

# **AM437x ARM® Cortex™-A9 Processors**

## **Technical Reference Manual**

Literature Number: SPRUHL7A  
April 2014–Revised October 2014

<b>Preface</b>	<b>132</b>
<b>1 Introduction</b>	<b>133</b>
1.1 AM437x Family	133
1.1.1 Device Features	133
1.1.2 Device Identification	135
1.1.3 Feature Identification	135
<b>2 Memory Map</b>	<b>137</b>
2.1 ARM Cortex-A9 Memory Map	138
2.1.1 L3 Memory Map	138
2.1.2 L4_WKUP Memory Map	140
2.1.3 L4_PER Peripheral Memory Map	141
2.1.4 L4 Fast Peripheral Memory Map	147
<b>3 ARM MPU Subsystem</b>	<b>149</b>
3.1 Introduction	150
3.1.1 Features	151
3.2 Integration	153
3.2.1 Clocking, Reset and Power Management	153
3.3 Functional Description	158
3.3.1 Cortex-A9 MPCore	158
<b>4 Interconnects</b>	<b>164</b>
4.1 Introduction	165
4.1.1 Terminology	165
4.1.2 L3 Interconnect	165
4.1.3 L4 Interconnect	170
<b>5 Initialization</b>	<b>171</b>
5.1 Introduction	172
5.2 Functional Description	172
5.2.1 Architecture	172
5.2.2 Functionality	173
5.2.3 Memory Map	174
5.2.4 Start-up and Configuration	179
5.2.5 Booting	181
5.2.6 Memory Booting	191
5.2.7 Peripheral Booting	225
5.2.8 Low Latency NOR Booting	232
5.2.9 Image Format	234
5.2.10 Table of Contents	235
5.2.11 Services for HLOS Support – API	236
5.2.12 Tracing	239
<b>6 Power, Reset, and Clock Management (PRCM)</b>	<b>243</b>
6.1 Introduction	244
6.2 Device Power-Management Architecture Building Blocks	244
6.3 Clock Management	244
6.3.1 Module Interface and Functional Clocks	244

6.3.2	Module-Level Clock Management .....	245
6.3.3	Clock Domain .....	248
6.4	Power Management .....	250
6.4.1	Power Domain .....	250
6.4.2	Power Domain Management .....	251
6.4.3	Power Modes.....	253
6.4.4	Main Oscillator Control During DeepSleep .....	257
6.4.5	Wakeup Sources/Events.....	258
6.4.6	Functional Sequencing for Power Management with Wakeup Processor.....	258
6.4.7	I/O Power Management and Daisy Chaining .....	261
6.5	PRCM Module Overview .....	262
6.5.1	Interface Descriptions .....	263
6.6	Clock Generation and Management.....	264
6.6.1	Terminology .....	264
6.6.2	Clock Structure.....	264
6.6.3	ADPLLs .....	266
6.6.4	ADPLLJ (Low Jitter DPLL) .....	267
6.6.5	M2 and N2 Change On-the-Fly .....	269
6.6.6	Spread Spectrum Clocking (SSC) .....	269
6.6.7	Core PLL Description.....	270
6.6.8	Peripheral PLL Description .....	273
6.6.9	MPU PLL Description .....	275
6.6.10	Display PLL Description .....	276
6.6.11	DDR PLL Description .....	277
6.6.12	EXTDEV PLL Description .....	278
6.6.13	PLL Bypass Modes .....	279
6.6.14	CLKOUT Signals.....	279
6.6.15	32-kHz Clock Structure .....	281
6.6.16	ADC0, ADC1, DCAN, and McASP Clocking .....	283
6.7	Reset Management.....	284
6.7.1	Overview .....	284
6.7.2	Reset Concepts and Definitions .....	284
6.7.3	Global Power On Reset (Cold Reset).....	285
6.7.4	Global Warm Reset.....	287
6.7.5	Reset Characteristics.....	290
6.7.6	EMAC Switch Reset Isolation .....	292
6.7.7	Reset Priority .....	292
6.7.8	Trace Functionality Across Reset.....	292
6.7.9	RTC PORz.....	292
6.8	Power-Up/Down Sequence.....	292
6.9	IO State .....	293
6.10	Voltage and Power Domains .....	293
6.10.1	Voltage Domains.....	293
6.10.2	Power Domains .....	293
6.11	Device Modules and Power Management Attributes List .....	294
6.11.1	Power Domain Power Down Sequence .....	296
6.11.2	Power Domain Power-Up Sequence.....	296
6.12	Power Management Registers .....	297
6.12.1	PRCM_PRM_CEFUSE Registers .....	297
6.12.2	PRCM_PRM_DEVICE Registers .....	300
6.12.3	PRCM_PRM_GFX Registers.....	316
6.12.4	PRM_MPU Registers.....	321
6.12.5	PRCM_PRM_PER Registers.....	327

6.12.6	PRCM_PRM_RTC Registers .....	404
6.12.7	PRM_WKUP Registers .....	405
6.12.8	PRCM_PRM_IRQ Registers .....	419
6.13	Clock Module Registers .....	429
6.13.1	PRCM_CM_CEFUSE Registers .....	429
6.13.2	PRCM_CM_DEVICE Registers .....	432
6.13.3	PRCM_CM_DPLL Registers .....	437
6.13.4	PRCM_CM_GFX Registers .....	459
6.13.5	PRCM_CM_MPU Registers .....	461
6.13.6	CM_PER Registers .....	464
6.13.7	PRCM_CM_RTC Registers .....	547
6.13.8	CM_WKUP Registers .....	549
<b>7</b>	<b>Control Module .....</b>	<b>622</b>
7.1	Introduction .....	623
7.2	Functional Description .....	623
7.2.1	Pad Control Registers .....	623
7.2.2	EDMA Event Multiplexing .....	625
7.2.3	Device Control and Status .....	626
7.2.4	DDR IO Control Settings .....	633
7.3	Registers .....	634
7.3.1	CONTROL_MODULE Registers .....	634
<b>8</b>	<b>Interrupts .....</b>	<b>1102</b>
8.1	ARM Cortex-A9 Interrupts .....	1103
8.2	PWM Events .....	1107
<b>9</b>	<b>Memory Subsystem .....</b>	<b>1109</b>
9.1	GPMC .....	1110
9.1.1	Introduction .....	1110
9.1.2	Integration .....	1113
9.1.3	Functional Description .....	1115
9.1.4	GPMC High-Level Programming Model Overview .....	1193
9.1.5	Use Cases .....	1204
9.1.6	GPMC Registers .....	1215
9.2	OCMC-RAM .....	1317
9.2.1	Introduction .....	1317
9.2.2	Integration .....	1318
9.3	EMIF .....	1319
9.3.1	Introduction .....	1319
9.3.2	Integration .....	1320
9.3.3	EMIF Functional Description .....	1322
9.3.4	EMIF Registers .....	1342
9.4	ELM .....	1517
9.4.1	Introduction .....	1517
9.4.2	Integration .....	1518
9.4.3	Functional Description .....	1519
9.4.4	Basic Programming Model .....	1522
9.4.5	ELM Registers .....	1527
<b>10</b>	<b>Enhanced Direct Memory Access (EDMA) .....</b>	<b>1563</b>
10.1	Introduction .....	1564
10.1.1	EDMA3 Controller Block Diagram .....	1564
10.1.2	Third-Party Channel Controller (TPCC) Overview .....	1565
10.1.3	Third-Party Transfer Controller (TPTC) Overview .....	1566
10.2	Integration .....	1567

10.2.1	Third-Party Channel Controller (TPCC) Integration .....	1567
10.2.2	Third-Party Transfer Controller (TPTC) Integration .....	1568
10.3	Functional Description .....	1570
10.3.1	Functional Overview .....	1570
10.3.2	Types of EDMA3 Transfers .....	1573
10.3.3	Parameter RAM (PaRAM) .....	1575
10.3.4	Initiating a DMA Transfer.....	1587
10.3.5	Completion of a DMA Transfer .....	1590
10.3.6	Event, Channel, and PaRAM Mapping .....	1591
10.3.7	EDMA3 Channel Controller Regions .....	1593
10.3.8	Chaining EDMA3 Channels.....	1595
10.3.9	EDMA3 Interrupts .....	1596
10.3.10	Memory Protection .....	1602
10.3.11	Event Queues .....	1606
10.3.12	EDMA3 Transfer Controller (EDMA3TC) .....	1608
10.3.13	Event Dataflow .....	1611
10.3.14	EDMA3 Prioritization .....	1611
10.3.15	EDMA3 Operating Frequency (Clock Control).....	1612
10.3.16	Reset Considerations .....	1612
10.3.17	Power Management .....	1612
10.3.18	Emulation Considerations .....	1612
10.3.19	EDMA Transfer Examples .....	1614
10.3.20	EDMA Events .....	1630
10.4	Registers .....	1633
10.4.1	EDMA3CC Registers .....	1633
10.4.2	EDMA3TC Registers.....	1725
10.5	Appendix A .....	1778
10.5.1	Debug Checklist .....	1778
10.5.2	Miscellaneous Programming/Debug Tips .....	1779
10.5.3	Setting Up a Transfer .....	1781
<b>11</b>	<b>ADC0: Touchscreen Controller .....</b>	<b>1783</b>
11.1	Introduction.....	1784
11.1.1	TSC_ADC (ADC0) Features .....	1784
11.1.2	Unsupported TSC_ADC_SS (ADC0) Features .....	1784
11.2	Integration .....	1785
11.2.1	TSC_ADC (ADC0) Connectivity Attributes.....	1785
11.2.2	TSC_ADC (ADC0) Clock and Reset Management .....	1786
11.2.3	TSC_ADC (ADC0) Pin List.....	1786
11.3	Functional Description .....	1787
11.3.1	Hardware Synchronized or Software Enabled .....	1787
11.3.2	Open Delay and Sample Delay .....	1787
11.3.3	Averaging of Samples (1, 2, 4, 8, and 16) .....	1787
11.3.4	One-Shot (Single) or Continuous Mode .....	1787
11.3.5	Interrupts .....	1787
11.3.6	DMA Requests .....	1788
11.3.7	Analog Front End (AFE) Functional Block Diagram .....	1788
11.4	Operational Modes .....	1790
11.4.1	PenCtrl and PenIRQ .....	1791
11.5	ADC0 Registers .....	1794
11.5.1	ADC0 Registers .....	1794
<b>12</b>	<b>ADC1: Magnetic Card Reader .....</b>	<b>1829</b>
12.1	Introduction.....	1830
12.1.1	MagneticCard Reader Features.....	1830

12.1.2	Unsupported Features .....	1831
12.2	Integration .....	1832
12.2.1	MagneticCard Reader Connectivity Attributes.....	1832
12.2.2	MagneticCard Reader Clock and Reset Management .....	1833
12.2.3	MagneticCard Reader Pin List.....	1833
12.3	Functional Description .....	1834
12.3.1	FSM Sequencer Functional Description.....	1834
12.3.2	AFE Functional Description .....	1839
12.3.3	FIFOs and DMA .....	1843
12.3.4	Power Management .....	1843
12.3.5	Magnetic Card Operation (Use Cases).....	1844
12.3.6	Simultaneous Control of ADC0.....	1845
12.4	Registers .....	1846
12.4.1	ADC1 Registers .....	1846
<b>13</b>	<b>Display Subsystem (DSS) .....</b>	<b>1920</b>
13.1	Introduction.....	1921
13.1.1	DSS Features.....	1921
13.1.2	Unsupported Features.....	1922
13.2	Integration .....	1923
13.2.1	DSS Connectivity Attributes .....	1923
13.2.2	DSS Clock and Reset Management.....	1923
13.2.3	DSS Pin List .....	1924
13.3	Functional Description .....	1925
13.3.1	Block Diagram .....	1925
13.3.2	Display Subsystem Environment.....	1926
13.3.3	Display Controller Functionalities .....	1945
13.3.4	RFBI Functionalities .....	1968
13.3.5	Hardware Requests.....	1972
13.4	Programming Model .....	1974
13.4.1	Display Subsystem Reset.....	1974
13.4.2	Display Subsystem Configuration Phase .....	1974
13.4.3	Display Controller Basic Programming Model.....	1975
13.4.4	RFBI Basic Programming Model .....	1996
13.5	Use Cases.....	2005
13.5.1	How to Configure the Scaling Unit in the DISPC Module.....	2005
13.5.2	Display Low-Power Refresh Settings.....	2017
13.6	Registers .....	2021
13.6.1	DSS_DISPC Registers .....	2021
13.6.2	DSS_TOP Registers.....	2111
13.6.3	DSS_RFBI Registers .....	2118
<b>14</b>	<b>Camera (VPFE) .....</b>	<b>2140</b>
14.1	Introduction.....	2141
14.1.1	VPFE Features .....	2141
14.1.2	Unsupported Features.....	2141
14.2	Integration .....	2142
14.2.1	VPFE Connectivity Attributes .....	2142
14.2.2	VPFE Clock and Reset Management .....	2143
14.2.3	VPFE Pin List .....	2143
14.3	Functional Description .....	2144
14.3.1	External IO Interface.....	2144
14.3.2	VPFE Data / Image Processing .....	2150
14.4	Programming Model .....	2165
14.4.1	Enabling and Disabling the VPFE Controller .....	2165

14.4.2	Configuring VPFE Registers .....	2165
14.4.3	VPFE Limitations .....	2168
14.5	Registers .....	2168
14.5.1	VPFE Registers .....	2168
<b>15</b>	<b>Ethernet Subsystem .....</b>	<b>2204</b>
15.1	Introduction .....	2205
15.1.1	Features .....	2205
15.1.2	Unsupported Features .....	2206
15.2	Integration .....	2207
15.2.1	Ethernet Switch Connectivity Attributes .....	2208
15.2.2	Ethernet Switch Clock and Reset Management .....	2209
15.2.3	Ethernet Switch Pin List .....	2210
15.2.4	Ethernet Switch RMII Clocking Details .....	2210
15.2.5	GMII Interface Signal Connections and Descriptions .....	2211
15.2.6	RMII Signal Connections and Descriptions .....	2213
15.2.7	RGMII Signal Connections and Descriptions .....	2215
15.3	Functional Description .....	2217
15.3.1	CPSW_3G Subsystem .....	2217
15.3.2	CPSW_3G .....	2222
15.3.3	Ethernet Mac Sliver (CPGMAC_SL) .....	2264
15.3.4	Command IDLE .....	2266
15.3.5	RMII Interface .....	2266
15.3.6	RGMII Interface .....	2267
15.3.7	Common Platform Time Sync (CPTS) .....	2268
15.3.8	MDIO .....	2273
15.4	Software Operation .....	2276
15.4.1	Transmit Operation .....	2276
15.4.2	Receive Operation .....	2278
15.4.3	Initializing the MDIO Module .....	2279
15.4.4	Writing Data to a PHY Register .....	2279
15.4.5	Reading Data from a PHY Register .....	2280
15.4.6	Initialization and Configuration of CPSW .....	2280
15.5	Ethernet Subsystem Registers .....	2281
15.5.1	CPSW_ALE Registers .....	2281
15.5.2	CPSW_CPDMA Registers .....	2291
15.5.3	CPSW_CPTS Registers .....	2344
15.5.4	CPSW_STATS Registers .....	2360
15.5.5	CPDMA_STATRAM Registers .....	2360
15.5.6	CPSW_PORT Registers .....	2394
15.5.7	CPSW_SL Registers .....	2452
15.5.8	CPSW_SS Registers .....	2466
15.5.9	CPSW_WR Registers .....	2480
15.5.10	MDIO Registers .....	2516
<b>16</b>	<b>Universal Serial Bus (USB) .....</b>	<b>2533</b>
16.1	Introduction .....	2534
16.1.1	Features .....	2534
16.1.2	Unsupported Features .....	2534
16.2	Integration .....	2535
16.2.1	USB Clock and Reset Management .....	2536
16.2.2	USB Pin List .....	2536
16.3	Use Cases .....	2537
16.3.1	USB Operational Mode Determination .....	2537
16.3.2	Typical Pin Connections of AM437x Device .....	2538

16.3.3	VBUS Voltage Sourcing Control .....	2539
16.3.4	Pull-up/Pull-down Resistors .....	2539
16.3.5	Clock, PLL, and PHY Initialization .....	2539
16.4	Reference Documentation .....	2539
<b>17</b>	<b>Multimedia Card (MMC) .....</b>	<b>2540</b>
17.1	Introduction .....	2541
17.1.1	MMCSD Features .....	2541
17.1.2	Unsupported MMCSD Features .....	2541
17.2	Integration .....	2542
17.2.1	MMCSD Connectivity Attributes .....	2543
17.2.2	MMCSD Clock and Reset Management .....	2544
17.2.3	MMCSD Pin List .....	2544
17.3	Functional Description .....	2546
17.3.1	MMC/SD/SDIO Functional Modes .....	2546
17.3.2	Resets .....	2552
17.3.3	Power Management .....	2553
17.3.4	Interrupt Requests .....	2556
17.3.5	DMA Modes .....	2558
17.3.6	Mode Selection .....	2561
17.3.7	Buffer Management .....	2561
17.3.8	Transfer Process .....	2564
17.3.9	Transfer or Command Status and Error Reporting .....	2565
17.3.10	Auto Command 12 Timings .....	2570
17.3.11	Transfer Stop .....	2572
17.3.12	Output Signals Generation .....	2573
17.3.13	Card Boot Mode Management .....	2575
17.3.14	CE-ATA Command Completion Disable Management .....	2577
17.3.15	Test Registers .....	2577
17.3.16	MMC/SD/SDIO Hardware Status Features .....	2578
17.4	Low-Level Programming Models .....	2579
17.4.1	Surrounding Modules Global Initialization .....	2579
17.4.2	MMC/SD/SDIO Controller Initialization Flow .....	2579
17.4.3	Operational Modes Configuration .....	2582
17.5	MMC/SD Registers .....	2583
17.5.1	MMCSD Registers .....	2583
<b>18</b>	<b>Interprocessor Communication .....</b>	<b>2638</b>
18.1	Mailbox .....	2639
18.1.1	Introduction .....	2639
18.1.2	Integration .....	2640
18.1.3	Functional Description .....	2642
18.1.4	Programming Guide .....	2646
18.1.5	MAILBOX Registers .....	2649
18.2	Spinlock .....	2708
18.2.1	SPINLOCK Registers .....	2708
<b>19</b>	<b>Timers .....</b>	<b>2744</b>
19.1	DMTimer .....	2745
19.1.1	Introduction .....	2745
19.1.2	Integration .....	2747
19.1.3	Functional Description .....	2752
19.1.4	DMTIMER Registers .....	2763
19.2	DMTimer 1ms .....	2784
19.2.1	Introduction .....	2784
19.2.2	Integration .....	2786

