only one PHY is used in this device, the application software can use one MDIOUSERACCESS<sub>n</sub> to trigger a completion interrupt; the other MDIOUSERACCESS<sub>n</sub> is not setup.

### 15.4.4 Writing Data to a PHY Register

The MDIO module includes a user access register (MDIOUSERACCESS<sub>n</sub>) to directly access a specified PHY device. To write a PHY register, perform the following:

1. Ensure that the GO bit in the MDIO user access register (MDIOUSERACCESS<sub>n</sub>) is cleared.

2. Write to the GO, WRITE, REGADR, PHYADR, and DATA bits in MDIOUSERACCESS $n$  corresponding to the PHY and PHY register you want to write.
3. The write operation to the PHY is scheduled and completed by the MDIO module. Completion of the write operation can be determined by polling the GO bit in MDIOUSERACCESS $n$  for a 0.
4. Completion of the operation sets the corresponding USERINTRAW bit (0 or 1) in the MDIO user command complete interrupt register (MDIOUSERINTRAW) corresponding to USERACCESS $n$  used. If interrupts have been enabled on this bit using the MDIO user command complete interrupt mask set register (MDIOUSERINTMASKSET), then the bit is also set in the MDIO user command complete interrupt register (MDIOUSERINTMASKED) and an interrupt is triggered on the CPU.

#### 15.4.5 Reading Data from a PHY Register

The MDIO module includes a user access register (MDIOUSERACCESS $n$ ) to directly access a specified PHY device. To read a PHY register, perform the following:

1. Ensure that the GO bit in the MDIO user access register (MDIOUSERACCESS $n$ ) is cleared.
2. Write to the GO, REGADR, and PHYADR bits in MDIOUSERACCESS $n$  corresponding to the PHY and PHY register you want to read.
3. The read data value is available in the DATA bits in MDIOUSERACCESS $n$  after the module completes the read operation on the serial bus. Completion of the read operation can be determined by polling the GO and ACK bits in MDIOUSERACCESS $n$ . After the GO bit has cleared, the ACK bit is set on a successful read.
4. Completion of the operation sets the corresponding USERINTRAW bit (0 or 1) in the MDIO user command complete interrupt register (MDIOUSERINTRAW) corresponding to USERACCESS $n$  used. If interrupts have been enabled on this bit using the MDIO user command complete interrupt mask set register (MDIOUSERINTMASKSET), then the bit is also set in the MDIO user command complete interrupt register (MDIOUSERINTMASKED) and an interrupt is triggered on the CPU.

#### 15.4.6 Initialization and Configuration of CPSW

To configure the 3PSW Ethernet Subsystem for operation the host must perform the following:

- Select the Interface (GMII/RGMII/MII) Mode in the Control Module.
- Configure pads (PIN muxing) as per the Interface Selected using the appropriate pin muxing conf\_XXX registers in the Control Module.
- Enable the 3PSW Ethernet Subsystem Clocks. See [Section 15.2.2](#) and to enable the appropriate clocks.
- Configure the PRCM Registers CM\_PER\_CPSW\_CLKSTCTRL and CM\_PER\_CPSW\_CLKSTCTRL to enable power and clocks to the 3PSW Ethernet Subsystem. See [Section 6.13.6](#) for register details.
- Apply soft reset to 3PSW Subsystem, CPSW\_3G, CPGMAC\_SL1/2, and CPDMA (see the soft reset registers in the following sections).
- Initialize the HDPs (Header Description Pointer) and CPs (Completion Pointer) to NULL.
- Configure the Interrupts (see [Chapter 8](#)).
- Configure the CPSW\_3G Control register.
- Configure the Statistics Port Enable register.
- Configure the ALE. (See [Section 15.3.2.7](#).)
- Configure the MDIO.
- Configure the CPDMA receive DMA controller.
- Configure the CPDMA transmit DMA controller.
- Configure the CPPI Tx and Rx Descriptors.
- Configure CPGMAC\_SL1 and CPGMAC\_SL2 as per the desired mode of operations.
- Start up RX and TX DMA (write to HDP of Rx and Tx).
- Wait for the completion of the transfer (HDP cleared to zero).

## 15.5 Ethernet Subsystem Registers

### 15.5.1 CPSW\_ALE Registers

Table 15-23 lists the memory-mapped registers for the CPSW\_ALE. All register offset addresses not listed in Table 15-23 should be considered as reserved locations and the register contents should not be modified.

**Table 15-23. CPSW\_ALE Registers**

Offset	Acronym	Register Name	Section
0h	CPSW_ALE_IDVER	ADDRESS LOOKUP ENGINE ID/VERSION REGISTER	<a href="#">Section 15.5.1.1</a>
8h	CPSW_ALE_CTRL	ADDRESS LOOKUP ENGINE CONTROL REGISTER	<a href="#">Section 15.5.1.2</a>
10h	CPSW_ALE_PRESCALE	ADDRESS LOOKUP ENGINE PRESCALE REGISTER	<a href="#">Section 15.5.1.3</a>
18h	CPSW_ALE_UNKNOWN_VLAN	ADDRESS LOOKUP ENGINE UNKNOWN VLAN REGISTER	<a href="#">Section 15.5.1.4</a>

**Table 15-25. CPSW\_ALE\_CTRL Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	EN_ALE	R/W	0h	Enable ALE 0h = Drop all packets 1h = Enable ALE packet processing
30	CLR_TBL	R/W	0h	Clear ALE address table - Setting this bit causes the ALE hardware to write all table bit values to zero. Software must perform a clear table operation as part of the ALE setup/configuration process. Setting this bit causes all ALE accesses to be held up for 64 clocks while the clear is performed. Access to all ALE registers will be blocked (wait states) until the 64 clocks have completed. This bit cannot be read as one because the read is blocked until the clear table is completed at which time this bit is cleared to zero.
29	AGE_OUT_NOW	R/W	0h	Age Out Address Table Now - Setting this bit causes the ALE hardware to remove (free up) any ageable table entry that does not have a set touch bit. This bit is cleared when the age out process has completed. This bit may be read. The age out process takes 4096 clocks best case (no ale packet processing during ageout) and 66550 clocks absolute worst case.
28-9	RESERVED	R	0h	
8	EN_P0_UNI_FLOOD	R/W	0h	Enable Port 0 (Host Port) unicast flood 0h = Do not flood unknown unicast packets to host port (p0) 1h = Flood unknown unicast packets to host port (p0)
7	LEARN_NO_VID	R/W	0h	Learn No VID 0h = VID is learned with the source address 1h = VID is not learned with the source address (source address is not tied to VID).
6	EN_VID0_MODE	R/W	0h	Enable VLAN ID = 0 Mode 0h = Process the packet with VID = PORT_VLAN[11 to 0] 1h = Process the packet with VID = 0.

**Table 15-25. CPSW\_ALE\_CTRL Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
5	EN_OUI_DENY	R/W	0h	Enable OUI Deny Mode - When set this bit indicates that a packet with a non OUI table entry matching source address will be dropped to the host unless the destination address matches a multicast table entry with the super bit set.
4	BYPASS	R/W	0h	ALE Bypass - When set, all packets received on ports 0 and 1 are sent to the host (only to the host).
3	RATE_LIMIT_TX	R/W	0h	Rate Limit Transmit mode 0h = Broadcast and multicast rate limit counters are received port based 1h = Broadcast and multicast rate limit counters are transmit port based
2	VLAN_AWARE	R/W	0h	ALE VLAN Aware - Determines what is done if VLAN not found. 0h = Flood if VLAN not found 1h = Drop packet if VLAN not found
1	EN_AUTH_MODE	R/W	0h	Enable MAC Authorization Mode - Mac authorization mode requires that all table entries be made by the host software. There are no learned address in authorization mode and the packet will be dropped if the source address is not found (and the destination address is not a multicast address with the super table entry bit set). 0h = The ALE is not in MAC authorization mode. 1h = The ALE is in MAC authorization mode.
0	EN_RATE_LIMIT	R/W	0h	Enable Broadcast and Multicast Rate Limit 0h = Broadcast/Multicast rates not limited 1h = Broadcast/Multicast packet reception limited to the port control register rate limit fields

### 15.5.1.3 CPSW\_ALE\_PRESCALE Register (offset = 10h) [reset = 0h]

CPSW\_ALE\_PRESCALE is shown in [Figure 15-17](#) and described in [Table 15-26](#).

**Table 15-40. CPSW\_CPDMA\_SOFT\_RESET Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	RESERVED	R	0h	
0	SOFT_RESET	R/W	0h	Software reset - Writing a one to this bit causes the CPDMA logic to be reset. Software reset occurs when the RX and TX DMA Controllers are in an idle state to avoid locking up the VBUSP bus. After writing a one to this bit, it may be polled to determine if the reset has occurred. If a one is read, the reset has not yet occurred. If a zero is read then reset has occurred.

### 15.5.2.8 CPSW\_DMACTRL Register (offset = 20h) [reset = 0h]

CPSW\_DMACTRL is shown in [Figure 15-31](#) and described in [Table 15-41](#).

R-0h			R/W-0h	R/W-0h	R/W-0h	R/W-0h	R/W-0h

**Table 15-41. CPSW\_DMACTRL Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	
15-8	TX_RLIM	R/W	0h	Transmit Rate Limit Channel Bus 00000000 - no rate-limited channels 10000000 - channel 7 is rate-limited 11000000 - channels 7 downto 6 are rate-limited 11100000 - channels 7 downto 5 are rate-limited 11110000 - channels 7 downto 4 are rate-limited 11111000 - channels 7 downto 3 are rate-limited 11111100 - channels 7 downto 2 are rate-limited 11111110 - channels 7 downto 1 are rate-limited 11111111 - channels 7 downto 0 are rate-limited all others invalid - this bus must be set msb towards lsb. tx_ptype must be set if any tx_rlim bit is set for fixed priority.
7-5	RESERVED	R	0h	
4	RX_CEF	R/W	0h	RX Copy Error Frames Enable - Enables DMA overrun frames to be transferred to memory (up to the point of overrun). The overrun error bit will be set in the frame EOP buffer descriptor. Overrun frame data will be filtered when rx_cef is not set. Frames coming from the receive FIFO with other error bits set are not effected by this bit. 0h = Frames containing overrun errors are filtered 1h = Frames containing overrun errors are transferred to memory
3	CMD_IDLE	R/W	0h	Command Idle 0h = Idle not commanded 1h = Idle Commanded (read idle in DMAStatus)
2	RX_OFFLEN_BLOCK	R/W	0h	Receive Offset/Length word write block. 0h = Do not block the DMA writes to the receive buffer descriptor offset/buffer length word. The offset/buffer length word is written as specified in CPPI 3.0. 1h = Block all CPDMA DMA controller writes to the receive buffer descriptor offset/buffer length words during CPPI packet processing. when this bit is set, the CPDMA will never write the third word to any receive buffer descriptor.

**Table 15-41. CPSW\_DMACTRL Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
1	RX_OWNERSHIP	R/W	0h	<p>Receive Ownership Write Bit Value.</p> <p>0h = The CPDMA writes the receive ownership bit to zero at the end of packet processing as specified in CPPI 3.0.</p> <p>1h = The CPDMA writes the receive ownership bit to one at the end of packet processing.</p> <p>Users who do not use the ownership mechanism can use this mode to preclude the necessity of software having to set this bit each time the buffer descriptor is used.</p>
0	TX_PTYPE	R/W	0h	<p>Transmit Queue Priority Type</p> <p>0h = The queue uses a round robin scheme to select the next channel for transmission.</p> <p>1h = The queue uses a fixed (channel 7 highest priority) priority scheme to select the next channel for transmission</p>

### 15.5.2.9 CPSW\_DMASTS Register (offset = 24h) [reset = 0h]

CPSW\_DMASTS is shown in [Figure 15-32](#) and described in [Table 15-42](#).

**Table 15-43. CPSW\_RX\_BUFFER\_OFFSET Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	
15-0	RX_BUFFER_OFFSET	R/W	0h	Receive Buffer Offset Value - The rx_buffer_offset will be written by the port into each frame SOP buffer descriptor buffer_offset field. The frame data will begin after the rx_buffer_offset value of bytes. A value of 0x0000 indicates that there are no unused bytes at the beginning of the data and that valid data begins on the first byte of the buffer. A value of 0x000F (decimal 15) indicates that the first 15 bytes of the buffer are to be ignored by the port and that valid buffer data starts on byte 16 of the buffer. This value is used for all channels.

### 15.5.2.11 CPSW\_EMCTRL Register (offset = 2Ch) [reset = 0h]

R-0h							
7	6	5	4	3	2	1	0
RESERVED							TS_PUSH
R-0h							W-0h

**Table 15-87. CPSW\_CPTS\_PUSH Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	RESERVED	R	0h	
0	TS_PUSH	W	0h	<p>Time stamp event push - When a logic high is written to this bit a time stamp event is pushed onto the event FIFO.</p> <p>The time stamp value is the time of the write of this register, not the time of the event read.</p> <p>The time stamp value can then be read on interrupt via the event registers.</p> <p>Software should not push a second time stamp event onto the event FIFO until the first time stamp value has been read from the event FIFO (there should be only one time stamp event in the event FIFO at any given time).</p> <p>This bit is write only and always reads zero.</p>

### 15.5.3.5 CPSW\_CPTS\_LOAD\_VAL Register (offset = 10h) [reset = 0h]

CPSW\_CPTS\_LOAD\_VAL is shown in [Figure 15-77](#) and described in [Table 15-88](#).

TIME STAMP LOAD VALUE REGISTER

**Figure 15-77. CPSW\_CPTS\_LOAD\_VAL Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TS_LOAD_VAL																															
R/W-0h																															

**Table 15-88. CPSW\_CPTS\_LOAD\_VAL Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	TS_LOAD_VAL	R/W	0h	Time Stamp Load Value - Writing the ts_load_en bit causes the value contained in this register to be written into the time stamp. The time stamp value is read by initiating a time stamp push event, not by reading this register. When reading this register, the value read is not the time stamp, but is the value that was last written to this register.

### 15.5.3.6 CPSW\_CPTS\_LOAD\_EN Register (offset = 14h) [reset = 0h]

CPSW\_CPTS\_LOAD\_EN is shown in [Figure 15-78](#) and described in [Table 15-89](#).

TIME STAMP LOAD ENABLE REGISTER

### 15.5.5 CPDMA\_STATERAM Registers

[Table 15-100](#) lists the memory-mapped registers for the CPDMA\_STATERAM. All register offset addresses not listed in [Table 15-100](#) should be considered as reserved locations and the register contents should not be modified.

**Table 15-100. CPDMA\_STATERAM REGISTERS**

Offset	Acronym	Register Name	Section
0h	CPSW_STATERAM_TX0_HDP	CPDMA_STATERAM TX CHANNEL 0 HEAD DESC POINTER *	<a href="#">Section 15.5.5.1</a>
4h	CPSW_STATERAM_TX1_HDP	CPDMA_STATERAM TX CHANNEL 1 HEAD DESC POINTER *	<a href="#">Section 15.5.5.2</a>
8h	CPSW_STATERAM_TX2_HDP	CPDMA_STATERAM TX CHANNEL 2 HEAD DESC POINTER *	<a href="#">Section 15.5.5.3</a>
Ch	CPSW_STATERAM_TX3_HDP	CPDMA_STATERAM TX CHANNEL 3 HEAD DESC POINTER *	<a href="#">Section 15.5.5.4</a>
10h	CPSW_STATERAM_TX4_HDP	CPDMA_STATERAM TX CHANNEL 4 HEAD DESC POINTER *	<a href="#">Section 15.5.5.5</a>
14h	CPSW_STATERAM_TX5_HDP	CPDMA_STATERAM TX CHANNEL 5 HEAD DESC POINTER *	<a href="#">Section 15.5.5.6</a>
18h	CPSW_STATERAM_TX6_HDP	CPDMA_STATERAM TX CHANNEL 6 HEAD DESC POINTER *	<a href="#">Section 15.5.5.7</a>
1Ch	CPSW_STATERAM_TX7_HDP	CPDMA_STATERAM TX CHANNEL 7 HEAD DESC POINTER *	<a href="#">Section 15.5.5.8</a>
20h	CPSW_STATERAM_RX0_HDP	CPDMA_STATERAM RX 0 CHANNEL 0 HEAD DESC POINTER *	<a href="#">Section 15.5.5.9</a>
24h	CPSW_STATERAM_RX1_HDP	CPDMA_STATERAM RX 1 CHANNEL 1 HEAD DESC POINTER *	<a href="#">Section 15.5.5.10</a>
28h	CPSW_STATERAM_RX2_HDP	CPDMA_STATERAM RX 2 CHANNEL 2 HEAD DESC POINTER *	<a href="#">Section 15.5.5.11</a>
2Ch	CPSW_STATERAM_RX3_HDP	CPDMA_STATERAM RX 3 CHANNEL 3 HEAD DESC POINTER *	<a href="#">Section 15.5.5.12</a>
30h	CPSW_STATERAM_RX4_HDP	CPDMA_STATERAM RX 4 CHANNEL 4 HEAD DESC POINTER *	<a href="#">Section 15.5.5.13</a>

### 15.5.5.1 CPSW\_STATERAM\_TX0\_HDP Register (offset = 0h) [reset = 0h]

CPSW\_STATERAM\_TX0\_HDP is shown in [Figure 15-88](#) and described in [Table 15-101](#).

CPDMA\_STATERAM TX CHANNEL 0 HEAD DESC POINTER \*

**Figure 15-88. CPSW\_STATERAM\_TX0\_HDP Register**

**Table 15-101. CPSW\_STATERAM\_TX0\_HDP Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	TX_HDP	R/W	0h	TX Channel (0..7) DMA Head Descriptor Pointer - Writing a TX DMA Buffer Descriptor address to a head pointer location initiates TX DMA operations in the queue for the selected channel. Writing to these locations when they are non-zero is an error (except at reset). Host software must initialize these locations to zero on reset.

### 15.5.5.2 CPSW\_STATERAM\_TX1\_HDP Register (offset = 4h) [reset = 0h]

CPSW\_STATERAM\_TX1\_HDP is shown in [Figure 15-89](#) and described in [Table 15-102](#).

CPDMA\_STATERAM TX CHANNEL 1 HEAD DESC POINTER \*

**Figure 15-89. CPSW\_STATERAM\_TX1\_HDP Register**

**Table 15-102. CPSW\_STATERAM\_TX1\_HDP Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	TX_HDP	R/W	0h	TX Channel (0..7) DMA Head Descriptor Pointer - Writing a TX DMA Buffer Descriptor address to a head pointer location initiates TX DMA operations in the queue for the selected channel. Writing to these locations when they are non-zero is an error (except at reset). Host software must initialize these locations to zero on reset.

### 15.5.5.3 CPSW\_STATERAM\_TX2\_HDP Register (offset = 8h) [reset = 0h]

CPSW\_STATERAM\_TX2\_HDP is shown in [Figure 15-90](#) and described in [Table 15-103](#).

CPDMA\_STATERAM TX CHANNEL 2 HEAD DESC POINTER \*

**Figure 15-90. CPSW\_STATERAM\_TX2\_HDP Register**

**Table 15-103. CPSW\_STATERAM\_TX2\_HDP Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	TX_HDP	R/W	0h	TX Channel (0..7) DMA Head Descriptor Pointer - Writing a TX DMA Buffer Descriptor address to a head pointer location initiates TX DMA operations in the queue for the selected channel. Writing to these locations when they are non-zero is an error (except at reset). Host software must initialize these locations to zero on reset.

#### 15.5.5.4 CPSW\_STATERAM\_TX3\_HDP Register (offset = Ch) [reset = 0h]

CPSW\_STATERAM\_TX3\_HDP is shown in [Figure 15-91](#) and described in [Table 15-104](#).

CPDMA\_STATERAM TX CHANNEL 3 HEAD DESC POINTER \*

**Figure 15-91. CPSW\_STATERAM\_TX3\_HDP Register**

**Table 15-104. CPSW\_STATERAM\_TX3\_HDP Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	TX_HDP	R/W	0h	TX Channel (0..7) DMA Head Descriptor Pointer - Writing a TX DMA Buffer Descriptor address to a head pointer location initiates TX DMA operations in the queue for the selected channel. Writing to these locations when they are non-zero is an error (except at reset). Host software must initialize these locations to zero on reset.

### 15.5.5.5 CPSW\_STATERAM\_TX4\_HDP Register (offset = 10h) [reset = 0h]

CPSW\_STATERAM\_TX4\_HDP is shown in [Figure 15-92](#) and described in [Table 15-105](#).

CPDMA\_STATERAM TX CHANNEL 4 HEAD DESC POINTER \*

**Figure 15-92. CPSW\_STATERAM\_TX4\_HDP Register**

**Table 15-105. CPSW\_STATERAM\_TX4\_HDP Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	TX_HDP	R/W	0h	TX Channel (0..7) DMA Head Descriptor Pointer - Writing a TX DMA Buffer Descriptor address to a head pointer location initiates TX DMA operations in the queue for the selected channel. Writing to these locations when they are non-zero is an error (except at reset). Host software must initialize these locations to zero on reset.

### 15.5.5.6 CPSW\_STATERAM\_TX5\_HDP Register (offset = 14h) [reset = 0h]

CPSW\_STATERAM\_TX5\_HDP is shown in [Figure 15-93](#) and described in [Table 15-106](#).

CPDMA\_STATERAM TX CHANNEL 5 HEAD DESC POINTER \*

**Figure 15-93. CPSW\_STATERAM\_TX5\_HDP Register**

**Table 15-106. CPSW\_STATERAM\_TX5\_HDP Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	TX_HDP	R/W	0h	TX Channel (0..7) DMA Head Descriptor Pointer - Writing a TX DMA Buffer Descriptor address to a head pointer location initiates TX DMA operations in the queue for the selected channel. Writing to these locations when they are non-zero is an error (except at reset). Host software must initialize these locations to zero on reset.

### 15.5.5.7 CPSW\_STATERAM\_TX6\_HDP Register (offset = 18h) [reset = 0h]

CPSW\_STATERAM\_TX6\_HDP is shown in [Figure 15-94](#) and described in [Table 15-107](#).

CPDMA\_STATERAM TX CHANNEL 6 HEAD DESC POINTER \*

**Figure 15-94. CPSW\_STATERAM\_TX6\_HDP Register**

**Table 15-107. CPSW\_STATERAM\_TX6\_HDP Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	TX_HDP	R/W	0h	TX Channel (0..7) DMA Head Descriptor Pointer - Writing a TX DMA Buffer Descriptor address to a head pointer location initiates TX DMA operations in the queue for the selected channel. Writing to these locations when they are non-zero is an error (except at reset). Host software must initialize these locations to zero on reset.

### 15.5.5.8 CPSW\_STATERAM\_TX7\_HDP Register (offset = 1Ch) [reset = 0h]

CPSW\_STATERAM\_TX7\_HDP is shown in [Figure 15-95](#) and described in [Table 15-108](#).

CPDMA\_STATERAM TX CHANNEL 7 HEAD DESC POINTER \*

**Figure 15-95. CPSW\_STATERAM\_TX7\_HDP Register**

**Table 15-108. CPSW\_STATERAM\_TX7\_HDP Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	TX_HDP	R/W	0h	TX Channel (0..7) DMA Head Descriptor Pointer - Writing a TX DMA Buffer Descriptor address to a head pointer location initiates TX DMA operations in the queue for the selected channel. Writing to these locations when they are non-zero is an error (except at reset). Host software must initialize these locations to zero on reset.

### 15.5.5.9 CPSW\_STATERAM\_RX0\_HDP Register (offset = 20h) [reset = 0h]

CPSW\_STATERAM\_RX0\_HDP is shown in [Figure 15-96](#) and described in [Table 15-109](#).

CPDMA\_STATERAM RX 0 CHANNEL 0 HEAD DESC POINTER \*

**Figure 15-96. CPSW\_STATERAM\_RX0\_HDP Register**

**Table 15-109. CPSW\_STATERAM\_RX0\_HDP Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	RX_HDP	R/W	0h	RX DMA Head Descriptor Pointer - Writing an RX DMA Buffer Descriptor address to this location allows RX DMA operations in the selected channel when a channel frame is received. Writing to these locations when they are non-zero is an error (except at reset). Host software must initialize these locations to zero on reset.

### 15.5.5.10 CPSW\_STATERAM\_RX1\_HDP Register (offset = 24h) [reset = 0h]

CPSW\_STATERAM\_RX1\_HDP is shown in [Figure 15-97](#) and described in [Table 15-110](#).

CPDMA\_STATERAM RX 1 CHANNEL 1 HEAD DESC POINTER \*

**Figure 15-97. CPSW\_STATERAM\_RX1\_HDP Register**

**Table 15-110. CPSW\_STATERAM\_RX1\_HDP Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	RX_HDP	R/W	0h	RX DMA Head Descriptor Pointer - Writing an RX DMA Buffer Descriptor address to this location allows RX DMA operations in the selected channel when a channel frame is received. Writing to these locations when they are non-zero is an error (except at reset). Host software must initialize these locations to zero on reset.

### 15.5.5.11 CPSW\_STATERAM\_RX2\_HDP Register (offset = 28h) [reset = 0h]

CPSW\_STATERAM\_RX2\_HDP is shown in [Figure 15-98](#) and described in [Table 15-111](#).

CPDMA\_STATERAM RX 2 CHANNEL 2 HEAD DESC POINTER \*

**Figure 15-98. CPSW\_STATERAM\_RX2\_HDP Register**

**Table 15-111. CPSW\_STATERAM\_RX2\_HDP Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	RX_HDP	R/W	0h	RX DMA Head Descriptor Pointer - Writing an RX DMA Buffer Descriptor address to this location allows RX DMA operations in the selected channel when a channel frame is received. Writing to these locations when they are non-zero is an error (except at reset). Host software must initialize these locations to zero on reset.

### 15.5.5.12 CPSW\_STATERAM\_RX3\_HDP Register (offset = 2Ch) [reset = 0h]

CPSW\_STATERAM\_RX3\_HDP is shown in [Figure 15-99](#) and described in [Table 15-112](#).

CPDMA\_STATERAM RX 3 CHANNEL 3 HEAD DESC POINTER \*

**Figure 15-99. CPSW\_STATERAM\_RX3\_HDP Register**

**Table 15-112. CPSW\_STATERAM\_RX3\_HDP Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	RX_HDP	R/W	0h	RX DMA Head Descriptor Pointer - Writing an RX DMA Buffer Descriptor address to this location allows RX DMA operations in the selected channel when a channel frame is received. Writing to these locations when they are non-zero is an error (except at reset). Host software must initialize these locations to zero on reset.

### 15.5.5.13 CPSW\_STATERAM\_RX4\_HDP Register (offset = 30h) [reset = 0h]

CPSW\_STATERAM\_RX4\_HDP is shown in [Figure 15-100](#) and described in [Table 15-113](#).

CPDMA\_STATERAM RX 4 CHANNEL 4 HEAD DESC POINTER \*

**Figure 15-100. CPSW\_STATERAM\_RX4\_HDP Register**

**Table 15-113. CPSW\_STATERAM\_RX4\_HDP Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	RX_HDP	R/W	0h	RX DMA Head Descriptor Pointer - Writing an RX DMA Buffer Descriptor address to this location allows RX DMA operations in the selected channel when a channel frame is received. Writing to these locations when they are non-zero is an error (except at reset). Host software must initialize these locations to zero on reset.

### 15.5.5.14 CPSW\_STATERAM\_RX5\_HDP Register (offset = 34h) [reset = 0h]

CPSW\_STATERAM\_RX5\_HDP is shown in [Figure 15-101](#) and described in [Table 15-114](#).

CPDMA\_STATERAM RX 5 CHANNEL 5 HEAD DESC POINTER \*

**Figure 15-101. CPSW\_STATERAM\_RX5\_HDP Register**

**Table 15-114. CPSW\_STATERAM\_RX5\_HDP Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	RX_HDP	R/W	0h	RX DMA Head Descriptor Pointer - Writing an RX DMA Buffer Descriptor address to this location allows RX DMA operations in the selected channel when a channel frame is received. Writing to these locations when they are non-zero is an error (except at reset). Host software must initialize these locations to zero on reset.

### 15.5.5.15 CPSW\_STATERAM\_RX6\_HDP Register (offset = 38h) [reset = 0h]

CPSW\_STATERAM\_RX6\_HDP is shown in [Figure 15-102](#) and described in [Table 15-115](#).

CPDMA\_STATERAM RX 6 CHANNEL 6 HEAD DESC POINTER \*

**Figure 15-102. CPSW\_STATERAM\_RX6\_HDP Register**

**Table 15-115. CPSW\_STATERAM\_RX6\_HDP Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	RX_HDP	R/W	0h	RX DMA Head Descriptor Pointer - Writing an RX DMA Buffer Descriptor address to this location allows RX DMA operations in the selected channel when a channel frame is received. Writing to these locations when they are non-zero is an error (except at reset). Host software must initialize these locations to zero on reset.

### 15.5.5.16 CPSW\_STATERAM\_RX7\_HDP Register (offset = 3Ch) [reset = 0h]

CPSW\_STATERAM\_RX7\_HDP is shown in [Figure 15-103](#) and described in [Table 15-116](#).

CPDMA\_STATERAM RX 7 CHANNEL 7 HEAD DESC POINTER \*

**Figure 15-103. CPSW\_STATERAM\_RX7\_HDP Register**

**Table 15-116. CPSW\_STATERAM\_RX7\_HDP Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	RX_HDP	R/W	0h	RX DMA Head Descriptor Pointer - Writing an RX DMA Buffer Descriptor address to this location allows RX DMA operations in the selected channel when a channel frame is received. Writing to these locations when they are non-zero is an error (except at reset). Host software must initialize these locations to zero on reset.

### 15.5.5.17 CPSW\_STATERAM\_TX0\_CP Register (offset = 40h) [reset = 0h]

CPSW\_STATERAM\_TX0\_CP is shown in [Figure 15-104](#) and described in [Table 15-117](#).

CPDMA\_STATERAM TX CHANNEL 0 COMPLETION POINTER REGISTER

**Figure 15-104. CPSW\_STATERAM\_TX0\_CP Register**

**Table 15-117. CPSW\_STATERAM\_TX0\_CP Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	TX_CP	R/W	0h	Tx Completion Pointer Register - This register is written by the host with the buffer descriptor address for the last buffer processed by the host during interrupt processing. The port uses the value written to determine if the interrupt should be deasserted.

### 15.5.5.18 CPSW\_STATERAM\_TX1\_CP Register (offset = 44h) [reset = 0h]

CPSW\_STATERAM\_TX1\_CP is shown in [Figure 15-105](#) and described in [Table 15-118](#).

CPDMA\_STATERAM TX CHANNEL 1 COMPLETION POINTER REGISTER \*

**Figure 15-105. CPSW\_STATERAM\_TX1\_CP Register**

**Table 15-118. CPSW\_STATERAM\_TX1\_CP Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	TX_CP	R/W	0h	Tx Completion Pointer Register - This register is written by the host with the buffer descriptor address for the last buffer processed by the host during interrupt processing. The port uses the value written to determine if the interrupt should be deasserted.

### 15.5.5.19 CPSW\_STATERAM\_TX2\_CP Register (offset = 48h) [reset = 0h]

CPSW\_STATERAM\_TX2\_CP is shown in [Figure 15-106](#) and described in [Table 15-119](#).

CPDMA\_STATERAM TX CHANNEL 2 COMPLETION POINTER REGISTER \*

**Figure 15-106. CPSW\_STATERAM\_TX2\_CP Register**

**Table 15-119. CPSW\_STATERAM\_TX2\_CP Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	TX_CP	R/W	0h	Tx Completion Pointer Register - This register is written by the host with the buffer descriptor address for the last buffer processed by the host during interrupt processing. The port uses the value written to determine if the interrupt should be deasserted.

### 15.5.5.20 CPSW\_STATERAM\_TX3\_CP Register (offset = 4Ch) [reset = 0h]

CPSW\_STATERAM\_TX3\_CP is shown in [Figure 15-107](#) and described in [Table 15-120](#).

CPDMA\_STATERAM TX CHANNEL 3 COMPLETION POINTER REGISTER \*

**Figure 15-107. CPSW\_STATERAM\_TX3\_CP Register**

**Table 15-120. CPSW\_STATERAM\_TX3\_CP Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	TX_CP	R/W	0h	Tx Completion Pointer Register - This register is written by the host with the buffer descriptor address for the last buffer processed by the host during interrupt processing. The port uses the value written to determine if the interrupt should be deasserted.

### 15.5.5.21 CPSW\_STATERAM\_TX4\_CP Register (offset = 50h) [reset = 0h]

CPSW\_STATERAM\_TX4\_CP is shown in [Figure 15-108](#) and described in [Table 15-121](#).

CPDMA\_STATERAM TX CHANNEL 4 COMPLETION POINTER REGISTER \*

**Figure 15-108. CPSW\_STATERAM\_TX4\_CP Register**

**Table 15-121. CPSW\_STATERAM\_TX4\_CP Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	TX_CP	R/W	0h	Tx Completion Pointer Register - This register is written by the host with the buffer descriptor address for the last buffer processed by the host during interrupt processing. The port uses the value written to determine if the interrupt should be deasserted.

### 15.5.5.22 CPSW\_STATERAM\_TX5\_CP Register (offset = 54h) [reset = 0h]

CPSW\_STATERAM\_TX5\_CP is shown in [Figure 15-109](#) and described in [Table 15-122](#).

CPDMA\_STATERAM TX CHANNEL 5 COMPLETION POINTER REGISTER \*

**Figure 15-109. CPSW\_STATERAM\_TX5\_CP Register**

**Table 15-122. CPSW\_STATERAM\_TX5\_CP Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	TX_CP	R/W	0h	Tx Completion Pointer Register - This register is written by the host with the buffer descriptor address for the last buffer processed by the host during interrupt processing. The port uses the value written to determine if the interrupt should be deasserted.

### 15.5.5.23 CPSW\_STATERAM\_TX6\_CP Register (offset = 58h) [reset = 0h]

CPSW\_STATERAM\_TX6\_CP is shown in [Figure 15-110](#) and described in [Table 15-123](#).

CPDMA\_STATERAM TX CHANNEL 6 COMPLETION POINTER REGISTER \*

**Figure 15-110. CPSW\_STATERAM\_TX6\_CP Register**

**Table 15-123. CPSW\_STATERAM\_TX6\_CP Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	TX_CP	R/W	0h	Tx Completion Pointer Register - This register is written by the host with the buffer descriptor address for the last buffer processed by the host during interrupt processing. The port uses the value written to determine if the interrupt should be deasserted.

### 15.5.5.24 CPSW\_STATERAM\_TX7\_CP Register (offset = 5Ch) [reset = 0h]

CPSW\_STATERAM\_TX7\_CP is shown in [Figure 15-111](#) and described in [Table 15-124](#).

CPDMA\_STATERAM TX CHANNEL 7 COMPLETION POINTER REGISTER \*

**Figure 15-111. CPSW\_STATERAM\_TX7\_CP Register**

**Table 15-124. CPSW\_STATERAM\_TX7\_CP Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	TX_CP	R/W	0h	Tx Completion Pointer Register - This register is written by the host with the buffer descriptor address for the last buffer processed by the host during interrupt processing. The port uses the value written to determine if the interrupt should be deasserted.

### 15.5.5.25 CPSW\_STATERAM\_RX0\_CP Register (offset = 60h) [reset = 0h]

CPSW\_STATERAM\_RX0\_CP is shown in [Figure 15-112](#) and described in [Table 15-125](#).

CPDMA\_STATERAM RX CHANNEL 0 COMPLETION POINTER REGISTER \*

**Figure 15-112. CPSW\_STATERAM\_RX0\_CP Register**

**Table 15-125. CPSW\_STATERAM\_RX0\_CP Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	RX_CP	R/W	0h	<p>Rx Completion Pointer Register - This register is written by the host with the buffer descriptor address for the last buffer processed by the host during interrupt processing.</p> <p>The port uses the value written to determine if the interrupt should be deasserted.</p> <p>Note: The value read is the completion pointer (interrupt acknowledge) value that was written by the CPDMA DMA controller (port).</p> <p>The value written to this register by the host is compared with the value that the port wrote to determine if the interrupt should remain asserted.</p> <p>The value written is not actually stored in the location.</p> <p>The interrupt is deasserted if the two values are equal.</p>

### 15.5.5.26 CPSW\_STATERAM\_RX1\_CP Register (offset = 64h) [reset = 0h]

CPSW\_STATERAM\_RX1\_CP is shown in [Figure 15-113](#) and described in [Table 15-126](#).

CPDMA\_STATERAM RX CHANNEL 1 COMPLETION POINTER REGISTER \*

**Figure 15-113. CPSW\_STATERAM\_RX1\_CP Register**

**Table 15-126. CPSW\_STATERAM\_RX1\_CP Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	RX_CP	R/W	0h	<p>Rx Completion Pointer Register - This register is written by the host with the buffer descriptor address for the last buffer processed by the host during interrupt processing.</p> <p>The port uses the value written to determine if the interrupt should be deasserted.</p> <p>Note: The value read is the completion pointer (interrupt acknowledge) value that was written by the CPDMA DMA controller (port).</p> <p>The value written to this register by the host is compared with the value that the port wrote to determine if the interrupt should remain asserted.</p> <p>The value written is not actually stored in the location.</p> <p>The interrupt is deasserted if the two values are equal.</p>

### 15.5.5.27 CPSW\_STATERAM\_RX2\_CP Register (offset = 68h) [reset = 0h]

CPSW\_STATERAM\_RX2\_CP is shown in [Figure 15-114](#) and described in [Table 15-127](#).