19.2.3	Functional Description .....	2788
19.2.4	DMTIMER_1MS Registers .....	2796
19.3	Sync Timer (32k) .....	2820
19.3.1	Introduction.....	2820
19.3.2	Integration .....	2821
19.3.3	Functional Description .....	2822
19.3.4	SYNCTIMER Registers.....	2823
19.4	Real-Time Clock (RTC).....	2827
19.4.1	Introduction.....	2827
19.4.2	Integration .....	2828
19.4.3	Functional Description .....	2830
19.4.4	Use Cases .....	2838
19.4.5	RTC Registers .....	2838
19.5	WATCHDOG.....	2876
19.5.1	Introduction.....	2876
19.5.2	Integration .....	2877
19.5.3	Functional Description .....	2879
19.5.4	WDT Registers .....	2886
<b>20</b>	<b>Pulse-Width Modulation Subsystem (PWMSS).....</b>	<b>2903</b>
20.1	Pulse-Width Modulation Subsystem (PWMSS) .....	2904
20.1.1	Integration .....	2906
20.1.2	PWMSS Registers .....	2909
20.2	Enhanced PWM (ePWM) Module .....	2914
20.2.1	Introduction.....	2914
20.2.2	Functional Description .....	2918
20.2.3	Use Cases .....	2978
20.2.4	PWMSS_EPWM Registers .....	3002
20.3	Enhanced Capture (eCAP) Module .....	3038
20.3.1	Introduction.....	3038
20.3.2	Functional Description .....	3039
20.3.3	Use Cases .....	3048
20.4	Enhanced Quadrature Encoder Pulse (eQEP) Module .....	3080
20.4.1	Introduction.....	3080
20.4.2	Functional Description .....	3083
20.4.3	PWMSS_EQEP Registers .....	3101
<b>21</b>	<b>Universal Asynchronous Receiver/Transmitter (UART).....</b>	<b>3128</b>
21.1	Introduction .....	3129
21.1.1	UART Mode Features .....	3129
21.1.2	IrDA Mode Features .....	3129
21.1.3	CIR Mode Features .....	3129
21.1.4	Unsupported UART Features.....	3129
21.2	Integration .....	3131
21.2.1	UART Connectivity Attributes.....	3131
21.2.2	UART Clock and Reset Management .....	3132
21.2.3	UART Pin List.....	3134
21.3	Functional Description .....	3135
21.3.1	Block Diagram .....	3135
21.3.2	Clock Configuration .....	3136
21.3.3	Software Reset .....	3136
21.3.4	Power Management .....	3136
21.3.5	Interrupt Requests .....	3138
21.3.6	FIFO Management .....	3141
21.3.7	Mode Selection .....	3149

	21.3.8 Protocol Formatting .....	3155
21.4	UART/IrDA/CIR Basic Programming Model .....	3178
	21.4.1 UART Programming Model .....	3178
	21.4.2 IrDA Programming Model .....	3184
21.5	UART Registers .....	3187
	21.5.1 UART Registers .....	3187
<b>22</b>	<b>I2C .....</b>	<b>3243</b>
22.1	Introduction .....	3244
	22.1.1 I2C Features .....	3244
	22.1.2 Unsupported I2C Features .....	3244
22.2	Integration .....	3245
	22.2.1 I2C Connectivity Attributes .....	3245
	22.2.2 I2C Clock and Reset Management .....	3246

## List of Tables

1-1.	Device Identification Registers .....	135
2-1.	L3 Memory Map .....	138
2-2.	L4_WKUP Memory Map .....	140
2-3.	L4_PER Peripheral Memory Map .....	141
2-4.	L4 Fast Peripheral Memory Map .....	147
3-1.	Summary of Configuration Registers in WkUpGen Unit .....	154
3-2.	WFI/WFE Control Register Field Descriptions .....	155
3-3.	WkupGenEnb Registers Field Descriptions .....	157
3-4.	WATCHDOG REGISTERS .....	158
3-5.	GLOBAL TIMER REGISTERS .....	158
3-6.	PL310 REGISTERS .....	159
3-7.	DISTRIBUTOR REGISTERS .....	161
3-8.	INTC REGISTERS .....	162
3-9.	SCU REGISTERS .....	162
4-1.	L3 Master — Slave Connectivity .....	168
4-2.	MConnID Assignment .....	169
5-1.	Public ROM Exception Vectors .....	175
5-2.	Dead Loops .....	176
5-3.	Boot Error Counters .....	177
5-4.	RAM Exception Vectors .....	178
5-5.	RAM Exception Handlers Location .....	178
5-6.	Tracing Data .....	178
5-7.	Crystal Frequencies Supported .....	181
5-8.	ROM Code Default Clock Settings .....	181
5-9.	Bootting Parameters Structure .....	183
5-10.	SYSBOOT Configuration Pins .....	184
5-11.	NOR Timings Parameters .....	195
5-12.	Pins Used for NOR Boot Common Signals .....	195
5-13.	Pins Used for NOR Boot Wait Pin Selection .....	195
5-14.	Pins Used for non-Mux NOR Boot .....	195
5-15.	Pins Used for Mux NOR Boot .....	197
5-16.	SYSBOOT Signals for NOR Boot .....	197
5-17.	Parameters for NAND Timings .....	199
5-18.	ONFI Parameters Page Description .....	201
5-19.	Supported NAND Devices .....	201
5-20.	4th NAND ID Data Byte .....	202
5-21.	Pins Used for NAND I2C Boot for I2C EEPROM Access .....	203
5-22.	NAND Geometry Information on I2C EEPROM .....	203
5-23.	Pins Used for NAND Boot .....	207
5-24.	Pins Used for NAND Boot Wait Pin Selection .....	208
5-25.	SYSBOOT Signals for NAND Boot .....	208
5-26.	Master Boot Record Structure .....	212
5-27.	Partition Entry .....	213
5-28.	Partition Types .....	213
5-29.	FAT Boot Sector .....	215
5-30.	FAT Directory Entry .....	218
5-31.	FAT Entry Description .....	219

5-32.	Pins Used for MMC0 Boot.....	219
5-33.	Pins Used for MMC1 Boot.....	219
5-34.	Pins Used for SPI Boot .....	220
5-35.	Pins Used for QSPI Boot .....	221
5-36.	SYSBOOT Signals for QSPI Boot.....	222
5-37.	Pins Used for USB_MS Boot.....	223
5-38.	SYSBOOT Signals for USB_MS Boot .....	223
5-39.	Blocks and Sectors Searched on non-XIP Memories.....	223
5-40.	Pins Used for EMAC Boot in MII Mode .....	227
5-41.	Pins Used for EMAC Boot in RGMII Mode .....	227
5-42.	Pins Used for EMAC Boot in RMII Mode .....	228
5-43.	Ethernet PHY Mode Selection .....	228
5-44.	Ethernet Clock Selection.....	228
5-45.	Pins Used for UART Boot .....	229
5-46.	Customized Descriptor Parameters .....	230
5-47.	Pins Used for USB_CL Boot .....	232
5-48.	SYSBOOT Signals for USB_CL Boot.....	232
5-49.	SYSBOOT Signals for Low Latency NOR Boot .....	233
5-50.	GP Device Image Format.....	235
5-51.	The TOC Item Fields .....	235
5-52.	Magic Values for MMC RAW Mode .....	235
5-53.	Filenames in TOC for GP Device.....	235
5-54.	L2 Cache Set Debug Register .....	236
5-55.	L2 Cache Clean and Invalidate Range of Physical Address.....	236
5-56.	L2 Cache Set Control Register .....	236
5-57.	L2 Cache Set Auxiliary Control Register .....	236
5-58.	L2 Cache Set Latency Control Register .....	237
5-59.	L2 Cache Set Pre-fetch Control Register.....	237
5-60.	L2 Cache Set Address Filtering Register.....	237
5-61.	L2 Cache Clean Set Way.....	237
5-62.	L1 Cache Set Pre-fetch Enable .....	237
5-63.	SCTLR Round-Robin Enable.....	238
5-64.	CP15 Set ACTLR Register .....	238
5-65.	Tracing Vectors .....	239
6-1.	Master Module Standby-Mode Settings .....	245
6-2.	Master Module Standby Status .....	246
6-3.	Module Idle Mode Settings .....	246
6-4.	Idle States for a Slave Module .....	247
6-5.	Slave Module Mode Settings in PRCM .....	247
6-6.	Module Clock Enabling Condition .....	248
6-7.	Clock Domain Functional Clock States .....	249
6-8.	Clock Domain States .....	250
6-9.	Clock Transition Mode Settings.....	250
6-10.	States of a Memory Area in a Power Domain .....	251
6-11.	States of a Logic Area in a Power Domain.....	251
6-12.	Power Domain Control and Status Registers .....	251
6-13.	Typical Power Modes .....	253
6-14.	USB Wakeup Use Cases Supported in System Sleep States.....	257
6-15.	CMD_STAT Field .....	260

6-16.	CMD_ID Field .....	260
6-17.	Output Clocks in Locked Condition.....	267
6-18.	Output Clocks Before Lock and During Relock Modes .....	267
6-19.	Output Clocks in Locked Condition.....	269
6-20.	Output Clocks Before Lock and During Relock Modes .....	269
6-21.	PLL and Clock Frequencies.....	271
6-22.	Core PLL Typical Frequencies (MHz).....	272
6-23.	Bus Interface Clocks .....	273
6-24.	Per PLL Typical Frequencies (MHz) .....	274
6-25.	Latency and Power for PLL Bypass Modes .....	279
6-26.	Effects of Temperature Drift on Relock .....	279
6-27.	32-kHz Clock Summary .....	281
6-28.	Reset Sources.....	291
6-29.	Core Logic Voltage and Power Domains .....	293
6-30.	Power Domain State Table .....	293
6-31.	Power Domain of Various Modules .....	294

### About This Manual

This TRM has been designated *Preliminary* because the documentation is in the formative or design phase of development. Texas Instruments reserves the right to change this TRM without notice.

Revision History will not be provided for this TRM as long as it is in the *Preliminary* phase of development.

### Related Documentation From Texas Instruments

For a complete listing of related documentation and development-support tools, visit [www.ti.com](http://www.ti.com).

### Terms and Abbreviations

Terms and abbreviations will be added to a future version of this document.

For example: Woco - Woco is a read / write type access defined as "Write - One - Change - Only, and a bit with this access type can be modified, but only once for a POR cycle".

## ***Introduction***

---

---

---

### **1.1 AM437x Family**

#### **1.1.1 Device Features**

This architecture is configured with different sets of features in different devices. This technical reference manual (TRM) details all of the features available in current and future devices. Some features may not be available or supported in your particular device. The features supported across different devices are shown in [Figure 1-1](#). For more information on the different packages, refer to your device-specific data manual.

Y = Supported.

N = Not supported.

**Figure 1-1. Device Features**

### 1.1.2 Device Identification

Several registers help identify the type and available features of the device. [Table 1-1](#) summarizes these registers.

**Table 1-1. Device Identification Registers**

Bit	Field	Value	Description
31-28	DEVREV		Device revision 0001b - Silicon Revision 1.1 0010b - Silicon Revision 1.2 See device errata for detailed information on functionality in each device revision. Reset value is revision-dependent.
27-12	PARTNUM		Device part number (unique JTAG) 0xB98C
11-1	MFGR		Manufacturer's ID 0x017
0	ID_LSB		Reserved - always 1.

### 1.1.3 Feature Identification

The AM437x family has many different feature sets available. The DEV\_FEATURE register in the control module identifies which features are available in each device for the AM437x family. See [DEV\\_FEATURE Register Values](#) and the DEV\_FEATURE register in [Section 7.3.1](#) for more information on the bits in the DEV\_FEATURE register.

**DEV\_FEATURE Register Values**

Reserved	0x1_0000_0000	0x1_FFFF_FFFF	4096MB	

- (1) The first 1MB of address space 0x0-0xFFFFF is inaccessible externally.
- (2) Ex/R/W – Execute/Read/Write.
- (3) Address 0x402F\_0000-0x402F\_03FF is not available on general purpose (GP) devices.
- (4) For PRU-ICSS0/1, the PRU can access the other PRU-ICSS memory space through internal expansion ports. The PRU can access the neighbor PRU-ICSS memory starting at 256KB/0x0004\_0000 range. The address seen by the 2nd PRU-ICSS will get translated by hardware logic in PRU-ICSS, 0x0004\_0000 will get subtracted.

## ARM MPU Subsystem

---

---

---

This chapter describes the MPU Subsystem for the device.

Topic	Page
<b>3.1 Introduction .....</b>	<b>150</b>
<b>3.2 Integration .....</b>	<b>153</b>
<b>3.3 Functional Description .....</b>	<b>158</b>

### 3.1 Introduction

The microprocessor unit (MPU) subsystem of the device handles transactions between the ARM core (ARM Cortex-A9 Processor) and the L3 interconnect.

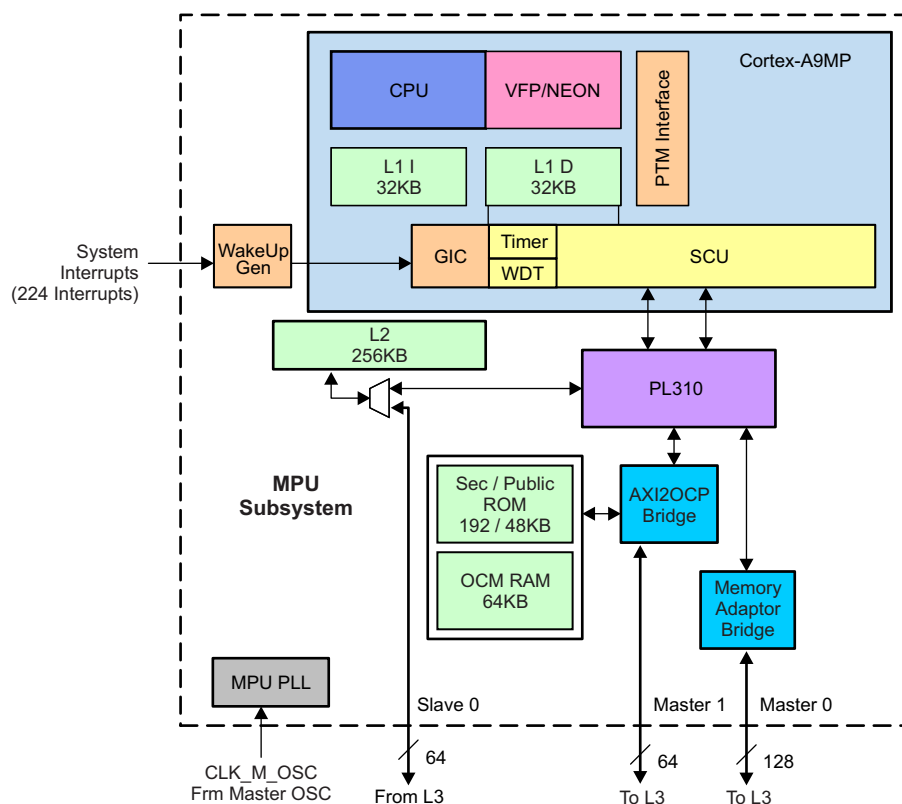

The Cortex-A9 is an ARMv7 compatible, 2-issue, in-order execution pipeline with integrated L1 and L2 caches with a NEON Single Instruction, Multiple Data (SIMD) Media Processing Unit.

The MPU subsystem includes CoreSight compliant logic to allow the debug subsystem access to the Cortex-A8 debug and emulation resources, including the Embedded Trace Macrocell.

The MPU subsystem includes 256KB of L2 cache. The L2 cache is controlled by a PL310. The CPU is configured to have 32KB of instruction cache and 32KB of data cache. The CPU includes a NEON and vector floating point (VFP) (FPU) coprocessors.

Figure 3-1 shows the MPU subsystem top-level block diagram and the power domain partitions.

**Figure 3-1. MPU Subsystem Block Diagram**

### 3.1.1 Features

This section outlines the key features of the MPU subsection:

- ARM Microprocessor
  - Cortex-A9 revision R2P10.
  - Symmetric Multi-Processor Architecture (Single CPU Configuration).
  - Superscalar, dynamic multi-issue technology with an efficient 8-stage pipeline.
  - Continuous fetch and decoding of two instructions per clock cycle.
  - Out-of-order (OoO) instruction dispatch and completion.
  - Integrated Cortex-A9 NEON Processing Engine (NPE) to enhance the capabilities of the FPU to include the ARM NEON Advanced SIMD support for accelerated media and signal processing computation.
  - VFPv3-D16 hardware to support single- and double-precision add, subtract, multiply, divide, multiply and accumulate and square root operations.
  - 32KB (L1) instruction and 32KB (L1) data cache with 32B line size and four-way set associative.
  - Memory Management Unit (MMU) with a two-level translation lookaside buffer (TLB) organization.
    - First level is a 32-entry, fully-associative micro-TLB implemented on each of the instruction and data sides.
    - Second level is a unified, two-way associative, 128-entry main TLB with support for a hardware TLB table walk.
  - Snoop Control Unit (SCU) ensures memory coherency in the system between CPU and other masters sharing cached data.
  - Integrated Timer and Watchdog Timer.
  - Integrated symmetric multiprocessing (SMP)-capable generic interrupt controller with 224 shared peripheral interrupts (SPI).
  - Two 64-bit AXI master ports to interface to the L2 controller.
    - Supports multiple outstanding transactions
    - Supports out-of-order data return
- L2 Cache Controller (PL310)
  - 256KB L2 Cache.
  - 16-way set associative.
  - 32B line size.
  - PL310 address filtering function used to split accesses between MA and AXI2OCP
  - Two slave ports
  - Two master ports.
  - Lockdown format C (way locking) for instruction and data.
  - Includes four 256-bit line fill buffers (LFB) shared by the master ports.
  - Each slave port includes two 256-bit line read buffers (LRB).
  - Includes four 256-bit store buffers with merge capability.
  - Support for 64-byte line fills issued to L3.
  - Support for using the 256KB L2 cache as SRAM. SRAM interface is memory mapped to chip level L3.

- Debug and Emulation
  - CPU debug requirements handled through chip-level debug subsystem.
  - Cross trigger interface (CTI) connects to a cross trigger matrix (CTM).
  - Includes a trigger interface to convert the TI trigger format to the ARM CTI format.
  - Program trace macrocell (PTM) to perform real-time instruction flow tracing based on program flow trace (PFT) architecture.
  - Generates trace only at certain points (waypoints) in program execution to reduce the amount of trace data generated.
  - Implemented in the emulation power domain (WKUP voltage domain).
  - A debug bridge connects the external debug OCP port to all the internal APB targets.
- AXI2OCP Bridge
  - Supports OCP 2.2.
  - Connected to PL310 slave port M1.
  - Single request, multiple data protocol on port.
  - Multiple targets, including two OCP ports (64-bit and 32-bit).
- Memory Adaptor
  - Connected to PL310 slave port M0.
  - Standard OCP 2.3 interface to chip-level L3 interconnect.
  - Full-speed interface to the PL310.

## 3.2 Integration

### 3.2.1 Clocking, Reset and Power Management

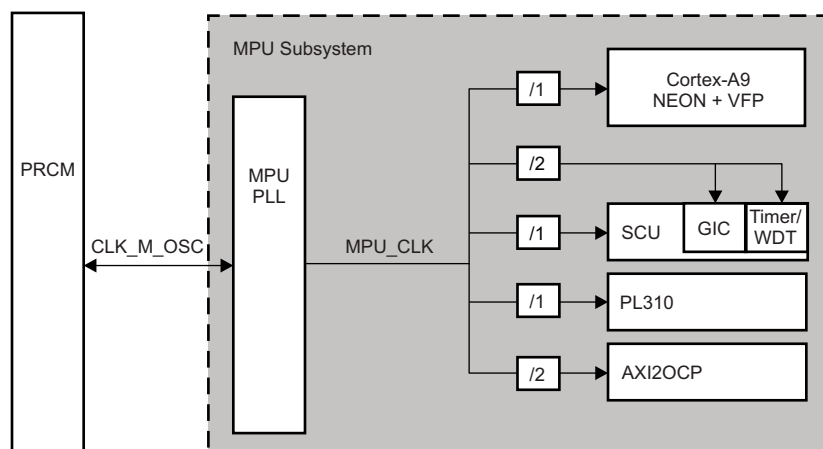

#### 3.2.1.1 Power Management

All power domains are controlled by the global PRCM. The power management supports for debug and emulation are also controlled by the global PRCM.