CPDMA\_STATERAM RX CHANNEL 2 COMPLETION POINTER REGISTER \*

**Figure 15-114. CPSW\_STATERAM\_RX2\_CP Register**

**Table 15-127. CPSW\_STATERAM\_RX2\_CP Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	RX_CP	R/W	0h	<p>Rx Completion Pointer Register - This register is written by the host with the buffer descriptor address for the last buffer processed by the host during interrupt processing.</p> <p>The port uses the value written to determine if the interrupt should be deasserted.</p> <p>Note: The value read is the completion pointer (interrupt acknowledge) value that was written by the CPDMA DMA controller (port).</p> <p>The value written to this register by the host is compared with the value that the port wrote to determine if the interrupt should remain asserted.</p> <p>The value written is not actually stored in the location.</p> <p>The interrupt is deasserted if the two values are equal.</p>

### 15.5.5.28 CPSW\_STATERAM\_RX3\_CP Register (offset = 6Ch) [reset = 0h]

CPSW\_STATERAM\_RX3\_CP is shown in [Figure 15-115](#) and described in [Table 15-128](#).

CPDMA\_STATERAM RX CHANNEL 3 COMPLETION POINTER REGISTER \*

**Figure 15-115. CPSW\_STATERAM\_RX3\_CP Register**

**Table 15-128. CPSW\_STATERAM\_RX3\_CP Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	RX_CP	R/W	0h	<p>Rx Completion Pointer Register - This register is written by the host with the buffer descriptor address for the last buffer processed by the host during interrupt processing.</p> <p>The port uses the value written to determine if the interrupt should be deasserted.</p> <p>Note: The value read is the completion pointer (interrupt acknowledge) value that was written by the CPDMA DMA controller (port).</p> <p>The value written to this register by the host is compared with the value that the port wrote to determine if the interrupt should remain asserted.</p> <p>The value written is not actually stored in the location.</p> <p>The interrupt is deasserted if the two values are equal.</p>

### 15.5.5.29 CPSW\_STATERAM\_RX4\_CP Register (offset = 70h) [reset = 0h]

CPSW\_STATERAM\_RX4\_CP is shown in [Figure 15-116](#) and described in [Table 15-129](#).

CPDMA\_STATERAM RX CHANNEL 4 COMPLETION POINTER REGISTER \*

**Figure 15-116. CPSW\_STATERAM\_RX4\_CP Register**

**Table 15-129. CPSW\_STATERAM\_RX4\_CP Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	RX_CP	R/W	0h	<p>Rx Completion Pointer Register - This register is written by the host with the buffer descriptor address for the last buffer processed by the host during interrupt processing.</p> <p>The port uses the value written to determine if the interrupt should be deasserted.</p> <p>Note: The value read is the completion pointer (interrupt acknowledge) value that was written by the CPDMA DMA controller (port).</p> <p>The value written to this register by the host is compared with the value that the port wrote to determine if the interrupt should remain asserted.</p> <p>The value written is not actually stored in the location.</p> <p>The interrupt is deasserted if the two values are equal.</p>

### 15.5.5.30 CPSW\_STATERAM\_RX5\_CP Register (offset = 74h) [reset = 0h]

CPSW\_STATERAM\_RX5\_CP is shown in [Figure 15-117](#) and described in [Table 15-130](#).

CPDMA\_STATERAM RX CHANNEL 5 COMPLETION POINTER REGISTER \*

**Figure 15-117. CPSW\_STATERAM\_RX5\_CP Register**

Bit	Field	Type	Reset	Description
31-0	RX_CP	R/W	0h	<p>Rx Completion Pointer Register - This register is written by the host with the buffer descriptor address for the last buffer processed by the host during interrupt processing.</p> <p>The port uses the value written to determine if the interrupt should be deasserted.</p> <p>Note: The value read is the completion pointer (interrupt acknowledge) value that was written by the CPDMA DMA controller (port).</p> <p>The value written to this register by the host is compared with the value that the port wrote to determine if the interrupt should remain asserted.</p> <p>The value written is not actually stored in the location.</p> <p>The interrupt is deasserted if the two values are equal.</p>

### 15.5.5.31 CPSW\_STATERAM\_RX6\_CP Register (offset = 78h) [reset = 0h]

CPSW\_STATERAM\_RX6\_CP is shown in [Figure 15-118](#) and described in [Table 15-131](#).

CPDMA\_STATERAM RX CHANNEL 6 COMPLETION POINTER REGISTER \*

**Figure 15-118. CPSW\_STATERAM\_RX6\_CP Register**

**Table 15-131. CPSW\_STATERAM\_RX6\_CP Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	RX_CP	R/W	0h	<p>Rx Completion Pointer Register - This register is written by the host with the buffer descriptor address for the last buffer processed by the host during interrupt processing.</p> <p>The port uses the value written to determine if the interrupt should be deasserted.</p> <p>Note: The value read is the completion pointer (interrupt acknowledge) value that was written by the CPDMA DMA controller (port).</p> <p>The value written to this register by the host is compared with the value that the port wrote to determine if the interrupt should remain asserted.</p> <p>The value written is not actually stored in the location.</p> <p>The interrupt is deasserted if the two values are equal.</p>

### 15.5.5.32 CPSW\_STATERAM\_RX7\_CP Register (offset = 7Ch) [reset = 0h]

CPSW\_STATERAM\_RX7\_CP is shown in [Figure 15-119](#) and described in [Table 15-132](#).

CPDMA\_STATERAM RX CHANNEL 7 COMPLETION POINTER REGISTER \*

**Figure 15-119. CPSW\_STATERAM\_RX7\_CP Register**

**Table 15-132. CPSW\_STATERAM\_RX7\_CP Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	RX_CP	R/W	0h	<p>Rx Completion Pointer Register - This register is written by the host with the buffer descriptor address for the last buffer processed by the host during interrupt processing.</p> <p>The port uses the value written to determine if the interrupt should be deasserted.</p> <p>Note: The value read is the completion pointer (interrupt acknowledge) value that was written by the CPDMA DMA controller (port).</p> <p>The value written to this register by the host is compared with the value that the port wrote to determine if the interrupt should remain asserted.</p> <p>The value written is not actually stored in the location.</p> <p>The interrupt is deasserted if the two values are equal.</p>

### 15.5.6 CPSW\_PORT Registers

[Table 15-133](#) lists the memory-mapped registers for the CPSW\_PORT. All register offset addresses not listed in [Table 15-133](#) should be considered as reserved locations and the register contents should not be modified.

**Table 15-133. CPSW\_PORT Registers**

Offset	Acronym	Register Name	Section
0h	CPSW_PORT_P0_CTRL		<a href="#">Section 15.5.6.1</a>

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	X	
15-9	RESERVED	R	0h	
8-4	P1_TX_MAX_BLKs	R/W	11h	Transmit FIFO Maximum Blocks - This value is the maximum number of 1k memory blocks that may be allocated to the FIFO's logical transmit priority queues. 0x11 is the recommended value of p1_tx_max_blks unless the port is in full duplex flow control mode. In flow control mode, the p1_rx_max_blks will need to increase in order to accept the required run out in full duplex mode. This value will need to decrease by the amount of increase in p1_rx_max_blks. 0xe is the minimum value tx max blks.
3-0	P1_RX_MAX_BLKs	R/W	3h	Receive FIFO Maximum Blocks - This value is the maximum number of 1k memory blocks that may be allocated to the FIFO's logical receive queue. This value must be greater than or equal to 0x3. It should be increased In full duplex flow control mode to 0x5 or 0x6 depending on the required runout space. The p1_tx_max_blks value must be decreased by the amount of increase in p1_rx_max_blks. 0x3 is the minimum value rx max blks and 0x6 is the maximum value.

### 15.5.6.20 CPSW\_PORT\_P1\_BLK\_CNT Register (offset = 10Ch) [reset = 41h]

CPSW\_PORT\_P1\_BLK\_CNT is shown in [Figure 15-139](#) and described in [Table 15-153](#).

Bit	Field	Type	Reset	Description
31-23	RESERVED	R	X	
22-16	PRI3_SEND_PERCENT	R/W	X	Priority 3 Transmit Percentage - This percentage value is sent from FIFO priority 3 (maximum) when the p1_pri3_shape_en is set (queue shaping enabled). This is the percentage of the wire that packets from priority 3 receive (which includes interpacket gap and preamble bytes). If shaping is enabled on this queue then this value must be between zero and 0d100 (not inclusive).
15	RESERVED	R	0h	
14-8	PRI2_SEND_PERCENT	R/W	0h	Priority 2 Transmit Percentage - This percentage value is sent from FIFO priority 2 (maximum) when the p1_pri2_shape_en is set (queue shaping enabled). This is the percentage of the wire that packets from priority 2 receive (which includes interpacket gap and preamble bytes). If shaping is enabled on this queue then this value must be between zero and 0d100 (not inclusive).
7	RESERVED	R	0h	
6-0	PRI1_SEND_PERCENT	R/W	0h	Priority 1 Transmit Percentage - This percentage value is sent from FIFO priority 1 (maximum) when the p1_pri1_shape_en is set (queue shaping enabled). This is the percentage of the wire that packets from priority 1 receive (which includes interpacket gap and preamble bytes). If shaping is enabled on this queue then this value must be between zero and 0d100 (not inclusive).

### 15.5.6.28 CPSW\_PORT\_P1\_RX\_DSCP\_PRI\_MAP0 Register (offset = 130h) [reset = 0h]

CPSW\_PORT\_P1\_RX\_DSCP\_PRI\_MAP0 is shown in [Figure 15-147](#) and described in [Table 15-161](#).

**Table 15-171. CPSW\_PORT\_P2\_MAX\_BLKs Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-9	RESERVED	R	0h	
8-4	P2_TX_MAX_BLKs	R/W	11h	Transmit FIFO Maximum Blocks - This value is the maximum number of 1k memory blocks that may be allocated to the FIFO's logical transmit priority queues. 0x11 is the recommended value of p2_tx_max_blks unless the port is in full duplex flow control mode. In flow control mode, the p2_rx_max_blks will need to increase in order to accept the required run out in full duplex mode. This value will need to decrease by the amount of increase in p2_rx_max_blks. 0xe is the minimum value tx max blks.
3-0	P2_RX_MAX_BLKs	R/W	3h	Receive FIFO Maximum Blocks - This value is the maximum number of 1k memory blocks that may be allocated to the FIFO's logical receive queue. This value must be greater than or equal to 0x3. It should be increased In full duplex flow control mode to 0x5 or 0x6 depending on the required runout space. The p2_tx_max_blks value must be decreased by the amount of increase in p2_rx_max_blks. 0x3 is the minimum value rx max blks and 0x6 is the maximum value.

### 15.5.6.39 CPSW\_PORT\_P2\_BLK\_CNT Register (offset = 20Ch) [reset = 41h]

CPSW\_PORT\_P2\_BLK\_CNT is shown in [Figure 15-158](#) and described in [Table 15-172](#).

CPSW PORT 2 FIFO BLOCK USAGE COUNT (READ ONLY)

**Table 15-190. CPSW\_SL\_MACCTRL Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-25	RESERVED	R	0h	
24	RX_CMF_EN	R/W	0h	RX Copy MAC Control Frames Enable - Enables MAC control frames to be transferred to memory. MAC control frames are normally acted upon (if enabled), but not copied to memory. MAC control frames that are pause frames will be acted upon if enabled in the MacControl register, regardless of the value of rx_cmf_en. Frames transferred to memory due to rx_cmf_en will have the control bit set in their EOP buffer descriptor. 0h (R/W) = MAC control frames are filtered (but acted upon if enabled). 1h (R/W) = MAC control frames are transferred to memory.
23	RX_CSF_EN	R/W	0h	RX Copy Short Frames Enable - Enables frames or fragments shorter than 64 bytes to be copied to memory. Frames transferred to memory due to rx_csf_en will have the fragment or undersized bit set in their receive footer. Fragments are short frames that contain CRC/align/code errors and undersized are short frames without errors. 0h (R/W) = Short frames are filtered 1h (R/W) = Short frames are transferred to memory.
22	RX_CEF_EN	R/W	0h	RX Copy Error Frames Enable - Enables frames containing errors to be transferred to memory. The appropriate error bit will be set in the frame receive footer. Frames containing errors will be filtered when rx_cef_en is not set. 0h (R/W) = Frames containing errors are filtered. 1h (R/W) = Frames containing errors are transferred to memory.
21	TX_SHORT_GAP_LIM_EN	R/W	0h	Transmit Short Gap Limit Enable When set this bit limits the number of short gap packets transmitted to 100ppm. Each time a short gap packet is sent, a counter is loaded with 10,000 and decremented on each wireside clock. Another short gap packet will not be sent out until the counter decrements to zero. This mode is included to preclude the host from filling up the FIFO and sending every packet out with short gap which would violate the maximum number of packets per second allowed.
20-19	RESERVED	R	0h	

**Table 15-190. CPSW\_SL\_MACCTRL Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
18	EXT_EN	R/W	0h	Control Enable - Enables the full duplex and gigabit mode to be selected from the FULLDUPLEX_IN and GIG_IN input signals and not from the full duplex and gig bits in this register. The FULLDUPLEX_MODE bit reflects the actual full duplex mode selected.
17	GIG_FORCE	R/W	0h	Gigabit Mode Force - This bit is used to force the CPGMAC_SL into gigabit mode if the input GMII_MTCLK has been stopped by the PHY.
16	IFCTL_B	R/W	0h	Connects to the speed_in input of the respective RMII gasket. When using RMII mode: 0h (R/W) = 10Mbps operation 1h (R/W) = 100Mbps operation
15	IFCTL_A	R/W	0h	Connects to the speed_in input of the respective RMII gasket. When using RMII mode: 0h (R/W) = 10Mbps operation 1h (R/W) = 100Mbps operation
14-13	RESERVED	R	0h	
12	CRS_FLOW_EN	R/W	0h	Carrier Sense Flow Control Enable When set this bit enables the GMII_MCRS (carrier sense) to be used as a hardware flow control in full duplex mode.
11	CMD_IDLE	R/W	0h	Command Idle 0h (R/W) = Idle not commanded 1h (R/W) = Idle Commanded (read idle in MacStatus)
10	TX_SHORT_GAP_EN	R/W	0h	Transmit Short Gap Enable 0h (R/W) = Transmit with a short IPG is disabled 1h (R/W) = Transmit with a short IPG (when TX_SHORT_GAP input is asserted) is enabled.
9-8	RESERVED	R	0h	
7	GIG	R/W	0h	Gigabit Mode 0h (R/W) = 10/100 mode 1h (R/W) = Gigabit mode (full duplex only) The GIG_OUT output is the value of this bit.
6	TX_PACE	R/W	0h	Transmit Pacing Enable 0h (R/W) = Transmit Pacing Disabled 1h (R/W) = Transmit Pacing Enabled
5	GMII_EN	R/W	0h	GMII Enable 0h (R/W) = GMII RX and TX held in reset. 1h (R/W) = GMII RX and TX released from reset.
4	TX_FLOW_EN	R/W	0h	Transmit Flow Control Enable - Determines if incoming pause frames are acted upon in full-duplex mode. Incoming pause frames are not acted upon in half-duplex mode regardless of this bit setting. The RX_MBP_Enable bits determine whether or not received pause frames are transferred to memory. 0h (R/W) = Transmit Flow Control Disabled. Full-duplex mode - Incoming pause frames are not acted upon. 1h (R/W) = Transmit Flow Control Enabled. Full-duplex mode - Incoming pause frames are acted upon.
3	RX_FLOW_EN	R/W	0h	Receive Flow Control Enable 0h (R/W) = Receive Flow Control Disabled Half-duplex mode - No flow control generated collisions are sent. Full-duplex mode - No outgoing pause frames are sent. 1h (R/W) = Receive Flow Control Enabled Half-duplex mode - Collisions are initiated when receive flow control is triggered. Full-duplex mode - Outgoing pause frames are sent when receive flow control is triggered.

**Table 15-190. CPSW\_SL\_MACCTRL Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
2	MTEST	R/W	0h	Manufacturing Test mode - This bit must be set to allow writes to the Backoff_Test and PauseTimer registers.
1	LOOPBACK	R/W	0h	<p>Loop Back Mode - Loopback mode forces internal full duplex mode regardless of whether the full duplex bit is set or not. The loopback bit should be changed only when GMII_en is deasserted.</p> <p>0h (R/W) = Not looped back 1h (R/W) = Loop Back Mode enabled</p>
0	FULLDUPLEX	R/W	0h	<p>Full Duplex mode - Gigabit mode forces full duplex mode regardless of whether the full duplex bit is set or not. The FULLDUPLEX_OUT output is the value of this register bit</p> <p>0h (R/W) = Half duplex mode 1h (R/W) = Full duplex mode</p>

### 15.5.7.3 CPSW\_SL\_MACSTS Register (offset = 8h) [reset = 80000000h]

CPSW\_SL\_MACSTS is shown in [Figure 15-176](#) and described in [Table 15-191](#).

CPGMAC\_SL MAC STATUS REGISTER

**Table 15-191. CPSW\_SL\_MACSTS Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	IDLE	R	1h	CPGMAC_SL IDLE - The CPGMAC_SL is in the idle state (valid after an idle command) 0h (R/W) = The CPGMAC_SL is not in the idle state. 1h (R/W) = The CPGMAC_SL is in the idle state.
30-5	RESERVED	R	0h	
4	EXT_GIG	R	0h	External GIG - This is the value of the EXT_GIG input bit.
3	EXT_FULLDUPLEX	R	0h	External Fullduplex - This is the value of the EXT_FULLDUPLEX input bit.
2	RESERVED	R	0h	
1	RX_FLOW_ACT	R	0h	Receive Flow Control Active - When asserted, indicates that receive flow control is enabled and triggered.
0	TX_FLOW_ACT	R	0h	Transmit Flow Control Active - When asserted, this bit indicates that the pause time period is being observed for a received pause frame. No new transmissions will begin while this bit is asserted except for the transmission of pause frames. Any transmission in progress when this bit is asserted will complete.

#### 15.5.7.4 CPSW\_SL\_SOFT\_RESET Register (offset = Ch) [reset = 0h]

CPSW\_SL\_SOFT\_RESET is shown in [Figure 15-177](#) and described in [Table 15-192](#).

CPGMAC\_SL SOFT RESET REGISTER

TX_BACKOFF							
R-0h							

**Table 15-194. CPSW\_SL\_BOFFTEST Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	RESERVED	R	0h	
30-26	PACEVAL	R/W	0h	Pacing Register Current Value. A non-zero value in this field indicates that transmit pacing is active. A transmit frame collision or deferral causes paceval to loaded with decimal 31, good frame transmissions (with no collisions or deferrals) cause paceval to be decremented down to zero. When paceval is nonzero, the transmitter delays 4 IPGs between new frame transmissions after each successfully transmitted frame that had no deferrals or collisions. Transmit pacing helps reduce "capture" effects improving overall network bandwidth.
25-16	RNDNUM	R/W	0h	Backoff Random Number Generator - This field allows the Backoff Random Number Generator to be read (or written in test mode only). This field can be written only when mtest has previously been set. Reading this field returns the generator's current value. The value is reset to zero and begins counting on the clock after the deassertion of reset.
15-12	COLL_COUNT	R	0h	Collision Count - The number of collisions the current frame has experienced.
11-10	RESERVED	R	0h	
9-0	TX_BACKOFF	R	0h	Backoff Count - This field allows the current value of the backoff counter to be observed for test purposes. This field is loaded automatically according to the backoff algorithm, and is decremented by one for each slot time after the collision.

### 15.5.7.7 CPSW\_SL\_RX\_PAUSE Register (offset = 18h) [reset = 0h]

CPSW\_SL\_RX\_PAUSE is shown in [Figure 15-180](#) and described in [Table 15-195](#).

CPGMAC\_SL RECEIVE PAUSE TIMER REGISTER

**Figure 15-180. CPSW\_SL\_RX\_PAUSE Register**

## 15.5.10 MDIO Registers

[Table 15-251](#) lists the memory-mapped registers for the MDIO. All register offset addresses not listed in [Table 15-251](#) should be considered as reserved locations and the register contents should not be modified.

**Table 15-251. MDIO REGISTERS**

Offset	Acronym	Register Name	Section
0h	MDIO_VER	MDIO Version Register	<a href="#">Section 15.5.10.1</a>
4h	MDIO_CTRL	MDIO Control Register	<a href="#">Section 15.5.10.2</a>
8h	MDIO_ALIVE	PHY Alive Status Register	<a href="#">Section 15.5.10.3</a>
Ch	MDIO_LINK	PHY Link Status Register	<a href="#">Section 15.5.10.4</a>
10h	MDIO_LINKINTRAW	MDIO Link Status Change Interrupt Register	<a href="#">Section 15.5.10.5</a>
14h	MDIO_LINKINTMASKED	MDIO Link Status Change Interrupt Register (Masked Value)	<a href="#">Section 15.5.10.6</a>
20h	MDIO_USERINTRAW	MDIO User Command Complete Interrupt Register (Raw Value)	<a href="#">Section 15.5.10.7</a>
24h	MDIO_USERINTMASKED	MDIO User Command Complete Interrupt Register (Masked Value)	<a href="#">Section 15.5.10.8</a>
28h	MDIO_USERINTMASKSET	MDIO User Command Complete Interrupt Mask Set Register	<a href="#">Section 15.5.10.9</a>
2Ch	MDIO_USERINTMASKCLR	MDIO User Interrupt Mask Clear Register	<a href="#">Section 15.5.10.10</a>
80h	MDIO_USERACCESS0	MDIO User Access Register 0	<a href="#">Section 15.5.10.11</a>
84h	MDIO_USERPHYSEL0	MDIO User PHY Select Register 0	<a href="#">Section 15.5.10.12</a>
88h	MDIO_USERACCESS1	MDIO User Access Register 1	<a href="#">Section 15.5.10.13</a>
8Ch	MDIO_USERPHYSEL1	MDIO User PHY Select Register 1	<a href="#">Section 15.5.10.14</a>

### 15.5.10.1 MDIO\_VER Register (offset = 0h) [reset = 70104h]

MDIO\_VER is shown in [Figure 15-234](#) and described in [Table 15-252](#).

**Figure 15-234. MDIO\_VER Register**

**Table 15-252. MDIO\_VER Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	MODID	R	7h	Identifies type of peripheral.
15-8	REVMAJ	R	1h	Management interface module major revision value.
7-0	REVMIN	R	4h	Management interface module minor revision value.

### 15.5.10.2 MDIO\_CTRL Register (offset = 4h) [reset = 81000FFh]

MDIO\_CTRL is shown in [Figure 15-235](#) and described in [Table 15-253](#).

**Figure 15-235. MDIO\_CTRL Register**

31	30	29	28	27	26	25	24
IDLE	EN	RESERVED1	HIGHEST_USER_CHANNEL				
R-1h	R/W-0h	R-0h	R-1h				
23	22	21	20	19	18	17	16
RESERVED2			PREAMBLE	FAULT	FAULTENB	INTTESTENB	RESERVED3
R-0h			R/W-0h	R/WC-0h	R/W-0h	R/W-0h	R-0h
15	14	13	12	11	10	9	8
CLKDIV							
R/W-FFh							
7	6	5	4	3	2	1	0
CLKDIV							
R/W-FFh							

**Table 15-253. MDIO\_CTRL Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	IDLE	R	1h	MDIO state machine IDLE. Set to 1 when the state machine is in the idle state. 0h = State machine is not in idle state. 1h = State machine is in idle state.
30	EN	R/W	0h	Enable control. If the MDIO state machine is active at the time it is disabled, it will complete the current operation before halting and setting the idle bit. If using byte access, the enable bit has to be the last bit written in this register. 0h = Disables the MDIO state machine. 1h = Enable the MDIO state machine.
29	RESERVED1	R	0h	
28-24	HIGHEST_USER_CHANNEL	R	1h	Highest user channel. This field specifies the highest user access channel that is available in the module and is currently set to 1. This implies that the MDIOUSERACCESS1 register is the highest available user access channel.
23-21	RESERVED2	R	0h	
20	PREAMBLE	R/W	0h	Preamble disable. 0h = Standard MDIO preamble is used. 1h = Disables this device from sending MDIO frame preambles.
19	FAULT	R/WC	0h	Fault indicator. This bit is set to 1 if the MDIO pins fail to read back what the device is driving onto them. This indicates a physical layer fault and the module state machine is reset. Writing a 1 to it clears this bit. 0h = No failure. 1h = Physical layer fault; the MDIO state machine is reset.
18	FAULTENB	R/W	0h	Fault detect enable. This bit has to be set to 1 to enable the physical layer fault detection. 0h = Disables the physical layer fault detection. 1h = Enables the physical layer fault detection.

**Table 15-253. MDIO\_CTRL Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
17	INTTESTENB	R/W	0h	Interrupt test enable. This bit can be set to 1 to enable the host to set the USERINT and LINKINT bits for test purposes. 0h = Interrupt bits are not set. 1h = Enables the host to set the USERINT and LINKINT bits for test purposes.
16	RESERVED3	R	0h	
15-0	CLKDIV	R/W	FFh	Clock divider. This field specifies the division ratio between CLK and the frequency of MDIO_CLK. MDIO_CLK is disabled when clkdiv is set to 0. MDIO_CLK frequency = clk frequency/(clkdiv+1).

### 15.5.10.3 MDIO\_ALIVE Register (offset = 8h) [reset = 0h]

MDIO\_ALIVE is shown in [Figure 15-236](#) and described in [Table 15-254](#).

**Figure 15-236. MDIO\_ALIVE Register**

**Table 15-254. MDIO\_ALIVE Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	ALIVE	R/WC	0h	<p>MDIO alive.</p> <p>Each of the 32 bits of this register is set if the most recent access to the PHY with address corresponding to the register bit number was acknowledged by the PHY, the bit is reset if the PHY fails to acknowledge the access.</p> <p>Both the user and polling accesses to a PHY will cause the corresponding alive bit to be updated.</p> <p>The alive bits are only meant to be used to give an indication of the presence or not of a PHY with the corresponding address.</p> <p>Writing a 1 to any bit will clear it, writing a 0 has no effect.</p>

#### 15.5.10.4 MDIO\_LINK Register (offset = Ch) [reset = 0h]

MDIO\_LINK is shown in [Figure 15-237](#) and described in [Table 15-255](#).

**Figure 15-237. MDIO\_LINK Register**

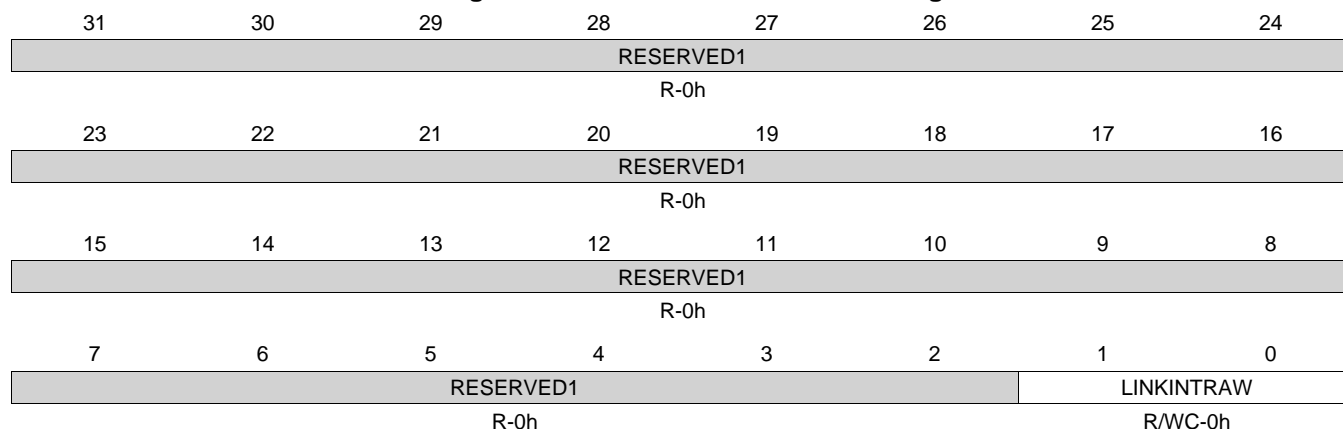

**Table 15-255. MDIO\_LINK Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-0	LINK	R	0h	<p>MDIO link state.</p> <p>This register is updated after a read of the Generic Status Register of a PHY.</p> <p>The bit is set if the PHY with the corresponding address has link and the PHY acknowledges the read transaction.</p> <p>The bit is reset if the PHY indicates it does not have link or fails to acknowledge the read transaction.</p> <p>Writes to the register have no effect.</p> <p>In addition, the status of the two PHYs specified in the MDIOUSERPHYSEL registers can be determined using the MLINK input pins.</p> <p>This is determined by the LINKSEL bit in the MDIOUSERPHYSEL register.</p>

### 15.5.10.5 MDIO\_LINKINTRAW Register (offset = 10h) [reset = 0h]

MDIO\_LINKINTRAW is shown in [Figure 15-238](#) and described in [Table 15-256](#).

**Figure 15-238. MDIO\_LINKINTRAW Register**

**Table 15-256. MDIO\_LINKINTRAW Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-2	RESERVED1	R	0h	
1-0	LINKINTRAW	R/WC	0h	MDIO link change event, raw value. When asserted 1, a bit indicates that there was an MDIO link change event (that is, change in the MDIOLINK register) corresponding to the PHY address in the MDIOUSERPHYSEL register. LINKINTRAW[0] and LINKINTRAW[1] correspond to MDIOUSERPHYSEL0 and MDIOUSERPHYSEL1, respectively. Writing a 1 will clear the event and writing 0 has no effect. If the INTTESTENB bit in the MDIOCONTROL register is set, the host may set the LINKINTRAW bits to a 1. This mode may be used for test purposes.

### 15.5.10.6 MDIO\_LINKINTMASKED Register (offset = 14h) [reset = 0h]

MDIO\_LINKINTMASKED is shown in [Figure 15-239](#) and described in [Table 15-257](#).

**Figure 15-239. MDIO\_LINKINTMASKED Register**

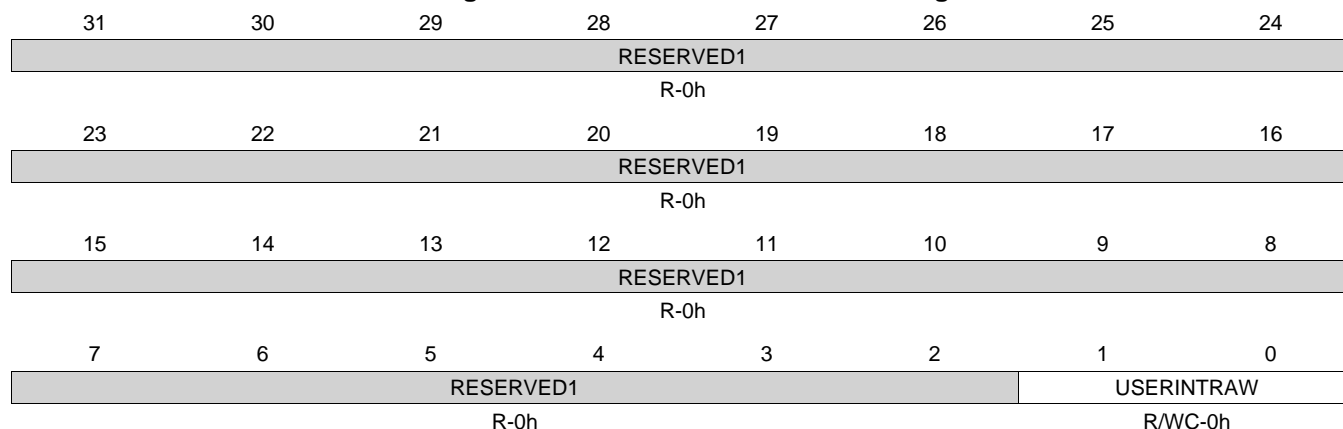

**Table 15-257. MDIO\_LINKINTMASKED Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-2	RESERVED1	R	0h	
1-0	LINKINTMASKED	R/WC	0h	MDIO link change interrupt, masked value. When asserted 1, a bit indicates that there was an MDIO link change event (that is, change in the MDIO Link register) corresponding to the PHY address in the MDIOUSERPHYSEL register and the corresponding LINKINTENB bit was set. LINKINTMASKED[0] and LINKINTMASKED[1] correspond to MDIOUSERPHYSEL0 and MDIOUSERPHYSEL1, respectively. Writing a 1 will clear the interrupt and writing 0 has no effect. If the INTTESTENB bit in the MDIOCONTROL register is set, the host may set the LINKINT bits to a 1. This mode may be used for test purposes.

### 15.5.10.7 MDIO\_USERINTRAW Register (offset = 20h) [reset = 0h]

MDIO\_USERINTRAW is shown in [Figure 15-240](#) and described in [Table 15-258](#).

**Figure 15-240. MDIO\_USERINTRAW Register**

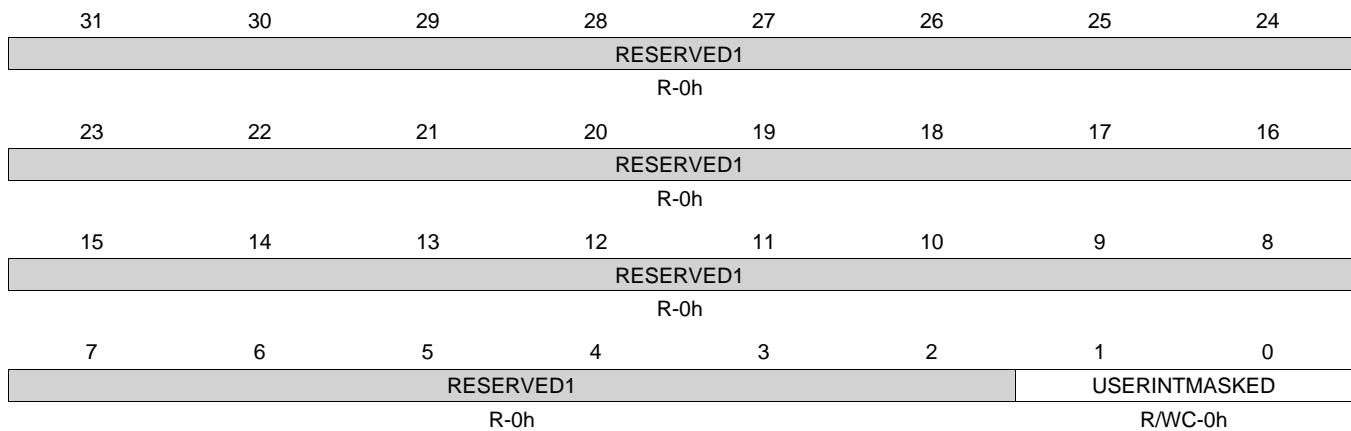

**Table 15-258. MDIO\_USERINTRAW Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-2	RESERVED1	R	0h	
1-0	USERINTRAW	R/WC	0h	<p>Raw value of MDIO user command complete event for the MDIOUSERACCESS1 register through the MDIOUSERACCESS0 register, respectively.</p> <p>When asserted 1, a bit indicates that the previously scheduled PHY read or write command using that particular MDIOUSERACCESSn register has completed.</p> <p>Writing a 1 will clear the event and writing 0 has no effect.</p> <p>If the INTTESTENB bit in the MDIOCONTROL register is set, the host may set the USERINTRAW bits to a 1.</p> <p>This mode may be used for test purposes.</p>

### 15.5.10.8 MDIO\_USERINTMASKED Register (offset = 24h) [reset = 0h]

MDIO\_USERINTMASKED is shown in [Figure 15-241](#) and described in [Table 15-259](#).

**Figure 15-241. MDIO\_USERINTMASKED Register**

**Table 15-259. MDIO\_USERINTMASKED Register Field Descriptions**

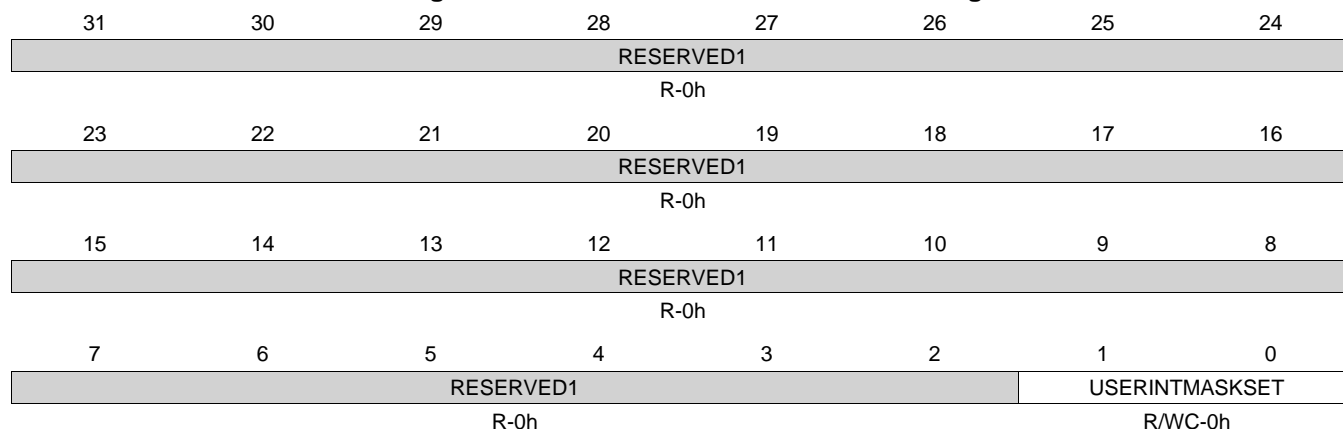

Bit	Field	Type	Reset	Description
31-2	RESERVED1	R	0h	
1-0	USERINTMASKED	R/WC	0h	Masked value of MDIO user command complete interrupt for the MDIOUSERACCESS1 register through the MDIOUSERACCESS0 register, respectively. When asserted 1, a bit indicates that the previously scheduled PHY read or write command using that particular MDIOUSERACCESSn register has completed and the corresponding USERINTMASKSET bit is set to 1. Writing a 1 will clear the interrupt and writing 0 has no effect. If the INTTESTENB bit in the MDIOCONTROL register is set, the host may set the USERINTMASKED bits to a 1. This mode may be used for test purposes.