#### 3.2.1.2 Clocking Management

The MPU PLL generates the MPU clock for the MPU subsystem, as shown in [Figure 3-2](#).

**Figure 3-2. MPU Subsystem Clocking Scheme**

#### 3.2.1.3 WakeUpGen

The WakeUpGen unit is responsible for generating a wakeup event from the incoming interrupts and enable bits. The WakeUpGen is implemented in the MPU always-on power domain.

##### 3.2.1.3.1 WkUpGen Configuration Registers

The WkUpGen unit has configuration registers which can be accessed via an OCP interface. [Table 3-1](#) summarizes the configuration registers in the WkUpGen unit.

The reserved bits in the WkUpGen configuration registers have the following properties: A) return a 0 on read and B) no effect on write.

IRQ8 is disabled by default and cannot be used for wake up. All other interrupts are enabled after reset.

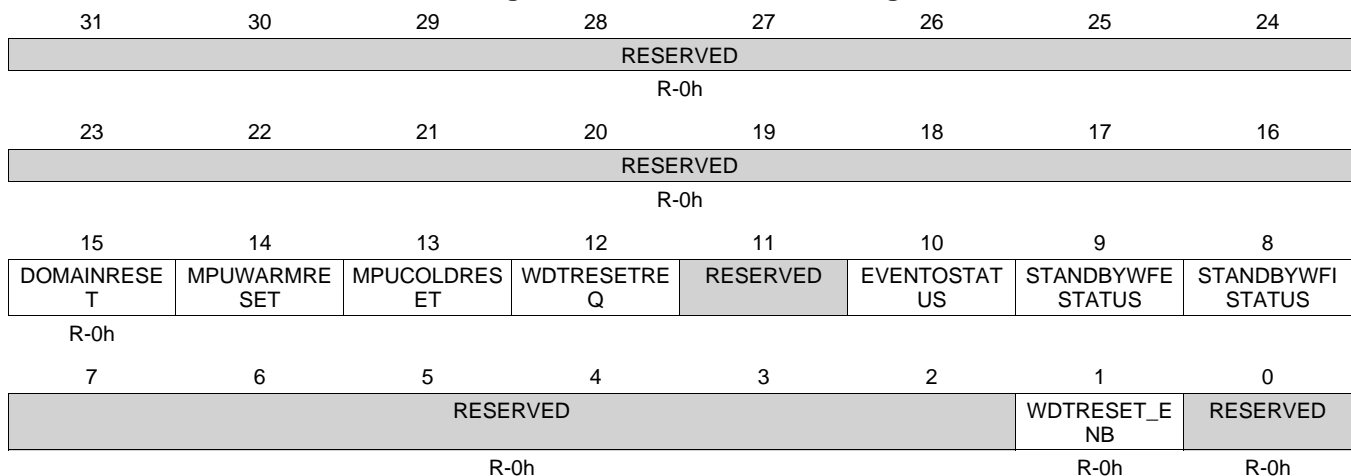

**Table 3-1. Summary of Configuration Registers in WkUpGen Unit**

Register	Description	RW <sup>(1)</sup>	Address Offset	Reset
Wkg_control_0	WakeUpGen Control and Status Register	P/S R, SW	0x000	0x0000_0000
WkUpGenEnb_0A	CPU0 WakeUp Enable for Interrupts 32 to 63	P/S RW	0x010	0xFFFF_FEFF
WkUpGenEnb_0B	CPU0 WakeUp Enable for Interrupts 64 to 95	P/S RW	0x014	0xFFFF_FFFF
WkUpGenEnb_0C	CPU0 WakeUp Enable for Interrupts 96 to 127	P/S RW	0x018	0xFFFF_FFFF
WkUpGenEnb_0D	CPU0 WakeUp Enable for Interrupts 128 to 159	P/S RW	0x01C	0xFFFF_FFFF
WkUpGenEnb_0E	CPU0 WakeUp Enable for Interrupts 160 to 191	P/S RW	0x020	0xFFFF_FFFF
WkUpGenEnb_0F	CPU0 WakeUp Enable for Interrupts 192 to 223	P/S RW	0x024	0xFFFF_FFFF
WkUpGenEnb_10	CPU0 WakeUp Enable for Interrupts 224 to 255	P/S RW	0x028	0xFFFF_FFFF
AuxCoreBoot0	Registers used by OS to boot of Aux Core	P/S RW	0x800	0x0000_0000
Reserved	Reserved	R	0x804	0x0000_0000
PTMsyncreq_mask	[31:8] used by syncreq generation logic. [7:0] are read-only and read as 0x0	P/S RW	0xC00	0x0000_0000
PTMsyncreq_en	[0] used by syncreq generation logic. [31:1] are read-only and read as 0x0	P/S RW	0xC04	0x0000_0000
TimestampCycleLo	[31:0] of the 48 bit free running counter. Reset by PIMPUAONRSTN	P/S R	0xC08	0x0000_0000
TimestampCycleHi	[47:32] of the 48 bit free running counter read as [15:0]. [31:16] are read as 0x0. Reset by PIMPUAONRSTN	P/S R	0xC0C	0x0000_0000

<sup>(1)</sup> P/S = Public/secure (privilege or user mode)  
R = Read-only

### 3.2.1.3.1.1 WFI/WFE Control\_0 and WFI/WFE Control\_1

Figure 3-3 shows the format of the WFI/WFE Control Register. Table 3-2 describes the WFI/WFE Control Register.

**Figure 3-3. WFI/WFE Control Register**

**Table 3-2. WFI/WFE Control Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	
15	DOMAINRESET	RO	0h	Set when the PIDOMAINRSTONLY is asserted (read only).
14	MPUWARMRESET	RWc	0h	Set when the PIMPU_RSTN signal is asserted. Cleared by a write.
13	MPUCOLDRESET	RWc	0h	Set when the PIMPU_PWRON_RSTN signal is asserted. Cleared by a write.
12	WDTRESETREQ		0h	Set when the WD timer reset request signal from the SCU is asserted.
11	RESERVED	R	0h	
10	EVENTOSTATUS	RWc	0h	Set when a rising edge of EVENTO from CPU is detected. Given only for visibility/debug purpose.
9	STANDBYWFESTATUS	RWc	0h	Set when a rising edge of StandbyWFE from CPU is detected. Given only for visibility/debug purpose.
8	STANDBYWFISTATUS	RWc	0h	Set when a rising edge of StandbyWFI from CPU is detected. Given only for visibility/debug purpose.
7-2	RESERVED	R	0h	
1	WDTRESET_ENB	RW	0h	Enable Watch Dog Timer Reset assertion. When set to 1'b1, it will enable POMPU_RESETREQ (mapped to PO_SPARE_B_0) to be asserted when the Watch Dog timer (in the SCU) of the corresponding CPU expires.
0	RESERVED	R	0h	

In the RW column, RWc means a register bit is readable and gets cleared by a write (any input data).

### 3.2.1.3.2 WkupGenEnb Registers

Figure 3-4 shows the format of the WkupGenEnb registers. Table 3-3 describes the WkupGenEnb registers.

Each register is 32-bit wide. The LSB is the enable bit for the lowest interrupt line in that group. For example, bit 0 of WakeUGenEnb\_0B is the enable bit for interrupt number 32. The enable bits are reset to 0 and can be set to 1 (by OCP configuration access) to enable the interrupt to wake up the CPU.

**Figure 3-4. WkupGenEnb Registers**

## 3.3 Functional Description

### 3.3.1 Cortex-A9 MPCore

#### 3.3.1.1 Timer and Watchdog Timer

The Cortex-A9 has its own timer and watchdog timer.

##### 3.3.1.1.1 Power Domain of Timer and Watchdog Timer

The timer and watchdog timer are in the system power and clock domain. When the system is in WFI or OFF state, the timer will stop running. Software must depend on the timer only when the system power domain is ON and the DPLL clock is not gated off. If a running timer is required when the system power domain is off, software must use the system timer at the top-level.

Conversely, since the watchdog timer is in the MPU system power domain, the watchdog timer will continue to run while the CPU alone is clock-gated (A9 core internal clock gated during WFI and subsystem (DPLL) clock is running). If the software depends on the watchdog timer to stop when the CPU is in this mode, the software must disable the watchdog timer before the CPU goes into low-power state.

##### 3.3.1.1.2 Watchdog Registers (Private Timer in ARM Documentation)

For register definitions, see the *ARM Cortex-A9 MPCore Technical Reference Manual* (available at [infocenter.arm.com/help/index.jsp](http://infocenter.arm.com/help/index.jsp)).

**Table 3-4. WATCHDOG REGISTERS**

Offset	Register Name
0x00	Private Timer Load
0x04	Private Timer Counter
0x08	Private Timer Control
0x0C	Private Timer Interrupt Status
0x20	Watchdog Load
0x24	Watchdog Counter
0x28	Watchdog Control
0x2C	Watchdog Interrupt Status
0x30	Watchdog Reset Status
0x34	Watchdog Disable

##### 3.3.1.1.3 Global Timer Registers

For register definitions, see the *ARM Cortex-A9 MPCore Technical Reference Manual* (available at [infocenter.arm.com/help/index.jsp](http://infocenter.arm.com/help/index.jsp)).

**Table 3-5. GLOBAL TIMER REGISTERS**

Offset	Register Name
0x00, 0x04	Global Timer Counter
0x08	Global Timer Control
0x0C	Global Timer Interrupt Status
0x10, 0x14	Comparator Value
0x18	Auto Increment

### 3.3.1.2 PL310 L2 Cache Controller

For the feature list of the PL310, see [Section 3.1.1](#).

The L2 cache controller on the MPU subsystem is the PL310. The L2 cache controller runs at the full CPU clock speed and is configured to have two slave ports and two master ports. All four ports are AXI interfaces with 64-bit data widths. All four ports run at full CPU speed.

The two master ports use load sharing to distribute the transactions. An address filtering mechanism is implemented but disabled by default. It can be enabled by software, if necessary.

The L2 cache size on the MPU subsystem is 256KB. The cache is configured as 16-way set associative, with a 32B line size. The L2 cache controller performs critical word first refilling with a pseudo-random cache replacement policy.

Parity checking is disabled on the L2 cache and parity bits are not implemented.

By default, the PL310 transforms all “shared” non-cacheable accesses to cacheable no-allocate for reads, or write-through no write-allocate for writes. This is the desired behavior for the MPU subsystem because the share bit must be set for coherent memory. The share attribute override feature (bit 22 of Auxiliary Control Register) must be disabled (that is, left in default state) in the PL310.

Cache lockdown by line and cache lockdown by master are implemented.

The PL310 includes logic to support cache event monitoring. All events that are monitored are routed to the HWDBG port.

The PL310 may be configured to generate interrupts on error conditions or event counter overflow and increment. The PL310 interrupt is routed to interrupt #0. When an interrupt occurs, software may look at register 2 (interrupt register) to determine the source of the interrupt.

#### 3.3.1.2.1 PL310 Registers

For register definitions, see the *CoreLink Level 2 Cache Controller L2C-310 Technical Reference Manual Revision: r3p2* (available at [infocenter.arm.com/help/index.jsp](http://infocenter.arm.com/help/index.jsp)).

**Table 3-6. PL310 REGISTERS**

Offset	Register Name
0x000 - 0x0FC	Cache ID and Cache Type
0x100 - 0x1FC	Control
0x200 - 0x2FC	Interrupts and Counter Control
0x300 - 0x6FC	Reserved
0x700 - 0x7FC	Cache Maintenance Operations
0x800 - 0x8FC	Reserved
0x900 - 0x9FC	Cache Lockdown
0xA00 - 0xBF0	Reserved
0xC00 - 0xCFC	Address Filtering
0xD00 - 0xEFC	Reserved
0xF00 - 0xFFC	Debug, Prefetch, and Power

#### 3.3.1.2.2 L2 as SRAM

The MPU subsystem supports usage of the 256KB L2 cache as general-purpose SRAM. The L2 cache comes up as disabled after reset. Software must ensure that the L2 cache is not enabled in this use case. Part usage of L2 as cache and part as SRAM is not supported.

L2 SRAM is memory mapped as a slave port on the chip-level interconnect. The MPU subsystem supports an OCMC64 module that converts the OCP accesses into SRAM accesses. The SRAM signals are muxed with the signals from PL310.

The input port PIUSEL2SRAM signal controls whether the PL310 path is used or the OCMC path. See the CTRL\_MPU\_L2 register.

The OCMC module is in the MPU voltage and power domain and is asynchronous to the chip-level L3 clock domain. The OCMC module can be clocked by MPU\_CLK/2, MPU\_CLK/3, MPU\_CLK/4, or MPU\_CLK/6. The input pin PIL2SRAMCLKDIV[1:0] determines the divide ratio.

- 00 - MPU\_CLK/2
- 01 - MPU\_CLK/3
- 10 - MPU\_CLK/4
- 11 - MPU\_CLK/6

**NOTE:** Always ensure that the OCMC (L2) is clocked at a frequency lower or equal to the chip-level L3 clock frequency by using the appropriate divide ratios. The ASYNC bridge on the OCMC path does not support response flow control, and if the above restriction is not posed, it could lead to a hang scenario because the OCMC can give responses faster than the rate at which the L3 can accept them.

In addition, changing the divide ratio (PIL2SRAMCLKDIV) or changing the L2 from cache to SRAM (PIUSEL2SRAM) dynamically is not permitted.

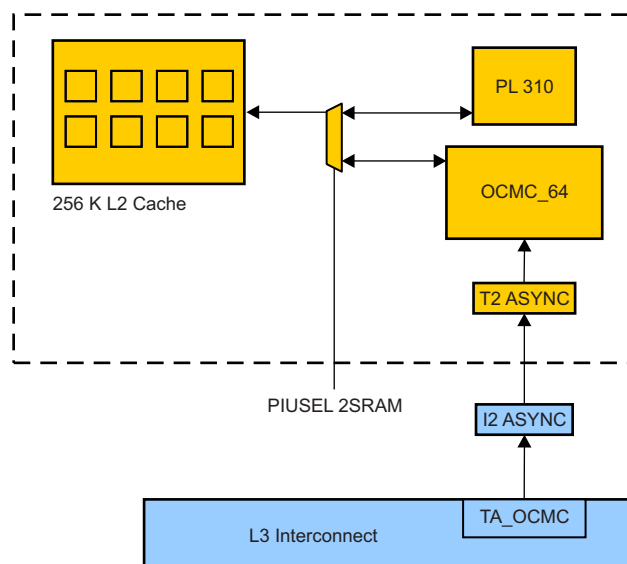

### 3.3.1.2.3 Power and Clock Gating Concerns

The MPU power domain must be ON while using the L2 as SRAM because the OCMC controller resides in the MPU power domain.

The MPU PLL cannot be clock-gated when OCMC is used for mapping L2 as SRAM because the OCMC controller receives the clock from the MPU PLL (see [Figure 3-5](#)). The MPU PLL supplies a clock to all of the MPU subsystem components, including the CPU. To achieve lower power in this use case, you must use CPU-level clock gating (inside the Cortex-A9).

For more details on CPU-level clock gating, see [Section 3.2, Integration](#).

**Figure 3-5. L2 Usage as SRAM**

### 3.3.1.3 Generalized Interrupt Controller (GIC)

For details about the GIC, see the *ARM Cortex-A9 MPCore Technical Reference Manual* (available at [infocenter.arm.com/help/index.jsp](http://infocenter.arm.com/help/index.jsp)). The Cortex-A9 GIC shares the same programmer's model as the GIC-PL390.

#### 3.3.1.3.1 Interrupts

The first 32 interrupts are mapped internally in the ARM MPU subsystem. For details on the available interrupts, see the *ARM Cortex-A9 MPCore Technical Reference Manual* (available at [infocenter.arm.com/help/index.jsp](http://infocenter.arm.com/help/index.jsp)).

There are also an additional 224 shared peripheral interrupts (SPI) which are external to the ARM MPU subsystem. For SPI interrupt definitions, see [Chapter 8, Interrupts](#).

#### 3.3.1.3.2 Distributor Registers

For register definitions, see the *ARM Cortex-A9 MPCore Technical Reference Manual* (available at [infocenter.arm.com/help/index.jsp](http://infocenter.arm.com/help/index.jsp)).

**Table 3-7. DISTRIBUTOR REGISTERS**

Offset	Register Name
0x000	Distributor Control
0x004	Interrupt Controller Type
0x008	SCU CPU Power Status
0x00C - 0x7C	Reserved
0x080 - 0x09C	Interrupt Security
0x100 - 0x11C	Interrupt Set-Enable
0x180 - 0x19C	Interrupt Clear-Enable
0x200 - 0x27C	Interrupt Set-Pending
0x280 - 0x29C	Interrupt Clear-Pending
0x300 - 0x31C	Active Bit
0x380 - 0x3FC	Reserved
0x400 - 0x4FC	Interrupt Processor Target
0xBFC	Reserved
0xC00 - 0xC3C	Interrupt Configuration
0xD00	PPI Status
0xD04 - 0xD1C	SPI Status
0xD80 - 0xEFC	Reserved
0xF00	Software Generated Interrupt

### 3.3.1.3.3 Interrupt Controller (INTC) Interface Registers

For register definitions, see the *ARM Cortex-A9 MPCore Technical Reference Manual* (available at [infocenter.arm.com/help/index.jsp](http://infocenter.arm.com/help/index.jsp)).

**Table 3-8. INTC REGISTERS**

Offset	Register Name
0x000	CPU Interface Control
0x004	Interrupt Priority Mask
0x008	Binary Point Register
0x00C	Interrupt Acknowledge
0x010	End of Interrupt
0x014	Running Priority
0x018	Highest Pending Interrupt
0x01C	Aliased Non-Secure Binary Point
0x0FC	CPU Interface Implementer ID

### 3.3.1.4 Snoop Control Unit (SCU)

The SCU connects the Cortex-A9 processor to the memory system through the AXI interfaces. The SCU functions is to initiate L2 AXI memory accesses.

**NOTE:** The Cortex SCU does not support hardware management of coherency of the instruction cache.

#### 3.3.1.4.1 SCU Registers

For register definitions, see the *ARM Cortex-A9 MPCore Technical Reference Manual* (available at [infocenter.arm.com/help/index.jsp](http://infocenter.arm.com/help/index.jsp)).

**Table 3-9. SCU REGISTERS**

Offset	Register Name
0x00	SCU Control
0x04	SCU Configuration
0x08	SCU CPU Power Status
0x0C	SCU Invalidate All Registers in Secure State
0x40	Filtering Start Address
0x44	Filtering End Address
0x50	SCU Access Control (SAC)
0x54	SCU Non-secure Access Control

### 3.3.1.5 AXI2OCP Interface

The AXI2OCP bridge is used to connect the AXI bus on the ARM A9 to the OCP native L3 interconnect (64-bit widths) and interrupt controller. The AXI2OCP bridge converts between AXI and OCP protocols and maintains a mapping of AXI tags to the OCP Tag ID.