### 15.5.10.9 MDIO\_USERINTMASKSET Register (offset = 28h) [reset = 0h]

MDIO\_USERINTMASKSET is shown in [Figure 15-242](#) and described in [Table 15-260](#).

**Figure 15-242. MDIO\_USERINTMASKSET Register**

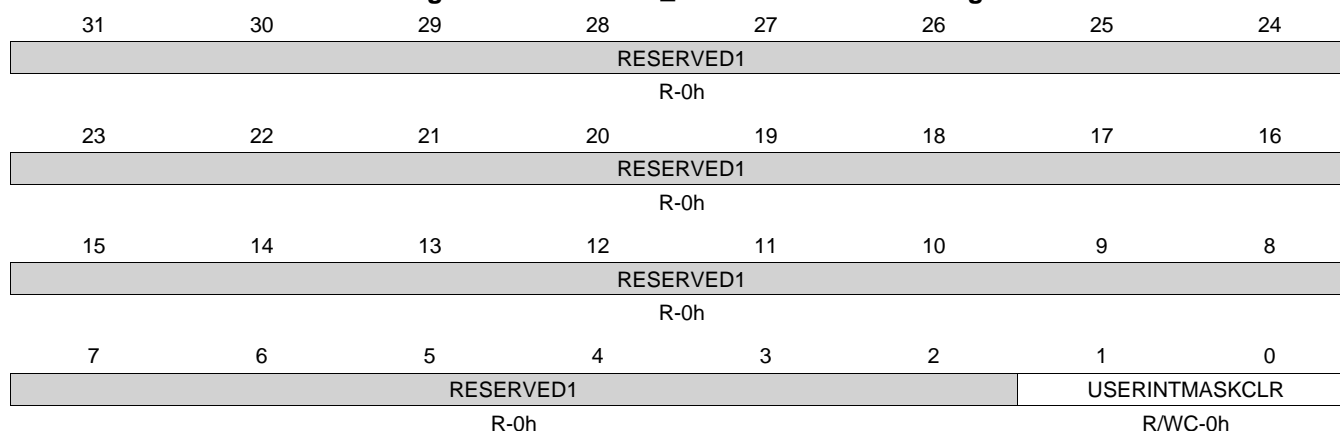

**Table 15-260. MDIO\_USERINTMASKSET Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-2	RESERVED1	R	0h	
1-0	USERINTMASKSET	R/WC	0h	MDIO user interrupt mask set for USERINTMASKED, respectively. Writing a bit to 1 will enable MDIO user command complete interrupts for that particular MDIOUSERACCESSn register. MDIO user interrupt for a particular MDIOUSERACCESSn register is disabled if the corresponding bit is 0. Writing a 0 to this register has no effect.

### 15.5.10.10 MDIO\_USERINTMASKCLR Register (offset = 2Ch) [reset = 0h]

MDIO\_USERINTMASKCLR is shown in [Figure 15-243](#) and described in [Table 15-261](#).

**Figure 15-243. MDIO\_USERINTMASKCLR Register**

**Table 15-261. MDIO\_USERINTMASKCLR Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-2	RESERVED1	R	0h	
1-0	USERINTMASKCLR	R/WC	0h	MDIO user command complete interrupt mask clear for USERINTMASKED, respectively. Writing a bit to 1 will disable further user command complete interrupts for that particular MDIOUSERACCESSn register. Writing a 0 to this register has no effect.

### 15.5.10.11 MDIO\_USERACCESS0 Register (offset = 80h) [reset = 0h]

MDIO\_USERACCESS0 is shown in [Figure 15-244](#) and described in [Table 15-262](#).

**Figure 15-244. MDIO\_USERACCESS0 Register**

31	30	29	28	27	26	25	24
GO	WRITE	ACK	RESERVED1			REGADR

23	22	21	20	19	18	17	16
REGADR			PHYADR				
R/W-0h			R/W-0h				
15	14	13	12	11	10	9	8
DATA							
R/W-0h							
7	6	5	4	3	2	1	0
DATA							
R/W-0h							

**Table 15-262. MDIO\_USERACCESS0 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	GO	R/W/S	0h	Go. Writing a 1 to this bit causes the MDIO state machine to perform an MDIO access when it is convenient for it to do so, this is not an instantaneous process. Writing a 0 to this bit has no effect. This bit is write able only if the MDIO state machine is enabled. This bit will self clear when the requested access has been completed. Any writes to the MDIOUSERACCESS0 register are blocked when the GO bit is 1. If byte access is being used, the GO bit should be written last.
30	WRITE	R/W	0h	Write enable. Setting this bit to a 1 causes the MDIO transaction to be a register write, otherwise it is a register read.
29	ACK	R/W	0h	Acknowledge. This bit is set if the PHY acknowledged the read transaction.
28-26	RESERVED1	R	0h	
25-21	REGADR	R/W	0h	Register address. Specifies the PHY register to be accessed for this transaction.
20-16	PHYADR	R/W	0h	PHY address. Specifies the PHY to be accesses for this transaction.
15-0	DATA	R/W	0h	User data. The data value read from or to be written to the specified PHY register.

### 15.5.10.12 MDIO\_USERPHYSEL0 Register (offset = 84h) [reset = 0h]

MDIO\_USERPHYSEL0 is shown in [Figure 15-245](#) and described in [Table 15-263](#).

**Figure 15-245. MDIO\_USERPHYSEL0 Register**

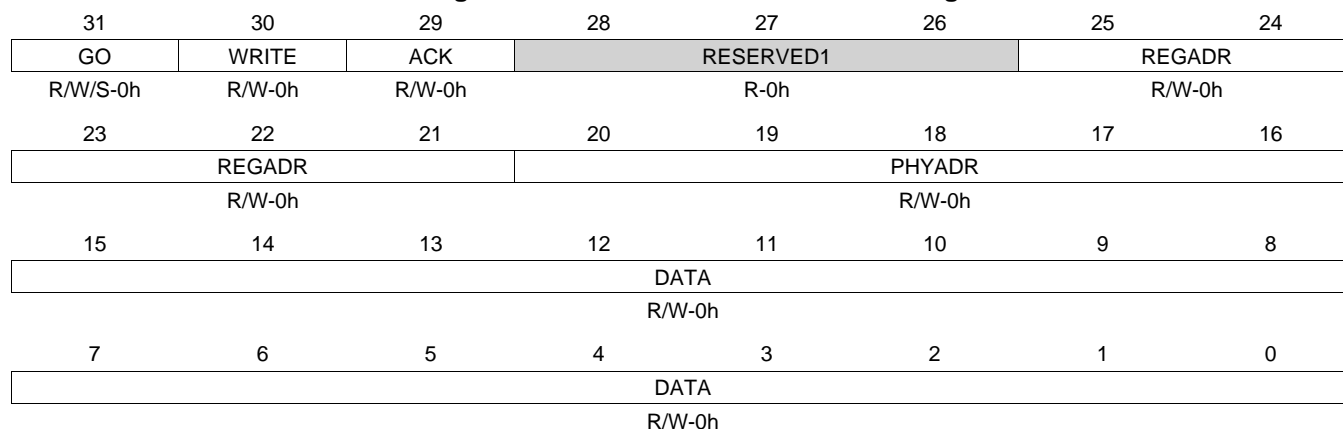

**Table 15-263. MDIO\_USERPHYSEL0 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-8	RESERVED1	R	0h	
7	LINKSEL	R/W	0h	Link status determination select. Set to 1 to determine link status using the MLINK pin. Default value is 0 which implies that the link status is determined by the MDIO state machine.
6	LINKINTENB	R/W	0h	Link change interrupt enable. Set to 1 to enable link change status interrupts for PHY address specified in PHYADDRMON. Link change interrupts are disabled if this bit is set to 0. 0h = Link change interrupts are disabled. 1h = Link change status interrupts for PHY address specified in PHYADDRMON bits are enabled.
5	RESERVED2	R	0h	
4-0	PHYADDRMON	R/W	0h	PHY address whose link status is to be monitored.

### 15.5.10.13 MDIO\_USERACCESS1 Register (offset = 88h) [reset = 0h]

MDIO\_USERACCESS1 is shown in [Figure 15-246](#) and described in [Table 15-264](#).

**Figure 15-246. MDIO\_USERACCESS1 Register**

**Table 15-264. MDIO\_USERACCESS1 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	GO	R/W/S	0h	Writing a 1 to this bit causes the MDIO state machine to perform an MDIO access when it is convenient for it to do so, this is not an instantaneous process. Writing a 0 to this bit has no effect. This bit is write able only if the MDIO state machine is enabled. This bit will self clear when the requested access has been completed. Any writes to the MDIOUSERACCESS0 register are blocked when the GO bit is 1. If byte access is being used, the GO bit should be written last.
30	WRITE	R/W	0h	Write enable. Setting this bit to a 1 causes the MDIO transaction to be a register write, otherwise it is a register read.
29	ACK	R/W	0h	Acknowledge. This bit is set if the PHY acknowledged the read transaction.
28-26	RESERVED1	R	0h	
25-21	REGADR	R/W	0h	Register address specifies the PHY register to be accessed for this transaction.
20-16	PHYADR	R/W	0h	PHY address specifies the PHY to be accesses for this transaction.
15-0	DATA	R/W	0h	User data. The data value read from or to be written to the specified PHY register.

### 15.5.10.14 MDIO\_USERPHYSEL1 Register (offset = 8Ch) [reset = 0h]

MDIO\_USERPHYSEL1 is shown in [Figure 15-247](#) and described in [Table 15-265](#).

**Figure 15-247. MDIO\_USERPHYSEL1 Register**

**Table 15-265. MDIO\_USERPHYSEL1 Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-8	RESERVED1	R	0h	
7	LINKSEL	R/W	0h	Link status determination select. Set to 1 to determine link status using the MLINK pin. Default value is 0 which implies that the link status is determined by the MDIO state machine.
6	LINKINTENB	R/W	0h	Link change interrupt enable. Set to 1 to enable link change status interrupts for PHY address specified in PHYADDRMON. Link change interrupts are disabled if this bit is cleared to 0. 0h = Link change interrupts are disabled 1h = Link change status interrupts for PHY address specified in PHYADDRMON bits are enabled.
5	RESERVED2	R	0h	
4-0	PHYADDRMON	R/W	0h	PHY address whose link status is to be monitored.

## ***Universal Serial Bus (USB)***

---

---

---

This chapter describes the universal serial bus (USB) of the device.

<b>Topic</b>	<b>Page</b>
<b>16.1 Introduction .....</b>	<b>2534</b>
<b>16.2 Integration .....</b>	<b>2535</b>
<b>16.3 Use Cases.....</b>	<b>2537</b>
<b>16.4 Reference Documentation.....</b>	<b>2539</b>

## 16.1 Introduction

USB (Universal Serial Bus) provides a low-cost connectivity solution for numerous consumer portable devices by implementing a mechanism for data transfer between USB devices.

The AM437x instantiates two independent instances of the Synopsys DWC3 (DesignWare Cores) USB subsystem (USB2SS) operating at USB2.0 speeds (480Mb/s), either of which can be independently configured to act as a USB Host or a USB Device. SuperSpeed (5.0 Gb/s) operation is not supported in either operational mode.

This document serves to describe the integration of the Synopsys DWC3 USB subsystem and should not be considered sufficient for those wishing to modify the existing Linux DWC3 driver(s) or create a new driver to support this controller implementation. For those who do wish to substantially modify the existing Linux DWC3 driver(s), or create new drivers, contact your TI sales representative for more information on how to obtain the Synopsys DWC3 Databook under NDA.

### 16.1.1 Features

The USB 2.0 subsystem, supports the following USB features:

- Operational modes:
  - Supports USB 2.0 Host mode at High-Speed (HS, 480 Mbps), Full-Speed (FS, 12 Mbps), and Low-Speed (LS, 1.5 Mbps)
  - Supports USB 2.0 Device mode at High-Speed (HS, 480 Mbps), and Full-Speed (FS, 12 Mbps). Low-Speed is not supported in Device mode.
  - Supports all modes of transfers - Control, Bulk, Interrupt, and Isochronous.
- A DRD (Dual-Role-Device - Host or Device) USB controller with the following features:
  - Compatible to the xHCI 1.0 specification in Host mode
  - Compatible with the USB 2.0 specification in Device mode
  - Supports 15 IN (Receive), 15 OUT (Transmit) endpoints (EPs), and one EP0 endpoint which is bidirectional
  - Internal DMA controller
  - Descriptor caching and data pre-fetching ensures high performance
  - Dynamic FIFO memory allocation for all endpoints
- Operation flexibility
  - Same programming model for HS, FS, and LS operation
  - Each controller instance can provide either USB Host or USB Device functionality
  - Multiple interrupt lines:
    - Four programmable interrupts
    - A MISC interrupt line for all miscellaneous events
- External requirements:
  - Needs an external Charge Pump for VBUS 5 V generation in Host mode. (Device mode does not require VBUS generation).

### 16.1.2 Unsupported Features

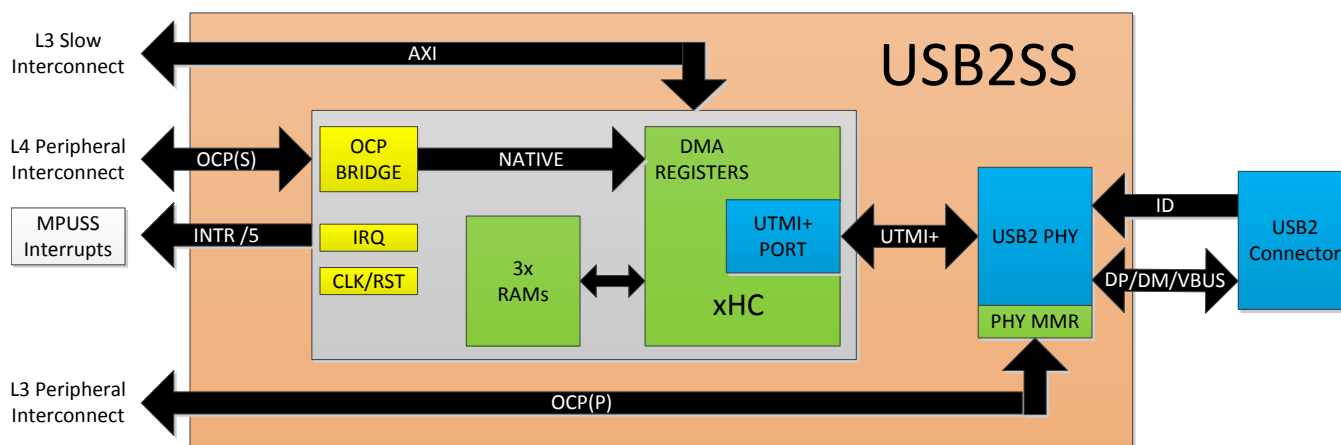

The following are USB features which are not supported:

- Battery Charger Support
- Accessory Charger Adaptor Support
- OTG functionality
- No Virtualization support
- SuperSpeed (5GB/s) operation

## 16.2 Integration

Figure 16-1 shows the functional block diagram of the USB 2.0 subsystem (USB2SS), which includes a wrapper module, a USB controller module, a PHY module, external interfaces, and internal interfaces.

**Figure 16-1. USB 2.0 Subsystem (USB2SS) Functional Block Diagram**

- The wrapper module, which provides:
  - A bridge to the system bus
  - Local MMR to configure and control the USB controller
  - Interrupt management
- The USB Core with a Dual-Role-Device Controller module and internal RAMs:
  - Compatible to the xHCI 1.0 standard in Host mode
  - Support for either USB Host or USB Device modes
  - Internal DMA controller for high-bandwidth, low overhead data transfer
  - Three local RAMs supporting:
    - Dynamic Tx/Rx FIFO memory allocation for all EPs
    - Descriptor caching and data pre-fetching for high performance
  - Supports all transfer types - Control, Bulk, Interrupt, and Isochronous
  - Supports high-bandwidth ISO mode
  - Supports 15 IN, 15 OUT endpoints (EPs), and one EP0 endpoint which is bidirectional
- The integrated USB PHY module:
  - A USB2 PHY connected to the core via internal UTMI+ port
- External interfaces (towards device boundary):
  - To USB Connector:
    - DP/DM - a bidirectional signal pair for HS, FS, LS mode operation
    - VBUS - an analog pin for monitoring the voltage on VBUS.
    - ID - an input signal for operating mode (Host/Device) determination.
  - To an external Charge Pump for VBUS 5V generation:
    - DRVVBUS - an active high output that controls an external 5V charge pump. The core uses this output to automatically ensure that VBUS has 5V supplied by the charge pump during Host mode operation.

- Internal interface (towards internal system):
  - An OCP slave interface for MMR transactions to/from the controller.
  - An OCP slave interface for MMR transactions to/from the PHY.
  - An AXI master interface for high-bandwidth DMA transactions.
  - Interrupt interface:
    - USB\_MAINn\_INT[3:0] - 4 programmable interrupts associated with DMA traffic
    - USB\_MISCIINT - single interrupt line for misc events

### 16.2.1 USB Clock and Reset Management

The USB2SS contains several functional clock domains: BUS, PHYMMR, and UTMI+ Interface.

[Table 16-1](#) provides the details of the clock drivers and the control of the clocks.

**Table 16-1. USB2SS Clock Sources and Clock Control**

Clock Signal	Max Frequency	Reference / Source	Comments
ocp_clk XHCI master/slave interface clock	100 MHz	CORE_CLKOUTM4 / 2	pd_per_l3s_gclk From PRCM
phy_clk Phy slave interface clock	100 MHz	CORE_CLKOUTM4 / 4	pd_per_l4s_gclk From PRCM
suspend_clk Phy low power functional clock	125 MHz	CLK_M_OSC	pd_usb_otg_ssrefclk From PRCM
phy_other_refclk960m UTMI source clock	960 MHz	USB_PHYCLK	DCOCLKLDO from Per PLL
phy_other_trefclk Phy reference clock	50 MHz	CLK_M_OSC	
phy_other_sparein[0] Phy auto-resume logic wakeup clock	32 KHz	CLK32K_RTC	pd_wakeup_usbphy_32khz_gclk From PRCM

### 16.2.2 USB Pin List

The names of the pins used by the USB2SS with descriptions are shown in [Table 16-2](#) and [Table 16-3](#).

**Table 16-2. USB Signal Pins Description**

Pin Name	IOZP	IPD/IPU	Nominal Voltage	Description
USBn_DP	IOZ		3.3V	USB 2.0 and 1.1 specification-compliant signal pins. They are HS/FS/LS bidirectional differential data pins.
USBn_DM	IOZ		3.3V	

**Table 16-3. USB Control, Configuration, and Monitor Signal Pins**

Pin Name	IOZP	Nominal Voltage	Description
USBn_DRVVBUS	O		An active-high digital output signal for VBUS power supply. Used to enable an external charge pump to supply +5V power to the VBUS port of the device as well as the VBUS port of the USB receptacle, when appropriate per the USB standard. Output is 0 at reset.
USBn_VBUS	A	5.0V	An analog input for monitoring the voltage on VBUS.
USBn_ID	A		Used to determine the operational mode (Host/Peripheral) of the controller. When grounded, the controller will operate as a USB Host. When left floating, the controller will operate as a USB Peripheral. NOTE: This pin should never be connected to a voltage source.
USBn_CE	O	3.3V	An active high digital output for PHY charge enable.

## 16.3 Use Cases

This is a standard USB 2.0 module, and is optimized for following applications and systems:

- Portable electronic devices
- High-bandwidth applications

It supports all typical USB connections, and [Table 16-4](#) shows some examples.

**Table 16-4. Typical Use Cases In Terms of Connections**

Connectors (Receptacle)	Signals to Use	SS	HS/FS	LS (Host only)	Comments
USB 2.0 Micro-AB	DP, DM, VBUS, ID	N	Y	Y	Support Host or Device operation, depending on state of the ID pin.
USB 2.0 Type-A	DP, DM, VBUS	N	Y	Y	Support HS/FS/LS Host
USB 2.0 Type-B	DP, DM, VBUS	N	Y	N	Only used for USB2.0 Device (no LS)

### 16.3.1 USB Operational Mode Determination

As the USB controller modules present in this device are DRD (Dual-Role Devices), they can support operation as either a USB Host or a USB Device. The operational mode determination is made based on the state of the USBn\_ID pin; when this pin is grounded, the controller will operate as a USB Host, when this pin is left floating, the controller assumes the role of a USB Device. For implementations that do not require DRD functionality, the USBn\_ID pin can either be left floating or can be grounded in the board design depending on the static role required. For implementations that do require DRD functionality, the USBn\_ID pin should be connected directly to the corresponding ID pin on a USB Micro-AB socket. In doing so, the USBn\_ID pin will be correctly terminated (open or grounded) depending on the cable attached and the controller will enter Host or Device mode accordingly. Refer to [Section 16.3.2](#) for more details.

### 16.3.2 Typical Pin Connections of AM437x Device

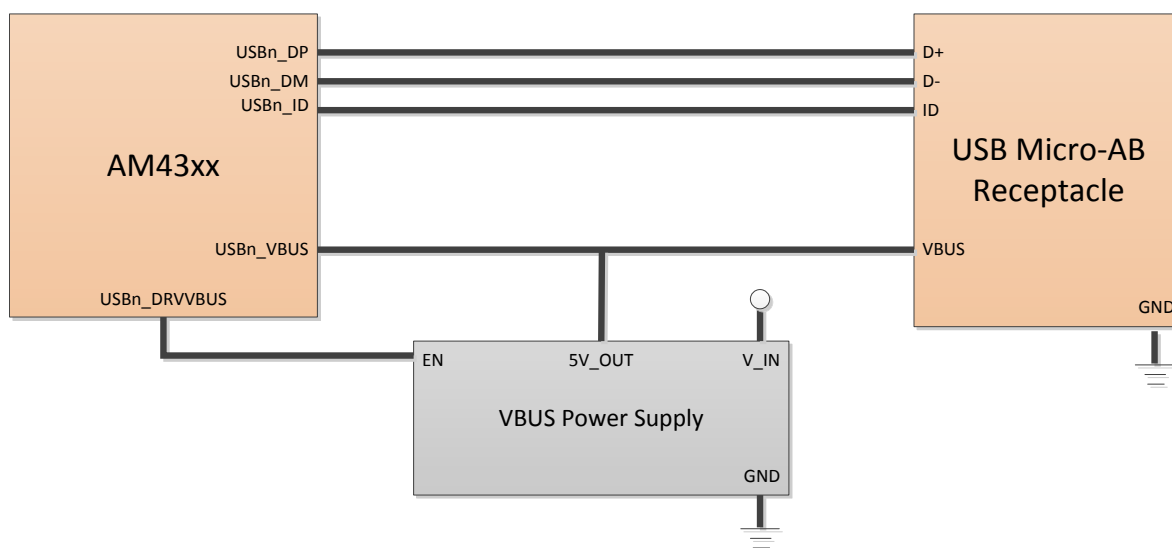

Figure 16-2. USB Dual-Role (Host or Device)

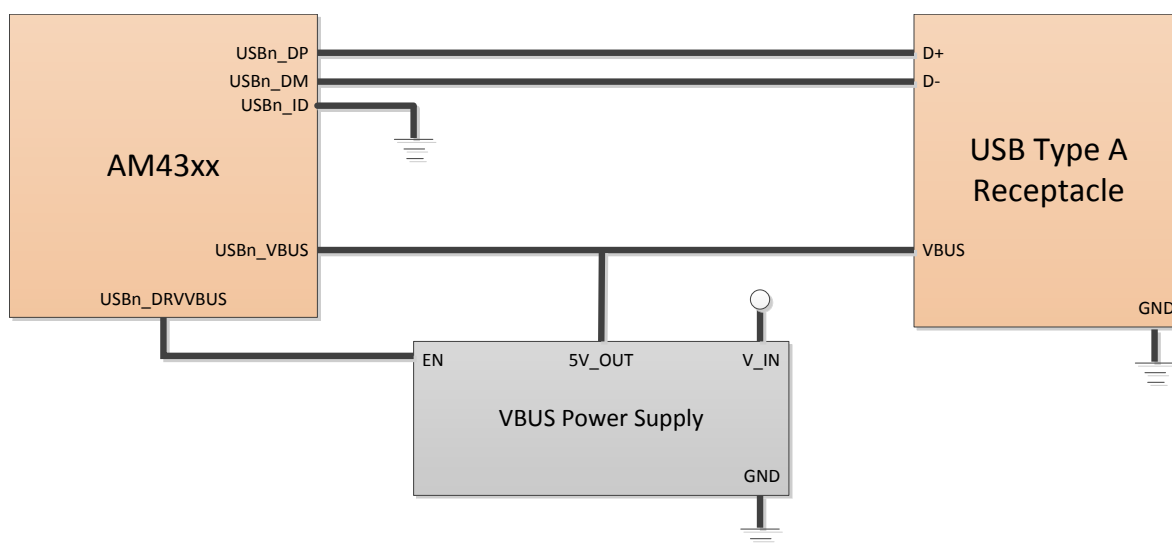

Figure 16-3. USB Host Only

Figure 16-4. USB Device Only

### 16.3.3 VBUS Voltage Sourcing Control

When either of the USB controllers assumes the role of a host, the controller is required to supply 5V to an attached device through its VBUS line. In order to achieve this task, the USB controller requires the use of external power logic (or a charge pump) capable of sourcing 5V power. The USB\_DRVVBUS pin is used as a control signal to enable/disable this external power logic to either source or disable power on the VBUS line. The control on the USB\_DRVVBUS is automatic and is handled by the USB controller. The control should be transparent to the user so long as the proper hardware connection and software initialization are in place. The USB controller drives the USB\_DRVVBUS signal high when it assumes the role of a host while the controller is in session. When assuming the role of a device, the controller drives the USB\_DRVVBUS signal low disabling the external charge pump/power logic; hence, no power is driven on the VBUS line (in this case, power is expected to be provided by the external host).

Note that both USB controllers are self-powered and the device does not rely on the voltage on the VBUS line sourced by an external host for controller operation when assuming the role of a device. The voltage present on the VBUS line is used to identify the presence of a Host. The USB PHY continually monitors the voltage on the VBUS and reports the status to USB controller.

### 16.3.4 Pull-up/Pull-down Resistors

As the USB controllers are dual role controllers, capable of assuming a role of a host or device, the required pull-up/pull-down resistors cannot exist external to the device. These pull-up/pulldown resistors exist internal to the device, within the PHY to be more specific, and are enabled or disabled based on the role the controller assumes allowing for dynamic hardware configuration. When assuming the role of a host, the data lines are pulled low by the PHY enabling the internal 15K $\Omega$  resistors. When assuming the role of a device the required 1.5K $\Omega$  pull-up resistor on the D+ line is enabled automatically to signify the USB capability to the external host as a FS device (HS operation is negotiated during reset bus condition).

### 16.3.5 Clock, PLL, and PHY Initialization

Prior to configuring the USB Module Registers, the USB Subsystem and PHY are required to be released from reset, relevant interconnects and clocks must be enabled and the PHY itself must be configured.

## 16.4 Reference Documentation

eXtensible Host Controller Interface For Universal Serial Bus (xHCI), Revision 1.0 with errata to 6/13/11, Intel Corp., June 13, 2011 (Request from USB-IF)

## ***Multimedia Card (MMC)***

---

---

This chapter describes the MMC of the device.

<b>Topic</b>	<b>Page</b>
<b>17.1 Introduction .....</b>	<b>2541</b>
<b>17.2 Integration .....</b>	<b>2542</b>
<b>17.3 Functional Description .....</b>	<b>2546</b>
<b>17.4 Low-Level Programming Models .....</b>	<b>2579</b>
<b>17.5 MMC/SD Registers .....</b>	<b>2583</b>

## 17.1 Introduction

### 17.1.1 MMCSD Features

The general features of the MMCSD host controller IP are:

- Built-in 1024-byte buffer for read or write
- Two DMA channels, one interrupt line
- Clock support
  - 96-MHz functional clock source input
  - up to 384Mbit/sec (48MByte/sec) in MMC mode 8-bit data transfer
  - up to 192Mbit/sec (24MByte/sec) in High-Speed SD mode 4-bit data transfer
  - up to 24Mbit/sec (3MByte/sec) in Default SD mode 1-bit data transfer
- Support for SDA 3.0 Part A2 programming model
- Serial link supports full compliance with:
  - MMC command/response sets as defined in the MMC standard specification v4.3.
  - SD command/response sets as defined in the SD Physical Layer specification v2.00
  - SDIO command/response sets and interrupt/read-wait suspend-resume operations as defined in the SD part E1 specification v 2.00
  - SD Host Controller Standard Specification sets as defined in the SD card specification Part A2 v2.00

### 17.1.2 Unsupported MMCSD Features

The MMCSD module features not supported in this device are shown in [Table 17-1](#).

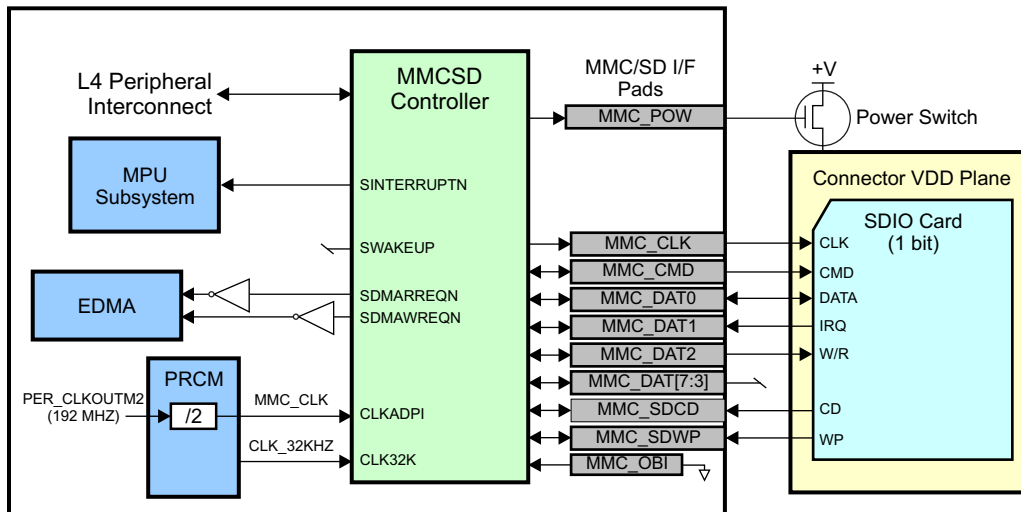

**Table 17-1. Unsupported MMCSD Features**

Feature	Reason
MMC Out-of-band interrupts	MMC_OBI input tied low
Master DMA operation	Disabled through synthesis parameter
Card Supply Control (MMCSD(1-2))	Signal not pinned out
Dual Data Rate (DDR) mode	Timing not supported

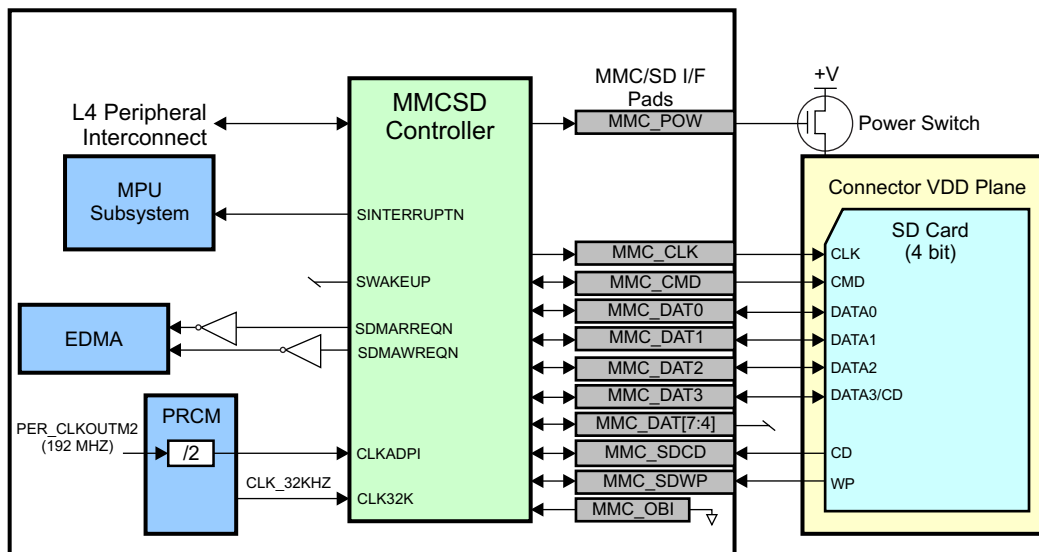

## 17.2 Integration

This device contains three instances of the Multimedia Card (MMC), Secure Digital (SD), and Secure Digital I/O (SDIO) high speed interface module (MMCSD). The controller provides an interface to an MMC, SD memory card or SDIO card.

The application interface is responsible for managing transaction semantics; the MMC/SDIO host controller deals with MMC/SDIO protocol at transmission level, packing data, adding CRC, start/end bit and checking for syntactical correctness. [Figure 17-1](#) through [Figure 17-3](#) below show examples of systems using the MMCSD controller. Note that the power switch control is only available on the MMCSD0 interface.

**Figure 17-1. MMCSD Module SDIO Application**

**Figure 17-2. MMCSD (4-bit) Card Application**

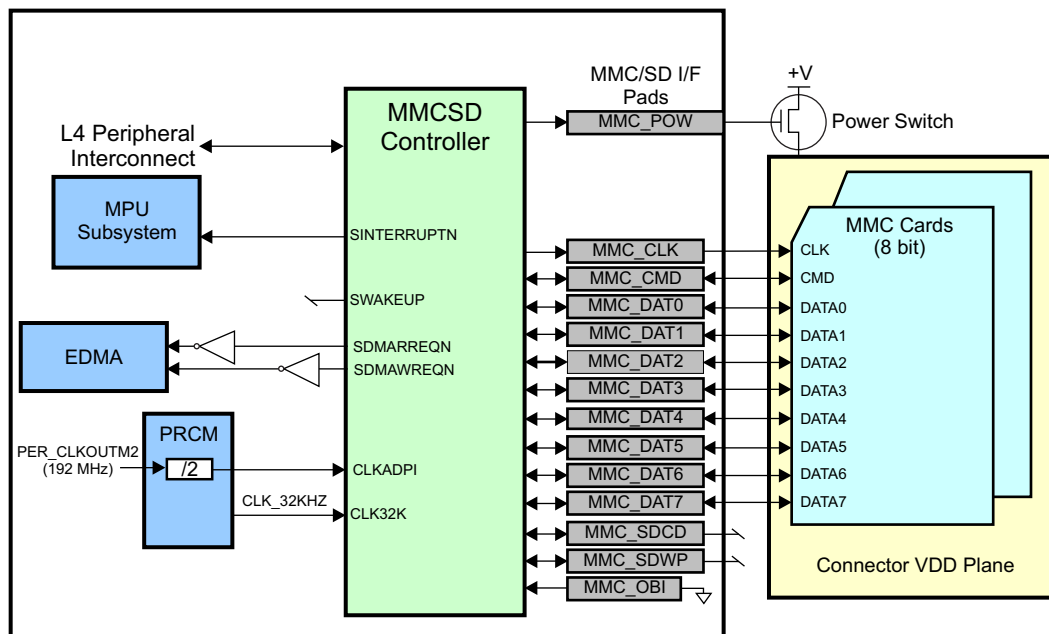

Figure 17-3. MMCSD Module MMC Application

### 17.2.1 MMCSD Connectivity Attributes

The general connectivity attributes for the three MMCSD modules are shown in [Table 17-2](#).

Table 17-2. MMCSD Connectivity Attributes

Attributes	Type
Power Domain	Peripheral Domain
Clock Domain	PD_PER_L4LS_GCLK (OCP) PD_PER_MMC_FCLK (Func) CLK_32KHZ (Debounce)
Reset Signals	PER_DOM_RST_N
Idle/Wakeup Signals	Smart Idle
Interrupt Requests	1 interrupt per instance to MPU Subsystem (MMCSDxINT)
DMA Requests	2 DMA requests per instance to EDMA (SDTXEVTx, SDRXEVTx) (Active low, need to be inverted in glue logic)
Physical Address	L4 Peripheral slave port

## 17.2.2 MMCSD Clock and Reset Management

The MMCSD controller has separate bus interface and functional clocks. The debounce clock is created by dividing the 48-MHz (24 MHz @ OPP50) clock in the PRCM by two and then dividing the resulting 24-MHz (12 MHz @ OPP50) clock by a fixed 732.4219 (366.2109 @ OPP50) in the Control Module to get a 32-kHz clock. This clock is fed back into the PRCM for clock gating. (See the CTRL\_CLK32KDIVRATIO register in [Chapter 7, Control Module](#), for more details).

**Table 17-3. MMCSD Clock Signals**

Clock Signal	Max Freq	Reference / Source	Comments
CLK Interface clock	100 MHz	CORE_CLKOUTM4 / 2	pd_per_l4ls_gclk from PRCM
CLKADPI Functional clock	48 MHz	PER_CLKOUTM2 / 4	pd_per_mmc_fclk from PRCM
CLK32 Input de-bounce clock	32.768 KHz	CLK_24 / 732.4219	clk_32KHz from PRCM

## 17.2.3 MMCSD Pin List

The MMCSD interface pins are summarized in [Table 17-4](#).

**Table 17-4. MMCSD Pin List**

Pin	Type	Description
MMCx_CLK	I/O <sup>(1)</sup>	MMC/SD serial clock output
MMCx_CMD	I/O	MMC/SD command signal
MMCx_DAT0	I/O	MMC/SD data signal
MMCx_DAT1	I/O	MMC/SD data signal, SDIO interrupt input
MMCx_DAT2	I/O	MMC/SD data signal, SDIO read wait output
MMCx_DAT[7:3]	I/O	MMC/SD data signals
MMCx_POW	O	MMC/SD power supply control (MMCSD0 only)
MMCx_SDCD	I	SD card detect (from connector)
MMCx_SDWP	I	SD write protect (from connector)
MMCx_OBI	I	MMC out of band interrupt

<sup>(1)</sup> This output signal is also used as a retiming input. The associated CONF\_<module>\_<pin>\_RXACTIVE bit for the output clock must be set to 1 to enable the clock input back to the module. It is also recommended to place a 33-ohm resistor in series (close to the processor) to avoid signal reflections.

The direction of the data lines depends on the selected data transfer mode as summarized in [Table 17-5](#).

**Table 17-5. DAT Line Direction for Data Transfer Modes**

	MMC/SD 1-bit mode	MMC/SD 4-bit mode	MMC/SD 8-bit mode	SDIO 1-bit mode	SDIO 4-bit mode
DAT[0]	I/O	I/O	I/O	I/O	I/O
DAT[1]	I <sup>(1)</sup>	I/O	I/O	I <sup>(2)</sup>	I/O or I <sup>(2)</sup>
DAT[2]	I <sup>(1)</sup>	I/O	I/O	I/O <sup>(3)</sup>	I/O or O <sup>(3)</sup>
DAT[3]	I <sup>(1)</sup>	I/O	I/O	I <sup>(1)</sup>	I/O
DAT[4]	I <sup>(1)</sup>	I <sup>(1)</sup>	I/O	I <sup>(1)</sup>	I <sup>(1)</sup>
DAT[5]	I <sup>(1)</sup>	I <sup>(1)</sup>	I/O	I <sup>(1)</sup>	I <sup>(1)</sup>
DAT[6]	I <sup>(1)</sup>	I <sup>(1)</sup>	I/O	I <sup>(1)</sup>	I <sup>(1)</sup>
DAT[7]	I <sup>(1)</sup>	I <sup>(1)</sup>	I/O	I <sup>(1)</sup>	I <sup>(1)</sup>

<sup>(1)</sup> Hi-Z state to avoid bus conflict.

<sup>(2)</sup> To support incoming interrupt from the SDIO card.

<sup>(3)</sup> To support read wait to the SDIO card. By default it is Input, Output only in read wait period.

The direction of the MMCSD data buffers are controlled by ADPDATDIROQ signals. ADPDATDIROQ[i] = 1 sets the corresponding DAT signal(s) in read position (input) and ADPDATDIROQ[i] = 0 sets the corresponding DAT signal(s) in write position (output). Additionally, the ADPDATDIRLS signals are provided (with opposite polarity) to control the direction of external level shifters. The value of these control signals for the various data modes are summarized in [Table 17-6](#).

**Table 17-6. ADPDATDIROQ and ADPDATDIRLS Signal States**

	MMC/SD 1-bit mode	MMC/SD 4-bit mode	MMC/SD 8-bit mode	SDIO 1-bit mode	SDIO 4-bit mode
DAT[0]	ADPDATDIRLS[0] = 0 / 1 ADPDATDIROQ[0] = 1 / 0	ADPDATDIRLS[0] = 0 / 1 ADPDATDIROQ[0] = 1 / 0	ADPDATDIRLS[0] = 0 / 1 ADPDATDIROQ[0] = 1 / 0	ADPDATDIRLS[0] = 0 / 1	ADPDATDIRLS[0] = 0 / 1 ADPDATDIROQ[0] = 1 / 0
DAT[2]	ADPDATDIRLS[2] = 0 ADPDATDIROQ[2] = 1	ADPDATDIRLS[2] = 0 / 1 ADPDATDIROQ[2] = 1 / 0	ADPDATDIRLS[2] = 0 / 1 ADPDATDIROQ[2] = 1 / 0	ADPDATDIRLS[2] = 0 / 1 ADPDATDIROQ[2] = 1 / 0	ADPDATDIRLS[2] = 0 / 1 ADPDATDIROQ[2] = 1 / 0
DAT[1]	ADPDATDIRLS[1] = 0	ADPDATDIRLS[1] = 0 / 1	ADPDATDIRLS[1] = 0 / 1	ADPDATDIRLS[1] = 0	ADPDATDIRLS[1] = 0 / 1
DAT[3]	ADPDATDIROQ[1] = 1	ADPDATDIROQ[1] = 1 / 0	ADPDATDIROQ[1] = 1 / 0	ADPDATDIROQ[1] = 1	ADPDATDIROQ[1] = 1 / 0
DAT[4]	ADPDATDIRLS[3] = 0	ADPDATDIRLS[3] = 0	ADPDATDIRLS[3] = 0 / 1	ADPDATDIRLS[3] = 0	ADPDATDIRLS[3] = 0
DAT[5]	ADPDATDIROQ[3] = 1	ADPDATDIROQ[3] = 1	ADPDATDIROQ[3] = 1 / 0	ADPDATDIROQ[3] = 1	ADPDATDIROQ[3] = 1
DAT[6]					
DAT[7]					

ADPDATIRLSx = 0 for input and 1 for output — these signals are not pinned out on this device.

ADPDATIROQx = 1 for output and 0 for input.

Grayed cells indicate that the data line is not used in the selected transfer mode.

## 17.3 Functional Description

One MMC/SD/SDIO host controller can support one MMC memory card, one SD card, or one SDIO card.

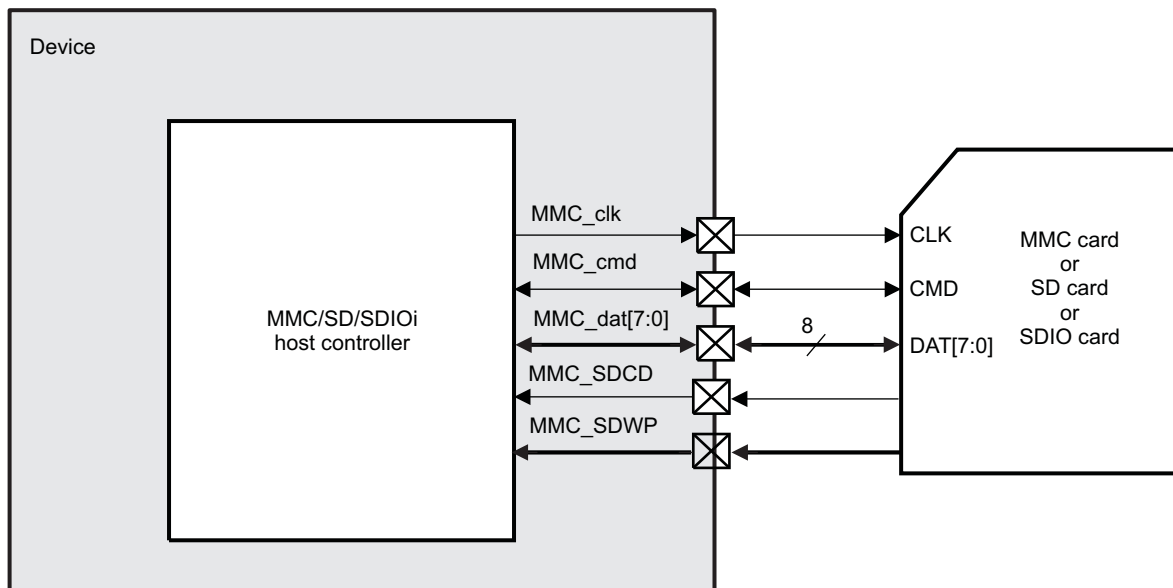

Other combinations (for example, two SD cards, one MMC card, and one SD card) are not supported through a single controller.

### 17.3.1 MMC/SD/SDIO Functional Modes

#### 17.3.1.1 MMC/SD/SDIO Connected to an MMC, an SD Card, or an SDIO Card

Figure 17-4 shows the MMC/SD/SDIO1 and MMC/SD/SDIO2 host controllers connected to an MMC, an SD, or an SDIO card and its related external connections.

**Figure 17-4. MMC/SD1/2 Connectivity to an MMC/SD Card**

**Figure 17-5. MMC/SD0 Connectivity to an MMC/SD Card**

Figure 17-5 shows the MMC/SD/SDIO0 host controller connected to an MMC, SD, or SDIO card and its related external connections. Note that MMC/SD/SDIO0 uses the same signals as MMC/SD/SDIO1 and 2 but adds MMC\_POW.

The following MMC/SD/SDIO controller pins are used

- **MMC\_CMD** This pin is used for two-way communication between the connected card and the MMC/SD/SDIO controller. The MMC/SD/SDIO controller transmits commands to the card and the memory card drives responses to the commands on this pin.
- **MMC\_DAT7-0** Depending on which type of card you are using, you may need to connect 1, 4, or 8 data lines. The number of DAT pins (the data bus width) is set by the Data Transfer Width (DTW) bit in the MMC control register (SD\_HCTL). For more information, see [Section 17.5.1, MMCSD Registers](#).
- **MMC\_CLK** This pin provides the clock to the memory card from the MMC/SD controller.
- **MMC\_POW** Used for MMC/SD card's cards on/off power supply control. When high, denotes power-on condition.
- **MMC\_SDCD** This input pin serves as the MMC/SD/SDIO carrier detect. This signal is received from a mechanical switch on the slot.
- **MMC\_SDWP** This input pin is used for the SD/SDIO card's write protect. This signal is received from a mechanical protect switch on the slot (system dependant). Applicable only for SD and SDIO cards that have a mechanical sliding tablet on the side of the card.

**Note:** The MMC\_CLK pin functions as an output but must be configured as an I/O to internally loopback the clock to time the inputs.

Table 17-7 provides a summary of these pins.

**Table 17-7. MMC/SD/SDIO Controller Pins and Descriptions**

Pin	Type	1-Bit Mode	4-Bit Mode	8-Bit Mode	Reset Value
MMC_CLK <sup>(1)</sup>	O	Clock Line	Clock Line	Clock Line	High impedance
MMC_CMD	I/O	Command Line	Command Line	Command Line	High impedance
MMC_DAT0	I/O	Data Line 0	Data Line 0	Data Line 0	0
MMC_DAT1	I/O	(not used)	Data Line 1	Data Line 1	0
MMC_DAT2	I/O	(not used)	Data Line 2	Data Line 2	0
MMC_DAT3	I/O	(not used)	Data Line 3	Data Line 3	0
MMC_DAT4	I/O	(not used)	(not used)	Data Line 4	0
MMC_DAT5	I/O	(not used)	(not used)	Data Line 5	0
MMC_DAT6	I/O	(not used)	(not used)	Data Line 6	0
MMC_DAT7	I/O	(not used)	(not used)	Data Line 7	0

<sup>(1)</sup> The MMC\_CLK pin functions as an output but must be configured as an I/O to internally loopback the clock to time the inputs.

### 17.3.1.2 Protocol and Data Format

The bus protocol between the MMC/SD/SDIO host controller and the card is message-based. Each message is represented by one of the following parts:

**Command:** A command starts an operation. The command is transferred serially from the MMC/SD/SDIO host controller to the card on the mmc\_cmd line.

**Response:** A response is an answer to a command. The response is sent from the card to the MMC/SD/SDIO host controller. It is transferred serially on the mmc\_cmd line.

**Data:** Data are transferred from the MMC/SD/SDIO host controller to the card or from a card to the MMC/SD/SDIO host controller using the DATA lines.

**Busy:** The mmc\_dat0 signal is maintained low by the card as far as it is programming the data received.

**CRC status:** CRC result is sent by the card through the mmc\_dat0 line when executing a write transfer. In the case of transmission error, occurring on any of the active data lines, the card sends a negative CRC status on mmc\_dat0. In the case of successful transmission, over all active data lines, the card sends a positive CRC status on mmc\_dat0 and starts the data programming procedure.

### 17.3.1.2.1 Protocol

There are two types of data transfer:

- Sequential operation
- Block-oriented operation

There are specific commands for each type of operation (sequential or block-oriented). See the *Multimedia Card System Specification*, the *SD Memory Card Specifications*, and the *SDIO Card Specification, Part E1* for details about commands and programming sequences supported by the MMC, SD, and SDIO cards.

#### CAUTION

Stream commands are supported only by MMC cards.

Figure 17-6 and Figure 17-7 show how sequential operations are defined. Sequential operation is only for 1-bit transfer and initiates a continuous data stream. The transfer terminates when a stop command follows on the mmc\_cmd line.

**Figure 17-6. Sequential Read Operation (MMC Cards Only)**

**Figure 17-7. Sequential Write Operation (MMC Cards Only)**

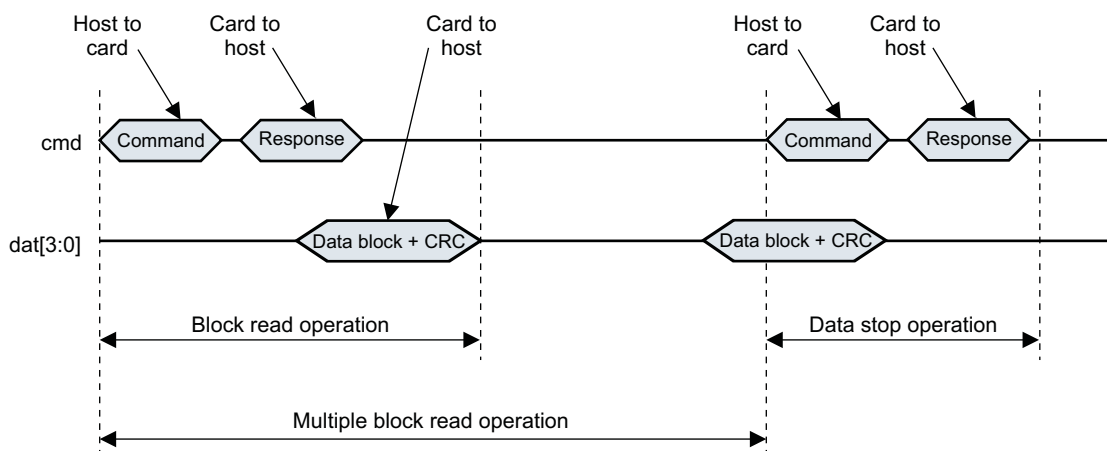

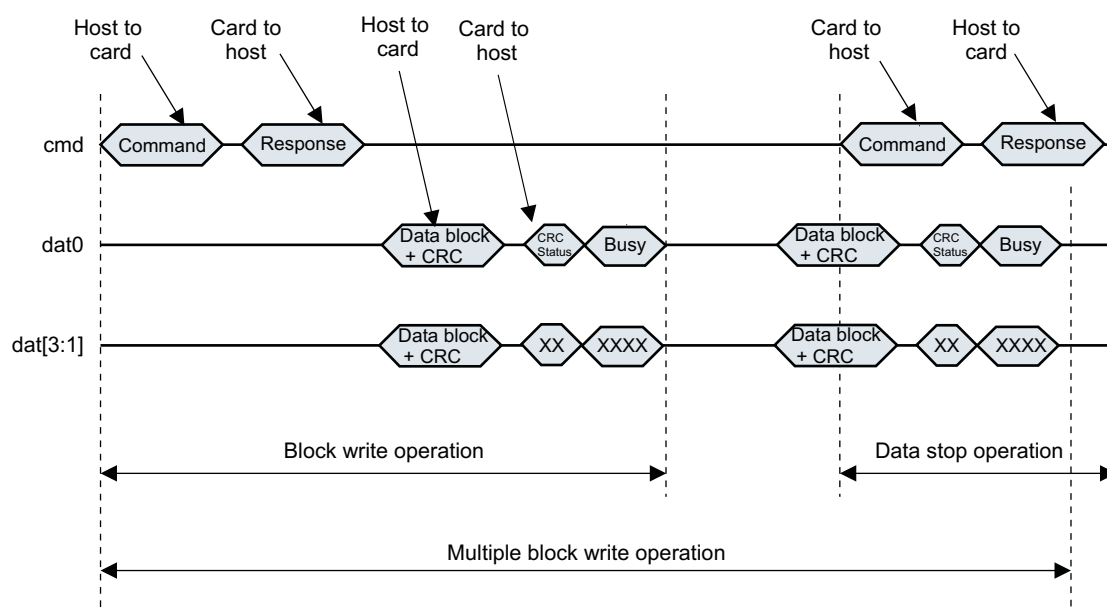

Figure 17-8 and Figure 17-9 show how multiple block-oriented operations are defined. A multiple block-oriented operation sends a data block plus CRC bits. The transfer terminates when a stop command follows on the mmc\_cmd line. These operations are available for all kinds of cards.

**Figure 17-8. Multiple Block Read Operation (MMC Cards Only)**

**Figure 17-9. Multiple Block Write Operation (MMC Cards Only)**

**NOTE:**

1. The card busy signal is not always generated by the card; the previous examples show a particular case.
2. It is the software's responsibility to do a software reset after a data timeout to ensure that mmc\_clk is stopped. The software reset is done by setting bit 26 in the SD\_SYSCTL register to 1.
3. For multiblock transfer, and especially for MMC cards, you can abort a transfer without using a stop command. Use a CMD23 before a data transfer to define the number of blocks that will be transferred, then the transfer stops automatically after the last block (provided the MMC card supports this feature).

### 17.3.1.2.2 Data Format

#### Coding Scheme for Command Token

Command packets always start with 0 and end with 1. The second bit is a transmitter bit<sup>1</sup> for a host command. The content is the command index (coded by 6 bits) and an argument (for example, an address), coded by 32 bits. The content is protected by 7-bit CRC checksum (see [Figure 17-10](#)).

**Figure 17-10. Command Token Format**

#### Coding Scheme for Response Token

Response packets always start with 0 and end with a 1. The second bit is a transmitter bit<sup>0</sup> for a card response. The content is different for each type of response (R1, R2, R3, R4, R5, and R6) and the content is protected by 7-bit CRC checksum. Depending on the type of commands sent to the card, the SD\_CMD register must be configured differently to avoid false CRC or index errors to be flagged on command response (see [Table 17-8](#)). For more details about response types, see the *Multimedia Card System Specification*, the *SD Memory Card Specification*, or the *SDIO Card Specification*.

**Table 17-8. Response Type Summary<sup>(1)</sup>**

Response Type SD_CMD[17:16] RSP_TYPE	Index Check Enable SD_CMD[20] CICE	CRC Check Enable SD_CMD[19] CCCE	Name of Response Type
00	0	0	No Response
01	0	1	R2
10	0	0	R3 (R4 for SD cards)
10	1	1	R1, R6, R5 (R7 for SD cards)
11	1	1	R1b, R5b

<sup>(1)</sup> The MMC/SD/SDIO host controller assumes that both clocks may be switched off, whatever the value set in the SD\_SYSCONFIG[9:8] CLOCKACTIVITY bit.

[Figure 17-11](#) and [Figure 17-12](#) depict the 48-bit and 136-bit response packets.

**Figure 17-11. 48-Bit Response Packet (R1, R3, R4, R5, R6)**

**Figure 17-12. 136-Bit Response Packet (R2)**

## Coding Scheme for Data Token

Data tokens always start with 0 and end with 1 (see [Figure 17-13](#), [Figure 17-14](#), [Figure 17-15](#), and [Figure 17-16](#)).

**Figure 17-13. Data Packet for Sequential Transfer (1-Bit)**

**Figure 17-14. Data Packet for Block Transfer (1-Bit)**

**Figure 17-15. Data Packet for Block Transfer (4-Bit)**

**Figure 17-16. Data Packet for Block Transfer (8-Bit)**

## 17.3.2 Resets

### 17.3.2.1 Hardware Reset

The module is reinitialized by the hardware.

The SD\_SYSSTS[0] RESETDONE bit can be monitored by the software to check if the module is ready-to-use after a hardware reset.

This hardware reset signal has a global reset action on the module. All configuration registers and all state machines are reset in all clock domains.

This hardware reset signal has a global reset action on the module. All configuration registers and all state-machines are reset in all clock domains.

### 17.3.2.2 Software Reset

The module is reinitialized by software through the SD\_SYSCONFIG[1] SOFTRESET bit. This bit has the same action on the module logic as the hardware signal except for:

- Debounce logic
- SD\_PSTATE, SD\_CAPA, and SD\_CUR\_CAPA registers (see corresponding register descriptions)

The SOFTRESET bit is active high. The bit is automatically reinitialized to 0 by the hardware. The SD\_SYSCTL[24] SRA bit has the same action as the SOFTRESET bit on the design.

The SD\_SYSSTS[0] RESETDONE bit can be monitored by the software to check if the module is ready-to-use after a software reset.

Moreover, two partial software reset bits are provided:

- SD\_SYSCTL[26] SRD bit
- SD\_SYSCTL[25] SRC bit

These two reset bits are useful to reinitialize data or command processes respectively in case of line conflict. When set to 1, a reset process is automatically released when the reset completes:

- The SD\_SYSCTL[26] SRD bit resets all finite state-machines and status management that handle data transfers on both the interface and functional side.
- The SD\_SYSCTL[25] SRC bit resets all finite state-machines and status management that handle command transfers on both the interface and functional side.

---

**NOTE:** If **any** of the clock inputs are not present for the MMC/SD/SDIO peripheral, the software reset will not complete.

---

### 17.3.3 Power Management

The MMC/SD/SDIO host controller can enter into different modes and save power:

- Normal mode
- Idle mode

The two modes are mutually exclusive (the module can be in normal mode or in idle mode). The MMC/SD/SDIO host controller is compliant with the PRCM module handshake protocol. When the MMC/SD/SDIO power domain is off, the only way to wake up the power domain and different MMC/SD/SDIO clocks is to monitor the mmc\_dat1 input pin state via a different GPIO line for each MMC/SD/SDIO interface.

#### 17.3.3.1 Normal Mode

The autogating of interface and functional clocks occurs when the following conditions are met:

- The SD\_SYSCONFIG[0] AUTOIDLE bit is set to 1.
- There is no transaction on the MMC interface.

The autogating of interface and functional clocks stops when the following conditions are met:

- A register access occurs through the L3 (or L4) interconnect.
- A wake-up event occurs (an interrupt from a SDIO card).
- A transaction on the MMC/SD/SDIO interface starts.

Then the MMC/SD/SDIO host controller enters in low-power state even if SD\_SYSCONFIG[0] AUTOIDLE is cleared to 0. The functional clock is internally switched off and only interconnect read and write accesses are allowed.

#### 17.3.3.2 Idle Mode

The clocks provided to MMC/SD/SDIO are switched off upon a PRCM module request. They are switched back upon module request. The MMC/SD/SDIO host controller complies with the PRCM module handshaking protocol:

- Idle request from the system power manager
- Idle acknowledgment from the MMC/SD/SDIO host controller

The idle acknowledgment varies according to the SD\_SYSCONFIG[4:3] SIDLEMODE bit field:

- 0: Force-idle mode. The MMC/SD/SDIO host controller acknowledges the system power manager request unconditionally.
- 1h: No-idle mode. The MMC/SD/SDIO host controller ignores the system power manager request and behaves normally as if the request was not asserted.
- 2h: Smart-idle mode. The MMC/SD/SDIO host controller acknowledges the system power manager request according to its internal state.

- 3h: Reserved.

During the smart-idle mode period, the MMC/SD/SDIO host controller acknowledges that the OCP and Functional clocks may be switched off whatever the value set in the SD\_SYSCONFIG[9:8] CLOCKACTIVITY field.

### 17.3.3.3 Transition from Normal Mode to Smart-Idle Mode

Smart-idle mode is enabled when the SD\_SYSCONFIG[4:3] SIDLEMODE bit field is set to 2h or 3h. The MMC/SD/SDIO host controller goes into idle mode when the PRCM issues an idle request, according to its internal activity. The MMC/SD/SDIO host controller acknowledges the idle request from the PRCM after ensuring the following:

- The current multi/single-block transfer is completed.
- Any interrupt or DMA request is asserted.
- There is no card interrupt on the SD\_dat1 signal.

As long as the MMC/SD/SDIO controller does not acknowledge the idle request, if an event occurs, the MMC/SD/SDIO host controller can still generate an interrupt or a DMA request. In this case, the module ignores the idle request from the PRCM.

As soon as the MMC/SD/SDIO controller acknowledges the idle request from the PRCM:

- If Smart-Idle mode the module does not assert any new interrupt or DMA request

### 17.3.3.4 Transition from Smart-Idle Mode to Normal Mode

The MMC/SD/SDIO host controller detects the end of the idle period when the PRCM deasserts the idle request. For the wake-up event, there is a corresponding interrupt status in the SD\_STAT register. The MMC/SD/SDIO host controller operates the conversion between wake-up and interrupt (or DMA request) upon exit from smart-idle mode if the associated enable bit is set in the SD\_ISE register.

Interrupts and wake-up events have independent enable/disable controls, accessible through the SD\_HCTL and SD\_ISE registers. The overall consistency must be ensured by software.

The interrupt status register SD\_STAT is updated with the event that caused the wake-up in the CIRQ bit when the SD\_IE[8] CIRQ\_ENABLE associated bit is enabled. Then, the wake-up event at the origin of the transition from smart-idle mode to normal mode is converted into its corresponding interrupt or DMA request. (The SD\_STAT register is updated and the status of the interrupt signal changes.)

When the idle request from the PRCM is deasserted, the module switches back to normal mode. The module is fully operational.

### 17.3.3.5 Force-Idle Mode

Force-idle mode is enabled when the SD\_SYSCONFIG[4:3] SIDLEMODE bit field is cleared to 0. Force-idle mode is an idle mode where the MMC/SD/SDIO host controller responds unconditionally to the idle request from the PRCM. Moreover, in this mode, the MMC/SD/SDIO host controller unconditionally deasserts interrupts and DMA request lines are asserted.

The transition from normal mode to force-idle mode does not affect the bits of the SD\_STAT register. In force-idle mode, the interrupt and DMA request lines are deasserted. Interface Clock (OCP) and functional clock (CLKADPI) can be switched off.

#### CAUTION

In Force-idle mode, an idle request from the PRCM during a command or a data transfer can lead to an unexpected and unpredictable result. When the module is idle, any access to the module generates an error as long as the OCP clock is alive.

The module exits the force-idle mode when the PRCM deasserts the idle request. Then the module switches back to normal mode. The module is fully operational. Interrupt and DMA request lines are optionally asserted one clock cycle later.

### 17.3.3.6 Local Power Management

Table 17-9 describes power-management features available for the MMC/SD/SDIO modules.

**Table 17-9. Local Power Management Features**

Feature	Registers	Description
Clock Auto Gating	SD_SYSCONFIG AUTOIDLE bit	This bit allows a local power optimization inside module, by gating the OCP clock upon the interface activity or gating the CLKADPI clock upon the internal activity.
Slave Idle Modes	SD_SYSCONFIG SIDLEMODE bit	Force-idle, No-idle, and Smart-idle modes
Clock Activity	SD_SYSCONFIG CLOCKACTIVITY bit	Please see Table 17-10 for configuration details.
Global Wake-Up Enable	SD_SYSCONFIG ENAWAKEUP bit	This bit enables the wake-up feature at module level.
Wake-Up Sources Enable	SD_HCTL register	This register holds one active high enable bit per event source able to generate wake-up signal.

**Table 17-10. Clock Activity Settings**

CLOCKACTIVITY Values	Clock State When Module is in IDLE State		Features Available when Module is in IDLE State	Wake-Up Events
	OCP Clock	CLKADPI		
00	OFF	OFF	None	Card Interrupt
10	OFF	ON	None	
01	ON	OFF	None	
11	ON	ON	All	

#### CAUTION

The PRCM module has no hardware means of reading CLOCKACTIVITY settings. Thus, software must ensure consistent programming between the CLOCKACTIVITY and MMC clock PRCM control bits.

### 17.3.4 Interrupt Requests

Several internal module events can generate an interrupt. Each interrupt has a status bit, an interrupt enable bit, and a signal status enable:

- The status of each type of interrupt is automatically updated in the SD\_STAT register; it indicates which service is required.
- The interrupt status enable bits of the SD\_IE register enable/disable the automatic update of the SD\_STAT register on an event-by-event basis.
- The interrupt signal enable bits of the SD\_ISE register enable/disable the transmission of an interrupt request on the interrupt line MMC\_IRQ (from the MMC/SD/SDIO host controller to the MPU subsystem interrupt controller) on an event-by-event basis.

If an interrupt status is disabled in the SD\_IE register, then the corresponding interrupt request is not transmitted, and the value of the corresponding interrupt signal enable in the SD\_ISE register is ignored.

When an interrupt event occurs, the corresponding status bit is automatically set to 1 (the MMC/SD/SDIO host controller updates the status bit) in the SD\_STAT register. If later a mask is applied on the interrupt in the SD\_ISE register, the interrupt request is deactivated.

When the interrupt source has not been serviced, if the interrupt status is cleared in the SD\_STAT register and the corresponding mask is removed from the SD\_ISE register, the interrupt status is not asserted again in the SD\_STAT register and the MMC/SD/SDIOi host controller does not transmit an interrupt request.

#### CAUTION

If the buffer write ready interrupt (BWR) or the buffer read ready only interrupt (BRR) are not serviced and are cleared in the SD\_STAT register, and the corresponding mask is removed, then the MMC/SD/SDIOi host controller will wait for the service of the interrupt without updating the status SD\_STAT or transmitting an interrupt request.

Table 17-11 lists the event flags, and their mask, that can cause module interrupts.

**Table 17-11. Events**

Event Flag	Event Mask	Map To	Description
SD_STAT[29] BADA	SD_IE[29] BADA_ENABLE	MMC_IRQ	Bad Access to Data space. This bit is set automatically to indicate a bad access to buffer when not allowed. This bit is set during a read access to the data register (SD_DATA) while buffer reads are not allowed (SD_PSTATE[11] BRE=0). This bit is set during a write access to the data register (SD_DATA) while buffer writes are not allowed (SD_STATE[10] BWE=0)
SD_STAT[28] CERR	SD_IE[28] CERR_ENABLE	MMC_IRQ	Card Error. This bit is set automatically when there is at least one error in a response of type R1, R1b, R6, R5 or R5b. Only bits referenced as type E(error) in status field in the response can set a card status error. An error bit in the response is flagged only if corresponding bit in card status response errors SD_CSRE is set. There is not card detection for auto CMD12 command.
SD_STAT[25] ADMAE	SD_IE[25] ADMAE_ENABLE	MMC_IRQ	ADMA error. This bit is set when the host controller detects errors during ADMA based data transfer. The stat of the ADMA at an error occurrence is saved in the ADMA Error Status Register. In addition, the host controller generates this interrupt when it detects invalid descriptor data (Valid=0) at the ST_FDS state.
SD_STAT[24] ACE	SD_IE[24] ACE_ENABLE	MMC_IRQ	Auto CMD12 error. This bit is set automatically when one of the bits in Auto CMD12 Error status register has changed from 0 to 1
SD_STAT[22] DEB	SD_IE[22] DEB_ENABLE	MMC_IRQ	Data End Bit error. This bit is set automatically when detecting a 0 at the end bit position of read data on DAT line or at the end position of the CRC status in write mode.

**Table 17-11. Events (continued)**

Event Flag	Event Mask	Map To	Description
SD_STAT[21] DCRC	SD_IE[21] DCRC_ENABLE	MMC_IRQ	Data CRC error. This bit is set automatically when there is a CRC16 error in the data phase response following a block read command or if there is a 3-bit CRC status different of a position "010" token during a block write command.
SD_STAT[20] DTO	SD_IE[20] DTO_ENABLE	MMC_IRQ	Data Timeout error. This bit is set automatically according to the following conditions: A) busy timeout for R1b, R5b response. B) busy timeout after write CRC status. C) write CRC status timeout, or D) read data timeout.
SD_STAT[19] CIE	SD_IE[19] CIE_ENABLE	MMC_IRQ	Command Index Error. This bit is set automatically when response index differs from corresponding command index previously emitted. The check is enabled through SD_CMD[20] CICE bit.
SD_STAT[18] CEB	SD_IE[18] CEB_ENABLE	MMC_IRQ	Command End Bit error. This bit is set automatically when detecting a 0 at the end bit position of a command response.
SD_STAT[17] CCRC	SD_IE[17] CCRC_ENABLE	MMC_IRQ	Command CRC error. This bit is set automatically when there is a CRC7 error in the command response. CRC check is enabled through the SD_CMD[19] CCCE bit.
SD_STAT[16] CTO	SD_IE[16] CTO_ENABLE	MMC_IRQ	Command Timeout error. This bit is set automatically when no response is received within 64 clock cycles from the end bit of the command. For commands the reply within 5 clock cycles, the timeout is still detected at 64 clock cycles.
SD_STAT[15] ERRI	SD_IE[15] ERRI_ENABLE	MMC_IRQ	Error Interrupt. If any of the bits in the Error Interrupt Status register (SD_STAT[24:15]) are set, the this bit is set to 1.
SD_STAT[10] BSR	SD_IE[10] BSR_ENABLE	MMC_IRQ	Boot Status Received interrupt. This bit is set automatically when SD_CON[18] BOOT_CF0 is set to 1 or 2h and boot status is received on the dat0 line. This interrupt is only used for MMC cards.
SD_STAT[8] CIRQ	SD_IE[8] CIRQ_ENABLE	MMC_IRQ	Card Interrupt. This bit is only used for SD, SDIO, and CE-ATA cards. In 1-bit mode, interrupt source is asynchronous (can be a source of asynchronous wake-up). In 4-bit mode, interrupt source is sampled during the interrupt cycle. In CE-ATA mode, interrupt source is detected when the card drive CMD line to zero during one cycle after data transmission end.
SD_STAT[5] BRR	SD_IE[5] BRR_ENABLE	MMC_IRQ	Buffer Read ready. This bit is set automatically during a read operation to the card when one block specified by SD_BLK[10:0] BLEN is completely written in the buffer. It indicates that the memory card has filled out the buffer and the local host needs to empty the buffer by reading it.
SD_STAT[4] BWR	SD_IE[4] BWR_ENABLE	MMC_IRQ	Buffer Write ready. This bit is automatically set during a write operation to the card when the host can write a complete block as specified by SD_BLK[10:0] BLEN. It indicates that the memory card has emptied one block from the buffer and the local host is able to write one block of data into the buffer.
SD_STAT[3] DMA	SD_IE[3] DMA_ENABLE	MMC_IRQ	DMA interrupt. This status is set when an interrupt is required in the ADMA instruction and after the data transfer is complete.
SD_STAT[2] BGE	SD_IE[2] BGE_ENABLE	MMC_IRQ	Block Gap event. When a stop at block gap is requested (SD_HCTL[16] SBGR), this bit is automatically set when transaction is stopped at the block gap during a read or write operation.
SD_STAT[1] TC	SD_IE[1] TC_ENABLE	MMC_IRQ	Transfer completed. This bit is always set when a read/write transfer is completed or between two blocks when the transfer is stopped due to a stop at block gap requested (SD_HCTL[16] SBGR). In read mode this bit is automatically set on completion of a read transfer (SD_PSTATE[9] RTA). In write mode, this bit is automatically set on completion of the DAT line use (SD_PSTATE[2] DLA).
SD_STAT[0] CC	SD_IE[0] CC_ENABLE	MMC_IRQ	Command complete. This bit is set when a 1-to-0 transition occurs in the register command inhibit (SD_PSTATE[0] CMDI). If the command is a type for which no response is expected, then the command complete interrupt is generated at the end of the command. A command timeout error (SD_STAT[16] CTO) has higher priority than command complete (SD_STAT[0] CC). If a response is expected but none is received, the a Command Timeout error is detected and signaled instead of the Command Complete interrupt.

### 17.3.4.1 Interrupt-Driven Operation

An interrupt enable bit must be set in the SD\_IE register to enable the module internal source of interrupt.

When an interrupt event occurs, the single interrupt line is asserted and the LH must:

- Read the SD\_STAT register to identify which event occurred.
- Write 1 into the corresponding bit of the SD\_STAT register to clear the interrupt status and release the interrupt line (if a read is done after this write, this would return 0).

---

**NOTE:** In the SD\_STAT register, Card Interrupt (CIRQ) and Error Interrupt (ERRI) bits cannot be cleared.

The SD\_STAT[8] CIRQ status bit must be masked by disabling the SD\_IE[8] CIRQ\_ENABLE bit (cleared to 0), then the interrupt routine must clear SDIO interrupt source in SDIO card common control register (CCCR).

The SD\_STAT[15] ERRI bit is automatically cleared when all status bits in SD\_STAT[31:16] are cleared.

---

### 17.3.4.2 Polling

When the interrupt capability of an event is disabled in the SD\_ISE register, the interrupt line is not asserted:

- Software can poll the status bit in the SD\_STAT register to detect when the corresponding event occurs.
- Writing 1 into the corresponding bit of the SD\_STAT register clears the interrupt status and does not affect the interrupt line state.