### 3.3.1.6 Memory Adaptor

The memory adaptor bridge is used to connect the AXI bus on the ARM A9 to the OCP native L3 interconnect (128-bit width). The memory adaptor contains logic to minimize cache miss latency.

### 3.3.1.7 Configuration Options

This section provides the configurable design options for the Cortex-A9.

Feature	Selected Option
Cortex-A9 processors	One
Instruction Cache Size	32KB
Data Cache Size	32KB
TLB size	128-entry
VFP / NEON	Included
Jazelle DBX extension	Included
Program Trace Macrocell (PTM)	Included
Power off and Dormant Wrappers	Included
Support for Parity Error Detection	Not Included
Accelerator Coherency Port	Included
Shared Peripheral Interrupts	224

## Interconnects

This chapter describes the interconnects of the device.

Topic	Page
4.1 Introduction .....	165

## 4.1 Introduction

The system interconnect is based on a 2-level hierarchical architecture (L3, L4) driven by system performance. The L4 interconnect is based on a fully native OCP infrastructure, directly complying with the OCIP2.2 reference standard.

### 4.1.1 Terminology

The following is a brief explanation of some terms used in this document:

**Initiator:** Module able to initiate read and write requests to the chip interconnect (typically: processors, DMA, etc.).

**Target:** Unlike an initiator, a target module cannot generate read/write requests to the chip interconnect, but it can respond to these requests. However, it may generate interrupts or a DMA request to the system (typically: peripherals, memory controllers). **Note:** A module can have several separate ports; therefore, a module can be an initiator and a target.

**Agent:** Each connection of one module to one interconnect is done using an agent, which is an adaptation (sometimes configurable) between the module and the interconnect. A target module is connected by a target agent (TA), and an initiator module is connected by an initiator agent (IA).

**Interconnect:** The decoding, routing, and arbitration logic that enable the connection between multiple initiator modules and multiple target modules connected on it.

**Register Target (RT):** Special TA used to access the interconnect internal configuration registers.

**Data-flow Signal:** Any signal that is part of a clearly identified transfer or data flow (typically: command, address, byte enables, etc.). Signal behavior is defined by the protocol semantics.

**Sideband Signal:** Any signal whose behavior is not associated to a precise transaction or data flow.

**Command Slot:** A command slot is a subset of the command list. It is the memory buffer for a single command. A total of 32 command slots exist.

**Out-of-band Error:** Any signal whose behavior is associated to a device error-reporting scheme, as opposed to in-band errors. Note: Interrupt requests and DMA requests are not routed by the interconnect in the device.

**ConnID:** Any transaction in the system interconnect is tagged by an in-band qualifier ConnID, which uniquely identifies the initiator at a given interconnect point. A ConnID is transmitted in band with the request and is used for error-logging mechanism.

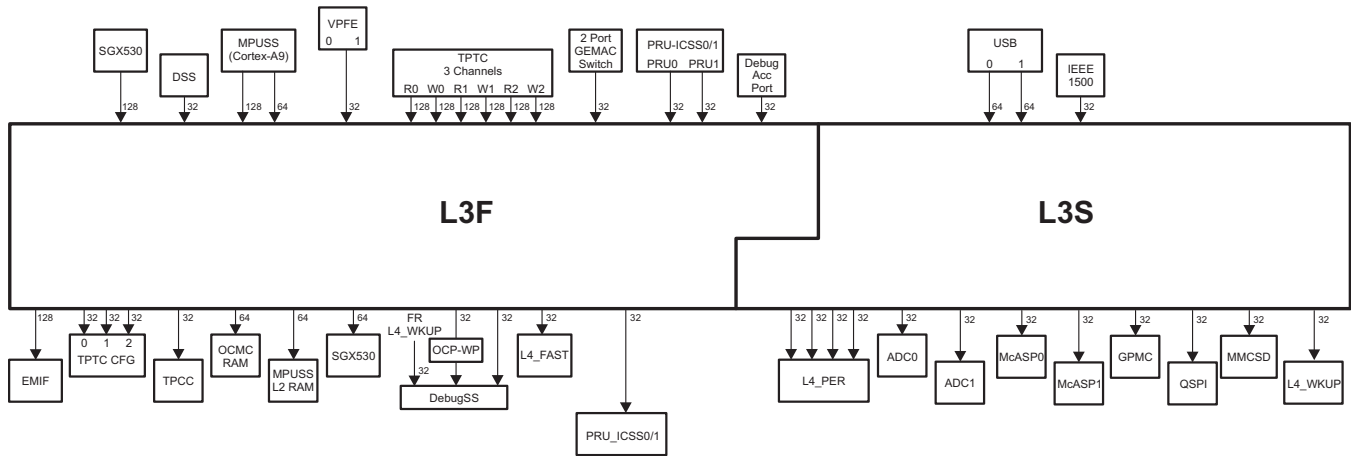

### 4.1.2 L3 Interconnect

The L3 high-performance interconnect is based on a Network-On-Chip (NoC) interconnect infrastructure. The NoC uses an internal packet-based protocol for forward (read command, write command with data payload) and backward (read response with data payload, write response) transactions. All exposed interfaces of this NoC interconnect, both for Targets and Initiators; comply with the OCIP2.2 reference standard.

#### 4.1.2.1 L3 Topology

The L3 topology is driven by performance requirements, bus types, and clocking structure. The main L3 paths are shown in [Figure 4-1](#). Arrows indicate the master/slave relationship not data flow. L3 is partitioned into two separate clock domains: L3F corresponds to L3 Fast clock domain and L3S corresponds to L3 Slow clock domain.

**Figure 4-1. L3 Topology**

#### 4.1.2.2 L3 Port Mapping

Each initiator and target core is connected to the L3 interconnect through a Network Interface Unit (NIU). The NIUs act as entry and exit points to the L3 Network-on-Chip (NoC) – converting between the IP's OCP protocol and the NoC's internal protocol, and also include various programming registers. All ports are single threaded with tags used to enable pipelined transactions. The interconnect includes:

##### Initiator Ports:

- L3F
  - Cortex A9 MPUSS 128-bit initiator port0 and 64-bit initiator port1
  - SGX530 128-bit initiator port
  - 3 EDMA3TC (TPTC) 128-bit read initiator ports
  - 3 EDMA3TC (TPTC) 128-bit write initiator ports
  - 2 PRU-ICSS0/1 32-bit initiator ports
  - 2 port Gigabit Ethernet Switch (CPGSW) 32-bit initiator port
  - Debug Subsystem 32-bit initiator port
  - VPFE0 32-bit initiator port
  - VPFE1 32-bit initiator port
  - DSS 32-bit initiator port
- L3S
  - 2 USB 64-bit initiator ports
  - P1500 32-bit initiator port

##### Target Ports:

- L3F
  - EMIF 128-bit target port
  - 3 EDMA3TC (TPTC) CFG 32-bit target ports
  - EDMA3CC (TPCC) CFG 32-bit target port
  - OCMC RAM0 64-bit target port
  - DebugSS 32-bit target port
  - SGX530 64-bit target port
  - L4\_FAST 32-bit target port
  - PRU-ICSS0/1 32-bit target port
  - MPUSS L2 RAM

- L3S
  - 4 L4\_PER peripheral 32-bit target ports
  - GPMC 32-bit target port
  - McASP0 32-bit target port
  - McASP1 32-bit target port
  - QSPI 32-bit target port
  - ADC0 32-bit target port
  - MMCSD 32-bit target port
  - L4\_WKUP wakeup 32-bit target port
  - ADC1 FIFO 32-bit target port

#### 4.1.2.3 Interconnect Connections

The L3 connections between bus masters and slave ports are shown in [Table 4-1](#). The L3 interconnect will return an address-hole error if any initiator attempts to access a target to which it has no connection.

**Table 4-1. L3 Master — Slave Connectivity**

Masters	Slaves																				
	EMIF	OCMC-RAM	MPUSS L2 RAM	TPTC0-2 CFG	TPCC	SGX530	L4_Fast	L4_PER Port0	L4_PER Port1	L4_PER Port2	L4_PER Port3	McASP0-1	GPMC	ADC0 FIFO / DMA	MMCS2 / DMA FIFO	L4_WKUP	DebugSS	NOC Regs	ADC1 FIFO / DMA	QSPI	PRU-ICSS1
MPUSS M1 (128-bit)	X																				
MPUSS M2 (64-bit)	X	X	X	X	X	X	X	X				X	X	X	X	X	X	X	X	X	X
TPTC0 RD	X	X	X		X		X			X		X	X	X	X	X			X	X	X
TPTC0 WR	X	X	X		X		X			X		X	X	X	X	X	X		X	X	X
TPTC1 RD	X	X	X		X		X			X		X	X	X	X	X			X	X	X
TPTC1 WR	X	X	X		X		X			X		X	X	X	X	X	X		X	X	X
TPTC2 RD	X	X	X		X		X				X	X	X	X	X	X			X	X	X
TPTC2 WR	X	X	X		X		X				X	X	X	X	X	X	X		X	X	X
PRU-ICSS (PRU0)	X	X	X	X	X		X		X			X	X	X	X	X	X	X	X	X	X
PRU-ICSS (PRU1)	X	X	X	X	X		X		X			X	X	X	X	X	X	X	X	X	X
GEMAC	X	X	X										X							X	
SGX530	X	X											X								
USB0	X	X	X										X								
USB1	X	X	X										X							X	
EMU (DAP)	X	X	X	X	X	X	X				X	X	X	X	X	X	X	X	X	X	X
IEEE1500	X	X	X	X	X	X	X				X	X	X	X	X	X	X	X	X	X	X
DSS	X	X	X										X								
VPFE0	X	X	X										X								
VPFE1	X	X	X										X								

#### 4.1.2.4 ConnID Assignment

Each L3 initiator includes a unique 6-bit master connection identifier (MConnID) that is used to identify the source of a transfer request.

**Table 4-2. MConnID Assignment**

Initiator	6-bit MConnID (Debug)	Instrumentation	Comment
MPUSS M1 (128-bit)	0x00	0	Connects only to EMIF
MPUSS M2 (64-bit)	0x01	SW	
DAP	0x04	SW	
P1500	0x05	SW	
PRU-ICSS0/1 (PRU0)	0x0C	SW	
PRU-ICSS0/1 (PRU1)	0x0D	SW	
Wakeup Processor	0x14	SW	Connects only to L4_WKUP
TPTC0 Read	0x18	0	
TPTC0 Write	0x19	SW	One WR port for data logging
TPTC1 Read	0x1A	0	
TPTC1 Write	0x1B	0	
TPTC2 Read	0x1C	0	
TPTC2 Write	0x1D	0	
SGX530	0x20	0	
OCP WP Traffic Probe	0x21 <sup>(1)</sup>	HW	Direct connect to DebugSS
OCP WP DMA Profiling	0x22 <sup>(1)</sup>	HW	Direct connect to DebugSS
OCP-WP Event Trace	0x23 <sup>(1)</sup>	HW	Direct connect to DebugSS
DSS	0x25	0	
VPFE0	0x2C	0	
VPFE1	0x2D	0	
GEMAC	0x30	0	
USB0_RD	0x34	0	
USB0_WR	0x35	0	
USB1_RD	0x36	0	
USB1_WR	0x37	0	
Stat Collector 0	0x3C	HW	
Stat Collector 1	0x3D	HW	
Stat Collector 2	0x3E	HW	
Stat Collector 3	0x3F	HW	

<sup>(1)</sup> These MConnIDs are generated within the OCP-WP module based on the H0, H1, and H2 configuration parameters.

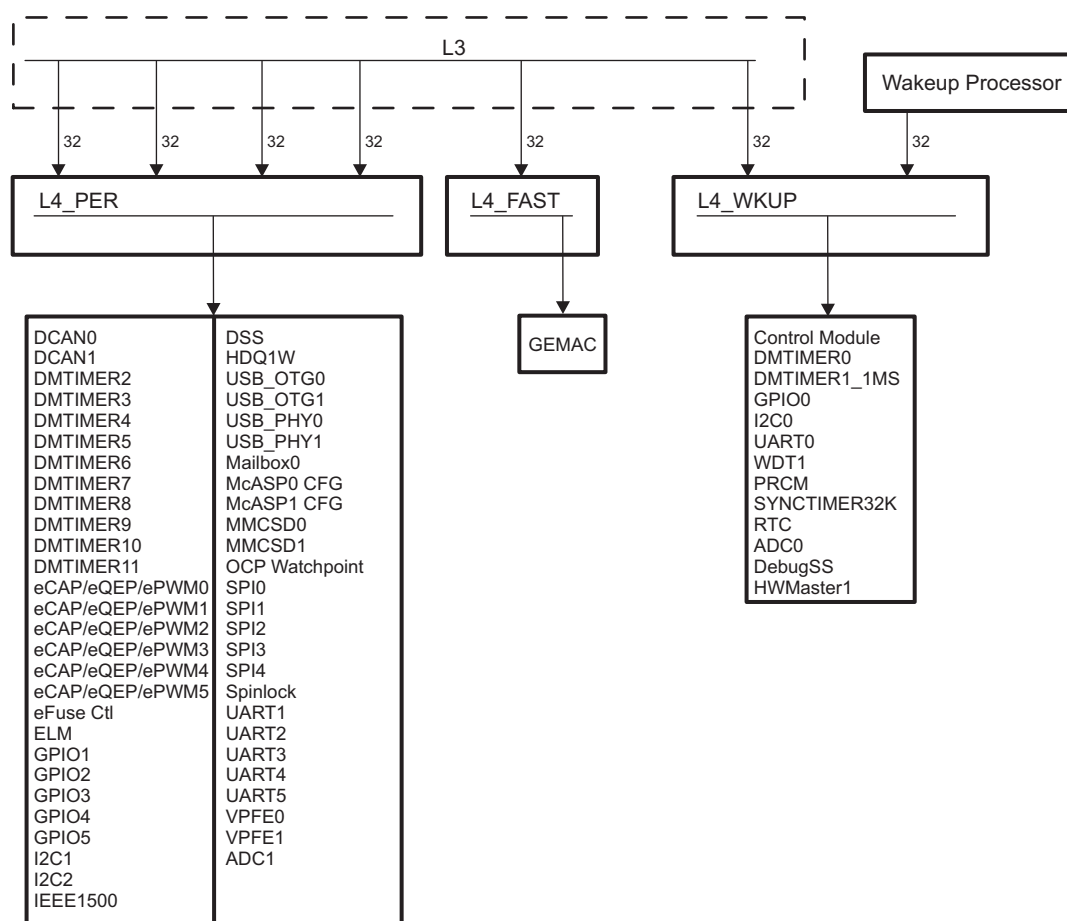

**NOTE:** Instrumentation refers to debug type. SW instrumentation means that the master can write data to be logged to the STM (similar to a printf()). HW indicates debug data captured automatically by hardware. A '0' entry indicates no debug capability.

### 4.1.3 L4 Interconnect

The L4 interconnect is a non-blocking peripheral interconnect that provides low latency access to a large number of low bandwidth, physically dispersed target cores. Each L4 can handle incoming traffic from up to four initiators and can distribute those communication requests to and collect related responses from up to 63 targets.

This device provides three interfaces with L3 interconnect for High Speed Peripheral, Standard Peripheral, and Wakeup Peripherals. [Figure 4-2](#) shows the L4 bus architecture and memory-mapped peripherals.

**Figure 4-2. L4 Topology**

## Initialization

This chapter describes the initialization of the device.

Topic	Page
5.1 Introduction .....	172
5.2 Functional Description .....	172

## 5.1 Introduction

This section describes the booting functionality of the device, referred hereafter as ROM Code. The booting functionality covers the following features:

- **Memory Booting:** booting the device by executing firmware stored on permanent memories like flash-memory or memory cards. This process usually occurs after a cold or warm reset of the device.
- **Peripheral Booting:** booting the device by downloading the executable code over a communication interface such as UART, USB, or Ethernet. This process is can also be used to flash a device.

The device always starts in secure mode. The Secure ROM Code handles early initialization. The Secure ROM code switches the device into public mode. Hence the Public ROM Code provides run-time services for cache maintenance.

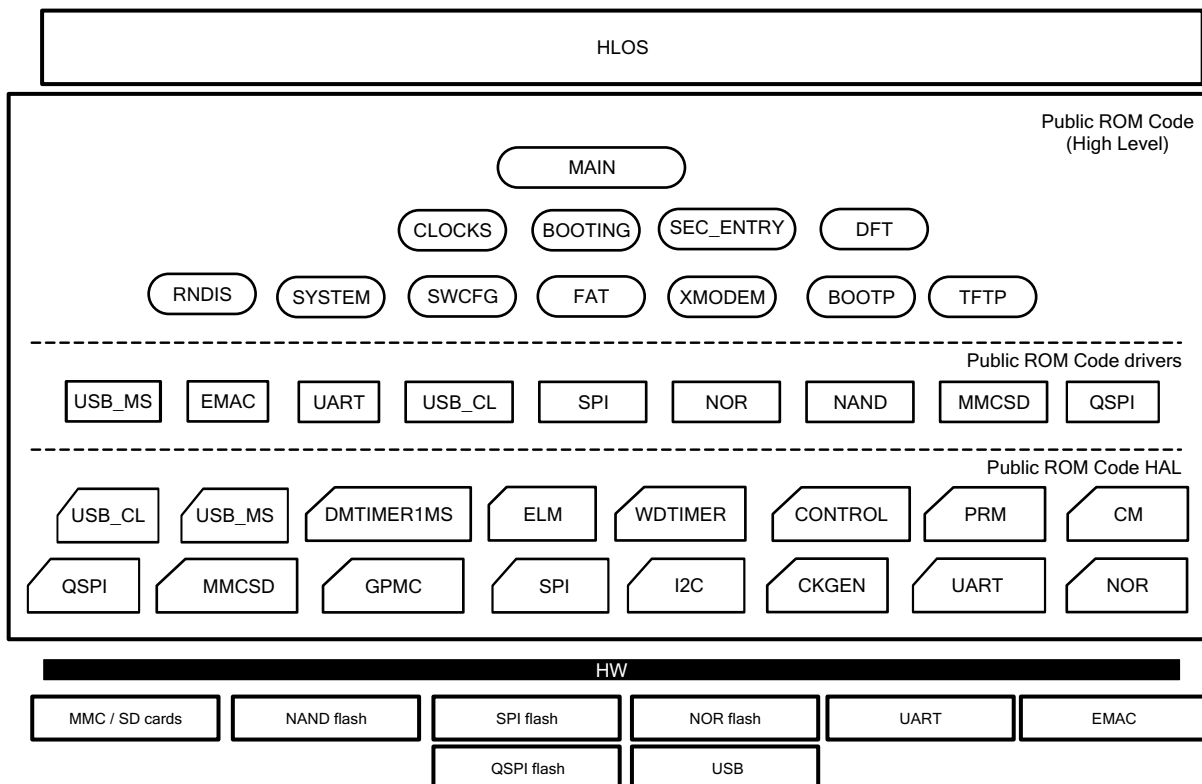

## 5.2 Functional Description

### 5.2.1 Architecture

**Figure 5-1** shows the architecture of the Public ROM Code. It is split into three main layers with a top-down approach: high-level, drivers, and hardware abstraction layer (HAL). One layer communicates with a lower level layer through a unified interface.

- The high-level layer implements the main tasks of the Public ROM Code: watchdog and clocks configuration and main booting routine.
- The driver layer implements the logical and communication protocols for any booting device in accordance with the interface specification.
- The HAL implements the lowest level code for interacting with the hardware infrastructure IPs. End booting devices attach to device IO pads.

**Figure 5-1. Public ROM Code Architecture**

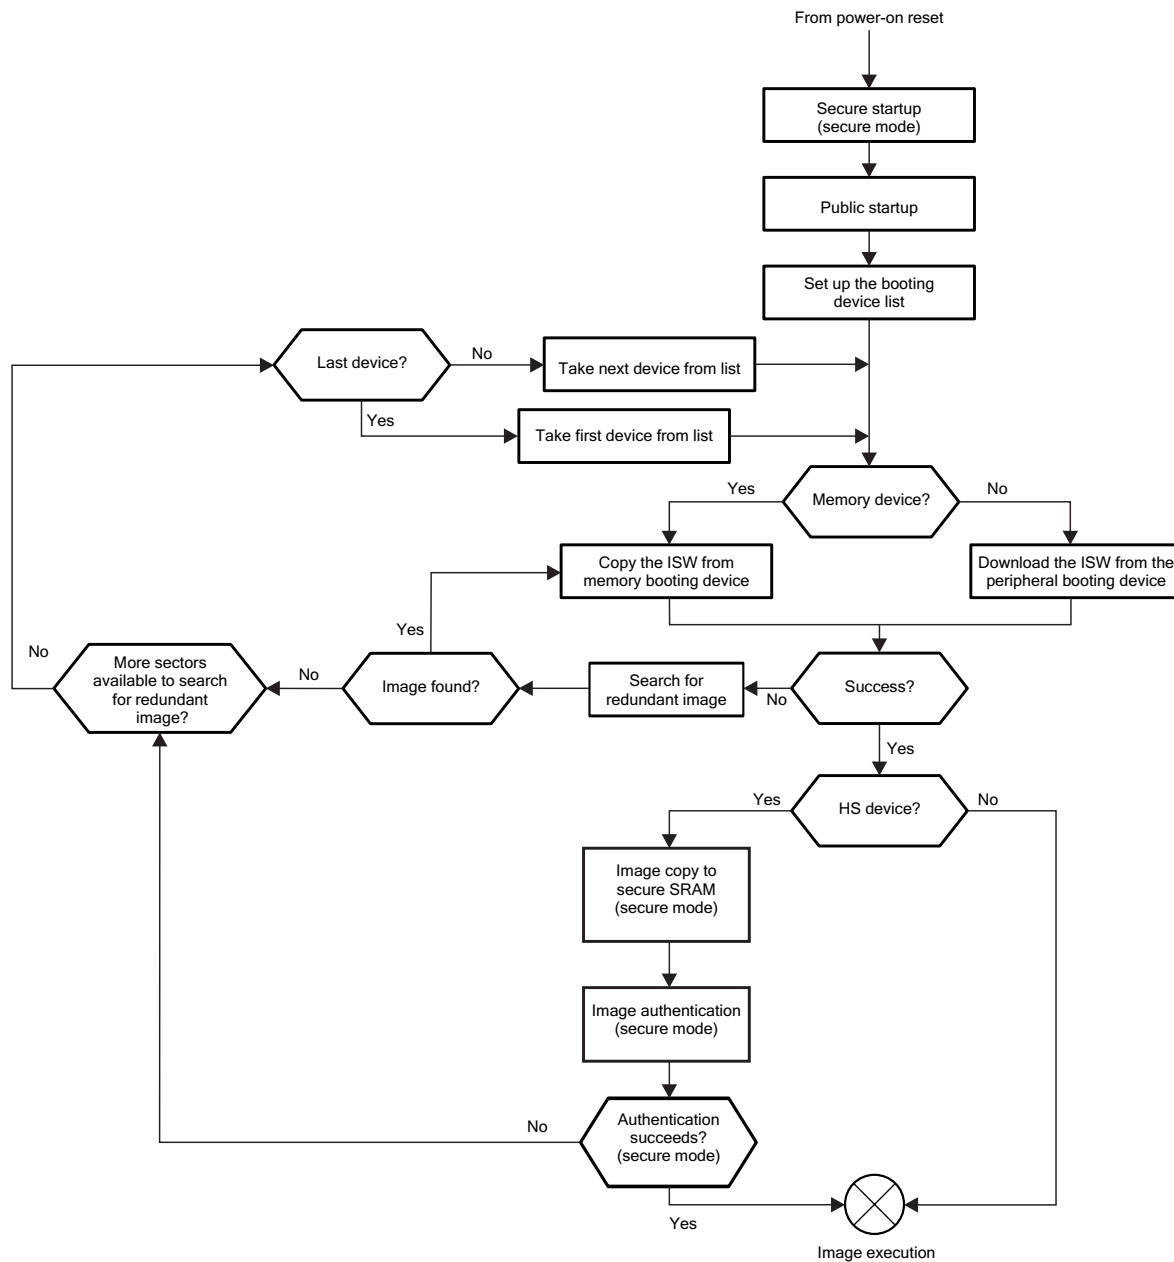

### 5.2.2 Functionality

[Figure 5-2](#) shows the high-level flow for the Public ROM Code booting procedure. The Public ROM Code starts after the secure startup. The ROM Code then performs platform configuration and initialization as part of the public start-up procedure.

The booting device list is based on the SYSBOOT pins. A booting device can be a memory booting device (soldered flash memory or temporarily booting device like memory card) or a peripheral interface connected to a host.

The main loop of the booting procedure searches the booting device list for an image from the currently selected booting device. This loop exits if a valid booting image is found and successfully executed or if the watchdog expires.

**Figure 5-2. Public ROM Code Boot Procedure**

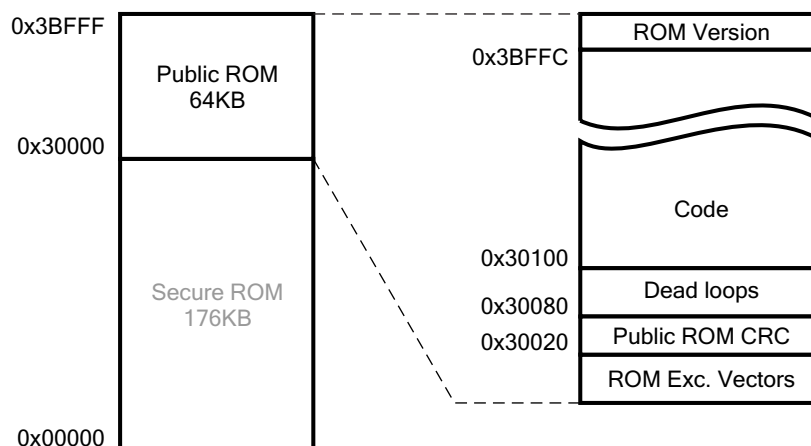

## 5.2.3 Memory Map

### 5.2.3.1 Public ROM Memory Map

Figure 5-3 shows the on-chip ROM memory map. The top holds the Public ROM Code. The Public ROM Code mapping includes:

- Exception vectors
- CRC
- Dead loops collection
- Code and const data sections
- ROM Version

**Figure 5-3. ROM Memory Map**

#### 5.2.3.1.1 Public ROM Exception Vectors

**Table 5-1** lists the Public ROM exception vectors. These vectors handle the standard exceptions that occur during the code execution. For example, if there is an issue accessing the memory region, it will generate a data abort exception when trying to read or write into that memory. The reset exception is redirected to the Public ROM Code startup. Other exceptions are redirected to their RAM handlers by loading appropriate addresses into the PC register.

**Table 5-1. Public ROM Exception Vectors**

Address	Exception	Content
30000h	Reset	Branch to the Public ROM Code startup
30004h	Undefined	PC = 40338E04h
30008h	SWI	PC = 40338E08h
3000Ch	Pre-fetch abort	PC = 40338E0Ch
30010h	Data abort	PC = 40338E10h
30014h	Unused	PC = 40338E14h
30018h	IRQ	PC = 40338E18h
3001Ch	FIQ	PC = 40338E1Ch

#### 5.2.3.1.2 Public ROM Code CRC

The Public ROM Code CRC is calculated as 32-bit CRC code (CRC-32-IEEE 802.3) for the address range 30000h – 3BFFCh. The 4-byte CRC code is stored at location 30020h.

#### 5.2.3.1.3 Dead Loops

**Table 5-2** lists the built-in dead loops used for different purposes. All dead loops are branch instructions coded in ARM mode. The fixed location of these dead loops facilitates debugging and testing. The first seven dead loops are linked to default ROM exception handlers mentioned in **Table 5-1** using RAM exception vectors mentioned in **Table 5-4** and **Table 5-5**.

**Table 5-2. Dead Loops**

Address	Purpose
30080h	Undefined exception default handler
30084h	SWI exception default handler
30088h	Pre-fetch abort exception default handler
3008Ch	Data abort exception default handler
30090h	Unused exception default handler
30094h	IRQ exception default handler
30098h	FIQ exception default handler
3009Ch	Validation tests PASS
300A0h	Validation tests FAIL
300A4h	Reserved
300A8h	Image not executed or returned.
300ACh	Reserved
300B0h	Reserved
300B4h	Reserved
300B8h	Reserved
300BCh	Reserved

#### 5.2.3.1.4 Code

This space is used to hold code and constant data.

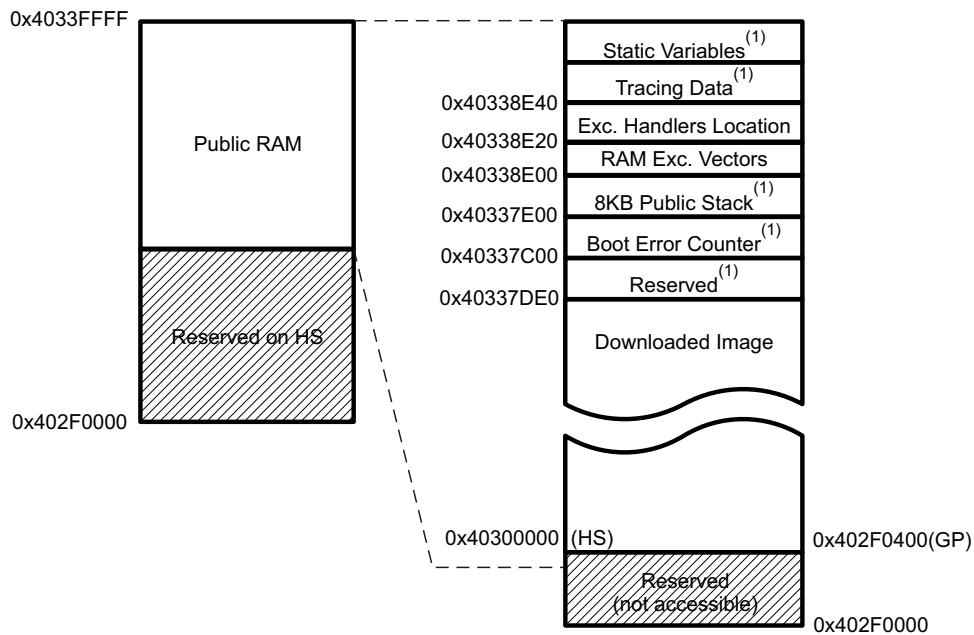

#### 5.2.3.1.5 Public ROM Code Version

The ROM Code version includes two decimal numbers: major and minor. The version identifies the ROM Code release version in a given IC. The ROM Code version is a 32-bit hexadecimal value located at address 3BFFCh. The minor Version is represented by the 1st byte and the major version is represented by the 2nd byte.

#### 5.2.3.2 Public L3 RAM Memory Map

The Public ROM Code makes use of the on chip RAM module connected to the L3 interconnect (referred hereafter as L3 RAM). Its usage is shown in [Figure 5-4](#). The Public L3 RAM memory map ranges from address 402F0000h to 4033FFFFh.

Figure 5-4. Public L3 RAM Memory Map

(1) Reserved for ROM use.

#### 5.2.3.2.1 Downloaded Image (ISW)

This area is used by the Public ROM Code to store the downloaded Initial SW. The downloaded image can be up to 286KB on GP Device. It resides from 0x402f0400 to 0x40337C00 in GP device.

**Note:** If ROM boots using USB\_MS boot mode, then the image can reside only from 0x40300000. This limits the maximum image size while using USB\_MS boot mode to 220KB.

#### 5.2.3.2.2 Boot Error Counters

Boot error counter registers contain the number of attempts a particular boot mode has failed after a cold reset. Each boot mode error counter is 32 bits wide. The device numbers 1, 2, 3, 4 mentioned are the sequential number in which boot modes are tried with a particular set of sysboot pin configuration. The SYSBOOT pin configuration is given in [Table 5-10](#).

Table 5-3. Boot Error Counters

Address	Boot Mode
40337DE0h	Device No. 1
40337DE4h	Device No. 2
40337DE8h	Device No. 3
40337DECh	Device No. 4

#### 5.2.3.2.3 Public Stack

Space reserved for stack.

#### 5.2.3.2.4 RAM Exception Vectors and Exception Handlers Location

The RAM exception vectors enable a simple means to redirect exceptions to custom handlers. [Table 5-4](#) shows content of the RAM space reserved for RAM vectors. The first seven addresses are ARM instructions which load the value located in the subsequent seven addresses into the PC register. These instructions execute when an exception occurs since they are called from the ROM exception vectors.

**Table 5-4. RAM Exception Vectors**

Address	Exception	Content
40338E00h	Reserved	Reserved
40338E04h	Undefined	PC = [40338E24h]
40338E08h	SWI	PC = [40338E28h]
40338E0Ch	Pre-fetch abort	PC = [40338E2Ch]
40338E10h	Data abort	PC = [40338E30h]
40338E14h	Unused	PC = [40338E34h]
40338E18h	IRQ	PC = [40338E38h]
40338E1Ch	FIQ	PC = [40338E3Ch]

As [Table 5-5](#) shows, Undefined, SWI, Unused and FIQ exceptions are redirected to a hardcoded dead loop. Pre-fetch abort, data abort, and IRQ exception are redirected to pre-defined ROM handlers. User code can redirect any exception to a custom handler by writing its address to the appropriate location from 4033D024h to 4033D03Ch or by overriding the branch (load into PC) instruction between addresses from 4033D004h to 4033D01Ch.

**Table 5-5. RAM Exception Handlers Location**

Address	Exception	Content
40338E20h	Reserved	30090h
40338E24h	Undefined	30080h
40338E28h	SWI	30084h
40338E2Ch	Pre-fetch abort	Address of default pre-fetch abort handler <sup>(1)</sup>
40338E30h	Data abort	Address of default data abort handler <sup>(1)</sup>
40338E34h	Unused	30090h
40338E38h	IRQ	Address of default IRQ handler
40338E3Ch	FIQ	30098h

<sup>(1)</sup> For more details, see [Section 5.2.3.1.1](#), *Public ROM Exception Vectors*.

### 5.2.3.2.5 Tracing Data

This area contains trace vectors reflecting the execution path of the public boot. [Section 5.2.12](#), *Tracing*, describes the different trace vectors and lists all the possible trace codes.

**Table 5-6. Tracing Data**

Address	Size (bytes)	Description
40338E40h	4	Current tracing vector, word 1
40338E44h	4	Current tracing vector, word 2
40338E48h	4	Current tracing vector, word 3
40338E4Ch	4	Current tracing vector, word 4
40338E50h	4	Current tracing vector, word 5
40338E54h	4	Reserved
40338E58h	4	Reserved
40338E5Ch	4	Reserved
40338E60h	4	Reserved
40338E64h	4	Reserved

### 5.2.3.2.6 Static Variables

This area contains the ROM Code static variables used during boot time.

### 5.2.3.3 Public ROM Exception Handling

When an exception occurs, ROM Code branches to the corresponding ROM Exception Handler. The ROM exception handler changes the PC value to the RAM Exception Vectors (ROM specific). The instruction at RAM Exception Vectors (ROM specific) contains an instruction to change the PC to the value written at Exception Handlers Location (User Modifiable). In this location, the default value is the location of deadloops. The user can overwrite these values to point to their specific Exception Handlers.

For example, if Undefined Instruction Abort, the flow is:

30004h → 40338E04h (Load PC with value at 40338E24h) → 30080h {Deadloop}

**Figure 5-5. The ROM Exception Handling Flow**

A Instruction to load the PC with the value at the exception handler location.

B User code can update values here to point to their specific exception handler.

### 5.2.3.3.1 Specific Cases of Abort Handlers

The default handlers for pre-fetch and data abort perform reads from CP15 debug registers to retrieve the reason of the abort

#### 5.2.3.3.1.1 Prefetch Abort

If pre-fetch abort: the IFAR register is read from CP15 and stored in R0. The IFSR register is read and stored in the R1 register. Then the ROM Code jumps to the pre-fetch abort dead loop (30088h).

#### 5.2.3.3.1.2 Data Abort

If data abort: the DFAR register is read from CP15 and stored in R0. The DFSR register is read and stored in the R1 register. Then the ROM Code jumps to the data abort dead loop (3008Ch).

## 5.2.4 Start-up and Configuration

### 5.2.4.1 ROM Code Startup

The Public ROM Code is physically located at the address 30000h that is immediately next to the Secure ROM Code.

**Figure 5-6. ROM Code Startup Sequence**

As [Figure 5-6](#) shows, the CPU jumps to the Public ROM Code reset vector once it has completed the secure boot initialization.

Once in public mode, the CPU:

1. Performs the public-side initialization and stack setup (compiler auto generated C- initialization or “scatter loading”)
2. Configures the public watchdog timer (set to three minutes)
3. Performs system clocks configuration
4. Jumps to the booting routine

#### 5.2.4.2 CPU State at Public Startup

The CPU L1 **instruction cache** and **branch prediction** mechanisms are not activated as part of the public boot process. The public vector base address is configured to the reset vector of Public ROM Code (30000h). MMU is left switched off during the public boot (hence L1 data cache off).

#### 5.2.4.3 Clocking Configuration

Support for the following frequencies are based on SYSBOOT[15:14].

**Table 5-7. Crystal Frequencies Supported**

SYSBOOT[15:14]	Crystal Frequency
00b	19.2 MHz
01b	24 MHz
10b	25 MHz
11b	26 MHz

The ROM Code configures the clocks and DLLs which are necessary for ROM Code execution:

- CORE ADPLLs is locked at 2 GHz and divided further to provide 100 MHz clocks for L3 functional clock and 100 MHz for Ethernet Module. The CORE ADPLLs is not reconfigured on warm reset if Ethernet isolation is enabled.
- MPU ADPLLs is locked to provide 300 MHz for the Cortex-A9.
- PER ADPLLJ is locked to provide 960 MHz and 192 MHz for peripheral blocks.

[Table 5-8](#) summarizes the ROM Code default settings for clocks. This default configuration enables all the ROM Code functions with minimized needs on power during boot.