---

**NOTE:** Please see the note in [Section 17.3.4.1](#) concerning CIRQ and ERRI bits clearing.

---

## 17.3.5 DMA Modes

The device supports DMA slave mode only. In this case, the controller is slave on DMA transaction managed by two separated requests (SDMAWREQN and SDMARREQN)

### 17.3.5.1 DMA Slave Mode Operations

The MMC/SD/SDIO controller can be interfaced with a DMA controller. At system level, the advantage is to discharge the local host (LH) of the data transfers. The module does not support wide DMA access (above 1024 bytes) for SD cards as specified in the *SD Card Specification* and *SD Host Controller Standard Specification*.

The DMA request is issued if the following conditions are met:

- The SD\_CMD[0] DE bit is set to 1 to trigger the initial DMA request (the write must be done when running the data transfer command).
- A command was emitted on the SD\_cmd line.
- There is enough space in the buffer of the MMC/SD/SDIO controller to write an entire block (BLEN writes).

### 17.3.5.1.1 DMA Receive Mode

In a DMA block read operation (single or multiple), the request signal **SDMARREQN** is asserted to its active level when a complete block is written in the buffer. The block size transfer is specified in the **SD\_BLK[10:0]** **BLEN** field.

The **SDMARREQN** signal is deasserted to its inactive level when the sDMA has read one single word from the buffer. Only one request is sent per block; the DMA controller can make a 1-shot read access or several DMA bursts, in which case the DMA controller must manage the number of burst accesses, according to block size **BLEN** field.

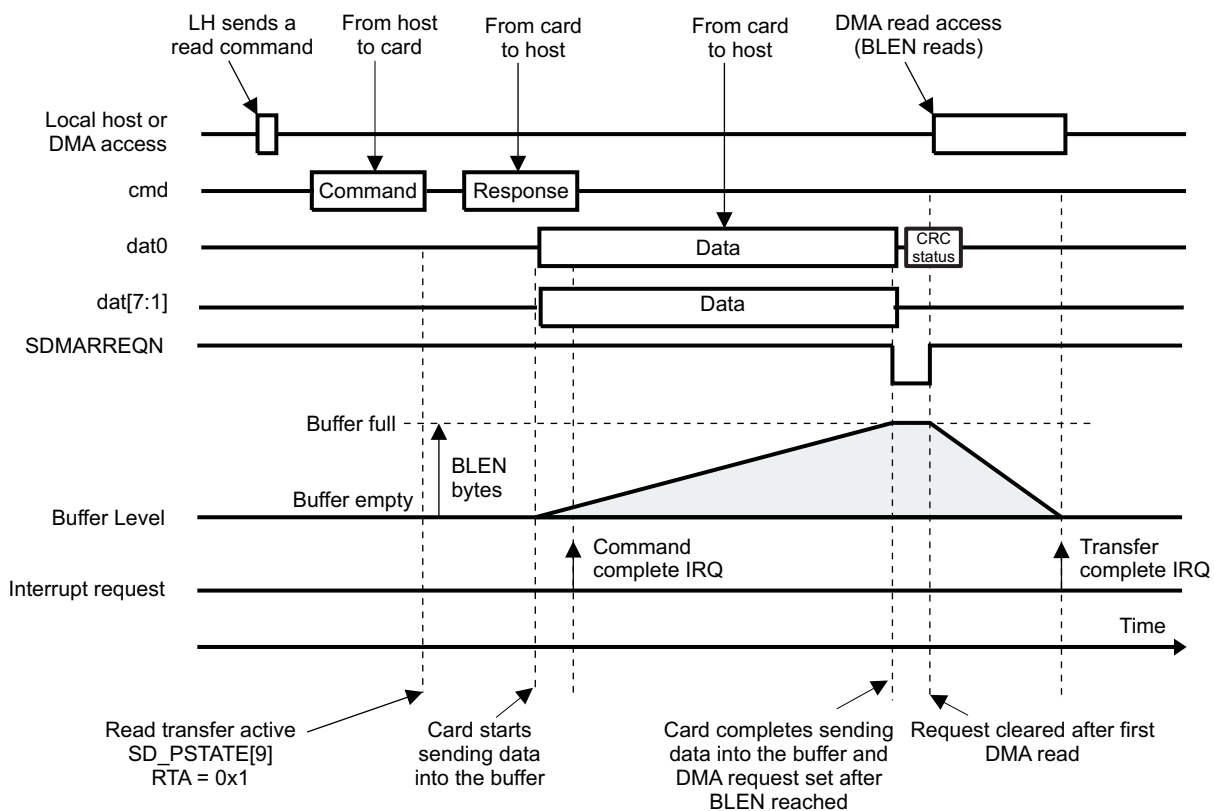

New DMA requests are internally masked if the sDMA has not read exactly **BLEN** bytes and a new complete block is not ready. As DMA accesses are in 32-bit, then the number of sDMA read is  $\text{Integer}(\text{BLEN}/4)+1$ .

The receive buffer never overflows. In multiple block transfers for block size above 512 bytes, when the buffer gets full, the **MMC\_CLK** clock signal (provided to the card) is momentarily stopped until the sDMA or the MPU performs a read access, which reads a complete block in the buffer.

Figure 17-17 provides a summary:

- DMA transfer size = **BLEN** buffer size in one shot or by burst
- One DMA request per block

Figure 17-17. DMA Receive Mode

### 17.3.5.1.2 DMA Transmit Mode

In a DMA block write operation (single or multiple), the request signal SDMAWREQN is asserted to its active level when a complete block is to be written to the buffer. The block size transfer is specified in the SD\_BLK[10:0] BLEN field.

The SDMAWREQN signal is deasserted to its inactive level when the sDMA has written one single word to the buffer.

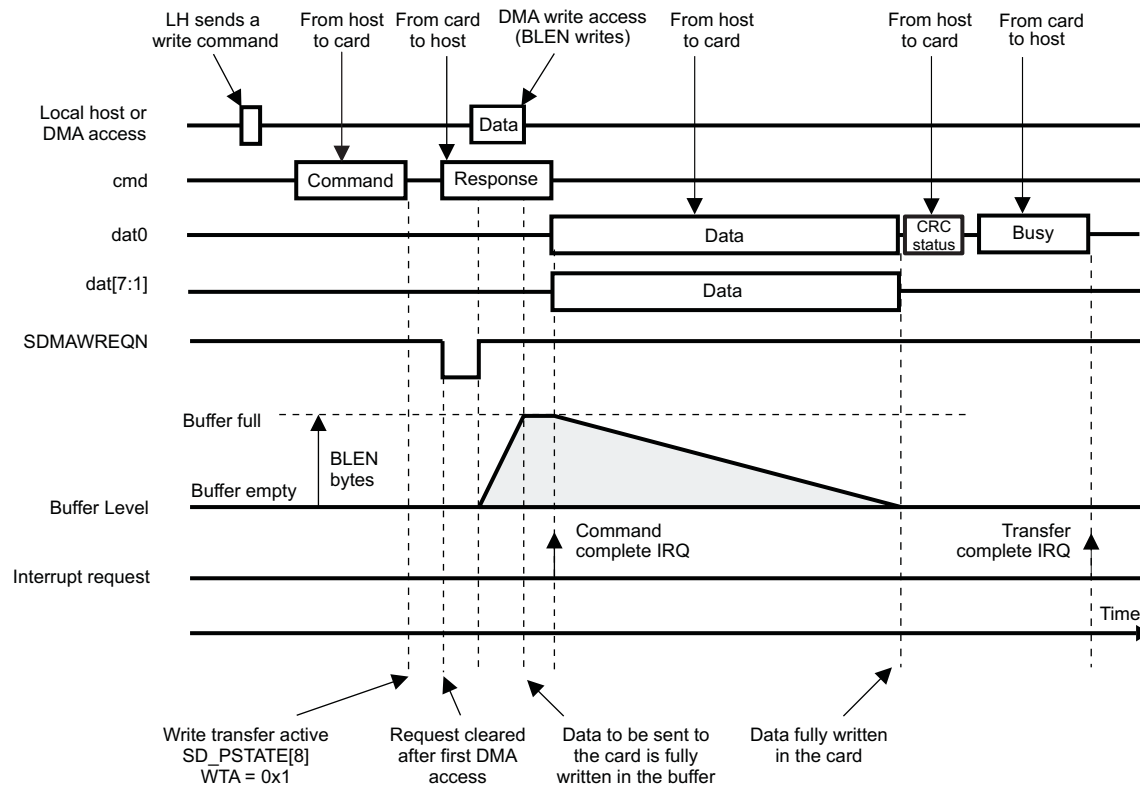

Only one request is sent per block; the DMA controller can make a 1-shot write access or multiple write DMA bursts, in which case the DMA controller must manage the number of burst accesses, according to block size BLEN field.

New DMA requests are internally masked if the sDMA has not written exactly BLEN bytes (as DMA accesses are in 32-bit, then the number of sDMA read is  $\text{Integer}(\text{BLEN}/4)+1$ ) and if there is not enough memory space to write a complete block in the buffer.

Figure 17-18 provides a summary:

- DMA transfer size = BLEN buffer size in one shot or by burst
- One DMA request per block

**Figure 17-18. DMA Transmit Mode**

### 17.3.6 Mode Selection

The MMC/SD/SDIO host controller can be use in two modes, MMC and SD/SDIO modes. It has been designed to be the most transparent with the type of card. The type of the card connected is differentiated by the software initialization procedure.

Software identifies the type of card connected during software initialization. For each given card type, there are corresponding commands. Some commands are not supported by all cards. See the *Multimedia Card System Specification*, the *SD Memory Card Specifications*, and the *SDIO Card Specification, Part E1* for more details.

The purpose of the module is to transfer commands and data, to whatever card is connected, respecting the protocol of the connected card. Writes and reads to the card must respect the appropriate protocol of that card.

### 17.3.7 Buffer Management

#### 17.3.7.1 Data Buffer

The MMC/SD/SDIO host controller uses a data buffer. This buffer transfers data from one data bus (Interconnect) to another data bus (SD, SDIO, or MMC card bus) and vice versa.

The buffer is the heart of the interface and ensures the transfer between the two interfaces (L4 and the card). To enhance performance, the data buffer is completed by a prefetch register and a post-write buffer that are not accessible by the host controller.

The read access time of the prefetch register is faster than the one of the data buffer. The prefetch register allows data to be read from the data buffer at an increased speed by preloading data into the prefetch register.

The entry point of the data buffer, the prefetch buffer, and the post-write buffer is the 32-bit register SD\_DATA. A write access to the SD\_DATA register followed by a read access from the SD\_DATA register corresponds to a write access to the post-write buffer followed by a read access to the prefetch buffer. As a consequence, it is normal that the data of the write access to the SD\_DATA register and the data of the read access to the SD\_DATA register are different.

The number of 32-bit accesses to the SD\_DATA register that are needed to read (or write) a data block with a size of SD\_BLK[10:0] BLEN, and equals the rounded up result of BLEN divided by 4. The maximum block size supported by the host controller is hard-coded in the register SD\_CAPA[17:16] MBL field and cannot be changed.

A read access to the SD\_DATA register is allowed only when the buffer read enable status is set to 1 (SD\_PSTATE[11] BRE); otherwise, a bad access (SD\_STAT[29] BADA) is signaled.

A write access to the SD\_DATA register is allowed only when the buffer write enable status is set to 1 (SD\_PSTATE[10] BWE); otherwise, a bad access (SD\_STAT[29] BADA) is signaled and the data is not written.

The data buffer has two modes of operation to store and read of the first and second portions of the data buffer:

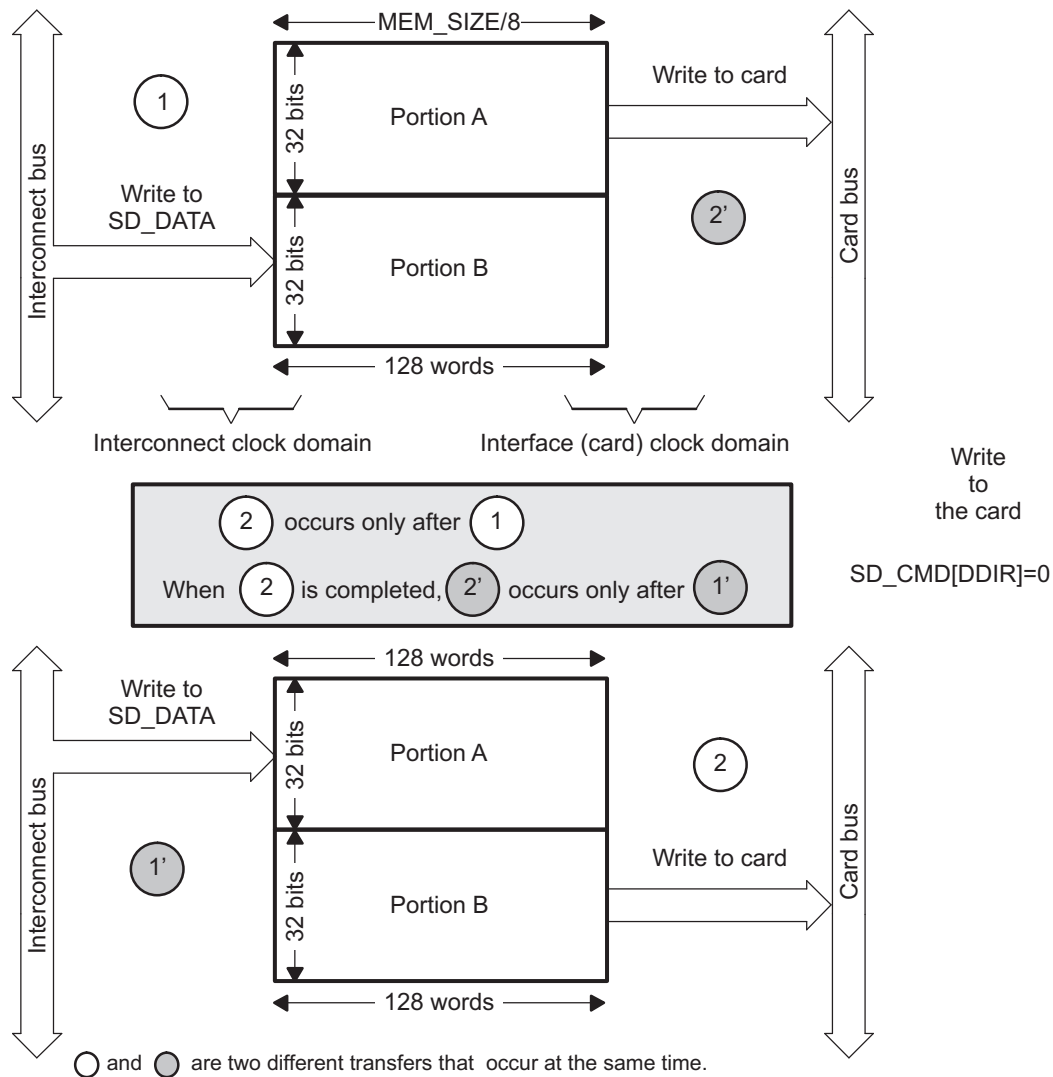

- When the size of the data block to transfer is less than or equal to MEM\_SIZE/2 (in double buffering), two data transfers can occur from one data bus to the other data bus and vice versa at the same time. The MMC/SD/SDIO controller uses the two portions of the data buffer in a ping-pong manner so that storing and reading of the first and second portions of the data buffer are automatically interchanged from time to time so that data may be read from one portion (for instance, through a DMA read access on the interconnect bus) while data (for instance, from the card) is being stored into the other portion and vice versa. When BLEN is less than or equal to 200h (that is, less or equal to 512Bytes), each of the two portions of the buffer that can be used have a size of BLEN (that is, 32-bits x BLEN div by 4). Not more than this total size of 2 times 32-bits x BLEN div by 4 can be used.
- When the size of the data block to transfer is larger than MEM\_SIZE/2, only one data transfer can occur from one data bus to the other data bus at a time. The MMC/SD/SDIO host controller uses the entire data buffer as a single portion. In this mode, a bad access (SD\_STAT[29] BADA) is signaled when two data transfers occur from one data bus to the other data bus and vice versa at the same time.

**CAUTION**

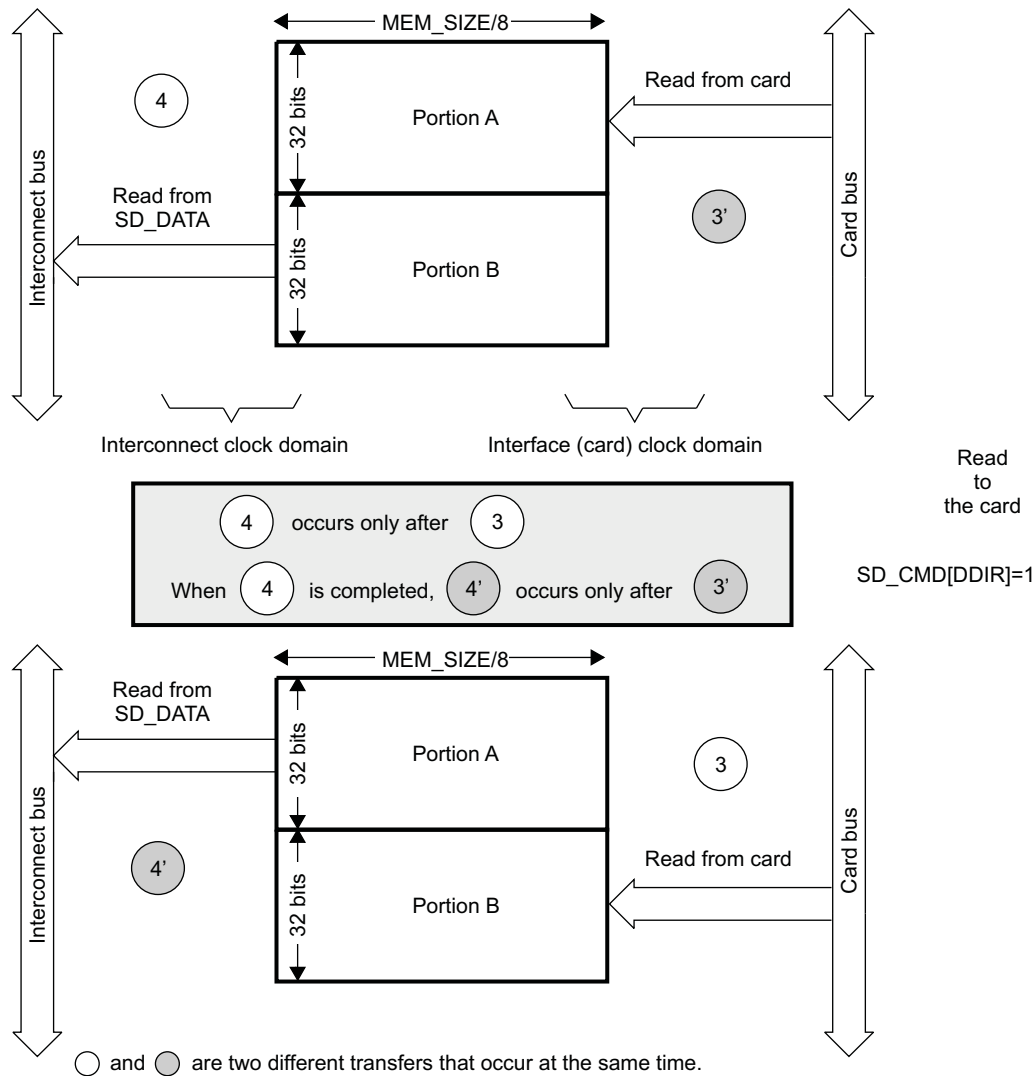

The SD\_CMD[4] DDIR bit must be configured before a transfer to indicate the direction of the transfer.

Figure 17-19 shows the buffer management for writing and Figure 17-20 shows the buffer management for reading.

**Figure 17-19. Buffer Management for a Write**

**Figure 17-20. Buffer Management for a Read**

#### 17.3.7.1.1 Memory Size, Block Length, and Buffer Management Relationship

The maximum block length and buffer management that can be targeted by system depend on memory depth setting.

**Table 17-12. Memory Size, BLEN, and Buffer Relationship**

Memory Size([5:2] MEMSIZE in bytes)	512	1024	2048	4096
Maximum block length supported	512	1024	2048	2048
Double-buffering for maximum block length	N/A	BLEN <= 512	BLEN <= 1024	BLEN <= 2048
Single-buffering for block length	BLEN<=512	512 < BLEN <= 1024	1024 < BLEN <= 2048	N/A

### 17.3.7.1.2 Data Buffer Status

The data buffer status is defined in the following interrupt status register and status register:

- Interrupt status registers (see ):
  - SD\_STAT[29] BADA Bad access to data space
  - SD\_STAT[5] BRR Buffer read ready
  - SD\_STAT[4] BWR Buffer write ready
- Status registers (see ):
  - SD\_PSTATE[11] BRE Buffer read enable
  - SD\_PSTATE[10] BWE Buffer write enable

### 17.3.8 Transfer Process

The process of a transfer is dependent on the type of command. It can be with or without a response, with or without data.

#### 17.3.8.1 Different Types of Commands

Different types of commands are specific to MMC, SD, or SDIO cards. See the *Multimedia Card System Specification*, the *SD Memory Card Specifications*, the *SDIO Card Specification, Part E1*, or the *SD Card Specification, Part A2, SD Host Controller Standard Specification* for more details.

#### 17.3.8.2 Different Types of Responses

Different types of responses are specific to MMC, SD, or SDIO cards. See the *Multimedia Card System Specification*, the *SD Memory Card Specifications*, the *SDIO Card Specification, Part E1*, or the *SD Card Specification, Part A2, SD Host Controller Standard Specification* for more details.

Table 17-13 shows how the MMC, SD, and SDIO responses are stored in the SD\_RSPxx registers.

**Table 17-13. MMC, SD, SDIO Responses in the SD\_RSPxx Registers**

Kind of Response	Response Field	Response Register
R1, R1b (normal response), R3, R4, R5, R5b, R6, R7	RESP[39:8] <sup>(1)</sup>	SD_RSP10[31:0]
R1b (Auto CMD12 response)	RESP[39:8] <sup>(1)</sup>	SD_RSP76[31:0]
R2	RESP[127:0] <sup>(1)</sup>	SD_RSP76[31:0] SD_RSP54[31:0] SD_RSP32[31:0] SD_RSP10[31:0]

<sup>(1)</sup> RESP refers to the command response format described in the specifications mentioned above.

When the host controller modifies part of the SD\_RSPxx registers, it preserves the unmodified bits.

The host controller stores the Auto CMD12 response in the SD\_RSP76[31:0] register because the Host Controller may have a multiple block data DAT line transfer executing concurrently with a command. This allows the host controller to avoid overwriting the Auto CMD12 response with the command response stored in SD\_RSP10 register and vice versa.

### 17.3.9 Transfer or Command Status and Error Reporting

Flags in the MMC/SD/SDIO host controller show status of communication with the card:

- A timeout (of a command, a data, or a response)
- A CRC

Error conditions generate interrupts. See [Table 17-14](#) and register description for more details.

**Table 17-14. CC and TC Values Upon Error Detected**

Error hold in the SD_STAT Register	CC	TC	Comments
29 BADA			No dependency with CC or TC. BADA is related to the register accesses. Its assertion is not dependent of the ongoing transfer.
28 CERR	1		CC is set upon CERR.
22 DEB		1	TC is set upon DEB.
21 DCRC		1	TC is set upon DCRC.
20 DTO			DTO and TC are mutually exclusive. DCRC and DEB cannot occur with DTO.
19 CIE	1		CC is set upon CIE.
18 CEB	1		CC is set upon CEB.
17 CCRC	1		CC can be set upon CCRC - See CTO comment
16 CTO			CTO and CC are mutually exclusive. CIE, CEB and CERR cannot occur with CTO. CTO can occur at the same time as CCRC it indicates a command abort due to a contention on CMD line. In this case no CC appears.

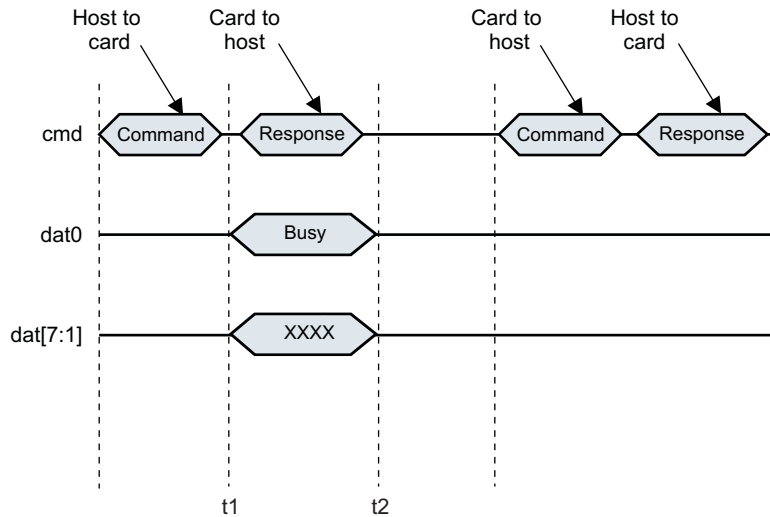

SD\_STAT[21] DCRC event can be asserted in the following conditions:

- Busy timeout for R1b, R5b response type
- Busy timeout after write CRC status
- Write CRC status timeout
- Read data timeout
- Boot acknowledge timeout

### 17.3.9.1 Busy Timeout for R1b, R5b Response Type

Figure 17-21 shows DCRD event condition asserted when there is a busy timeout for R1b or R5b responses.

**Figure 17-21. Busy Timeout for R1b, R5b Responses**

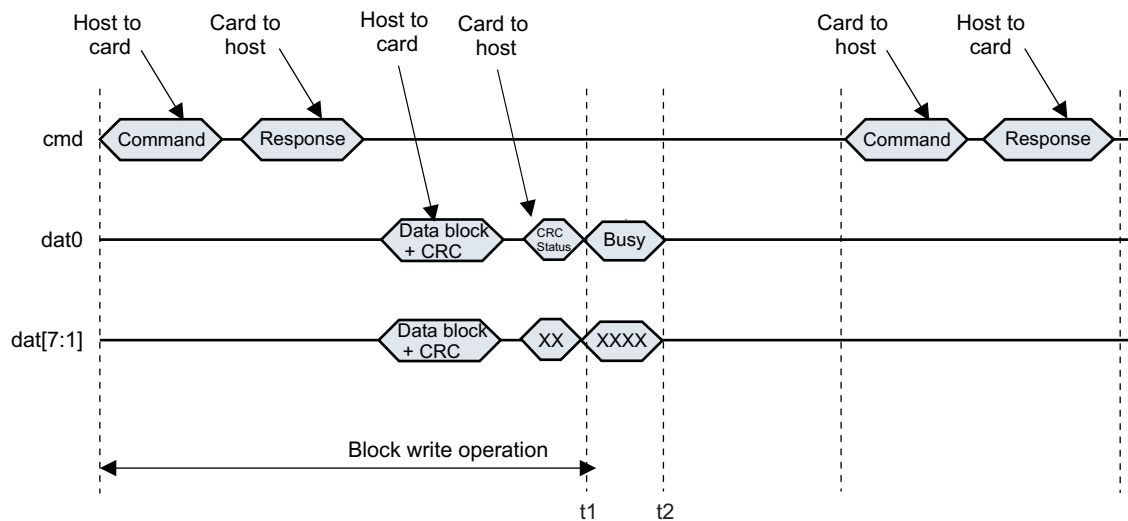

t1 - Data timeout counter is loaded and starts after R1b, R5b response type.

t2 - Data timeout counter stops and if it is 0, SD\_STAT[21] DCRC is generated.

### 17.3.9.2 Busy Timeout After Write CRC Status

Figure 17-22 shows DCRC event condition asserted when there is busy timeout after write CRC status.

**Figure 17-22. Busy Timeout After Write CRC Status**

t1 - Data timeout counter is loaded and starts after CRC status.

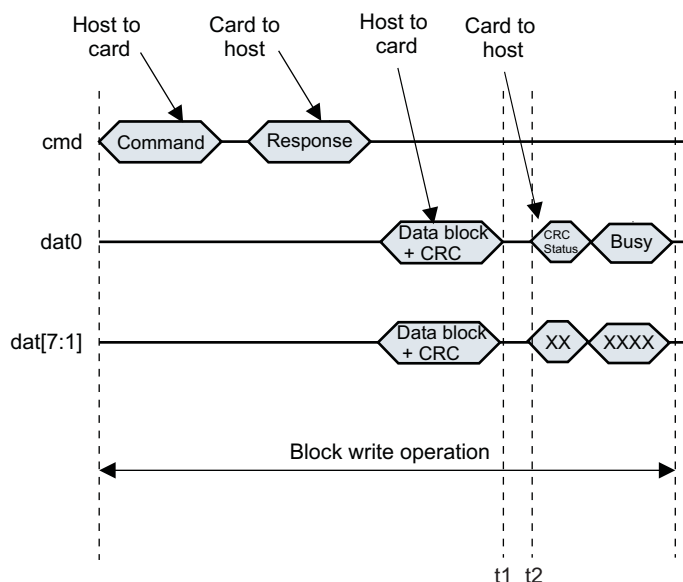

t2 - Data timeout counter stops and if it is 0, SD\_STAT[21] DCRC is generated.

### 17.3.9.3 Write CRC Status Timeout

Figure 17-23 shows DCRC event condition asserted when there is write CRC status timeout.

**Figure 17-23. Write CRC Status Timeout**

t1 - Data timeout counter is loaded and starts after Data block + CRC.

t2 - Data timeout counter stops and if it is 0, SD\_STAT[21] DCRC is generated.

### 17.3.9.4 Read Data Timeout

Figure 17-24 shows DCRC event condition asserted when there is read data timeout.

**Figure 17-24. Read Data Timeout**

t1 - Data timeout counter is loaded and starts after Command transmission.

t2 - Data timeout counter stops and if it is 0, SD\_STAT[21] DCRC is generated.

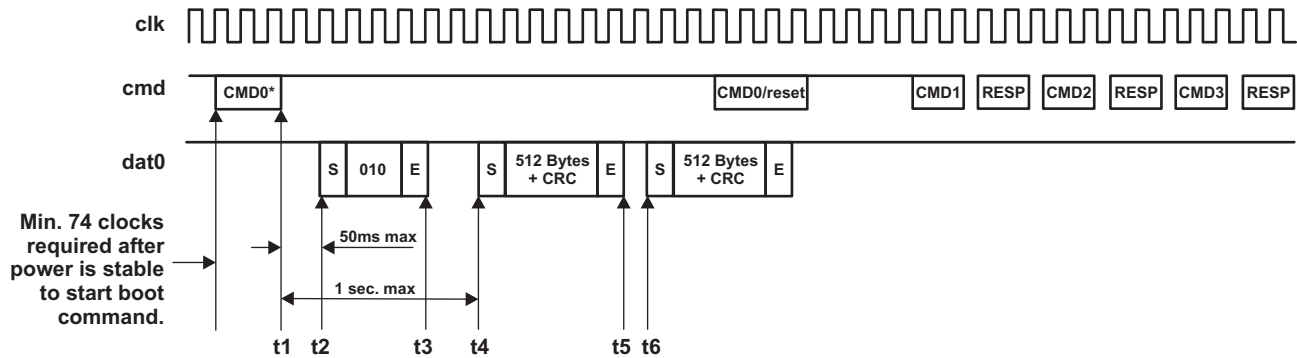

t3 - Data timeout counter is loaded and starts after Data block + CRC transmission.

t4 - Data timeout counter stops and if it is 0, SD\_STAT[21] DCRC is generated.

### 17.3.9.5 Boot Acknowledge Timeout

Figure 17-25 shows DCRC event condition asserted when there is boot acknowledge timeout and CMD0 is used.

**Figure 17-25. Boot Acknowledge Timeout When Using CMD0**

\* Refer to MMC Specification for correct argument.

t1 - Data timeout counter is loaded and starts after CMD0.

t2 - Data timeout counter stops and if it is 0, SD\_STAT[21] DCRC is generated.

t3 - Data timeout counter is loaded and starts.

t4 - Data timeout counter stops and if it is 0, SD\_STAT[21] DCRC is generated.

t5 - Data timeout counter is loaded and starts after Data + CRC transmission.

t6 - Data timeout counter stops and if it is 0, SD\_STAT[21] DCRC is generated.

Figure 17-26 shows DCRC event condition asserted when there is boot acknowledge timeout and CMD line is held low.

**Figure 17-26. Boot Acknowledge Timeout When CMD Held Low**

t1 - Data timeout counter is loaded and starts after cmd line is tied to 0.

t2 - Data timeout counter stops and if it is 0, SD\_STAT[21] DCRC is generated.

t3 - Data timeout counter is loaded and starts.

t4 - Data timeout counter stops and if it is 0, SD\_STAT[21] DCRC is generated.

t5 - Data timeout counter is loaded and starts after Data + CRC transmission.

t6 - Data timeout counter stops and if it is 0, SD\_STAT[21] DCRC is generated.

### 17.3.10 Auto Command 12 Timings

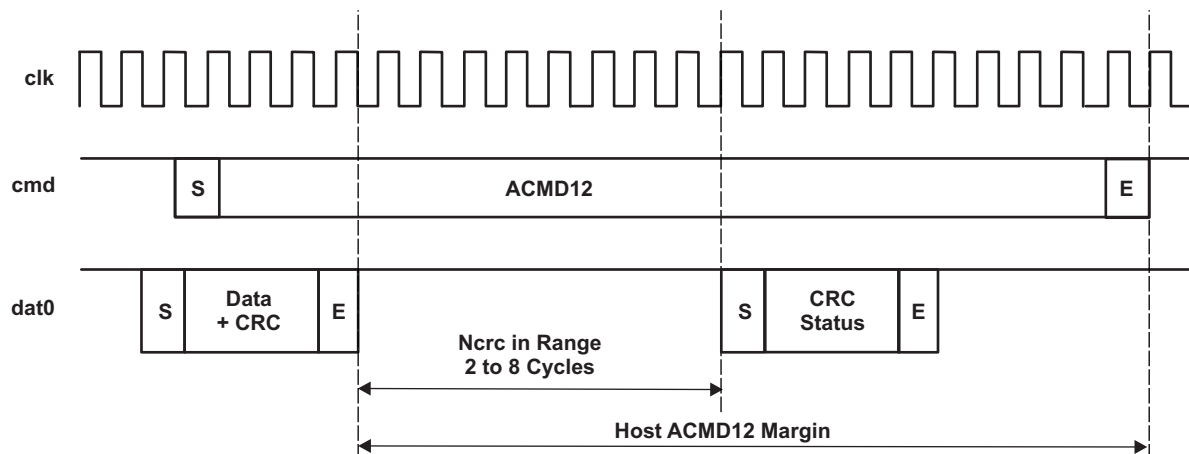

With the UHS definition of SD cards with higher frequency for MMC clocks up to 208, SD standard imposes a specific timing for Auto CMD12 "end bit" arrival.

#### 17.3.10.1 Auto Command 12 Timings During Write Transfer

A margin named Ncrc in range of 2 to 8 cycles has been defined for SDR50 and SDR104 card components for write data transfers, as auto command 12 'end bit' shall arrive after the CRC status "end bit".

Figure 17-27 shows auto CMD12 timings during write transfer.

**Figure 17-27. Auto CMD12 Timing During Write Transfer**

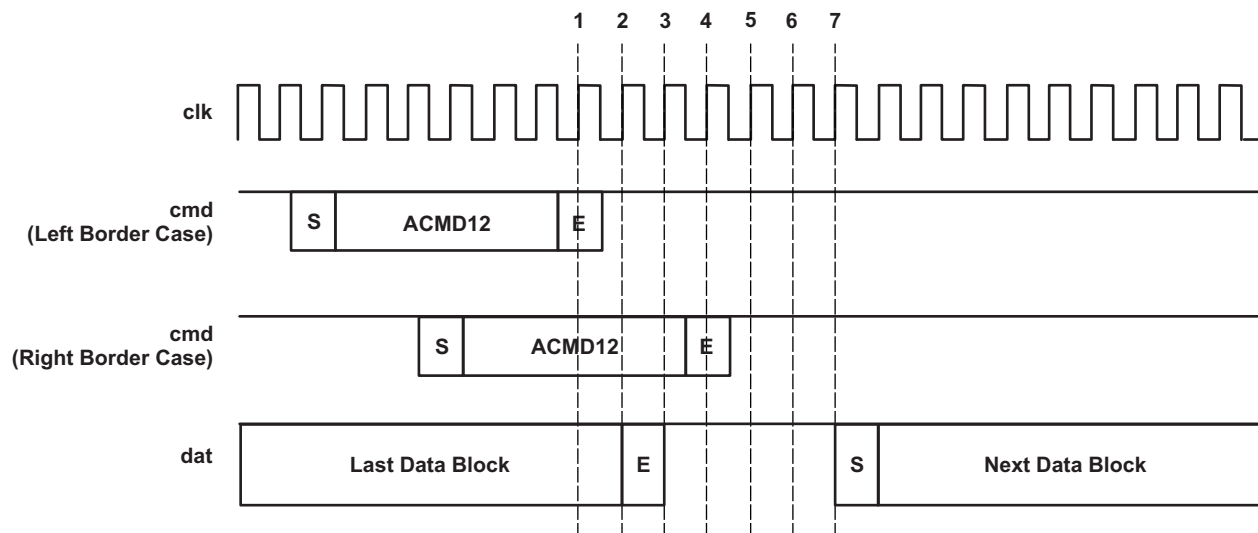

The Host controller has a margin of 18 clock cycles to make sure that auto CMD12 'end bit' arrives after the CRC status. This margin does not depend on MMC bus configuration, DDR or standard transfer, 1,4 or 8 bus width.