**Table 5-8. ROM Code Default Clock Settings**

Clock	Frequency (MHz)	Source (Source Frequency)
L3_FCLK	100	CORE_CLKOUTM4 (100 MHz)
SPI_CLK	48	PER_CLKOUTM2 (192 MHz)
MMC_CLK	96	PER_CLKOUTM2 (192 MHz)
UART_CLK	48	PER_CLKOUTM2 (192 MHz)
I2C_CLK	48	PER_CLKOUTM2 (192 MHz)
MPU_CLK	300	MPU_PLL (300 MHz)
USB_PHY_CLK	960	PER_CLKDCOLDO (960 MHz)
QSPI_CLK	12	PER_CLKOUTM2 (192 MHz)
MHZ_250_CLK (Ethernet)	100	CORE_CLKOUTM5 (100 MHz)
MHZ_50_CLK (Ethernet)	50	CORE_CLKOUTM5 (100 MHz)
MHZ_5_CLK (Ethernet)	5	CORE_CLKOUTM5 (100 MHz)

The DLLs and PRCM clock dividers are configured with the ROM Code default values after cold or warm reset in order to give the same working conditions to the Public ROM Code sequence.

## 5.2.5 Booting

### 5.2.5.1 Overview

[Figure 5-7](#) shows the booting procedure. First a booting device list is created. The list consists of all devices which will be searched for a booting image. The list is filled in based on the SYSBOOT pins.

**Figure 5-7. ROM Code Booting Procedure**

Once the booting device list is set up, the booting routine examines the devices enumerated in the list sequentially and executes either the memory booting or peripheral booting procedure depending on the booting device type.

- The memory booting procedure executes when the booting device type is one of NOR, NAND, MMC, SPI-EEPROM, QSPI-EEPROM or USB Pen drive (Mass Storage Class).  
The memory booting procedure reads data from a memory type device. If a valid booting image is found and successfully read from the external memory device:
  - When ROM transfers control to the ISW, it passes a parameter to a Boot Parameter Structure in R0. The Boot Parameter Structure can be used to determine the boot device, reset reason, etc. The fields of this structure are described in [Table 5-9](#).
- The peripheral booting executes when the booting device type is Ethernet, USB Client Mode or UART. The peripheral booting procedure downloads data from a host (commonly a PC) to the device by Ethernet, USB Client Mode, or UART links. The ROM Code uses a host-slave logical protocol for synchronization. Upon successful UART, USB Client Mode or Ethernet connection the host sends the image binary contents. The peripheral booting procedure is described in [Section 5.2.7, Peripheral Booting](#).

**Table 5-9. Booting Parameters Structure**

Offset	Field	Size (bytes)	Description
00h	Reserved	4	Reserved
04h	Device Descriptor Address	4	Pointer to the memory device descriptor that has been used during the memory booting process (used internally for ROM testing).
08h	Current Booting Device	1	Code of device used for booting: 00h – void, no device 01h – NOR 02h – NOR (wait monitoring on) 03h – NOR2 04h – NOR2 (wait monitoring on) 05h – NAND 06h – NAND with I2C 07h – MMC/SD port 0 08h – MMC/SD port 1 0Ah – SPI 0Bh – QSPI 0Ch – SPI2 0Dh – USB_MS 41h – UART0 45h – USB_CL 47h – CPGMAC0
09h	Reset Reason	1	Current reset reason bit mask (bit=1-event present): [0] – Power-on reset [1] – Global software reset [2] – Security violation reset [4] – Watchdog1 reset [5] – External warm reset [9] – IcePick reset Other bits – Reserved
0Ah	Reserved	10	Reserved

#### 5.2.5.1.1 Device List

The ROM Code creates the device list based on information gathered from the SYSBOOT configuration pins sensed in the control module. The pins are used to index the device table from which the list of devices is extracted

## 5.2.5.2 SYSBOOT Configuration Pins

**Table 5-10. SYSBOOT Configuration Pins**

Notes for SYSBOOT configuration pins:

- (1) SYSBOOT[17] selects the default mux mode of XDMA\_EVENT\_INTR0. When SYSBOOT[17]=0, default mux mode of XDMA\_EVENT\_INTR0 is mode0. When SYSBOOT[17]=1, default mux mode of XDMA\_EVENT\_INTR0 is mode3, which enables CLKOUT1 on the terminal.
- (2) DSS\_HSYNC terminal is SYSBOOT[17] input. DSS\_VSYNC terminal is SYSBOOT[16]. DSS\_DATA[15:0] terminals are respectively SYSBOOT[15:0] inputs. All are latched on the rising edge of PWRONTSTn.
- (3) Note that even though some bits may be a don't care for ROM code, all SYSBOOT values are latched into the CTRL\_STS register and may be used by software after ROM execution has completed.

The ROM Code uses the row pointed by the SYSBOOT pins value. The device list is filled in with the 1st to 4th devices.

[Table 5-10](#) is the decoding table for SYSBOOT pin configuration. The following shortcuts are used in the table:

- MMC1: MMC or SD card (MMC port 1)
- MMC0: MMC or SD card (MMC port 0)
- NAND\_I2C: NAND flash memory / read geometry from EEPROM on I2C0
- NOR: NOR device with or without wait monitoring <sup>(5)</sup>
- UART: UART interface (UART port 0)
- EMAC: Ethernet interface (EMAC port 1)
- SPI: SPI EEPROM (SPI 0, CS0)
- USB\_CL: USB Client Mode (USB0 interface)
- USB\_MS: USB Mass Storage Class (USB1 interface)
- QSPI: Quad SPI interface (QSPI, CS0)

---

**NOTE:** For any SYSBOOT value that is selected, please be aware of the pin muxing implications. For example, if the boot mode selected is EMAC, NAND, SPI, NANDI2C, the SOC will drive EMAC, GPMC, SPI and I2C pins, in that order, depending on which boot device finally succeeds. For specific details of the pins driven by each device, see the description of the boot device in this document.

---

To extend the boot flow to boot from devices that are not natively supported by the ROM, or if the user needs a different booting configuration, use USB\_MS boot. For example, if a customer wants to boot from an unsupported NAND device or UART with different configuration, the system can be configured to boot from another inexpensive boot media like SPI flash and the code for configuring and booting from the unsupported NAND device can be loaded into the SPI flash. This is known as a secondary boot.

A “Low Latency NOR boot mechanism” ([Section 5.2.8, Low Latency NOR Booting](#)) is provided where minimal execution is performed from ROM Code for configuring the GPMC interface and then directly jump to the code contained in the connected NOR flash device.

## 5.2.6 Memory Booting

### 5.2.6.1 Overview

The memory booting procedure executes external code located in memory device types.

<sup>(5)</sup> Wait monitoring is enabled or disabled based on SYSBOOT pins in [Table 5-10](#).

**Figure 5-8. Memory Booting**

The following memory booting devices are supported:

- MMC/SD cards
- NOR flash
- NAND flash
- SPI EEPROMs
- Quad SPI EEPROMs
- USB Mass Storage device

Two groups of permanent booting devices are distinguished by the need of code shadowing. The code shadowing means copying a code from an indirectly addressable device into a location (typically a RAM area) from where the code can be executed. Devices which are directly addressable are called eXecute In Place (XIP) devices.

Figure 5-8 shows the memory booting flowchart. The Image execution step is about performing the shadowing of the image that is copying the image from external mass storage (non-XIP) into internal RAM. The next sections detail procedures for device initialization and detection in addition to the description of the sector read routine for each supported device type. A sector is a logical unit of 512 bytes.

The detection of whether an image is present on a selected device differs by device type:

- On a GP Device type, a booting image (bootloader) is considered to be present when the first four bytes of the sector are not equal to 00000000h or FFFFFFFFh.

During the first read sector call, the first sector is copied to a temporary RAM buffer. Once the image is found and the destination address is known from the decoding the header, the content of the temporary buffer is moved to the target RAM location so it is not needed to re-read the first image sector. On a GP device the GP header is discarded, and only executable code is located in RAM with the first executable instruction located at the destination address.

MMC/SD cards (in raw mode), SPI, and NAND devices hold up to four copies of the booting image. The ROM Code searches for one valid image out of the four, if present, by walking over the first four blocks of the mass storage space. Other XIP devices (NOR) use only one copy of the booting image.

### 5.2.6.2 Image Shadowing for non-XIP Memories

The GP device shadowing uses the following approach.

**Figure 5-9. Image Shadowing on GP Device**

### 5.2.6.3 NOR Memory

The ROM Code can boot directly from NOR devices. A NOR flash memory behaves as an eXecute In Place (XIP) device. NOR flash devices are supported under the following assumptions:

- GPMC is the communication interface.
- Connect up to 1Gb (128MB) memories.
- Only x16 data bus width (x8 not supported).
- Asynchronous protocol.
- Supports address / data multiplexed mode and non-muxed mode.
- GPMC clock is 50 MHz.
- Device connected to CS0 mapped to address 0x08000000h.
- Wait pin signal WAIT0 is monitored or ignored depending on the SYSBOOT pin configuration mentioned in [Table 5-10](#).
- Flexible muxing options for gpmc address lines for non-muxed and muxed NOR devices based on SYSBOOT pin configuration mentioned in [Table 5-10](#).

Depending on the SYSBOOT pins, the GPMC is configured to use the WAIT signal connected on the WAIT pin or not. Wait pin polarity is set to stall accessing memory when the WAIT pin is low. The wait monitoring is intended to be used with memories which require long time for initialization after reset or need to pause while reading data.

The boot procedure from a NOR device is:

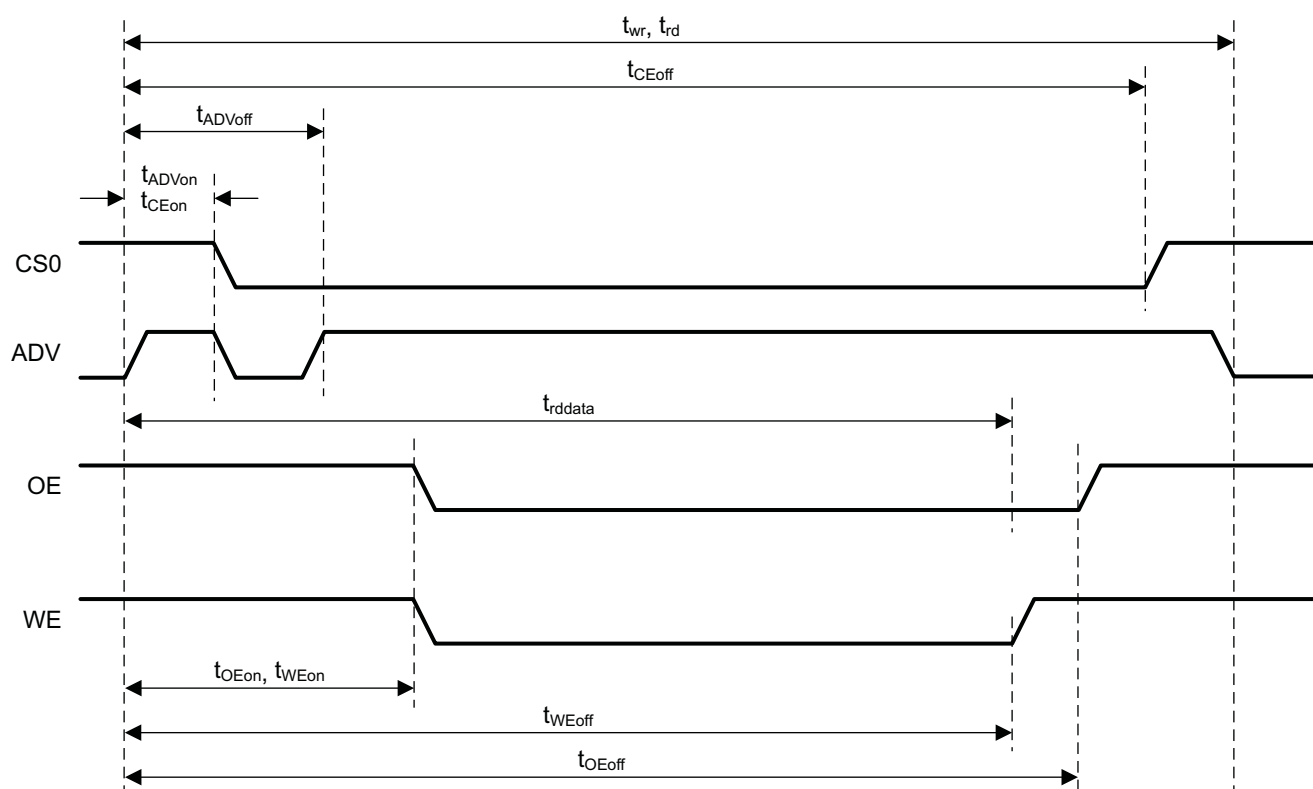

1. Configure GPMC for NOR device access.
2. Set the image location to 0x08000000h
3. Verify if a bootable image is present at the image location.
4. If the image is not found, return from NOR booting to the main booting loop.

### 5.2.6.3.1 NOR Initialization and Detection

#### 5.2.6.3.1.1 GPMC Initialization

Figure 5-10 and Table 5-11 describe the GPMC timing settings configured for NOR boot and other address-data accessible devices.

**Figure 5-10. GPMC NOR Timings**

**Table 5-11. NOR Timings Parameters**

Parameter	Description	Value (clock cycles)
$t_{wr}$	write cycle period	17
$t_{rd}$	read cycle period	17
$t_{CEon}$	CE low time	1
$t_{CEoff}$	CE high time	16
$t_{ADVon}$	ADV low time	1
$t_{ADVoff}$	ADV high time	2
$t_{OEon}$	OE low time	3
$t_{WEon}$	WE low time	3
$t_{rddata}$	data latch time	15
$t_{OEoff}$	OE high time	16
$t_{WEoff}$	WE high time	15

### 5.2.6.3.1.2 Device Detection

There is no specific identification routine executed prior to booting from an NOR device.

### 5.2.6.3.2 Pins Used

[Table 5-12](#) lists the pins configured by the ROM for NOR boot mode. Not all pins are driven at boot time. The decision as to which pins need to be driven is based on the type of NOR flash selected.

**Table 5-12. Pins Used for NOR Boot Common Signals**

Signal Name	Pin Used in NOR	CTRL_CONF Register	Register Setting
cs0	gpmc_cs0	CTRL_CONF_GPMC_CS0	0x00010000

### 5.2.6.3.2.1 SYSBOOT Signals

Table 5-16 describes the SYSBOOT signals relevant to NOR boot.

**Table 5-16. SYSBOOT Signals for NOR Boot**

SYSBOOT[7:6]	Used for Pinmux option selection in NOR 00b – pinmux option 0 is selected for NOR 01b – pinmux option 1 is selected for NOR 1xb – pinmux option 2 is selected for NOR
SYSBOOT[8]	Decides which pin WAIT needs to be connected to the NOR flash. 0b – Wait mux option 0 1b – Wait mux option 1

**Table 5-16. SYSBOOT Signals for NOR Boot (continued)**

SYSBOOT[9]	During NOR Boot this pin will be used to determine if Wait is enabled. 0b – Ignore WAIT input 1b – Use WAIT input
SYSBOOT[11]	Address Muxing 0b – No Addr/Data Muxing 1b – Addr/Data Muxing

#### 5.2.6.4 NAND Memory

The NAND flash memory is not XIP and requires shadowing before the code can be executed.

##### 5.2.6.4.1 Features

- GPMC is the communication interface
- Device size from 512Mb (64MB)
- x8 and x16 bus width
- Support for the following page sizes:
  - 2048 bytes + 64 spare bytes
  - 4096 bytes + 128 or 218 spare bytes
- Only supports devices where chip select can be de-asserted during read, program, or erase cycles, without interrupting the operation
- Single Level Cell (SLC) and Multiple Level Cell (MLC) devices
- Device Identification based on ONFI or ROM table
- ECC correction: 8 bits per sector for most devices (16 bits per sector for devices with large spare area)
- Support for disabling ECC correction, so that the in-built ECC correction mechanisms on some NANDs can be used.
- GPMC timings adjusted for NAND access
- GPMC clock is 50 MHz
- Device connected to CS0
- Wait pin signal WAIT0 connected to NAND BUSY output based on SYSBOOT[8] <sup>(1)</sup>
- Four physical blocks are searched for an image. The block size depends on device.

##### 5.2.6.4.2 Initialization and Detection

The initialization routine for NAND devices includes three parts: GPMC initialization, device detection with parameters determination, and bad block detection.

###### 5.2.6.4.2.1 ONFI Support

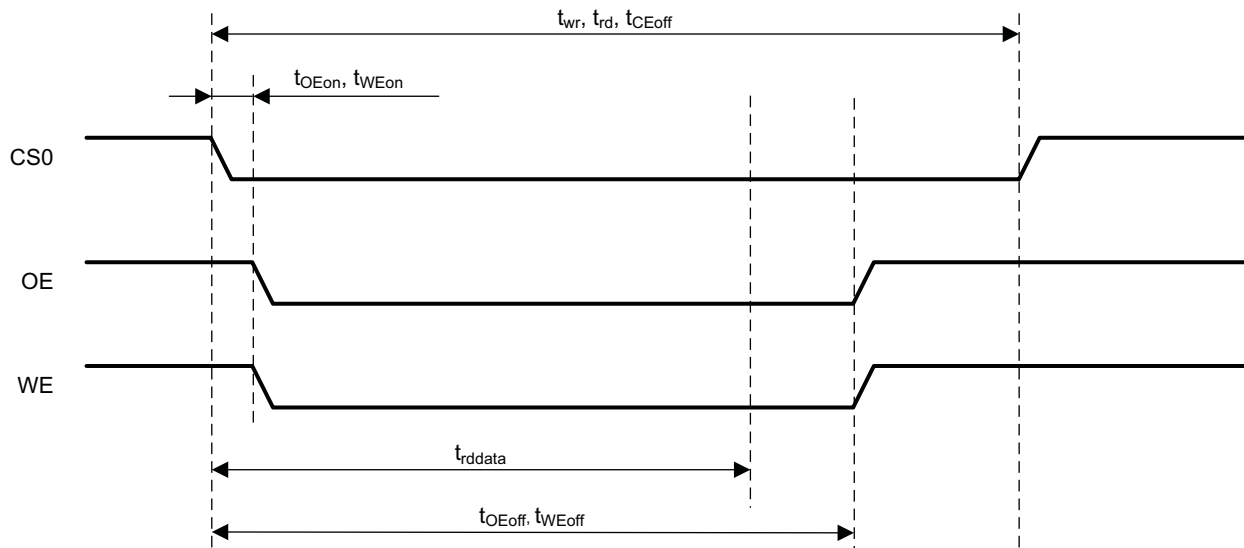

The NAND identification starts with ONFI detection.

###### 5.2.6.4.2.2 GPMC Initialization

The GPMC interface is configured to NAND devices. The address bus is released since a NAND device does not use it. The data bus width is initially set to 8 bits and changed to 16 bits if needed after device parameters determination. The following scheme is applied since NAND devices require different timings when compared to regular NOR devices:

<sup>(1)</sup> See [Table 5-10, SYSBOOT Configuration Pins](#).