### 17.3.10.2 Auto Command 12 Timings During Read Transfer

With UHS very high speed cards gap timing between 2 successive cards has been extended to 4 cycles instead of 2. By the way it gives more flexibility for Host Auto CMD12 arrival in order to receive the last complete and reliable block. SD controller only follows the 'Left Border Case' defined by SD UHS specification.

Figure 17-28 shows ACMD12 timings during read transfer.

**Figure 17-28. Auto Command 12 Timings During Read Transfer**

The Auto CMD12 arrival sent by the Host controller is not sensitive to the MMC bus configuration whether it is DDR or standard transfer and whether it is a 1,4 or 8 bit bus width transfer.

### 17.3.11 Transfer Stop

Whenever a transfer is initiated, the transmission may be willed to stop whereas it is still not finished. Several cases can be faced depending on the transfer type:

- Multiple blocks oriented transfers (for which transfer length is known)
- Continuous stream transfers (which have an infinite length)

---

**NOTE:** Since the MMC/SD/SDIO controller manages transfers based on a block granularity, the buffer will accept a block only if there is enough space to completely store it. Consequently, if a block is pending in the buffer, no command will be sent to the card because the card clock will be shut off by the controller.

---

The MMC/SD/SDIO controller includes two features which make a transfer stop more convenient and easier to manage:

- Auto CMD12 (for MMC and SD only).

This feature is enabled by setting the SD\_CMD[2] ACEN bit to 1 (this setting is relevant for a MMC/SD transfer with a known number of blocks to transfer). When the Auto CMD12 feature is enabled, the MMC/SD/SDIO controller will automatically issue a CMD12 command when the expected number of blocks has been exchanged.

- Stop at block gap

This feature is enabled by setting the SD\_HCTL[16] SBGR bit to 1. When enabled, this capability holds the transfer on until the end of a block boundary. If a stop transmission is needed, software can use this pause to send a CMD12 to the card.

Table 17-15 shows the common ways to stop a transfer, indicating command to send and features to enable.

**Table 17-15. MMC/SD/SDIO Controller Transfer Stop Command Summary**

		WRITE Transfer		READ Transfer	
		MMC/SD	SDIO	MMC/SD	SDIO
Single block		Transfer ends automatically Wait TC	Transfer ends automatically Wait TC	Transfer ends automatically Wait TC	Transfer ends automatically Wait TC
Multi blocks (finite or infinite)	Before the programmed block boundary	Send CMD12 Wait TC	Send CMD52 Wait TC	Send CMD12 Wait TC	Send CMD52 Wait TC
	Stop at the end of the transfer (finite transfer only)	Auto CMD12 active Transfer ends automatically Wait TC	Set SD_HCTL[16] SBGR bit to 1. Send CMD52 Wait TC	Auto CMD12 active Transfer ends automatically Wait TC	<b>If READ_WAIT supported</b> Stop at block gap Wait TC  <b>If READ_WAIT not supported</b> Send CMD52 Wait TC

---

**NOTE:** The MMC/SD/SDIO controller will send the stop command to the card on a block boundary, regardless the moment the command was written to the controller registers.

---

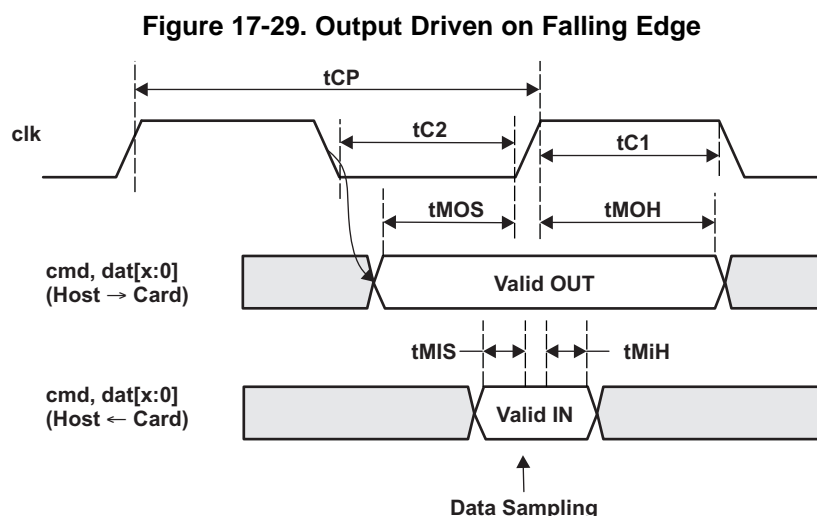

### 17.3.12 Output Signals Generation

The MMC/SD/SDIO output signals can be driven on either falling edge or rising edge depending on the SD\_HCTL[2] HSPE bit. This feature allows to reach better timing performance, and thus to increase data transfer frequency.

#### 17.3.12.1 Generation on Falling Edge of MMC Clock

The controller is by default in this mode to maximize hold timings. In this case, SD\_HCTL[2] HSPE bit is cleared to 0.

Figure 17-29 shows the output signals of the module when generating from the falling edge of the MMC clock.

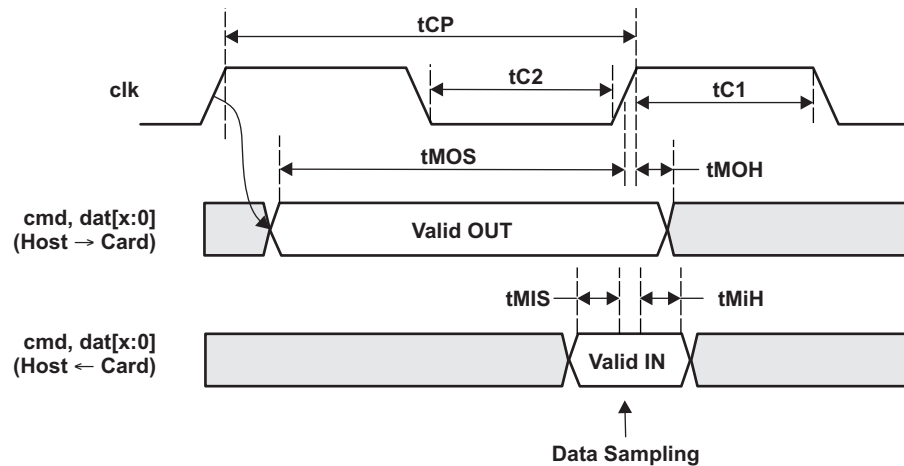

#### 17.3.12.2 Generation on Rising Edge of MMC Clock

This mode increases setup timings and allows reaching higher bus frequency. This feature is activated by setting SD\_HCTL[2] HSPE bit to 1. The controller shall be set in this mode to support SDR transfers.

**NOTE:** Do not use this feature in Dual Data Rate mode (when SD\_CON[19] DDR is set to 1).

Figure 17-30 shows the output signals of the module when generating from the rising edge of the MMC clock.

**Figure 17-30. Output Driven on Rising Edge**

### 17.3.13 Card Boot Mode Management

Boot Operation Mode allows the MMC/SD/SDIO host controller to read boot data from the connected slave (MMC device) by keeping CMD line low after power-on (or sending CMD0 with specific argument) before issuing CMD1. The data can be read from either boot area or user area, depending on register setting. Power-on boot defines a way for the boot-code to be accessed by the MMC/SD/SDIO host controller without an upper-level software driver, speeding the time it takes for a controller to access the boot code.

The two possible ways to issue a boot command (either issuing a CMD0 or driving the CMD line to 0 during the whole boot phase) are described in the following sections.

#### 17.3.13.1 Boot Mode Using CMD0

Figure 17-31 shows the timing diagram of a boot sequence using CMD0.

**Figure 17-31. Boot Mode With CMD0**

\* Refer to MMC Specification for correct argument.

- Configure:
  - SD\_CON[BOOT\_CF0] to 0
  - SD\_CON[BOOT\_ACK] (if an acknowledge will be received) to 0x1
  - SD\_BLK with the correct block length and number of block
  - SD\_SYSCTL[DTO] for timeout
 If transfer is done in DDR mode also set SD\_CON[DDR] to 1.
- Write register SD\_ARG with correct argument (see MMC Specification).
- Write in SD\_CMD register to start CMD0 transfer with these bit fields set:
  - INDX set to 0x00
  - DP set to '1'
  - DDIR set to '1'
  - MSBS set to '1'
  - BCE set to '1'
- If boot status is not received within the timing defined, the SD\_STAT[DTO] will be generated. Otherwise the SD\_STAT[BSR] is arisen.
- After the transfer is complete, the controller will generate the SD\_STAT[TC], and then the system can emit another CMD0 (SD\_CON[BOOT\_ACK] previously cleared to 0x0) to exit the card from boot state.
- If the system wants to abort the boot sequence it must issue a CMD0 with SD\_CMD[CMD\_TYPE] set to 0x3 (SD\_CON[BOOT\_ACK] previously cleared to 0x0) during the transfer to abort transfer and enable card to exit from boot state.

#### 17.3.13.2 Boot Mode With CMD Held Low

Figure 17-32 shows the timing diagram of a boot sequence with CMD line tied to 0.

**Figure 17-32. Boot Mode With CMD Line Tied to 0**

- Configure:
  - SD\_CON[BOOT\_CF0] and SD\_CON[BOOT\_ACK] (if an acknowledge will be received) to 0x1
  - SD\_BLK with correct block length and number of block
  - SD\_SYSCCTL[DTO] for timeout
  - If transfer is done in DDR mode also set SD\_CON[DDR] to 1.
- Write in SD\_CMD register to start boot sequence with:
  - DP set to '1'
  - DDIR set to '1'
  - MSBS set to '1'
  - BCE set to '1'

This leads the controller to force CMD line to '0'.
- If the boot status is not received within the timing defined, the SD\_STAT[DTO] will be generated. Otherwise the SD\_STAT[BSR] is arisen.
- After the transfer is complete, the controller will generate the SD\_STAT[TC], and then the system must clear SD\_CON[BOOT\_CF0] to 0x0 to release the CMD line and enable the card to exit from boot state.
- If the system wants to abort the boot sequence it must clear SD\_CON[BOOT\_CF0] to 0x0 during transfer to enable the card to exit from boot state.

### 17.3.14 CE-ATA Command Completion Disable Management

The MMC/SD/SDIO controller supports CE-ATA features, in particular the detection of command completion token. When a command that requires a command completion signal (SD\_CON[12] CEATA and SD\_CMD[2] ACEN set to 1) is launched, the host system is no longer allowed to emit a new command in parallel of data transfer unless it is a command completion disable token.

The settings to emit a command completion disable token follow:

- SD\_CON[12] CEATA is set to 1.
- SD\_CON[2] HR set to 1.
- Clear the SD\_ARG register.
- Write into SD\_CMD register with value 0000 0000h.

When a command completion disable token was emitted (that is, SD\_STAT[0] CC received), the host system is again allowed to emit another type of command (for example a transfer abort command CMD12 to abort transfer).

A critical case can be met when command completion signal disable (CCSD) is emitted during the last data block transfer, the sequence on command line could be sent very close to command completion signal (CCS) token sent by the card.

Three cases can be met:

- CCS is receive just before CCSD is emitted:  
An interrupt CIRQ is generated with CCS detection, CCSD is transmitted to card then an interrupt CC is generated when CCSD ends. In this case, card consider the CCSD sequence.
- CCS is not generated or generated during the CCSD transfer:  
The CCS bit cannot be detected (conflict is not possible as they drive the same level on command line, then no CIRQ interrupt is generated; besides CC interrupt is generated when CCSD ends).
- CCS is generated without CCSD token required:  
Only the interrupt CIRQ is generated when CCS is detected.

### 17.3.15 Test Registers

Test registers are available to be compliant with SD Host controller specification. This feature is useful to generate interrupts manually for driver debugging. The Force Event register (SD\_FE) is used to control the Error Interrupt Status and Auto CMD12 Error Status. The System Test register (SD\_SYSTEST) is used to control the signals that connect to I/O pins when the module is configured in system test (SD\_CON[4] MODE = 1) mode for boundary connectivity verification.

### 17.3.16 MMC/SD/SDIO Hardware Status Features

Table 17-16 summarizes the MMC/SD/SDIO hardware status features.

**Table 17-16. MMC/SD/SDIO Hardware Status Features**

Feature	Type	Register/Bit Field/Observability Control	Description
Interrupt flags		See <a href="#">Section 17.3.4</a> .	
CMD line signal level	Status	[24] CLEV	Indicates the level of the cmd line
DAT lines signal level	Status	[23:20] DLEV	Indicates the level of the data lines
Buffer read enable	Status	[11] BRE	Readable data exists in the buffer.
Buffer write enable	Status	[10] BWE	Indicates whether there is enough space in the buffer to write BLEN bytes of data
Read transfer active	Status	[9] RTA	This status is used for detecting completion of a read transfer.
Write transfer active	Status	[8] WTA	This status indicates a write transfer active.
Data line active	Status	[2] DLA	Indicates whether the data lines are active
Command Inhibit (data lines)	Status	[1] DATI	Indicates whether issuing of command using data lines is allowed
Command inhibit (CMD line)	Status	[0] CMDI	Indicates whether issuing of command using CMD line is allowed

## 17.4 Low-Level Programming Models

### 17.4.1 Surrounding Modules Global Initialization

This section identifies the requirements of initializing the surrounding modules when the module has to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the MMC/SD/SDIO modules.

**Table 17-17. Global Init for Surrounding Modules**

Surrounding Modules	Comments
PRCM	Module interface and functional clocks must be enabled. For more information, see <a href="#">Chapter 6, Power, Reset, and Clock Management</a> .
Control module	Module-specific pad muxing and configuration must be set in the control module. See <a href="#">Chapter 7, Control Module</a> .
(optional) MPU INTC	MPU INTC configuration must be done to enable the interrupts from the SD module. See <a href="#">Chapter 8, Interrupts</a> .
(optional) EDMA	DMA configuration must be done to enable the module DMA channel requests. See <a href="#">Chapter 10, EDMA</a> .
(optional) Interconnect	For more information about the interconnect configuration, see <a href="#">Chapter 4, Interconnects</a> .

---

**NOTE:** The MPU interrupt controller and the EDMA configurations are necessary, if the interrupt and DMA based communication modes are used.

---

### 17.4.2 MMC/SD/SDIO Controller Initialization Flow

The next sections outline the four steps to initialize the MMC/SD/SDIO controller:

- Initialize Clocks
- Software reset of the controller
- Set module's hardware capabilities
- Set module's Idle and Wake-Up modes

#### 17.4.2.1 Enable OCP and CLKADPI Clocks

Prior to any SD register access one must enable the SD OCP clock and CLKADPI clock in PRCM module registers. For more information, see [Chapter 6, Power, Reset, and Clock Management](#).

### 17.4.2.2 SD Soft Reset Flow

Figure 17-33 shows the soft reset process of MMC/SD/SDIO controller.

**Figure 17-33. MMC/SD/SDIO Controller Software Reset Flow**

### 17.4.2.3 Set SD Default Capabilities

Software must read capabilities (in boot ROM for instance) and is allowed to set (write) SD\_CAPA[26:24] and SD\_CUR\_CAPA[23:0] registers before the MMC/SD/SDIO host driver is started.

### 17.4.2.4 Wake-Up Configuration

Table 17-18 details SD controller wake-up configuration.

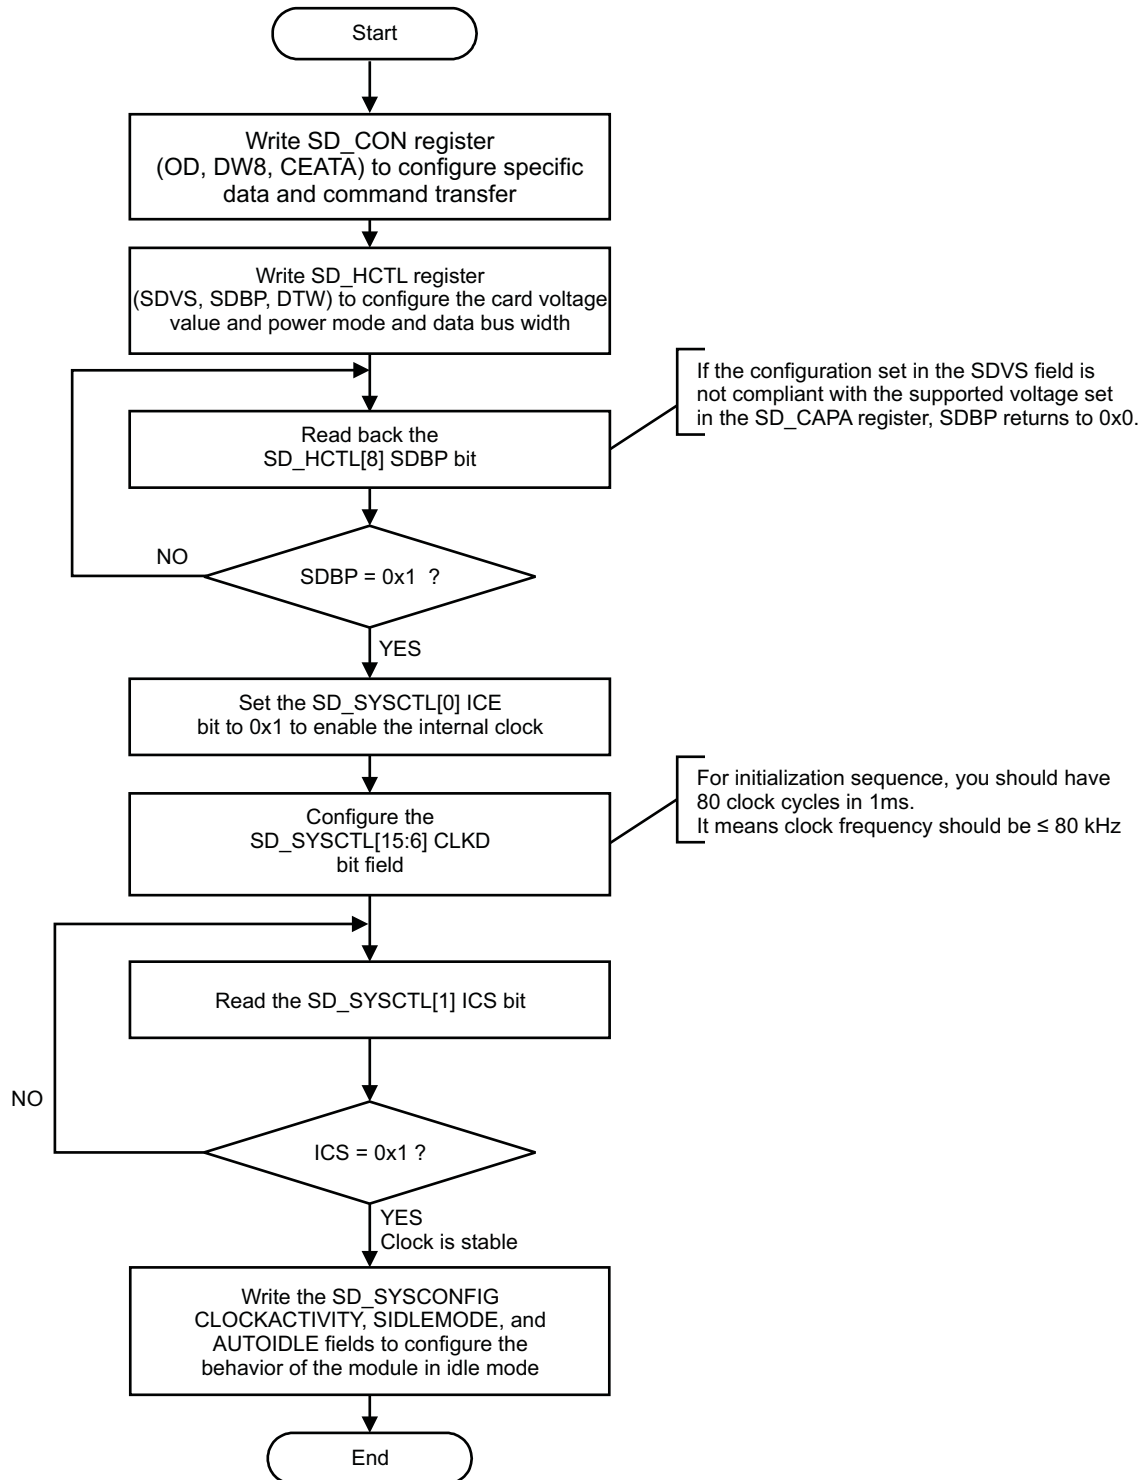

**Table 17-18. MMC/SD/SDIO Controller Wake-Up Configuration**

Step	Access Type	Register/Bit Field/Programming Model
Configure wake-up bit (if necessary).	W	SD_SYSCONFIG[2] ENAWAKEUP
Enable wake-up events on SD card interrupt (if necessary).	W	SD_HCTL[24] IWE
SDIO Card onlyEnable card interrupt (if necessary).	W	SD_IE[8] CIRQENABLE

### 17.4.2.5 MMC Host and Bus Configuration

Figure 17-34 details the MMC bus configuration process.

**Figure 17-34. MMC/SD/SDIO Controller Bus Configuration Flow**

## 17.4.3 Operational Modes Configuration

### 17.4.3.1 Basic Operations for MMC/SD/SDIO Host Controller

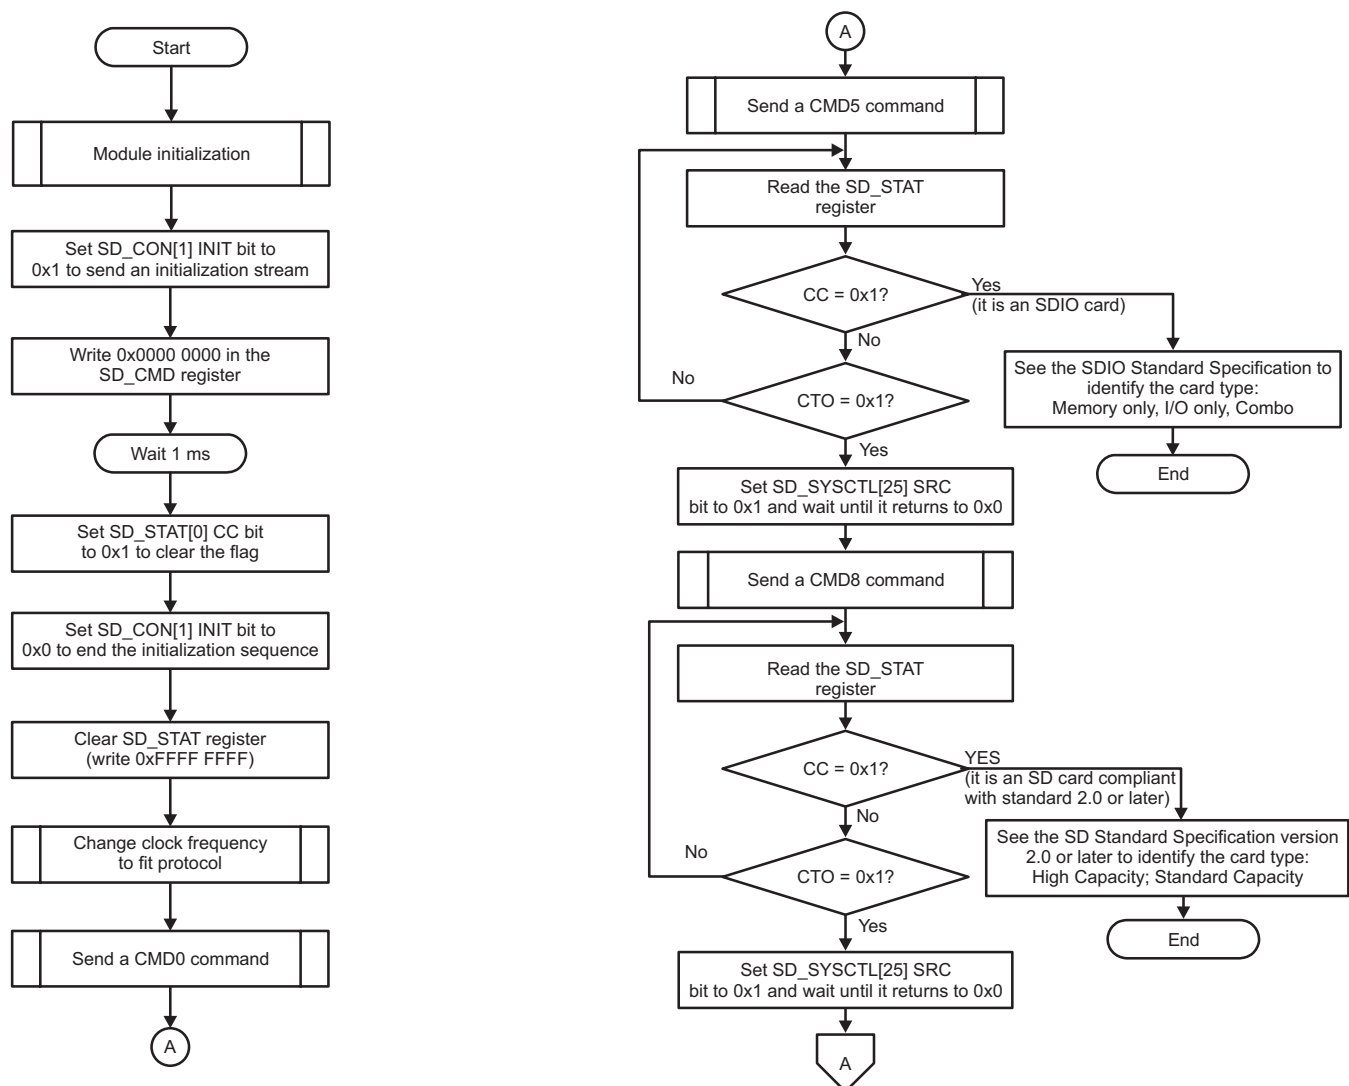

The MMC/SD/SDIO controller performs data transfers: data to card (referred to as write transfers) and data from card (referred to as read transfers).

The host controller requires transfers to run on a block-by-block basis, rather than on a DMA burst size basis. A single DMA request (or block request interrupt) is signaled for each block. Pipelining is supported as long as the block size is less than one half of the memory buffer size.

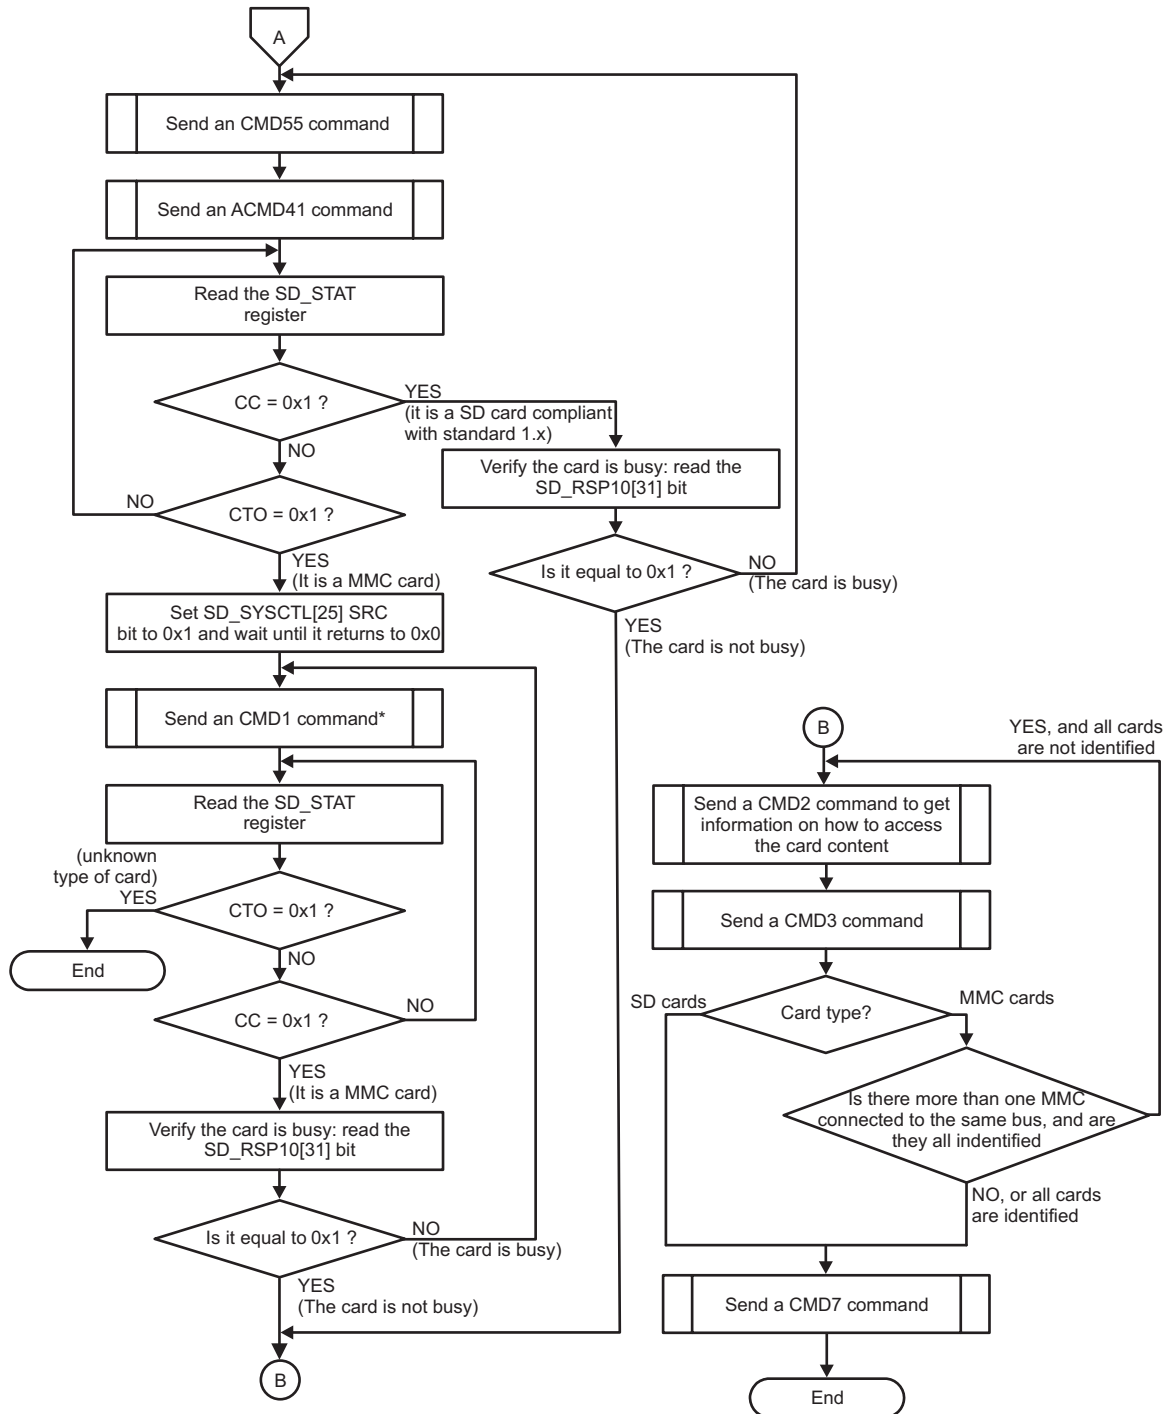

### 17.4.3.2 Card Detection, Identification, and Selection

Figure 17-35 and Figure 17-36 show the card identification and selection process.

**Figure 17-35. MMC/SD/SDIO Controller Card Identification and Selection - Part 1**

**Figure 17-36. MMC/SD/SDIO Controller Card Identification and Selection - Part 2**

## 17.5 MMC/SD Registers

### 17.5.1 MMCSD Registers

Table 17-19 lists the memory-mapped registers for the MMCSD. All register offset addresses not listed in Table 17-19 should be considered as reserved locations and the register contents should not be modified.

**Table 17-19. MMCSD Registers**

Offset	Acronym	Register Name	Section
110h	SD_SYSCONFIG	System Configuration	<a href="#">Section 17.5.1.1</a>
114h	SD_SYSSTATUS	System Status	<a href="#">Section 17.5.1.2</a>
124h	SD_CSRE	Card status response error	<a href="#">Section 17.5.1.3</a>
128h	SD_SYSTEST	System Test	<a href="#">Section 17.5.1.4</a>
12Ch	SD_CON	Configuration	<a href="#">Section 17.5.1.5</a>
130h	SD_PWCNT	Power counter	<a href="#">Section 17.5.1.6</a>
200h	SD_SDMASA	SDMA System address:	<a href="#">Section 17.5.1.7</a>
204h	SD_BLK	Transfer Length Configuration	<a href="#">Section 17.5.1.8</a>
208h	SD_ARG	Command argument	<a href="#">Section 17.5.1.9</a>
20Ch	SD_CMD	Command and transfer mode	<a href="#">Section 17.5.1.10</a>
210h	SD_RSP10	Command Response 0 and 1	<a href="#">Section 17.5.1.11</a>
214h	SD_RSP32	Command Response 2 and 3	<a href="#">Section 17.5.1.12</a>
218h	SD_RSP54	Command Response 4 and 5	<a href="#">Section 17.5.1.13</a>
21Ch	SD_RSP76	Command Response 6 and 7	<a href="#">Section 17.5.1.14</a>
220h	SD_DATA	Data	<a href="#">Section 17.5.1.15</a>
224h	SD_PSTATE	Present state	<a href="#">Section 17.5.1.16</a>
228h	SD_HCTL	Host Control	<a href="#">Section 17.5.1.17</a>
22Ch	SD_SYSCTL	SD system control	<a href="#">Section 17.5.1.18</a>
230h	SD_STAT	SD interrupt status	<a href="#">Section 17.5.1.19</a>
234h	SD_IE	SD interrupt enable	<a href="#">Section 17.5.1.20</a>
238h	SD_ISE	SD interrupt enable set	<a href="#">Section 17.5.1.21</a>
23Ch	SD_AC12	Auto CMD12 Error Status	<a href="#">Section 17.5.1.22</a>
240h	SD_CAPA	Capabilities	<a href="#">Section 17.5.1.23</a>
248h	SD_CUR_CAPA	Maximum current capabilities	<a href="#">Section 17.5.1.24</a>
250h	SD_FE	Force Event	<a href="#">Section 17.5.1.25</a>
254h	SD_ADMAES	ADMA Error Status	<a href="#">Section 17.5.1.26</a>
258h	SD_ADMASAL	ADMA System address Low bits	<a href="#">Section 17.5.1.27</a>
25Ch	SD_ADMASAH	ADMA System address High bits	<a href="#">Section 17.5.1.28</a>
2FCh	SD_REV	Versions	<a href="#">Section 17.5.1.29</a>

### 17.5.1.1 SD\_SYSCONFIG Register (offset = 110h) [reset = 0h]

SD\_SYSCONFIG is shown in [Figure 17-37](#) and described in [Table 17-20](#).

This register allows controlling various parameters of the OCP interface.

**Figure 17-37. SD\_SYSCONFIG Register**

31	30	29	28	27	26	25	24

### 17.5.1.2 SD\_SYSSTATUS Register (offset = 114h) [reset = 0h]

SD\_SYSSTATUS is shown in [Figure 17-38](#) and described in [Table 17-21](#).

This register provides status information about the module excluding the interrupt status information.

### 17.5.1.3 SD\_CSRE Register (offset = 124h) [reset = 0h]

SD\_CSRE is shown in [Figure 17-39](#) and described in [Table 17-22](#).

This register enables the host controller to detect card status errors of response type R1, R1b for all cards and of R5, R5b and R6 response for cards types SD or SDIO. When a bit SD\_CSRE[i] is set to 1, if the corresponding bit at the same position in the response SD\_RSP10[i] is set to 1, the host controller indicates a card error (SD\_STAT[28] CERR bit) interrupt status to avoid the host driver reading the response register (SD\_RSP10). No automatic card error detection for autoCMD12 is implemented; the host system has to check autoCMD12 response register (SD\_RSP76) for possible card errors.

#### 17.5.1.4 SD\_SYSTEST Register (offset = 128h) [reset = 0h]

SD\_SYSTEST is shown in [Figure 17-40](#) and described in [Table 17-23](#).

This register is used to control the signals that connect to I/O pins when the module is configured in system test (SYSTEST) mode for boundary connectivity verification. In SYSTEST mode, a write into SD\_CMD register will not start a transfer. The buffer behaves as a stack accessible only by the local host (push and pop operations). In this mode, the Transfer Block Size (SD\_BLK[10:0] BLEN bits) and the Blocks count for current transfer (SD\_BLK[31:16] NBLK bits) are needed to generate a Buffer write ready interrupt (SD\_STAT[4] BWR bit) or a Buffer read ready interrupt (SD\_STAT[5] BRR bit) and DMA requests if enabled.

### 17.5.1.5 SD\_CON Register (offset = 12Ch) [reset = 0h]

SD\_CON is shown in [Figure 17-41](#) and described in [Table 17-24](#).

This register is used: To select the functional mode for any card. To send an initialization sequence to any card. To enable the detection on the mmc\_dat[1] signal of a card interrupt for SDIO cards only. It also configures the parameters related to the card detect and write protect input signals

Bit	Field	Type	Reset	Description
31-22	RESERVED	R	0h	
21	SDMA_LnE	R/W	0h	Slave DMA Level/Edge Request. The waveform of the DMA request can be configured either edge sensitive with early de-assertion on first access to SD_DATA register or late de-assertion, request remains active until last allowed data written into SD_DATA. 0h (R/W) = Slave DMA edge sensitive. 1h (R/W) = Slave DMA level sensitive.
20	DMA_MnS	R/W	0h	DMA Master or Slave selection. When this bit is set and the controller is configured to use the DMA, Ocp master interface is used to get datas from system using ADMA2 procedure (direct access to the memory). This option is only available if generic parameter MADMA_EN is asserted to 1. 0h (R/W) = The controller is slave on data transfers with system. 1h (R/W) = Not available on this device.
19	DDR	R/W	0h	Dual Data Rate mode. When this register is set, the controller uses both clock edge to emit or receive data. Odd bytes are transmitted on falling edges and even bytes are transmitted on rise edges. It only applies on Data bytes and CRC, Start, end bits and CRC status are kept full cycle. This bit field is only meaningful and active for even clock divider ratio of SD_SYSCTL[CLKD], it is insensitive to SD_HCTL[HSPE] setting. Note: DDR mode is not supported on this device. Always set this bit to 0. 0h (R/W) = Standard modeData are transmitted on a single edge. 1h (R/W) = Data Bytes and CRC are transmitted on both edges.

**Table 17-24. SD\_CON Register Field Descriptions (continued)**

**Table 17-24. SD\_CON Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
10-9	DVAL	R/W	0h	Debounce filter value (all cards). This register is used to define a debounce period to filter the card detect input signal (SDCD). The usage of the card detect input signal (SDCD) is optional and depends on the system integration and the type of the connector housing that accommodates the card. 0h (R/W) = 33 us debounce period 1h (R/W) = 231 us debounce period 2h (R/W) = 1 ms debounce period 3h (R/W) = 8.4 ms debounce period
8	WPP	R/W	0h	Write protect polarity (SD and SDIO cards only). This bit selects the active level of the write protect input signal (SDWP). The usage of the write protect input signal (SDWP) is optional and depends on the system integration and the type of the connector housing that accommodates the card. 0h (R/W) = Active high level 1h (R/W) = Active low level
7	CDP	R/W	0h	Card detect polarity (all cards). This bit selects the active level of the write protect input signal (SDWP). The usage of the write protect input signal (SDWP) is optional and depends on the system integration and the type of the connector housing that accommodates the card. 0h (R/W) = Active high level 1h (R/W) = Active low level
6	MIT	R/W	0h	MMC interrupt command (MMC cards only). This bit must be set to 1, when the next write access to the command register (SD_CMD) is for writing a MMC interrupt command (CMD40) requiring the command timeout detection to be disabled for the command response. 0h (R/W) = Command timeout enabled. 1h (R/W) = Command timeout disabled.
5	DW8	R/W	0h	8-bit mode MMC select (MMC cards only). For SD/SDIO cards, this bit must be cleared to 0. For MMC card, this bit must be set following a valid SWITCH command (CMD6) with the correct value and extend CSD index written in the argument. Prior to this command, the MMC card configuration register (CSD and EXT_CSD) must be verified for compliancy with MMC standard specification. 0h (R/W) = 1-bit or 4-bit data width 1h (R/W) = 8-bit data width
4	MODE	R/W	0h	Mode select (all cards). This bit selects the functional mode. 0h (R/W) = Functional mode. Transfers to the MMC/SD/SDIO cards follow the card protocol. The MMC clock is enabled. MMC/SD transfers are operated under the control of the SD_CMD register. 1h (R/W) = SYSTEST mode. SYSTEST mode. The signal pins are configured as general-purpose input/output and the 1024-byte buffer is configured as a stack memory accessible only by the local host or system DMA. The pins retain their default type (input, output or in-out). SYSTEST mode is operated under the control of the SYSTEST register.

**Table 17-24. SD\_CON Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
3	STR	R/W	0h	Stream command (MMC cards only). This bit must be set to 1 only for the stream data transfers (read or write) of the adtc commands. Stream read is a class 1 command (CMD11READ_DAT_UNTIL_STOP). Stream write is a class 3 command (CMD20WRITE_DAT_UNTIL_STOP). 0h (R/W) = Block oriented data transfer 1h (R/W) = Stream oriented data transfer
2	HR	R/W	0h	Broadcast host response (MMC cards only). This register is used to force the host to generate a 48-bit response for bc command type. It can be used to terminate the interrupt mode by generating a CMD40 response by the core. In order to have the host response to be generated in open drain mode, the register SD_CON[OD] must be set to 1. When SD_CON[12] CEATA bit is set to 1 and SD_ARG cleared to 0, when writing 0000 0000h into SD_CMD register, the host controller performs a 'command completion signal disable' token (i.e., mmc_cmd line held to 0 during 47 cycles followed by a 1). 0h (R/W) = The host does not generate a 48-bit response instead of a command. 1h (R/W) = The host generates a 48-bit response instead of a command or a command completion signal disable token.
1	INIT	R/W	0h	Send initialization stream (all cards). When this bit is set to 1, and the card is idle, an initialization sequence is sent to the card. An initialization sequence consists of setting the mmc_cmd line to 1 during 80 clock cycles. The initialization sequence is mandatory - but it is not required to do it through this bit - this bit makes it easier. Clock divider (SD_SYCTL [15:6] CLKD bits) should be set to ensure that 80 clock periods are greater than 1ms. Note: In this mode, there is no command sent to the card and no response is expected. A command complete interrupt will be generated once the initialization sequence is completed. SD_STAT[0] CC bit can be polled. 0h (R/W) = The host does not send an initialization sequence 1h (R/W) = The host sends an initialization sequence
0	OD	R/W	0h	Card open drain mode (MMC cards only). This bit must be set to 1 for MMC card commands 1, 2, 3 and 40, and if the MMC card bus is operating in open-drain mode during the response phase to the command sent. Typically, during card identification mode when the card is either in idle, ready or ident state. It is also necessary to set this bit to 1, for a broadcast host response (see Broadcast host response register SD_CON[2] HR bit). 0h (R/W) = No open drain 1h (R/W) = Open drain or broadcast host response

### 17.5.1.6 SD\_PWCNT Register (offset = 130h) [reset = 0h]

SD\_PWCNT is shown in [Figure 17-42](#) and described in [Table 17-25](#).

This register is used to program a mmc counter to delay command transfers after activating the PAD power, this value depends on PAD characteristics and voltage.

**Figure 17-42. SD\_PWCNT Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

This register is used to introduce a delay between the PAD ACTIVE pin assertion and the command issued. 0h (R/W) = No additional delay added 1h (R/W) = TCF delay (card clock period) 2h (R/W) = TCF x 2 delay (card clock period) FFFEh (R/W) = TCF x 65534 delay (card clock period) FFFFh (R/W) = TCF x 65535 delay (card clock period)

### 17.5.1.7 SD\_SDMA Register (offset = 200h) [reset = 0h]

SD\_SDMA is shown in [Figure 17-43](#) and described in [Table 17-26](#).

This register is used to program a mmc counter to delay command transfers after activating the PAD power. This value depends on PAD characteristics and voltage.

**Figure 17-43. SD\_SDMA Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

It can be accessed only if no transaction is executing (i.e., after a transaction has stopped).</p> <p>Read operations during transfers may return an invalid value.</p> <p>The Host Driver shall initialize this register before starting a SDMA transaction.</p> <p>After SDMA has stopped, the next system address of the next contiguous data position can be read from this register.</p> <p>The SDMA transfer waits at the every boundary specified by the Host SDMA Buffer Boundary in the Block Size register.</p> <p>The Host Controller generates DMA Interrupt to request the Host Driver to update this register.</p> <p>The Host Driver sets the next system address of the next data position to this register.</p> <p>When the most upper byte of this register (003h) is written, the Host Controller restarts the SDMA transfer.</p> <p>When restarting SDMA by the Resume command or by setting Continue Request in the Block Gap Control register, the Host Controller shall start at the next contiguous address stored here in the SDMA System Address register.</p> <p>ADMA does not use this register.</p>

### 17.5.1.8 SD\_BLK Register (offset = 204h) [reset = 0h]

SD\_BLK is shown in [Figure 17-44](#) and described in [Table 17-27](#).

This register shall be used for any card. SD\_BLK[BLK] is the block size register. SD\_BLK[NBLK] is the block count register.

**Figure 17-44. SD\_BLK Register**

### 17.5.1.9 SD\_ARG Register (offset = 208h) [reset = 0h]

SD\_ARG is shown in [Figure 17-45](#) and described in [Table 17-28](#).

This register contains command argument specified as bit 39-8 of Command-Format. These registers must be initialized prior to sending the command itself to the card (write action into the register SD\_CMD register). Only exception is for a command index specifying stuff bits in arguments, making a write unnecessary.

**Figure 17-45. SD\_ARG Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

### 17.5.1.10 SD\_CMD Register (offset = 20Ch) [reset = 0h]

SD\_CMD is shown in [Figure 17-46](#) and described in [Table 17-29](#).

SD\_CMD[31:16] = the command register. SD\_CMD[15:0] = the transfer mode. This register configures the data and command transfers. A write into the most significant byte send the command. A write into SD\_CMD[15:0] registers during data transfer has no effect. This register can be used for any card. In SYSTEST mode, a write into SD\_CMD register will not start a transfer.

**Figure 17-46. SD\_CMD Register**

**Table 17-29. SD\_CMD Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-30	RESERVED	R	0h	
29-24	INDX	R/W	0h	Command index binary encoded value from 0 to 63 specifying the command number send to card (CMD0 or ACMD0 to CMD63 or ACMD63).
23-22	CMD_TYPE	R/W	0h	Command type. This register specifies three types of special commands: Suspend, Resume and Abort. These bits shall be cleared to 0b00 for all other commands. 0h (R/W) = Others commands 1h (R/W) = Upon CMD52 "Bus Suspend" operation 2h (R/W) = Upon CMD52 "Function Select" operation 3h (R/W) = Upon CMD12 or CMD52 "I/O Abort" command
21	DP	R/W	0h	Data present select. This register indicates that data is present and mmc_dat line shall be used. It must be cleared to 0 in the following conditions: Command using only mmc_cmd line. Command with no data transfer but using busy signal on mmc_dat0. Resume command. 0h (R/W) = Command with no data transfer 1h (R/W) = Command with data transfer
20	CICE	R/W	0h	Command Index check enable. This bit must be set to 1 to enable index check on command response to compare the index field in the response against the index of the command. If the index is not the same in the response as in the command, it is reported as a command index error (SD_STAT[19] CIE bit set to 1) Note: The CICE bit cannot be configured for an Auto CMD12, then index check is automatically checked when this command is issued. 0h (R/W) = Index check disable 1h (R/W) = Index check enable

**Table 17-29. SD\_CMD Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
19	CCCE	R/W	0h	Command CRC check enable. This bit must be set to 1 to enable CRC7 check on command response to protect the response against transmission errors on the bus. If an error is detected, it is reported as a command CRC error (SD_STAT[17] CCRC bit set to 1). Note: The CCCE bit cannot be configured for an Auto CMD12, and then CRC check is automatically checked when this command is issued. 0h (R/W) = CRC7 check disable 1h (R/W) = CRC7 check enable
18	RESERVED	R	0h	
17-16	RSP_TYPE	R/W	0h	Response type. This bits defines the response type of the command. 0h (R/W) = No response 1h (R/W) = Response Length 136 bits 2h (R/W) = Response Length 48 bits 3h (R/W) = Response Length 48 bits with busy after response
15-6	RESERVED	R	0h	
5	MSBS	R/W	0h	Multi/Single block select. This bit must be set to 1 for data transfer in case of multi block command. For any others command this bit shall be cleared to 0. 0h (R/W) = Single block. If this bit is 0, it is not necessary to set the register SD_BLK[31:16] NBLK bits. 1h (R/W) = Multi block. When Block Count is disabled (SD_CMD[1] BCE bit is cleared to 0) in Multiple block transfers (SD_CMD[5] MSBS bit is set to 1), the module can perform infinite transfer.
4	DDIR	R/W	0h	Data transfer Direction. Select This bit defines either data transfer will be a read or a write. 0h (R/W) = Data Write (host to card) 1h (R/W) = Data Read (card to host)
3	RESERVED	R	0h	
2	ACEN	R/W	0h	Auto CMD12 Enable (SD cards only). When this bit is set to 1, the host controller issues a CMD12 automatically after the transfer completion of the last block. The Host Driver shall not set this bit to issue commands that do not require CMD12 to stop data transfer. In particular, secure commands do not require CMD12. For CE-ATA commands (SD_CON[12] CEATA bit set to 1), auto CMD12 is useless therefore when this bit is set the mechanism to detect command completion signal, named CCS, interrupt is activated. 0h (R/W) = Auto CMD12 disable 1h (R/W) = Auto CMD12 enable or CCS detection enabled.
1	BCE	R/W	0h	Block Count Enable (Multiple block transfers only). This bit is used to enable the block count register (SD_BLK [31:16] NBLK bits). When Block Count is disabled (SD_CMD[1] BCE bit is cleared to 0) in Multiple block transfers (SD_CMD[5] MSBS bits is set to 1), the module can perform infinite transfer. 0h (R/W) = Block count disabled for infinite transfer. 1h (R/W) = Block count enabled for multiple block transfer with known number of blocks
0	DE	R/W	0h	DMA Enable. This bit is used to enable DMA mode for host data access. 0h (R/W) = DMA mode disable 1h (R/W) = DMA mode enable

### 17.5.1.11 SD\_RSP10 Register (offset = 210h) [reset = 0h]

SD\_RSP10 is shown in [Figure 17-47](#) and described in [Table 17-30](#).

This 32-bit register holds bits positions [31:0] of command response type R1, R1b, R2, R3, R4, R5, R5b, or R6.

**Figure 17-47. SD\_RSP10 Register**

### 17.5.1.15 SD\_DATA Register (offset = 220h) [reset = 0h]

SD\_DATA is shown in [Figure 17-51](#) and described in [Table 17-34](#).

This register is the 32-bit entry point of the buffer for read or write data transfers. The buffer size is 32bitsx256(1024 bytes). Bytes within a word are stored and read in little endian format. This buffer can be used as two 512 byte buffers to transfer data efficiently without reducing the throughput. Sequential and contiguous access is necessary to increment the pointer correctly. Random or skipped access is not allowed. In little endian, if the local host accesses this register byte-wise or 16bit-wise, the least significant byte (bits [7:0]) must always be written/read first. The update of the buffer address is done on the most significant byte write for full 32-bit DATA register or on the most significant byte of the last word of block transfer. Example 1Byte or 16-bit access: Mbyteen[3:0]=0001 (1-byte) => Mbyteen[3:0]=0010 (1-byte) => Mbyteen[3:0]=1100 (2-bytes) OK. Mbyteen[3:0]=0001 (1-byte) => Mbyteen[3:0]=0010 (1-byte) => Mbyteen[3:0]=0100 (1-byte) OK. Mbyteen[3:0]=0001 (1-byte) => Mbyteen[3:0]=0010 (1-byte) => Mbyteen[3:0]=1000 (1-byte) Bad.

**Figure 17-51. SD\_DATA Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bit	Field	Type	Reset	Description
31-25	RESERVED	R	0h	
24	CLEV	R	0h	mmc_cmd line signal level. This status is used to check the mmc_cmd line level to recover from errors, and for debugging. The value of this register after reset depends on the mmc_cmd line level at that time. 0h (R/W) = The mmc_cmd line level is 0. 1h (R/W) = The mmc_cmd line level is 1.
23-20	DLEV	R	0h	mmc_dat [3:0] line signal level mmc_dat3 equal to or greater than bit 23. mmc_dat2 equal to or greater than bit 22. mmc_dat1 equal to or greater than bit 21. mmc_dat0 equal to or greater than bit 20. This status is used to check mmc_dat line level to recover from errors, and for debugging. This is especially useful in detecting the busy signal level from mmc_dat0 . The value of these registers after reset depends on the mmc_dat lines level at that time.
19	WP	R	0h	Write Protect. MMC/SD/SDIO1 only. SDIO cards only. This bit reflects the write protect input pin (SDWP) level. The value of this register after reset depends one the protect input pin (SDWP) level at that time. 0h (R/W) = If SD_CON[8] WPP is cleared to 0 (default), the card is write protected, otherwise the card is not write protected. 1h (R/W) = If SD_CON[8] WPP is cleared to 0 (default), the card is not write protected, otherwise the card is write protected.

**Table 17-35. SD\_PSTATE Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
18	CDPL	R	0h	Card Detect Pin Level. MMC/SD/SDIO1 only. SDIO cards only. This bit reflects the inverse value of the card detect input pin (SDCD). Debouncing is not performed on this bit and is valid only when Card State is stable. (SD_PSTATE[17] is set to 1). This bit must be debounced by software. The value of this register after reset depends on the card detect input pin (SDCD) level at that time. 0h (R/W) = The value of the card detect input pin (SDCD) is 1. 1h (R/W) = The value of the card detect input pin (SDCD) is 0.
17	CSS	R	0h	Card State Stable. This bit is used for testing. It is set to 1 only when Card Detect Pin Level is stable (SD_PSTATE[18] CPDL). Debouncing is performed on the card detect input pin (SDCD) to detect card stability. This bit is not affected by software reset. 0h (R/W) = Reset or Debouncing. 1h (R/W) = Reset or Debouncing.
16	CINS	R	0h	Card inserted. This bit is the debounced value of the card detect input pin (SDCD). An inactive to active transition of the card detect input pin (SDCD) will generate a card insertion interrupt (SD_STAT[CINS]). A active to inactive transition of the card detect input pin (SDCD) will generate a card removal interrupt (SD_STAT[REM]). This bit is not affected by a software reset. 0h (R/W) = If SD_CON[CDP] is cleared to 0 (default), no card is detected. The card may have been removed from the card slot. If SD_CON[CDP] is set to 1, the card has been inserted. 1h (R/W) = If SD_CON[CDP] is cleared to 0 (default), the card has been inserted from the card slot. If SD_CON[CDP] is set to 1, no card is detected. The card may have been removed from the card slot.
15-12	RESERVED	R	0h	
11	BRE	R	0h	Buffer read enable. This bit is used for non-DMA read transfers. It indicates that a complete block specified by SD_BLK [10:0] BLEN bits has been written in the buffer and is ready to be read. It is cleared to 0 when the entire block is read from the buffer. It is set to 1 when a block data is ready in the buffer and generates the Buffer read ready status of interrupt (SD_STAT[5] BRR bit). 0h (R/W) = Read BLEN bytes disable 1h (R/W) = Read BLEN bytes enable. Readable data exists in the buffer.
10	BWE	R	0h	Buffer Write enable. This status is used for non-DMA write transfers. It indicates if space is available for write data. 0h (R/W) = There is no room left in the buffer to write BLEN bytes of data. 1h (R/W) = There is enough space in the buffer to write BLEN bytes of data.

**Table 17-35. SD\_PSTATE Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
9	RTA	R	0h	Read transfer active. This status is used for detecting completion of a read transfer. It is set to 1 after the end bit of read command or by activating a continue request (SD_HCTL[17] CR bit) following a stop at block gap request. This bit is cleared to 0 when all data have been read by the local host after last block or after a stop at block gap request. 0h (R/W) = No valid data on the mmc_dat lines. 1h (R/W) = Read data transfer on going.
8	WTA	R	0h	Write transfer active. This status indicates a write transfer active. It is set to 1 after the end bit of write command or by activating a continue request (SD_HCTL[17] CR bit) following a stop at block gap request. This bit is cleared to 0 when CRC status has been received after last block or after a stop at block gap request. 0h (R/W) = No valid data on the mmc_dat lines. 1h (R/W) = Write data transfer on going.
7-3	RESERVED	R	0h	
2	DLA	R	0h	mmc_dat line active. This status bit indicates whether one of the mmc_dat lines is in use. In the case of read transactions (card to host) This bit is set to 1 after the end bit of read command or by activating continue request SD_HCTL[17] CR bit. This bit is cleared to 0 when the host controller received the end bit of the last data block or at the beginning of the read wait mode. In the case of write transactions (host to card) This bit is set to 1 after the end bit of write command or by activating continue request SD_HCTL[17] CR bit. This bit is cleared to 0 on the end of busy event for the last block. The host controller must wait 8 clock cycles with line not busy to really consider not "busy state" or after the busy block as a result of a stop at gap request. 0h (R/W) = mmc_dat line inactive 1h (R/W) = mmc_dat line active
1	DATI	R	0h	Command inhibit (mmc_dat). This status bit is generated if either mmc_dat line is active (SD_PSTATE[2] DLA bit) or Read transfer is active (SD_PSTATE[9] RTA bit) or when a command with busy is issued. This bit prevents the local host to issue a command. A change of this bit from 1 to 0 generates a transfer complete interrupt (SD_STAT[1] TC bit). 0h (R/W) = Issuing of command using the mmc_dat lines is allowed 1h (R/W) = Issuing of command using mmc_dat lines is not allowed
0	CMDI	R	0h	Command inhibit(mmc_cmd). This status bit indicates that the mmc_cmd line is in use. This bit is cleared to 0 when the most significant byte is written into the command register. This bit is not set when Auto CMD12 is transmitted. This bit is cleared to 0 in either the following cases: After the end bit of the command response, excepted if there is a command conflict error (SD_STAT[17] CCRC bit or SD_STAT[18] CEB bit set to 1) or a Auto CMD12 is not executed (SD_AC12[0] ACNE bit). After the end bit of the command without response (SD_CMD [17:16] RSP_TYPE bits set to "00"). In case of a command data error is detected (SD_STAT[19] CTO bit set to 10, this register is not automatically cleared. 0h (R/W) = Issuing of command using mmc_cmd line is allowed 1h (R/W) = Issuing of command using mmc_cmd line is not allowed

### 17.5.1.17 SD\_HCTL Register (offset = 228h) [reset = 0h]

SD\_HCTL is shown in [Figure 17-53](#) and described in [Table 17-36](#).

This register defines the host controls to set power, wake-up and transfer parameters. SD\_HCTL[31:24] = Wake-up control. SD\_HCTL[23:16] = Block gap control. SD\_HCTL[15:8] = Power control. SD\_HCTL[7:0] = Host control. If your device does not support MMC cards, then those bits in this register which are meant for MMC card use should be assumed to be reserved.

**Figure 17-53. SD\_HCTL Register**

Bit	Field	Type	Reset	Description
31-28	RESERVED	R	0h	
27	OBWE	R/W	0h	Wake-up event enable for 'out-of-band' Interrupt. This bit enables wake-up events for 'out-of-band' assertion. Wake-up is generated if the wake-up feature is enabled (SD_SYSCONFIG[2] ENAWAKEUP bit). The write to this register is ignored when SD_CON[14] OBIE bit is not set. 0h (R/W) = Disable wake-up on 'out-of-band' Interrupt 1h (R/W) = Enable wake-up on 'out-of-band' Interrupt
26	REM	R/W	0h	Wake-up event enable on SD card removal. This bit enables wake-up events for card removal assertion. Wake-up is generated if the wake-up feature is enabled (SD_SYSCONFIG[2] ENAWAKEUP bit). 0h (R/W) = Disable wake-up on card removal 1h (R/W) = Enable wake-up on card removal
25	INS	R/W	0h	Wake-up event enable on SD card insertion. This bit enables wake-up events for card insertion assertion. Wake-up is generated if the wake-up feature is enabled (SD_SYSCONFIG[2] ENAWAKEUP bit). 0h (R/W) = Disable wake-up on card insertion 1h (R/W) = Enable wake-up on card insertion
24	IWE	R/W	0h	Wake-up event enable on SD card interrupt. This bit enables wake-up events for card interrupt assertion. Wake-up is generated if the wake-up feature is enabled (SD_SYSCONFIG[2] ENAWAKEUP bit) and enable status bit is set (SD_IE[8] CIRQ_ENABLE bit). 0h (R/W) = Disable wake-up on card interrupt 1h (R/W) = Enable wake-up on card interrupt
23-20	RESERVED	R	0h	

**Table 17-36. SD\_HCTL Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
19	IBG	R/W	0h	Interrupt block at gap. This bit is valid only in 4-bit mode of SDIO card to enable interrupt detection in the interrupt cycle at block gap for a multiple block transfer. For MMC cards and for SD card this bit should be cleared to 0. 0h (R/W) = Disable interrupt detection at the block gap in 4-bit mode 1h (R/W) = Enable interrupt detection at the block gap in 4-bit mode
18	RWC	R/W	0h	Read wait control. The read wait function is optional only for SDIO cards. If the card supports read wait, this bit must be enabled, then requesting a stop at block gap (SD_HCTL[16] SBGR bit) generates a read wait period after the current end of block. Be careful, if read wait is not supported it may cause a conflict on mmc_dat line. 0h (R/W) = Disable read wait control. Suspend/resume cannot be supported. 1h (R/W) = Enable read wait control
17	CR	R/W	0h	Continue request. This bit is used to restart a transaction that was stopped by requesting a stop at block gap (SD_HCTL[16] SBGR bit). Set this bit to 1 restarts the transfer. The bit is automatically cleared to 0 by the host controller when transfer has restarted, that is, mmc_dat line is active (SD_PSTATE[2] DLA bit) or transferring data (SD_PSTATE[8] WTA bit). The Stop at block gap request must be disabled (SD_HCTL[16] SBGR bit =0) before setting this bit. 0h (R/W) = No affect 1h (R/W) = Transfer restart
16	SBGR	R/W	0h	Stop at block gap request. This bit is used to stop executing a transaction at the next block gap. The transfer can restart with a continue request (SD_HCTL[17] CR bit) or during a suspend/resume sequence. In case of read transfer, the card must support read wait control. In case of write transfer, the host driver shall set this bit after all block data written. Until the transfer completion (SD_STAT[1] TC bit set to 1), the host driver shall leave this bit set to 1. If this bit is set, the local host shall not write to the data register (SD_DATA). 0h (R/W) = Transfer mode 1h (R/W) = Stop at block gap
15-12	RESERVED	R	0h	
11-9	SDVS	R/W	0h	SD bus voltage select (All cards). The host driver should set these bits to select the voltage level for the card according to the voltage supported by the system (SD_CAPA[26] VS18 bit, SD_CAPA[25] VS30 bit, SD_CAPA[24] VS33 bit) before starting a transfer. If MMCSD 2: This field must be set to 5h. If MMCSD 3: This field must be set to 5h. 5h (R/W) = 1.8 V (Typical) 6h (R/W) = 3.0 V (Typical) 7h (R/W) = 3.3 V (Typical)

**Table 17-36. SD\_HCTL Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
8	SDBP	R/W	0h	SD bus power. Before setting this bit, the host driver shall select the SD bus voltage (SD_HCTL [11:9] SDVS bits). If the host controller detects the No card state, this bit is automatically cleared to 0. If the module is power off, a write in the command register (SD_CMD) will not start the transfer. A write to this bit has no effect if the selected SD bus voltage is not supported according to capability register (SD_CAPA[VS*]). 0h (R/W) = Power off 1h (R/W) = Power on
7	CDSS	R/W	0h	Card Detect Signal Selection. This bit selects source for the card detection. When the source for the card detection is switched, the interrupt should be disabled during the switching period by clearing the Interrupt Status/Signal Enable register in order to mask unexpected interrupt being caused by the glitch. The Interrupt Status/Signal Enable should be disabled during over the period of debouncing. 0h (R/W) = SDCD# is selected (for normal use). 1h (R/W) = The Card Detect Test Level is selected (for test purposes).
6	CDTL	R/W	0h	Card Detect Test Level. This bit is enabled while the Card Detect Signal Selection is set to 1 and it indicates card inserted or not. 0 = No card 1 = Card inserted.
5	RESERVED	R	0h	
4-3	DMAS	R/W	0h	DMA Select. One of the supported DMA modes can be selected. The host driver shall check support of DMA modes by referencing the Capabilities register. Use of selected DMA is determined by DMA Enable of the Transfer Mode register. This register is only meaningful when MADMA_EN is set to 1. When MADMA_EN is cleared to 0 the bit field is read only and returned value is 0. 0h (R/W) = Reserved 1h (R/W) = Reserved 2h (R/W) = 32-bit Address ADMA2 is selected. 3h (R/W) = Reserved
2	HSPE	R/W	0h	High Speed Enable. Before setting this bit, the Host Driver shall check the High Speed Support in the Capabilities register. If this bit is cleared to 0 (default), the Host Controller outputs CMD line and DAT lines at the falling edge of the SD Clock. If this bit is set to 1, the Host Controller outputs CMD line and DAT lines at the rising edge of the SD Clock. This bit shall not be set when dual data rate mode is activated in SD_CON[DDR]. 0h (R/W) = Normal speed mode 1h (R/W) = High speed mode
1	DTW	R/W	0h	Data transfer width. This bit must be set following a valid SET_BUS_WIDTH command (ACMD6) with the value written in bit 1 of the argument. Prior to this command, the SD card configuration register (SCR) must be verified for the supported bus width by the SD card. 0h (R/W) = 1-bit Data width (mmc_dat0 used) 1h (R/W) = 4-bit Data width (mmc_dat[3:0] used)
0	RESERVED	R	0h	

### 17.5.1.18 SD\_SYSCTL Register (offset = 22Ch) [reset = 0h]

SD\_SYSCTL is shown in [Figure 17-54](#) and described in [Table 17-37](#).

This register defines the system controls to set software resets, clock frequency management and data timeout. SD\_SYSCTL[31:24] = Software resets. SD\_SYSCTL[23:16] = Timeout control. SD\_SYSCTL[15:0] = Clock control.

**Figure 17-54. SD\_SYSCTL Register**

Bit	Field	Type	Reset	Description
31-27	RESERVED	R	0h	
26	SRD	R/W	0h	Software reset for mmc_dat line. This bit is set to 1 for reset and released to 0 when completed. Due to additional implementation logic, the reset does not immediately start when asserted. The proper procedure is: (a) Set to 1 to start reset, (b) Poll for 1 to identify start of reset, and (c) Poll for 0 to identify reset is complete. mmc_dat finite state machine in both clock domain are also reset. These registers are cleared by the SD_SYSCTL[26] SRD bit: SD_DATA. SD_PSTATEBRE, BWE, RTA, WTA, DLA and DATI. SD_HCTLSBGR and CR. SD_STATBRR, BWR, BGE and TC Interconnect and MMC buffer data management is reinitialized. Note: If a soft reset is issued when an interrupt is asserted, data may be lost. 0h (R/W) = Reset completed 1h (R/W) = Software reset for mmc_dat line
25	SRC	R/W	0h	Software reset for mmc_cmd line. This bit is set to 1 for reset and released to 0 when completed. Due to additional implementation logic, the reset does not immediately start when asserted. The proper procedure is: (a) Set to 1 to start reset, (b) Poll for 1 to identify start of reset, and (c) Poll for 0 to identify reset is complete. mmc_cmd finite state machine in both clock domain are also reset. These registers are cleared by the SD_SYSCTL[25] SRC bit: SD_PSTATECMDI. SD_STATCC Interconnect and MMC command status management is reinitialized. Note: If a soft reset is issued when an interrupt is asserted, data may be lost. 0h (R/W) = Reset completed 1h (R/W) = Software reset for mmc_cmd line
24	SRA	R/W	0h	Software reset for all. This bit is set to 1 for reset , and released to 0 when completed. This reset affects the entire host controller except for the card detection circuit and capabilities registers. 0h (R/W) = Reset completed 1h (R/W) = Software reset for all the design
23-20	RESERVED	R	0h	

**Table 17-37. SD\_SYSTL Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
19-16	DTO	R/W	0h	<p>Data timeout counter value and busy timeout. This value determines the interval by which mmc_dat lines timeouts are detected. The host driver needs to set this bit field based on: The maximum read access time (NAC) (Refer to the SD Specification Part1 Physical Layer). The data read access time values (TAAC and NSAC) in the card specific data register (CSD) of the card. The timeout clock base frequency (SD_CAPA [5:0] TCF bits). If the card does not respond within the specified number of cycles, a data timeout error occurs (SD_STAT[20] DTO bit). The SD_SYSTL[19,16] DTO bit field is also used to check busy duration, to generate busy timeout for commands with busy response or for busy programming during a write command. Timeout on CRC status is generated if no CRC token is present after a block write. 0h (R/W) = <math>TCF \times 2^{13}</math> 1h (R/W) = <math>TCF \times 2^{14}</math> Eh (R/W) = <math>TCF \times 2^{27}</math> Fh (R/W) = Reserved</p>
15-6	CLKD	R/W	0h	<p>Clock frequency select. These bits define the ratio between a reference clock frequency (system dependant) and the output clock frequency on the mmc_clk pin of either the memory card (MMC, SD, or SDIO). 0h (R/W) = Clock Ref bypass 1h (R/W) = Clock Ref bypass 2h (R/W) = Clock Ref / 2 3h (R/W) = Clock Ref / 3 3FFh (R/W) = Clock Ref / 1023</p>
5-3	RESERVED	R	0h	
2	CEN	R/W	0h	<p>Clock enable. This bit controls if the clock is provided to the card or not. 0h (R/W) = The clock is not provided to the card . Clock frequency can be changed . 1h (R/W) = The clock is provided to the card and can be automatically gated when SD_SYSCONFIG[0] AUTOIDLE bit is set to 1 (default value). The host driver shall wait to set this bit to 1 until the Internal clock is stable (SD_SYSTL[1] ICS bit).</p>
1	ICS	R	0h	<p>Internal clock stable (status)This bit indicates either the internal clock is stable or not. 0h (R/W) = The internal clock is not stable. 1h (R/W) = The internal clock is stable after enabling the clock (SD_SYSTL[0] ICE bit) or after changing the clock ratio (SD_SYSTL[15:6] CLKD bits).</p>
0	ICE	R/W	0h	<p>Internal clock enable. This register controls the internal clock activity. In very low power state, the internal clock is stopped. Note: The activity of the debounce clock (used for wake-up events) and the interface clock (used for reads and writes to the module register map) are not affected by this register. 0h (R/W) = The internal clock is stopped (very low power state). 1h (R/W) = The internal clock oscillates and can be automatically gated when SD_SYSCONFIG[0] AUTOIDLE bit is set to 1 (default value).</p>

### 17.5.1.19 SD\_STAT Register (offset = 230h) [reset = 0h]

SD\_STAT is shown in [Figure 17-55](#) and described in [Table 17-38](#).

The interrupt status regroups all the status of the module internal events that can generate an interrupt. SD\_STAT[31:16] = Error Interrupt Status. SD\_STAT[15:0] = Normal Interrupt Status. The error bits are located in the upper 16 bits of the SD\_STAT register. All bits are cleared by writing a 1 to them. Additionally, bits 15 and 8 serve as special error bits. These cannot be cleared by writing a 1 to them. Bit 15 (ERRI) is automatically cleared when the error causing to ERRI to be set is handled. (that is, when bits 31:16 are cleared, bit 15 will be automatically cleared). Bit 8 (CIRQ) is cleared by writing a 0 to SD\_IE[8] (masking the interrupt) and servicing the interrupt.