**Figure 5-11. GPMC NAND Timings**

**Table 5-17. Parameters for NAND Timings**

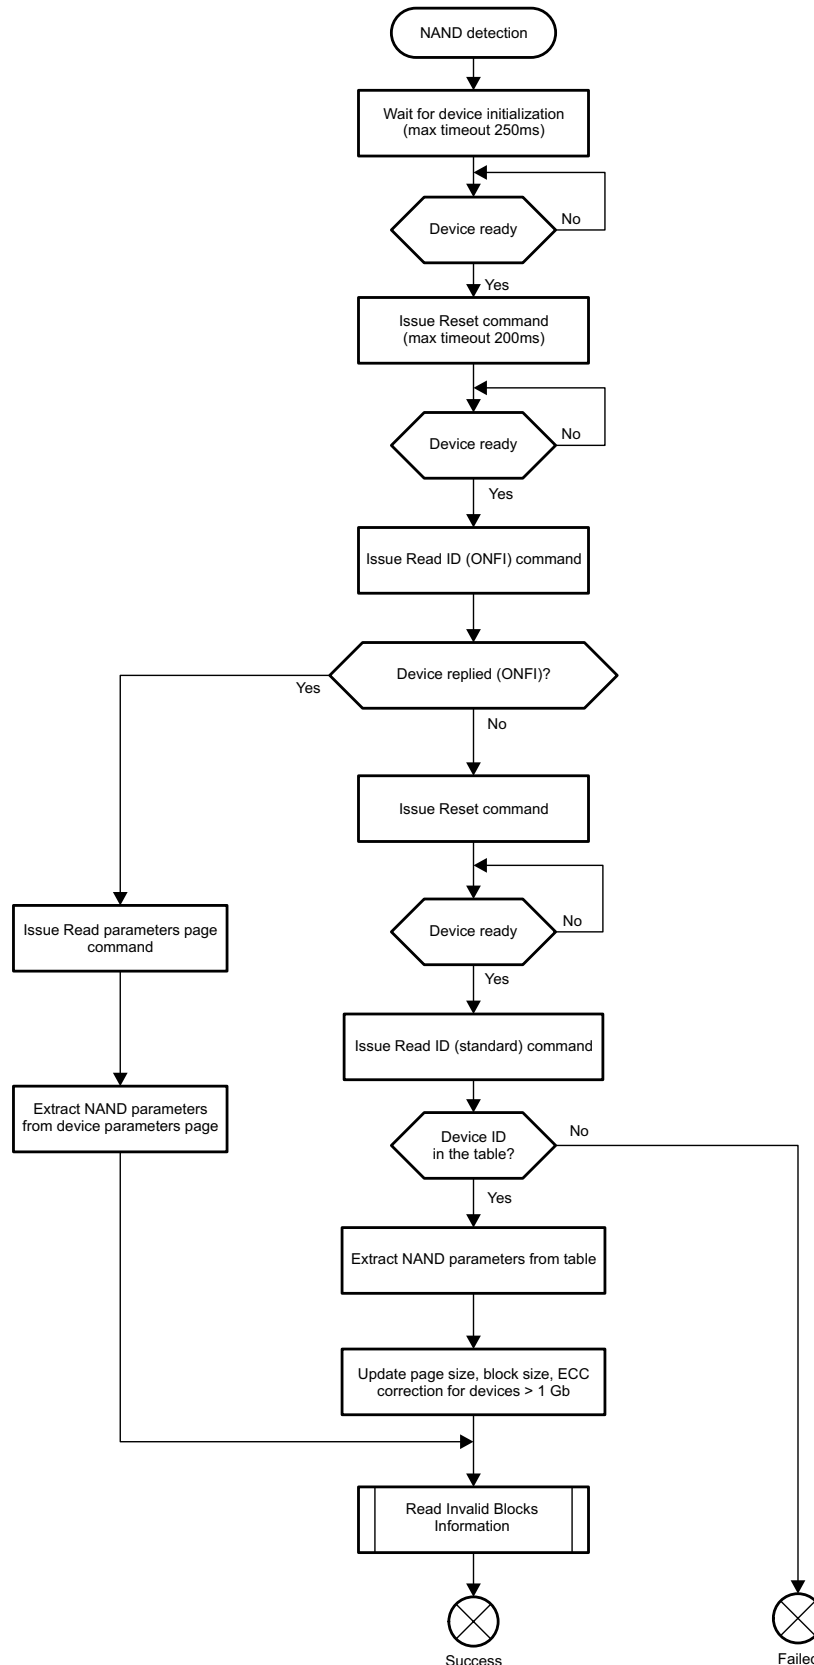

Parameter	Description	Value (clock cycles)
$t_{wr}$	write cycle period	30
$t_{rd}$	read cycle period	30
$t_{CEon}$	CE low (not marked on the figure)	0
$t_{OEon}$	CE low to OE low time	7
$t_{WEon}$	CE low to WE low time	5
$t_{rddata}$	CE low to data latch time	21
$t_{OEoff}$	CE low to OE high time	24
$t_{WEoff}$	CE low to WE high time	22

Figure 5-11 and Table 5-17 describe the timings configured for NAND device access.

#### 5.2.6.4.2.3 Device Detection and Parameters

The ROM Code first performs an initial wait for device auto initialization (with a 250 ms timeout) with polling of the ready information. It then identifies the NAND type connected to the GPMC interface. The GPMC is initialized using 8-bit asynchronous mode. The NAND device is reset (command FFh) and its status is polled until ready for operation (with a 200 ms timeout). The ONFI Read ID (command 90h / address 20h) is sent to the NAND device. If it replies with the ONFI signature (4 bytes), then a Read parameters page (command ECh) is sent. If the parameters page does not have the ONFI signature, then the ONFI identification fails.

If the ONFI identification passes, the information shown in Table 5-18 is then extracted: page size, spare area size, number of pages per block, and the addressing mode. The remaining data bytes from the parameters page stream are simply ignored. The detection procedure is described in Figure 5-12. Once the device has been successfully detected, the ROM Code changes GPMC to 16-bit bus width if necessary.

**Figure 5-12. NAND Device Detection**

NOTE: Timeouts are based on ONFI timing requirements and NAND reset timing specifications.

**Table 5-18. ONFI Parameters Page Description**

Offset	Description	Size (bytes)
6	Features supported	2
80	Number of data bytes per page	4
84	Number of spare bytes per page	2
92	Number of pages per block	4
101	Number of address cycles	1

If the ONFI Read ID command fails (it will fail with any device not supporting ONFI) then the device is reset again with polling for device to be ready (with a 200 ms timeout). Then, the standard Read ID (command 90h / address 00h) is sent. If the Device ID (2nd byte of the ID byte stream) is recognized as a supported device, then the device parameters are extracted from an internal ROM Code table. The list of supported devices is in [Table 5-19](#).

**Table 5-19. Supported NAND Devices**

Capacity	Device ID	Bus Width	Page Size
512 Mb	F0	x8	2048
	C0	x16	
	A0	x8	
	B0	x16	
	F2	x8	
	C2	x16	
	A2	x8	
	B2	x16	
1 Gb	F1	x8	2048
	C1	x16	
	A1	x8	
	B1	x16	
2 Gb	DA	x8	2048
	CA	x16	
	AA	x8	
	BA	x16	
	83	x8	
	93	x16	
4 Gb	DC	x8	2048
	CC	x16	2048/4096
	AC	x8	
	BC	x16	2048
	84	x8	
	94	x16	
8 Gb	D3	x8	2048/4096
	C3	x16	
	A3	x8	
	B3	x16	
	85	x8	2048
	95	x16	

**Table 5-19. Supported NAND Devices (continued)**

Capacity	Device ID	Bus Width	Page Size
16 Gb	D5	x8	2048/4096
	C5	x16	
	A5	x8	
	B5	x16	
	86	x8	2048
	96	x16	
32 Gb	D7	x8	2048/4096
	C7	x16	
	A7	x8	
	B7	x16	
	87	x8	2048
	97	x16	
64 Gb	DE	x8	2048/4096
	CE	x16	
	AE	x8	
	BE	x16	

When the parameters are retrieved from the ROM table: page size and block size are updated based on 4th byte of NAND ID data. Due to inconsistency among manufacturers, only devices of at least 2Gb (included) have these parameters updated. Therefore, the ROM Code supports 4kB page devices but only if their size, according to the table, is at least 2Gb. Devices smaller than 2Gb have the block size parameter fixed to 128kB. [Table 5-20](#) shows the 4th ID Data byte encoding used in ROM Code.

**Table 5-20. 4th NAND ID Data Byte**

Item	Description	I/O #							
		7	6	5	4	3	2	1	0
Page Size	1kB							0	0
	2kB							0	1
	4kB							1	0
	8kB							1	1
Cell type	2 levels					0	0		
	4 levels					0	1		
	8 levels					1	0		
	16 levels					1	1		
Block Size	64kB			0	0				
	128kB			0	1				
	256kB			1	0				
	512kB			1	1				

#### 5.2.6.4.2.4 Reading NAND Geometry from I2C EEPROM

ROM supports a special boot mode called NANDI2C to support NAND devices whose geometry cannot be detected by the ROM automatically using methods described in the previous section (Figure 5-12). If this boot mode is selected, the ROM code reads NAND geometry from an I2C EEPROM. If the read is successful, ROM code moves to the next steps of NAND boot beginning with reading bad blocks information.

If the I2C EEPROM read fails, the ROM will fall back to querying the NAND for the geometry information, as described above.

**Note:** The NAND bus width configuration mentioned in the I2C EEPROM overrides the BUSWIDTH configuration selected by SYSBOOT pins.

Table 5-21 lists the device pins configured by the ROM for NANDI2C boot mode, in addition to the NAND boot pins described in the previous sections.

**Table 5-21. Pins Used for NAND I2C Boot for I2C EEPROM Access**

Signal Name	Pin Used	CTRL_CONF Register	Register Setting
I2C SCL	i2c0_scl	CTRL_CONF_I2C0_SCL	0x000e0000
I2C SDA	i2c0_sda	CTRL_CONF_I2C0_SDA	0x000e0000

ROM accesses the I2C EEPROM at I2C slave address 0x50 and reads 7 bytes starting from address offset 0x80. The format of this NAND geometry information follows:

**Table 5-22. NAND Geometry Information on I2C EEPROM**

Byte address	Information	
	Upper Nibble	Lower Nibble
0x80	Magic Number – 0x10	
0x81	Magic Number – 0xb3	
0x82	Magic Number – 0x57	
0x83	Magic Number – 0xa6	
0x84	NAND column address (word/byte offset within a page) size in bytes, Example: 2	NAND row address (page offset) size in bytes. Example: 3
0x85	Page size ( $2^N$ ) exponent "N". Example (for page size of 2048): 11	Pages per block ( $2^N$ ) exponent "N" Example (for number of blocks 64): 6
0x86	NAND bus width 0 → 8-bit, 1 → 16-bit	ECC Type 0 → No ECC, 1 → BCH8, 2 → BCH16

#### 5.2.6.4.2.5 ECC Correction

The default ECC correction applied is BCH 8 bits per sector using the GPMC and ELM hardware.

For device ID codes D3h, C3h, D5h, C5h, D7h, C7h, DEh, CEh when manufacturer code (first ID byte) is 98h the Cell type information is checked in the 4th byte of ID data. If it is equal to 10b then the ECC correction applied is BCH 16 bits per sector.

In addition, ECC computation done by the ROM can be turned off completely by using SYSBOOT[6]. This is particularly useful when interfacing with NAND devices that have built in ECC engines.

#### 5.2.6.4.2.6 Bad Block Verification

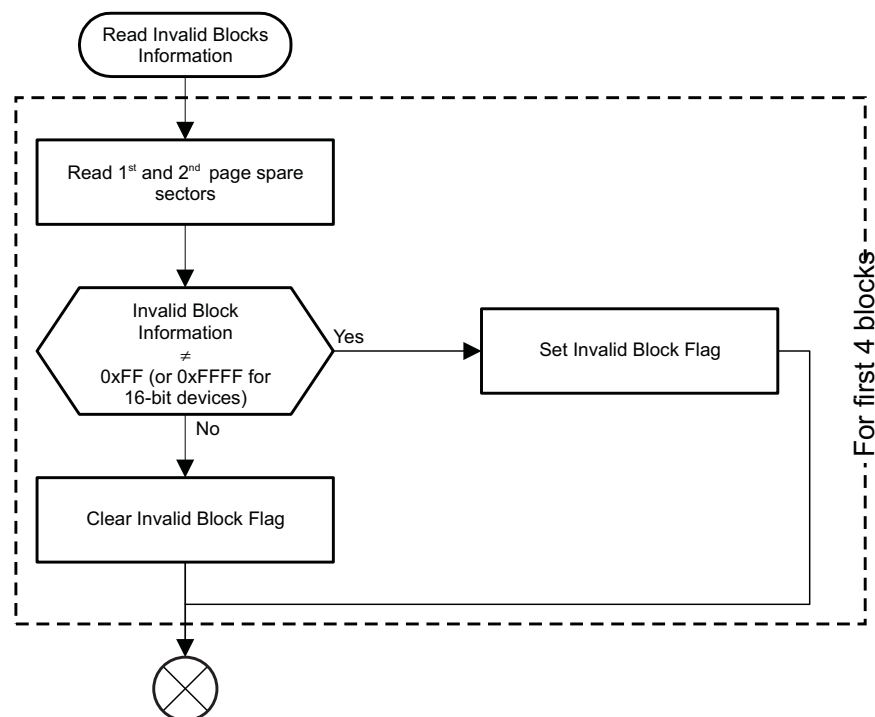

Invalid blocks are blocks with invalid bits whose reliability cannot be guaranteed by the manufacturer. Invalid bits are identified in the factory or during the programming and reported in the initial invalid block information located in the spare area on the 1st and 2nd page of each block. Since the ROM Code is looking for an image in the first four blocks, it must detect block validity status of these blocks. Blocks which are detected as invalid are not accessed later on.

The valid block status is coded in the spare areas of the first two pages of a block:

- 8-bit device: first byte equals FFh in 1st and 2nd pages
- 16-bit device: first word equals FFFFh in 1st and 2nd pages

Figure 5-13 shows the invalid block detection routine. The routine reads spare areas and checks validity data pattern.

**Figure 5-13. NAND Invalid Blocks Detection**

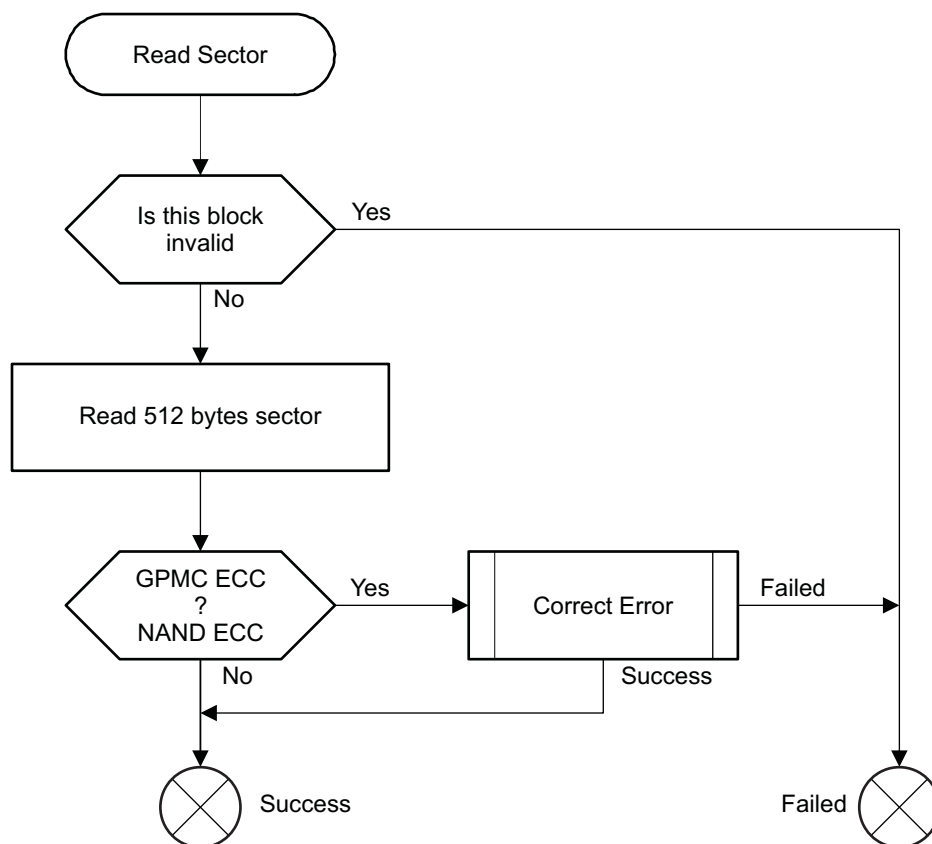

#### 5.2.6.4.3 NAND Read Sector Procedure

The ROM Code reads data from NAND devices in 512-byte sectors. The read function fails in two cases:

- The accessed sector is within a block marked as invalid
- The accessed sector contains an error which cannot be corrected with ECC

Figure 5-14 shows the read sector routine for NAND devices. The ROM Code uses a normal read (command 00h 30h) to read NAND page data.

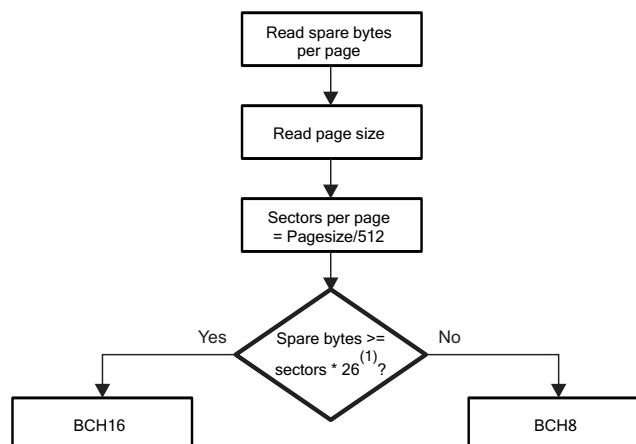

**Figure 5-14. NAND Read Sector Procedure**

Page data can contain errors due to memory alteration. The ROM Code uses an ECC correction algorithm to detect and possibly correct those errors. The ECC algorithm used is BCH with capability for correcting 8b or 16b errors per sector. Selecting between BCH8 and BCH16 ECC scheme is shown in [Figure 5-15](#). The BCH data is automatically calculated by the GPMC on reading each 512-byte sector. The computed ECC is compared against ECC stored in the spare area for the corresponding page. Depending on the page size, the amount of ECC data bytes stored in the corresponding spare area is different.