**Table 17-38. SD\_STAT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-30	RESERVED	R	0h	
29	BADA	R/W	0h	Bad access to data space. This bit is set automatically to indicate a bad access to buffer when not allowed: During a read access to the data register (SD_DATA) while buffer reads are not allowed (SD_PSTATE[11] BRE bit =0). During a write access to the data register (SD_DATA) while buffer writes are not allowed (SD_PSTATE[10] BWE bit=0). 0h (W) = Status bit unchanged 0h (R) = No interrupt 1h (W) = Status is cleared. 1h (R) = Bad access
28	CERR	R/W	0h	Card error. This bit is set automatically when there is at least one error in a response of type R1, R1b, R6, R5 or R5b. Only bits referenced as type E (error) in status field in the response can set a card status error. An error bit in the response is flagged only if corresponding bit in card status response error SD_CSRE is set. There is no card error detection for autoCMD12 command. The host driver shall read SD_RSP76 register to detect error bits in the command response. 0h (W) = Status bit unchanged 0h (R) = No error 1h (W) = Status is cleared. 1h (R) = Card error
27-26	RESERVED	R	0h	

**Table 17-38. SD\_STAT Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
25	ADMAE	R/W	0h	ADMA Error. This bit is set when the Host Controller detects errors during ADMA based data transfer. The state of the ADMA at an error occurrence is saved in the ADMA Error Status Register. In addition, the Host Controller generates this interrupt when it detects invalid descriptor data (Valid=0) at the ST_FDS state. ADMA Error State in the ADMA Error Status indicates that an error occurs in ST_FDS state. The Host Driver may find that Valid bit is not set at the error descriptor. 0h (W) = Status bit unchanged 0h (R) = No interrupt 1h (W) = Status is cleared. 1h (R) = ADMA error
24	ACE	R/W	0h	Auto CMD12 error. This bit is set automatically when one of the bits in Auto CMD12 Error status register has changed from 0 to 1. 0h (W) = Status bit unchanged 0h (R) = No error 1h (W) = Status is cleared. 1h (R) = AutoCMD12 error
23	RESERVED	R	0h	
22	DEB	R/W	0h	Data End Bit error. This bit is set automatically when detecting a 0 at the end bit position of read data on mmc_dat line or at the end position of the CRC status in write mode. 0h (W) = Status bit unchanged 0h (R) = No error 1h (W) = Status is cleared. 1h (R) = Data end bit error
21	DCRC	R/W	0h	Data CRC Error. This bit is set automatically when there is a CRC16 error in the data phase response following a block read command or if there is a 3-bit CRC status different of a position "010" token during a block write command. 0h (W) = Status bit unchanged 0h (R) = No error 1h (W) = Status is cleared. 1h (R) = Data CRC error
20	DTO	R/W	0h	Data timeout error. This bit is set automatically according to the following conditions: Busy timeout for R1b, R5b response type. Busy timeout after write CRC status. Write CRC status timeout. Read data timeout. 0h (W) = Status bit unchanged 0h (R) = No error 1h (W) = Status is cleared. 1h (R) = Time out
19	CIE	R/W	0h	Command index error. This bit is set automatically when response index differs from corresponding command index previously emitted. It depends on the enable bit (SD_CMD[20] CICE). 0h (W) = Status bit unchanged 0h (R) = No error 1h (W) = Status is cleared. 1h (R) = Command index error

**Table 17-38. SD\_STAT Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
18	CEB	R/W	0h	Command end bit error. This bit is set automatically when detecting a 0 at the end bit position of a command response. 0h (W) = Status bit unchanged 0h (R) = No error 1h (W) = Status is cleared. 1h (R) = Command end bit error
17	CCRC	R/W	0h	Command CRC error. This bit is set automatically when there is a CRC7 error in the command response depending on the enable bit (SD_CMD[19] CCCE). 0h (W) = Status bit unchanged 0h (R) = No error 1h (W) = Status is cleared. 1h (R) = Command CRC error
16	CTO	R/W	0h	Command timeout error. This bit is set automatically when no response is received within 64 clock cycles from the end bit of the command. For commands that reply within 5 clock cycles - the timeout is still detected at 64 clock cycles. 0h (W) = Status bit unchanged 0h (R) = No error 1h (W) = Status is cleared. 1h (R) = Time Out
15	ERRI	R	0h	Error interrupt. If any of the bits in the Error Interrupt Status register (SD_STAT [31:16]) are set, then this bit is set to 1. Therefore the host driver can efficiently test for an error by checking this bit first. Writes to this bit are ignored. 0h (R/W) = No interrupt 1h (R/W) = Error interrupt event(s) occurred
14-11	RESERVED	R	0h	
10	BSR	R/W	0h	Boot Status Received Interrupt. This bit is set automatically when SD_CON[BOOT] is set 1 or 2 and a boot status is received on DAT[0] line. This interrupt is only useful for MMC card. 0h (W) = Status bit unchanged 0h (R) = No interrupt 1h (W) = Status is cleared. 1h (R) = Boot Status Received Interrupt occurred.
9	OBI	R	0h	Out-of-band interrupt (This interrupt is only useful for MMC card). This bit is set automatically when SD_CON[14] OBIE bit is set and an out-of-band interrupt occurs on OBI pin. The interrupt detection depends on polarity controlled by SD_CON[13] OBIP bit. The out-of-band interrupt signal is a system specific feature for future use, this signal is not required for existing specification implementation. 0h (W) = Status bit unchanged 0h (R) = No out-of-band interrupt 1h (W) = Status is cleared. 1h (R) = Interrupt out-of-band occurs

**Table 17-38. SD\_STAT Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
8	CIRQ	R	0h	<p>Card interrupt. This bit is only used for SD and SDIO cards.</p> <p>In 1-bit mode, interrupt source is asynchronous (can be a source of asynchronous wake-up).</p> <p>In 4-bit mode, interrupt source is sampled during the interrupt cycle.</p> <p>In CE-ATA mode, interrupt source is detected when the card drives mmc_cmd line to zero during one cycle after data transmission end. All modes above are fully exclusive.</p> <p>The controller interrupt must be clear by setting SD_IE[8] CIRQ_ENABLE to 0, then the host driver must start the interrupt service with card (clearing card interrupt status) to remove card interrupt source.</p> <p>Otherwise the Controller interrupt will be reasserted as soon as SD_IE[8] CIRQ_ENABLE is set to 1.</p> <p>Writes to this bit are ignored.</p> <p>0h (R/W) = No card interrupt 1h (R/W) = Generate card interrupt</p>
7	CREM	R/W	0h	<p>Card Removal.</p> <p>This bit is set automatically when SD_PSTATE[CINS] changes from 1 to 0.</p> <p>A clear of this bit doesn't affect Card inserted present state (SD_PSTATE[CINS]).</p> <p>0h (W) = Status bit unchanged 0h (R) = Card State stable or debouncing 1h (R) = Card Removed 1h (W) = Status is cleared</p>
6	CINS	R/W	0h	<p>Card Insertion.</p> <p>This bit is set automatically when SD_PSTATE[CINS] changes from 0 to 1.</p> <p>A clear of this bit doesn't affect Card inserted present state (SD_PSTATE[CINS]).</p> <p>0h (W) = Status bit unchanged 0h (R) = Card State stable or debouncing 1h (W) = Status is cleared. 1h (R) = Card inserted</p>
5	BRR	R/W	0h	<p>Buffer read ready.</p> <p>This bit is set automatically during a read operation to the card (see class 2 - block oriented read commands) when one block specified by the SD_BLK [10:0] BLEN bit field is completely written in the buffer.</p> <p>It indicates that the memory card has filled out the buffer and that the local host needs to empty the buffer by reading it.</p> <p>Note: If the DMA receive-mode is enabled, this bit is never set instead a DMA receive request to the main DMA controller of the system is generated.</p> <p>0h (W) = Status bit unchanged 0h (R) = Not ready to read buffer 1h (W) = Status is cleared. 1h (R) = Ready to read buffer</p>

**Table 17-38. SD\_STAT Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
4	BWR	R/W	0h	<p>Buffer write ready.</p> <p>This bit is set automatically during a write operation to the card (see class 4 - block oriented write command) when the host can write a complete block as specified by SD_BLK [10:0] BLEN.</p> <p>It indicates that the memory card has emptied one block from the buffer and that the local host is able to write one block of data into the buffer.</p> <p>Note: If the DMA transmit mode is enabled, this bit is never set instead, a DMA transmit request to the main DMA controller of the system is generated.</p> <p>0h (W) = Status bit unchanged  0h (R) = Not ready to write buffer  1h (W) = Status is cleared.  1h (R) = Ready to write buffer</p>
3	DMA	R/W	0h	<p>DMA Interrupt.</p> <p>This status is set when an interrupt is required in the ADMA instruction and after the data transfer completion.</p> <p>0h (W) = Status bit unchanged  0h (R) = DMA Interrupt detected  1h (W) = Status is cleared.  1h (R) = No DMA Interrupt</p>
2	BGE	R/W	0h	<p>Block gap event.</p> <p>When a stop at block gap is requested (SD_HCTL[16] SBGR bit), this bit is automatically set when transaction is stopped at the block gap during a read or write operation.</p> <p>0h (W) = Status bit unchanged  0h (R) = No block gap event  1h (R) = Transaction stopped at block gap  1h (W) = Status is cleared</p>
1	TC	R/W	0h	<p>Transfer completed.</p> <p>This bit is always set when a read/write transfer is completed or between two blocks when the transfer is stopped due to a stop at block gap request (SD_HCTL[16] SBGR bit).</p> <p>0h (W) = Status bit unchanged  0h (R) = No transfer complete  1h (W) = Status is cleared  1h (R) = Data transfer complete</p>
0	CC	R/W	0h	<p>Command complete.</p> <p>This bit is set when a 1-to-0 transition occurs in the register command inhibit (SD_PSTATE[0] CMDI bit)</p> <p>0h (W) = Status bit unchanged  0h (R) = No command complete  1h (W) = Status is cleared  1h (R) = Command complete</p>

### 17.5.1.20 SD\_IE Register (offset = 234h) [reset = 0h]

SD\_IE is shown in [Figure 17-56](#) and described in [Table 17-39](#).

This register allows to enable/disable the module to set status bits, on an event-by-event basis.  
SD\_IE[31:16] = Error Interrupt Status Enable. SD\_IE[15:0] = Normal Interrupt Status Enable.

### 17.5.1.21 SD\_ISE Register (offset = 238h) [reset = 0h]

SD\_ISE is shown in [Figure 17-57](#) and described in [Table 17-40](#).

This register allows you to enable/disable the module to set status bits, on an event-by-event basis.  
SD\_ISE[31:16] = Error Interrupt Signal Enable. SD\_ISE[15:0] = Normal Interrupt Signal Enable.

### 17.5.1.22 SD\_AC12 Register (offset = 23Ch) [reset = 0h]

SD\_AC12 is shown in [Figure 17-58](#) and described in [Table 17-41](#).

The host driver may determine which of the errors cases related to Auto CMD12 has occurred by checking this SD\_AC12 register when an auto CMD12 error interrupt occurs. This register is valid only when auto CMD12 is enabled (SD\_CMD[2] ACEN bit) and auto CMD12Error (SD\_STAT[24] ACE bit) is set to 1. These bits are automatically reset when starting a new adtc command with data.

Bit	Field	Type	Reset	Description
31-29	RESERVED	R	0h	
28	BUS_64BIT	R/W	0h	64 Bit System Bus Support. Setting 1 to this bit indicates that the Host Controller supports 64-bit address descriptor mode and is connected to 64-bit address system bus. 0h (R/W) = 32-bit System bus address 1h (R/W) = 64-bit System bus address
27	RESERVED	R	0h	
26	VS18	R/W	0h	Voltage support 1.8 V. Initialization of this register (via a write access to this register) depends on the system capabilities. The host driver shall not modify this register after the initialization. This register is only reinitialized by a hard reset (via mmc_RESET signal). 0h (W) = 1.8 V not supported 0h (R) = 1.8 V not supported 1h (R) = 1.8 V supported 1h (W) = 1.8 V supported
25	VS30	R/W	0h	Voltage support 3.0V. Initialization of this register (via a write access to this register) depends on the system capabilities. The host driver shall not modify this register after the initialization. This register is only reinitialized by a hard reset (via mmc_RESET signal). 0h (W) = 3.0 V not supported 0h (R) = 3.0 V not supported 1h (R) = 3.0 V supported 1h (W) = 3.0 V supported

**Table 17-42. SD\_CAPA Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
24	VS33	R/W	0h	Voltage support 3.3V. Initialization of this register (via a write access to this register) depends on the system capabilities. The host driver shall not modify this register after the initialization. This register is only reinitialized by a hard reset (via mmc_RESET signal). 0h (W) = 3.3 V not supported 0h (R) = 3.3 V not supported 1h (R) = 3.3 V supported 1h (W) = 3.3 V supported
23	SRS	R	0h	Suspend/resume support (SDIO cards only). This bit indicates whether the host controller supports Suspend/Resume functionality. 0h (R/W) = The Host controller does not suspend/resume functionality. 1h (R/W) = The Host controller supports suspend/resume functionality.
22	DS	R	0h	DMA support. This bit indicates that the Host controller is able to use DMA to transfer data between system memory and the Host controller directly. 0h (R/W) = DMA not supported 1h (R/W) = DMA supported
21	HSS	R	0h	High-speed support. This bit indicates that the host controller supports high speed operations and can supply an up-to-52 MHz clock to the card. 0h (R/W) = DMA not supported 1h (R/W) = DMA supported
20	RESERVED	R	0h	
19	AD2S	R	0h	This bit indicates whether the Host Controller is capable of using ADMA2. It depends on setting of generic parameter MADMA_EN. 0h (R/W) = ADMA2 supported 1h (R/W) = ADMA2 not supported
18	RESERVED	R	0h	
17-16	MBL	R	0h	Maximum block length. This value indicates the maximum block size that the host driver can read and write to the buffer in the host controller. The host controller supports 512 bytes and 1024 bytes block transfers. 0h (R/W) = 512 bytes 1h (R/W) = 1024 bytes 2h (R/W) = 2048 bytes
15-14	RESERVED	R	0h	
13-8	BCF	R	0h	Base clock frequency for clock provided to the card. ARRAY(0x1bfe1b0)
7	TCU	R	0h	Timeout clock unit. This bit shows the unit of base clock frequency used to detect Data Timeout Error (SD_STAT[20] DTO bit). 0h (R/W) = kHz 1h (R/W) = MHz
6	RESERVED	R	0h	
5-0	TCF	R	0h	Timeout clock frequency. The timeout clock frequency is used to detect Data Timeout Error (SD_STAT[20] DTO bit). 0h (R/W) = The timeout clock frequency depends on the frequency of the clock provided to the card. The value of the timeout clock frequency is not available in this register.

### 17.5.1.24 SD\_CUR\_CAPA Register (offset = 248h) [reset = 0h]

SD\_CUR\_CAPA is shown in [Figure 17-60](#) and described in [Table 17-43](#).

This register indicates the maximum current capability for each voltage. The value is meaningful if the voltage support is set in the capabilities register (SD\_CAPA). Initialization of this register (via a write access to this register) depends on the system capabilities. The host driver shall not modify this register after the initialization. This register is only reinitialized by a hard reset (via mmc\_RESET signal).

### 17.5.1.25 SD\_FE Register (offset = 250h) [reset = 0h]

SD\_FE is shown in [Figure 17-61](#) and described in [Table 17-44](#).

The Force Event register is not a physically implemented register. Rather, it is an address at which the Error Interrupt Status register can be written. The effect of a write to this address will be reflected in the Error Interrupt Status Register, if corresponding bit of the Error Interrupt Status Enable Register is set.

### 17.5.1.26 SD\_ADMAES Register (offset = 254h) [reset = 0h]

SD\_ADMAES is shown in [Figure 17-62](#) and described in [Table 17-45](#).

When an ADMA Error Interrupt has occurred, the ADMA Error States field in this register holds the ADMA state and the ADMA System Address Register holds the address around the error descriptor. For recovering the error, the Host Driver requires the ADMA state to identify the error descriptor address as follows: ST\_STOP: Previous location set in the ADMA System Address register is the error descriptor address. ST\_FDS: Current location set in the ADMA System Address register is the error descriptor address. ST\_CADR: This state is never set because do not generate ADMA error in this state. ST\_TFR: Previous location set in the ADMA System Address register is the error descriptor address. In the case of a write operation, the Host Driver should use ACMD22 to get the number of written block rather than using this information, since unwritten data may exist in the Host Controller. The Host Controller generates the ADMA Error Interrupt when it detects invalid descriptor data (Valid = 0) at the ST\_FDS state. In this case, ADMA Error State indicates that an error occurs at ST\_FDS state. The Host Driver may find that the Valid bit is not set in the error descriptor.

**Figure 17-62. SD\_ADMAES Register**

1-0	AES	R/W	0h	ADMA Error State. This field indicates the state of ADMA when an error occurred during an ADMA data transfer. This field never indicates "10" because ADMA never stops in this state. 0h (R) = ST_STOP (Stop DMA). Contents of the SYS_SDR register 1h (W) = ST_STOP (Stop DMA). Points to the error descriptor. 2h (R) = Never set this state. (Not used) 3h (W) = ST_TFR (Transfer Data). Points to the 'next' of the error descriptor.

### 17.5.1.27 SD\_ADMA\_SAL Register (offset = 258h) [reset = 0h]

SD\_ADMA\_SAL is shown in [Figure 17-63](#) and described in [Table 17-46](#).

This register holds the byte address of the executing command of the Descriptor table. The 32-bit Address Descriptor uses the lower 32 bits of this register. At the start of ADMA, the Host Driver shall set the start address of the Descriptor table.

**Figure 17-63. SD\_ADMA\_SAL Register**

23-16	SREV	R	0h	Specification Version Number. This status indicates the Standard SD Host Controller Specification Version. The upper and lower 4-bits indicate the version. 0h (R/W) = SD Host Specification Version 1.0
15-1	RESERVED	R	0h	
0	SIS	R	0h	Slot Interrupt Status. This status bit indicates the inverted state of interrupt signal for the module. By a power on reset or by setting a software reset for all (SD_SYSCTL[24] SRA), the interrupt signal shall be deasserted and this status shall read 0. 0h = Interrupt signal deasserted. 1h = Interrupt signal asserted.

## ***Interprocessor Communication***

---

---

---

This chapter describes the interprocessor communication of the device.

<b>Topic</b>	<b>Page</b>
<b>18.1 Mailbox .....</b>	<b>2639</b>
<b>18.2 Spinlock .....</b>	<b>2708</b>

## 18.1 Mailbox

### 18.1.1 Introduction

#### 18.1.1.1 Features

Global features of the Mailbox module are:

- OCP slave interface (L4) supports:
  - 32-bit data bus width
  - 8/16/32 bit access supported
  - 9-bit address bus width
  - Burst not supported
- 8 mailbox sub-modules
- Each mailbox sub module allows 1-way communication between 2 initiators
- Flexible mailbox/initiators assignment scheme
- 4 messages per mailbox sub-module
- 32-bit message width
- Support of 16/32-bit addressing scheme
- Non-intrusive emulation
- 4 interrupts (one per user: 1 to MPU Subsystem, 2 to PRU-ICSS, and 1 to Wakeup Processor)

#### 18.1.1.2 Unsupported Features

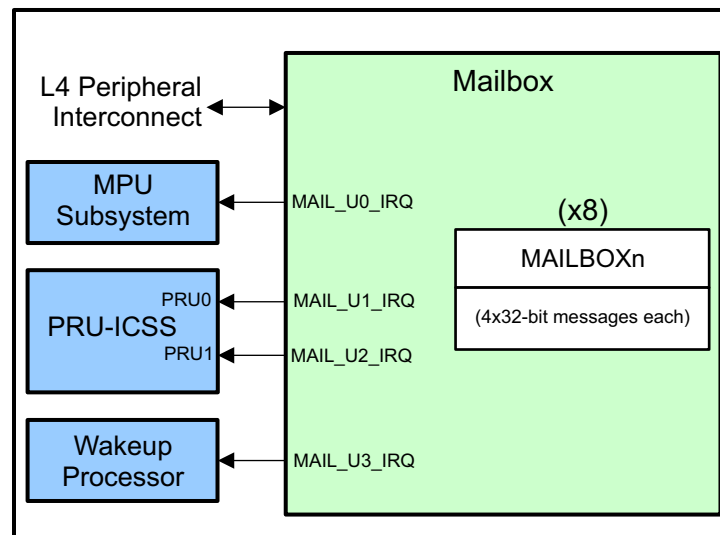

There are no unsupported features for Mailbox on this device.

## 18.1.2 Integration

This device contains a single instantiation of the Mailbox module at the system level. The mailbox function is made of eight sub-module mailboxes each supporting a 1-way communication between two initiators. The communication protocol from the sender to the receiver is implemented with mailbox registers using interrupts. The sender sends information to the receiver by writing to the mailbox. Interrupt signaling is used to notify the receiver a message has been queued or the sender for overflow situation.

The eight mailboxes are enough to handle communications between the MPU Subsystem, PRU-ICSS PRUs, and Wakeup Processor. Note that because the Wakeup Processor has access to only L4\_Wakeup peripherals it does not have access to the Mailbox registers. A mailbox interrupt can still be sent to the Wakeup Processor to trigger message notification. The actual message payload must be placed in either the internal memory of the Wakeup Processor or in the Control Module Interprocessor Message registers (IPC\_MSG\_REG{0-15}).

**Figure 18-1. Mailbox Integration**

### 18.1.2.1 Mailbox Connectivity Attributes

The general connectivity for the Mailbox is shown in [Table 18-1](#).

**Table 18-1. Mailbox Connectivity Attributes**

Attributes	Type
Power Domain	Peripheral Domain
Clock Domain	L4PER_L4LS_GCLK
Reset Signals	PER_DOM_RST_N
Idle/Wakeup Signals	Smart Idle
Interrupt Requests	4 Interrupts mail_u0 (MBINT0) – to MPU Subsystem mail_u1 – to PRU-ICSS (PRU0) mail_u2 – to PRU-ICSS (PRU1) mail_u3 – to Wakeup Processor
DMA Requests	None
Physical Address	L4 Peripheral slave port

### 18.1.2.2 Mailbox Clock and Reset Management

The mailbox function operates from the L4 interface clock.

**Table 18-2. Mailbox Clock Signals**

Clock Signal	Max Freq	Reference / Source	Comments
Functional / Interface clock	100 MHz	CORE_CLKOUTM4 / 2	pd_per_l4ls_gclk From PRCM

### 18.1.2.3 Mailbox Pin List

The Mailbox module does not include any external interface pins.

### 18.1.3 Functional Description

This device has the following mailbox instances:

- System mailbox

[Table 18-3](#) shows Mailbox Implementation in this device, where u is the user number and m is the mailbox number.

**Table 18-3. Mailbox Implementation**

Mailbox Type	User Number(u)	Mailbox Number(m)	Messages per Mailbox
System mailbox	0 to 3	0 to 7	4

The mailbox module provides a means of communication through message queues among the users (depending on the mailbox module instance). The individual mailbox modules (8 for the system mailbox instance), or FIFOs, can associate (or de-associate) with any of the processors using the MAILBOX\_IRQENABLE\_SET\_u (or MAILBOX\_IRQENABLE\_CLR\_u) register.

The system mailbox module includes the following user subsystems:

- User 0: MPU Subsystem (u = 0)
- User 1: PRU\_ICSS PRU0 (u = 1)
- User 2: PRU\_ICSS PRU1 (u = 2)
- User 3: Wakeup Processor (u = 3)

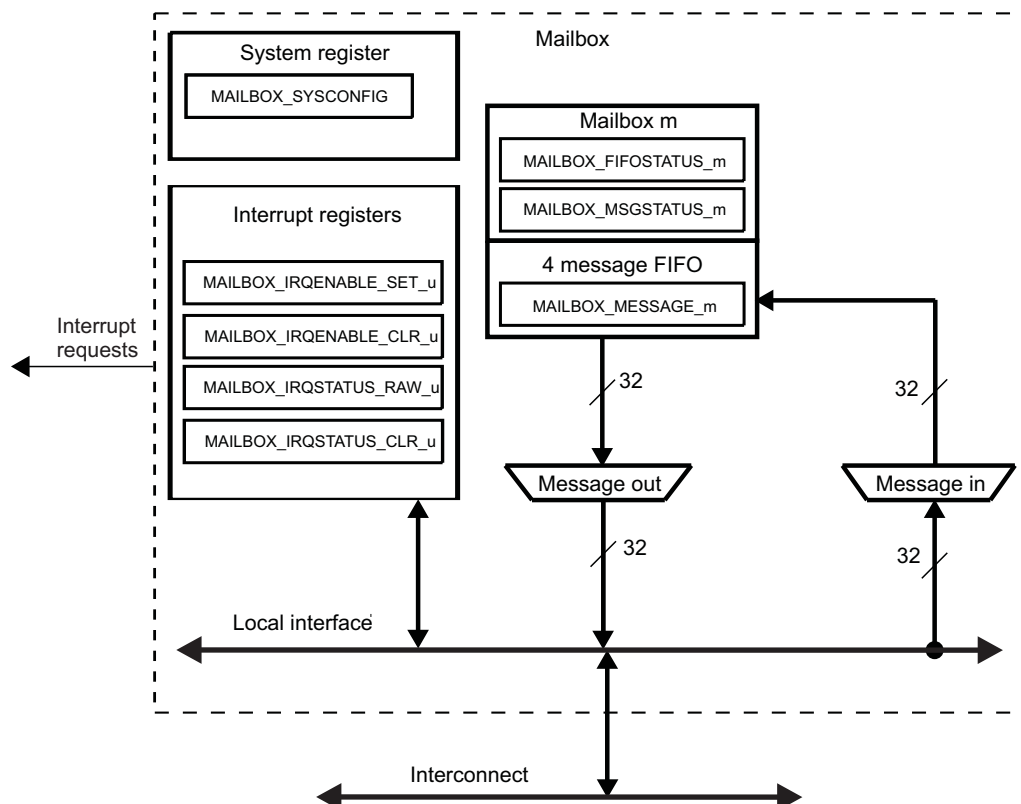

Each user has a dedicated interrupt signal from the corresponding mailbox module instance and dedicated interrupt enabling and status registers. Each MAILBOX\_IRQSTATUS\_RAW\_u/MAILBOX\_IRQSTATUS\_CLR\_u interrupt status register corresponds to a particular user.

For the system mailbox instance, a user can query its interrupt status register through the L4\_STANDARD interconnect.

### 18.1.3.1 Mailbox Block Diagram

Figure 18-2 shows the mailbox block diagram.

**Figure 18-2. Mailbox Block Diagram**

### 18.1.3.2 Software Reset

The mailbox module supports a software reset through the MAILBOX\_SYSCONFIG[0].SOFTRESET bit. Setting this bit to 1 enables an active software reset that is functionally equivalent to a hardware reset. Reading the MAILBOX\_SYSCONFIG[0] SOFTRESET bit gives the status of the software reset:

- Read 1: the software reset is on-going
- Read 0: the software reset is complete

The software must ensure that the software reset completes before doing mailbox operations.

### 18.1.3.3 Power Management

Table 18-4 describes power-management features available for the mailbox module.

**Table 18-4. Local Power Management Features**

Feature	Registers	Description
Clock autogating	NA	Feature not available
Slave idle modes	MAILBOX_SYSCONFIG[3:2].SIDLEMODE	Force-idle, no-idle and smart-idle modes are available
Clock activity	NA	Feature not available
Master standby modes	NA	Feature not available
Global wake-up enable	NA	Feature not available
Wake-up sources enable	NA	Feature not available

The mailbox module can be configured using the MAILBOX\_SYSCONFIG[3:2] SIDLEMODE bit field to one of the following acknowledgment modes:

- Force-idle mode (SIDLEMODE = 0x0): The mailbox module immediately enters the idle state on receiving a low-power-mode request from the PRCM module. In this mode, the software must ensure that there are no asserted output interrupts before requesting this mode to go into the idle state.
- No-idle mode (SIDLEMODE = 0x1): The mailbox module never enters the idle state.
- Smart-idle mode (SIDLEMODE = 0x2): After receiving a low-power-mode request from the PRCM module, the mailbox module enters the idle state only after all asserted output interrupts are acknowledged.

#### 18.1.3.4 Interrupt Requests

An interrupt request allows the user of the mailbox to be notified when a message is received or when the message queue is not full. There is one interrupt per user. [Table 18-5](#) lists the event flags, and their mask, that can cause module interrupts.

**Table 18-5. Interrupt Events**

Non-Maskable Event Flag <sup>(1)</sup>	Maskable Event Flag	Event Mask Bit	Event Unmask Bit	Description
MAILBOX_IRQSTATUS_RAW_u[0+m*2].NEWMMSGSTATUSUUMBm	MAILBOX_IRQSTATUS_CLR_u[0+m*2].NEWMMSGSTATUSUUMBm	MAILBOX_IRQENABLE_CLR_u[0+m*2].		
MAILBOX_IRQSTATUS_RAW_u[0+m*2].NEWMMSGSTATUSUUMBm	MAILBOX_IRQSTATUS_CLR_u[0+m*2].NEWMMSGSTATUSUUMBm	MAILBOX_IRQENABLE_CLR_u[0+m*2].NEWMMSGSTATUSUUMBm	MAILBOX_IRQENABLE_SET_u[0+m*2].NEWMMSGSTATUSUUMBm	Mailbox m receives a new message
MAILBOX_IRQSTATUS_RAW_u[1+m*2].NOTFULLSTATUSUMBm	MAILBOX_IRQSTATUS_CLR_u[1+m*2].NOTFULLSTATUSUMBm	MAILBOX_IRQENABLE_CLR_u[1+m*2].NOTFULLSTATUSUMBm	MAILBOX_IRQENABLE_SET_u[1+m*2].NOTFULLSTATUSUMBm	Mailbox m message queue is not full

<sup>(1)</sup> MAILBOX.MAILBOX\_IRQSTATUS\_RAW\_u register is mostly used for debug purposes.

#### CAUTION

Once an event generating the interrupt request has been processed by the software, it must be cleared by writing a logical 1 in the corresponding bit of the MAILBOX\_IRQSTATUS\_CLR\_u register. Writing a logical 1 in a bit of the MAILBOX\_IRQSTATUS\_CLR\_u register will also clear to 0 the corresponding bit in the appropriate MAILBOX\_IRQSTATUS\_RAW\_u register.

An event can generate an interrupt request when a logical 1 is written to the corresponding unmask bit in the MAILBOX\_IRQENABLE\_SET\_u register. Events are reported in the appropriate MAILBOX\_IRQSTATUS\_CLR\_u and MAILBOX\_IRQSTATUS\_RAW\_u registers.

An event stops generating interrupt requests when a logical 1 is written to the corresponding mask bit in the MAILBOX\_IRQENABLE\_CLR\_u register. Events are only reported in the appropriate MAILBOX\_IRQSTATUS\_RAW\_u register.

In case of the MAILBOX\_IRQSTATUS\_RAW\_u register, the event is reported in the corresponding bit even if the interrupt request generation is disabled for this event.

### 18.1.3.5 Assignment

#### 18.1.3.5.1 Description

To assign a receiver to a mailbox, set the new message interrupt enable bit corresponding to the desired mailbox in the MAILBOX\_IRQENABLE\_SET\_u register. The receiver reads the MAILBOX\_MESSAGE\_m register to retrieve a message from the mailbox.

An alternate method for the receiver that does not use the interrupts is to poll the MAILBOX\_FIFOSTATUS\_m and/or MAILBOX\_MSGSTATUS\_m registers to know when to send or retrieve a message to or from the mailbox. This method does not require assigning a receiver to a mailbox. Because this method does not include the explicit assignment of the mailbox, the software must avoid having multiple receivers use the same mailbox, which can result in incoherency.

To assign a sender to a mailbox, set the queue-not-full interrupt enable bit of the desired mailbox in the MAILBOX\_IRQENABLE\_SET\_u register, where u is the number of the sending user. However, direct allocation of a mailbox to a sender is not recommended because it can cause the sending processor to be constantly interrupted.

It is recommended that register polling be used to:

- Check the status of either the MAILBOX\_FIFOSTATUS\_m or MAILBOX\_MSGSTATUS\_m registers
- Write the message to the corresponding MAILBOX\_MESSAGE\_m register, if space is available

The sender might use the queue-not-full interrupt when the initial mailbox status check indicates the mailbox is full. In this case, the sender can enable the queue-not-full interrupt for its mailbox in the appropriate MAILBOX\_IRQENABLE\_SET\_u register. This allows the sender to be notified by interrupt only when a FIFO queue has at least one available entry.

Reading the MAILBOX\_IRQSTATUS\_CLR\_u register determines the status of the new message and the queue-not-full interrupts for a particular user. Writing 1 to the corresponding bit in the MAILBOX\_IRQSTATUS\_CLR\_u register acknowledges, and subsequently clears, an interrupt.

#### CAUTION

Assigning multiple senders or multiple receivers to the same mailbox is not recommended.

### 18.1.3.6 Sending and Receiving Messages

#### 18.1.3.6.1 Description

When a 32-bit message is written to the MAILBOX\_MESSAGE\_m register, the message is appended into the FIFO queue. This queue holds four messages. If the queue is full, the message is discarded. Queue overflow can be avoided by first reading the MAILBOX\_FIFOSTATUS\_m register to check that the mailbox message queue is not full before writing a new message to it. Reading the MAILBOX\_MESSAGE\_m register returns the message at the beginning of the FIFO queue and removes it from the queue. If the FIFO queue is empty when the MAILBOX\_MESSAGE\_m register is read, the value 0 is returned. The new message interrupt is asserted when at least one message is in the mailbox message FIFO queue. To determine the number of messages in the mailbox message FIFO queue, read the MAILBOX\_MSGSTATUS\_m register.

### 18.1.3.7 16-Bit Register Access

#### 18.1.3.7.1 Description

So that 16-bit processors can access the mailbox module, the module allows 16-bit register read and write access, with restrictions for the MAILBOX\_MESSAGE\_m registers. The 16-bit half-words are organized in little endian fashion; that is, the least-significant 16 bits are at the low address and the most-significant 16 bits are at the high address (low address + 0x02). All mailbox module registers can be read or written to directly using individual 16-bit accesses with no restriction on interleaving, except the MAILBOX\_MESSAGE\_m registers, which must always be accessed by either single 32-bit accesses or two consecutive 16-bit accesses.

#### CAUTION

When using 16-bit accesses to the MAILBOX\_MESSAGE\_m registers, the order of access must be the least-significant half-word first (low address) and the most-significant half-word last (high address). This requirement is because of the update operation by the message FIFO of the MAILBOX\_MSGSTATUS\_m registers. The update of the FIFO queue contents and the associated status registers and possible interrupt generation occurs only when the most-significant 16 bits of a MAILBOX\_MESSAGE\_m are accessed.

### 18.1.4 Programming Guide

#### 18.1.4.1 Low-level Programming Models

This section covers the low-level hardware programming sequences for configuration and usage of the mailbox module.

##### 18.1.4.1.1 Global Initialization

##### 18.1.4.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements of initializing the surrounding modules when the mailbox module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration of the mailbox.

See [Section 18.1.2](#) for further information.

**Table 18-6. Global Initialization of Surrounding Modules for System Mailbox**

Surrounding Modules	Comments
PRCM	Mailbox functional/interface clock must be enabled.
Interrupt Controllers	MPU interrupt controller must be configured to enable the interrupt request generation to the MPU.

### 18.1.4.1.1.2 Mailbox Global Initialization

#### 18.1.4.1.1.2.1 Main Sequence - Mailbox Global Initialization

This procedure initializes the mailbox module after a power-on or software reset.

**Table 18-7. Mailbox Global Initialization**

Step	Register/Bitfield/Programming Model	Value
Perform a software reset	MAILBOX_SYSCONFIG[0].SOFTRESET	1
Wait until reset is complete	MAILBOX_SYSCONFIG[0].SOFTRESET	0
Set idle mode configuration	MAILBOX_SYSCONFIG[3:2].SIDLEMODE	0x-

### 18.1.4.1.2 Operational Modes Configuration

#### 18.1.4.1.2.1 Main Sequence - Sending a Message (Polling Method)

**Table 18-8. Sending a Message (Polling Method)**

Step	Register/Bitfield/Programming Model	Value
IF : Is FIFO full ?	MAILBOX_FIFOSTATUS_m[0].FIFOFULL MB	=1h
Wait until at least one message slot is available	MAILBOX_FIFOSTATUS_m[0].FIFOFULL MB	=0h
ELSE		
Write message	MAILBOX_MESSAGE_m[31:0].MESSAGEVALUEMBM	----h
ENDIF		

#### 18.1.4.1.2.2 Main Sequence - Sending a Message (Interrupt Method)

**Table 18-9. Sending a Message (Interrupt Method)**

Step	Register/Bitfield/Programming Model	Value
IF : Is FIFO full ?	MAILBOX_FIFOSTATUS_m[0].FIFOFULL MB	=1h
Enable interrupt event	MAILBOX_IRQENABLE_SET_u[1+ m*2]	1h
User(processor) can perform another task until interrupt occurs		
ELSE		
Write message	MAILBOX_MESSAGE_m[31:0].MESSAGEVALUEMBM	----h
ENDIF		

### 18.1.4.1.2.3 Main Sequence - Receiving a Message (Polling Method)

**Table 18-10. Receiving a Message (Polling Method)**

Step	Register/Bitfield/Programming Model	Value
IF : Number of messages is not equal to 0	MAILBOX_MSGSTATUS_m[2:0].NBOFM SGMB	!=0h
Read message	MAILBOX_MESSAGE_m[31:0].MESSAG EVALUEMBM	----h
ENDIF		

### 18.1.4.1.2.4 Main Sequence - Receiving a Message (Interrupt Method)

**Table 18-11. Receiving a Message (Interrupt Method)**

Step	Register/Bitfield/Programming Model	Value
Enable interrupt event	MAILBOX_IRQENABLE_SET_u[0 + m*2]	1h
User(processor) can perform anothr task until interrupt occurs		

## 18.1.4.1.3 Events Servicing

### 18.1.4.1.3.1 Sending Mode

Table 18-12 describes the events servicing in sending mode.

**Table 18-12. Events Servicing in Sending Mode**

Step	Register/Bitfield/Programming Model	Value
Read interrupt status bit	MAILBOX_IRQSTATUS_CLR_u[1 + m*2]	1
Write message	MAILBOX_MESSAGE_m[31:0].MESSAG EVALUEMBM	----h
Write 1 to acknowledge interrupt	MAILBOX_IRQSTATUS_CLR_u[1 + m*2]	1

### 18.1.4.1.3.2 Receiving Mode

Table 18-13 describes the events servicing in receiving mode.

**Table 18-13. Events Servicing in Receiving Mode**

Step	Register/Bitfield/Programming Model	Value
Read interrupt status bit	MAILBOX_IRQSTATUS_CLR_u[0 + m*2]	1
IF : Number of messages is not equal to 0 ?	MAILBOX_MSGSTATUS_m[2:0].NBOFM SGMB	!=0h
Read message	MAILBOX_MESSAGE_m[31:0].MESSAG EVALUEMBM	----h
ELSE		
Write 1 to acknowledge interrupt	MAILBOX_IRQSTATUS_CLR_u[0 + m*2]	1
ENDIF		

## 18.1.5 MAILBOX Registers

Table 18-14 lists the memory-mapped registers for the MAILBOX. All register offset addresses not listed in Table 18-14 should be considered as reserved locations and the register contents should not be modified.

**Table 18-14. MAILBOX REGISTERS**

Offset	Acronym	Register Name	Section
0h	MLB_REVISION		<a href="#">Section 18.1.5.1</a>
10h	MLB_SYSCONFIG		<a href="#">Section 18.1.5.2</a>
40h	MLB_MESSAGE_0		<a href="#">Section 18.1.5.3</a>
44h	MLB_MESSAGE_1		<a href="#">Section 18.1.5.4</a>