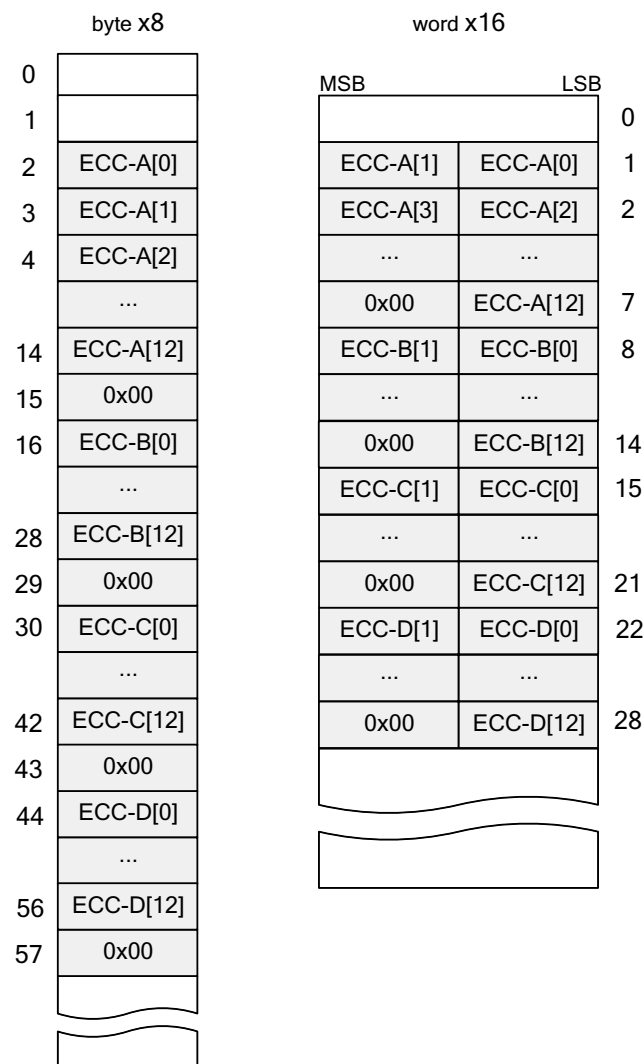

[Figure 5-16](#) and [Figure 5-17](#) show the mapping of ECC data inside the spare area for respectively 2KB-page and 4KB-page devices. If both ECC data are equal then the Read Sector function returns the read 512-byte sector without error. Otherwise the ROM Code tries to correct errors in the corresponding sector (this procedure is assisted by the ELM hardware) and returns the data if successful. If errors are uncorrectable, the function returns with FAIL.

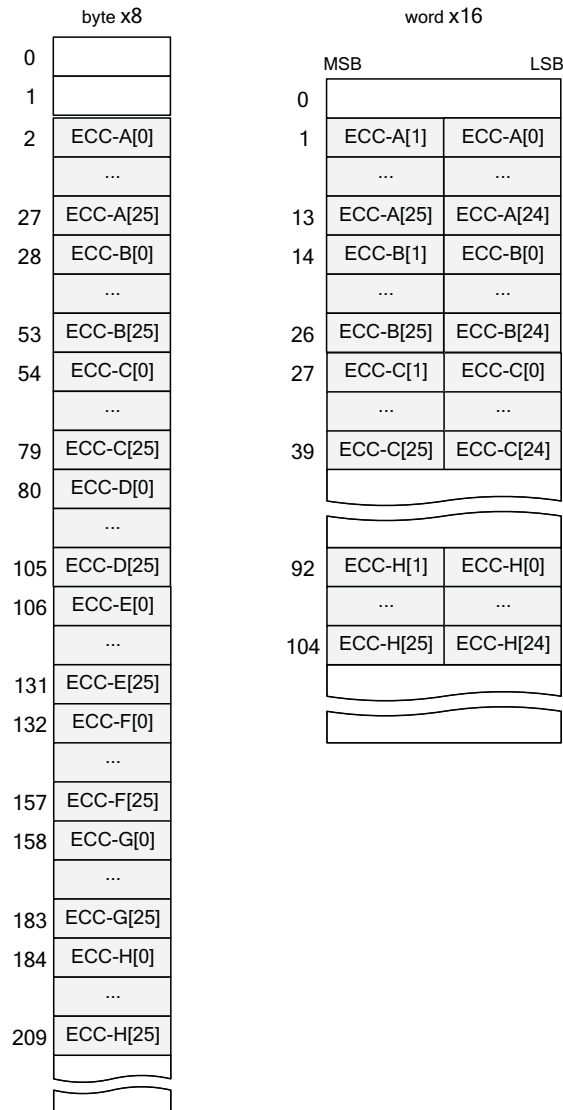

**Figure 5-15. NAND ECC Scheme Selection Procedure**

(1) 26 is the number of ECC bytes needed for the 512-byte sector in the BCH16 scheme.

**Figure 5-16. ECC Data Mapping for 2KB Page and 8b BCH Encoding**

**Figure 5-17. ECC Data Mapping for 4KB Page and 16b BCH Encoding**

#### 5.2.6.4.4 Pins Used

Table 5-23 lists the device pins configured by the ROM for NAND boot mode. Not all the pins are driven at boot time.

**Table 5-23. Pins Used for NAND Boot**

Signal Name	Pin Used	CTRL_CONF Register	Register Setting
cs0	gpmc_cs0	CTRL_CONF_GPMC_CS0	0x00010000
advn_ale	gpmc_advn_ale	CTRL_CONF_GPMC_ADV_N_ALE	0x00010000
oen_ren	gpmc_oen_ren	CTRL_CONF_GPMC_OEN_REN	0x00010000
be0n_cle	gpmc_be0n_cle	CTRL_CONF_GPMC_BE0N_CLE	0x00010000
Wen	gpmc_wen	CTRL_CONF_GPMC_WEN	0x00010000
Clk	gpmc_clk	CTRL_CONF_GPMC_CLK	0x00060000
ad0 - ad15	gpmc_ad0 - gpmc_ad15	CTRL_CONF_GPMC_AD0 to CTRL_CONF_GPMC_AD15	0x00060000

**Table 5-24. Pins Used for NAND Boot Wait Pin Selection**

Signal name	Pin Used Pinmux Option 0	CTRL_CONF Register	Register Setting	Pin Used Pinmux Option 1	CTRL_CONF Register	Register Setting
wait	gpmc_wait0	CTRL_CONF_ GPMC_WAIT0	0x00060000	gpmc_csn3	CTRL_CONF_ GPMC_CSN3	0x00600001

#### 5.2.6.4.4.1 SYSBOOT Signals

Table 5-25 lists the SYSBOOT signals for NAND boot.

**Table 5-25. SYSBOOT Signals for NAND Boot**

SYSBOOT[6]	Used by Boot ROM to determine if NAND ECC is handled by ROM or NAND device. Please note that when ROM is booting from external NAND, WAIT monitoring will be forced by ROM code. SYSBOOT setting is not required to enable/disable Wait monitoring. 0 – ECC done by ROM 1 – ECC done by NAND Device
SYSBOOT[8]	Decides which pin READY/BUSY needs to be connected to when NAND is selected. 0 – Wait mux option 0 1 – Wait mux option 1

### 5.2.6.5 MMC/SD Cards

#### 5.2.6.5.1 Overview

The ROM Code supports booting from MMC/SD cards in the following conditions:

- MMC/SD Cards compliant to [6], [9] of low and high capacities.
- MMC/SD cards connected to MMC interface #0 and #1.
- Support for 3.3 V or 1.8 V I/O voltages.
- Initial 1-bit MMC Mode and optional 4-bit mode, if MMC/SD card supports it.
- Clock Frequency: identification mode: 240 KHz; data transfer mode up to 12 MHz.
- Only one card connected to the bus.
- Raw mode, image data read directly from sectors in the user area.
- File system mode (FAT16/32 supported with or without Master Boot Record), image data is read from a booting file.

#### 5.2.6.5.2 System Interconnection

An MMC/SD card or eMMC/eSD/managed NAND memory device can connect to MMC0 or MMC1 interface.

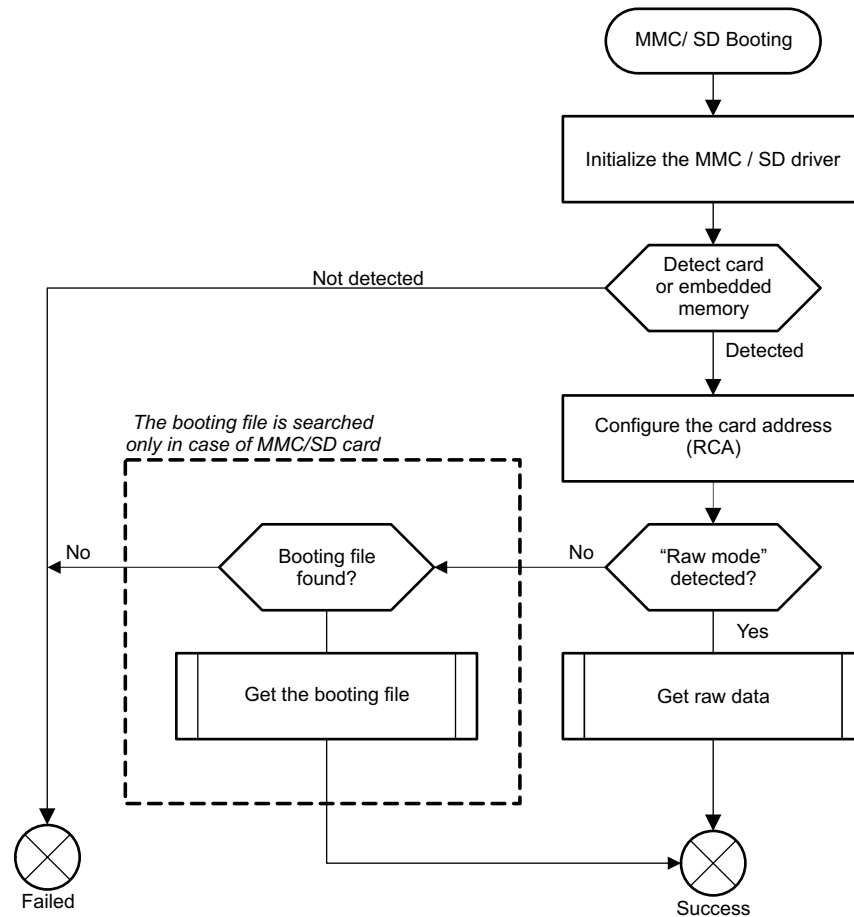

Note:

- The ROM Code does not handle the card detection feature on card cage.
- If MMC1 is used, the GPMC interface is not usable, due to pin muxing options.
- MMC0 and MMC1 support sector mode without querying the card.

#### 5.2.6.5.3 Booting Procedure

Figure 5-18 shows the high level flowchart of the eMMC, eSD, and MMC/SD booting procedure. The booting file is searched only if booting from a card. eMMC and eSD embedded memories only support raw mode.

Figure 5-18. MMC/SD Booting

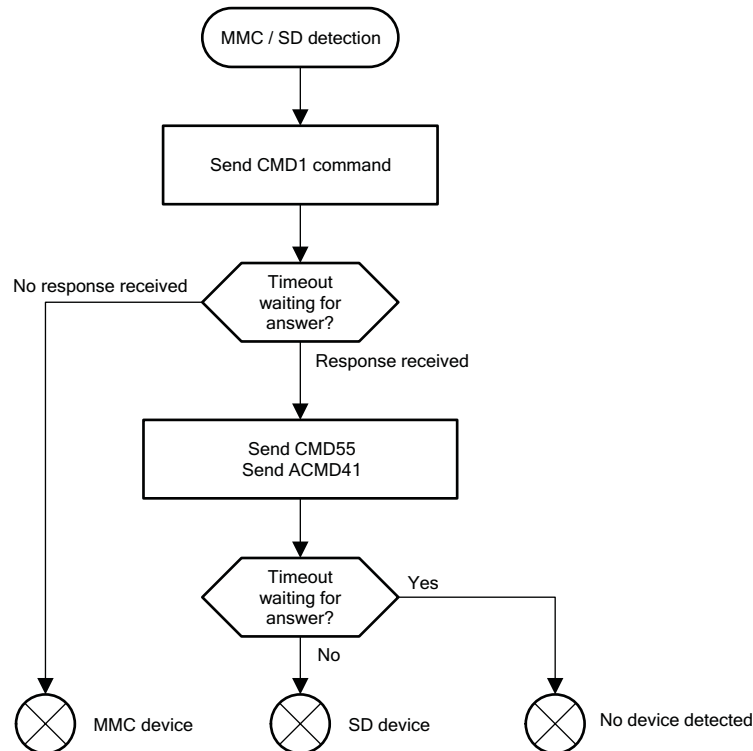

#### 5.2.6.5.4 Initialization and Detection

The ROM Code attempts to initialize the memory device or card connected on MMC interface. If neither memory device nor card is detected then the ROM Code carries on to the next booting device. The standard identification process and Relative Card Address (RCA) assignment are used. However, the ROM Code assumes that only one memory or card is present on the bus. This first sequence uses the CMD signal which is common to SD and MMC devices.

MMC and SD standards detail this phase as initialization phase. Both standards differ in the first commands involved: CMD1 and ACMD41. The ROM Code uses this difference in command set to discriminate between MMC and SD devices: CMD1 is supported only by the MMC standard, whereas ACMD41 is only supported by SD standard.

The ROM Code first sends a CMD1 to the device and gets a response only if an MMC device is connected. If no response is received, then ACMD41 (ACMD41 is made out of CMD55 and ACMD41) is sent and a response is expected from an SD device. If no response is received, then it is assumed that no device is connected and the ROM Code exits the MMC/SD Booting procedure with FAIL. [Figure 5-19](#) shows the detection procedure.

At first the ROM queries the card with CMD1, ARG = 0, to get the OCR from the card. Bit 30 of the response received from the card is set to 1 by the ROM, and this modified value is used as the argument for subsequent CMD1. This is done to indicate to the card that the ROM supports sector addressing. This mode might not be compatible with older (older than v4.4) versions of cards.

**Figure 5-19. MMC/SD Detection Procedure**

The contents of an MMC/SD card can be formatted as raw binary or within a FAT file system. eMMC/eSD devices only support raw mode. The ROM Code reads out raw sectors from image or the booting file within the file system and boots from it.

#### 5.2.6.5.5 MMC/SD Read Sector Procedure in Raw Mode

In raw mode the booting image can be located at one of the four consecutive locations in the main area:

- offset 0x0
- 0x40000 (256KB)
- 0x80000 (512KB)
- 0xC0000 (768KB)

A booting image must not exceed 256KB in size. However, it is possible to flash a device with an image greater than 256KB starting at one of the four locations and the ROM Code will not check the image size. The only drawback is that the image will cross the subsequent image boundary.

The raw mode is detected by reading sectors #0, #512, #1024 #1536. The content of these sectors is then verified for presence of a TOC structure as described in 10. In the case of a GP Device, a Configuration Header (CH) must be located in the first sector followed by a GP header <sup>(1)</sup>. The CH might be void (only containing a CHSETTINGS item for which the valid field is zero).

<sup>(1)</sup> See [Section 5.2.9, Image Format](#).

### 5.2.6.5.6 MMC/SD Read Sector Procedure in FAT Mode

MMC/SD Cards hold a FAT file system which ROM Code reads and processes. The image used by the booting procedure is taken from a specific booting file named "MLO". This file must be in the root directory on an active primary partition of type FAT16 or FAT32. Please refer to [8] and [10] for a more detailed description of MMC/SD file system support.

An MMC/SD card can be configured either as floppy-like or hard-drive-like.

- When acting as floppy-like, the content of the card is a single file system without any Master Boot Record (MBR) holding a partition table.
- When acting as hard-drive-like, an MBR is present in the first sector of the card. This MBR holds a table of partitions, one of which must be FAT16/32, primary and active.

According to [8], the card should always hold an MBR except for MMC cards using floppy-like file system (please refer to the CSD internal Register fields FILE\_FORMAT\_GRP and FILE\_FORMAT in [6]). However, depending on the used operating system the MMC/SD card will be formatted either with partitions (using an MBR) or without. The ROM Code supports both types, described in the following section.

The ROM Code retrieves a map of the booting file from the FAT table. The booting file map is a collection of all FAT table entries related to the booting file (a FAT entry points to a cluster holding part of the file). The booting procedure uses this map to access any 512 byte sector within the booting file without involving ROM Code FAT module.

The sector read procedure utilizes standard MMC/SD raw data read function. The sector address is generated based on the booting memory file map collected during the initialization. Hence the ROM Code can address sectors freely within the booting file space.

### 5.2.6.5.7 FAT File System

The following sections describe functions used by the ROM Code but do not fully describe the Master Boot Record and the FAT file system:

- Recognize if a sector is the 1st sector of an MBR
- Recognize if a sector is the 1st sector of a FAT16/32
- Find the 1st cluster of the booting file
- Buffer the booting file FAT entries.

If true, an active FAT 16/32 partition is searched in all 4 MBR partition entries, based on the type field. If the MBR entries are not valid, or if no useable partition is found, then the ROM Code returns to the booting procedure with FAIL. The extended partitions are not checked. The booting file must reside in a primary partition.

If a partition is found, then its first sector is read and used further on. If no MBR is present (if a floppy-like system), the first sector of the device is read and used further on.

The read sector is checked to be a valid FAT16 or FAT32 partition. If this fails, and another partition type is used (that is, Linux FS or any other), or if the partition is not valid, the ROM Code returns with FAIL.

Otherwise, the root directory entries are searched for a file named depending on the booting device. The Long File Names (LFN) format is not used and only file names in 8.3 format are searched for. If no valid file is found, the ROM Code returns with FAIL.

Once the file is found, the ROM Code reads the File Allocation Table (FAT) and buffers the single-linked chain of clusters in a FAT Buffer which the booting procedure uses to access the file directly sector by sector. For FAT16 and FAT32 (valid if a specific flag has been set in the FAT32 Boot Sector), multiples copies of the FAT exist (ROM Code supports only two copies). When buffering FAT entries, the two FATs are compared. If they do not match, only entries from the last FAT are used. The FAT Buffer holds sector numbers and not cluster numbers. The ROM Code converts each cluster entry to one or several sector entries, if applicable.

Figure 5-20 shows the whole process.

**Figure 5-20. SD/MMC Booting, Get Booting File**

#### 5.2.6.5.7.1 Master Boot Record (MBR)

The Master Boot Record is the 1st sector of a memory device. It is made out of some executable code and 4 partition entries. The aim of such a structure is to divide the hard disk in partitions mostly used to boot different systems (Microsoft Windows®, Linux, or others). [Table 5-26](#) and [Table 5-27](#) describe the structure. [Table 5-28](#) describes the valid partition types searched by the ROM Code.

**Table 5-26. Master Boot Record Structure**

Offset	Length (bytes)	Entry Description	Value
0000h	446	Optional Code	
01BEh	16	Partition Table Entry	(see <a href="#">Table 5-27</a> )
01CEh	16	Partition Table Entry	(see <a href="#">Table 5-27</a> )
01DEh	16	Partition Table Entry	(see <a href="#">Table 5-27</a> )
01EEh	16	Partition Table Entry	(see <a href="#">Table 5-27</a> )
01FEh	2	Signature	AA55h

**Table 5-27. Partition Entry**

Offset	Length (bytes)	Entry Description	Value
0000h	1	Partition State	00h: Inactive 80h: Active
0001h	1	Partition Start Head	Hs
0002h	2	Partition Start Cylinder and Sector	Cs[7:0]-Cs[9:8]-Ss[5:0]
0004h	1	Partition Type	See <a href="#">Table 5-28</a> for partial partition types
0005h	1	Partition End Head	He
0006h	2	Partition End Cylinder and Sector	Ce[7:0]-Ce[9:8]-Se[5:0]
0008h	4	First sector position relative to the beginning of media	LBAs=Cs.H.S+ Hs.S+ Ss-1
000Ch	4	Number of sectors in partition	LBAe=Ce.H.S+ He.S+ Se-1 Nbs= LBAe-LBAs+1

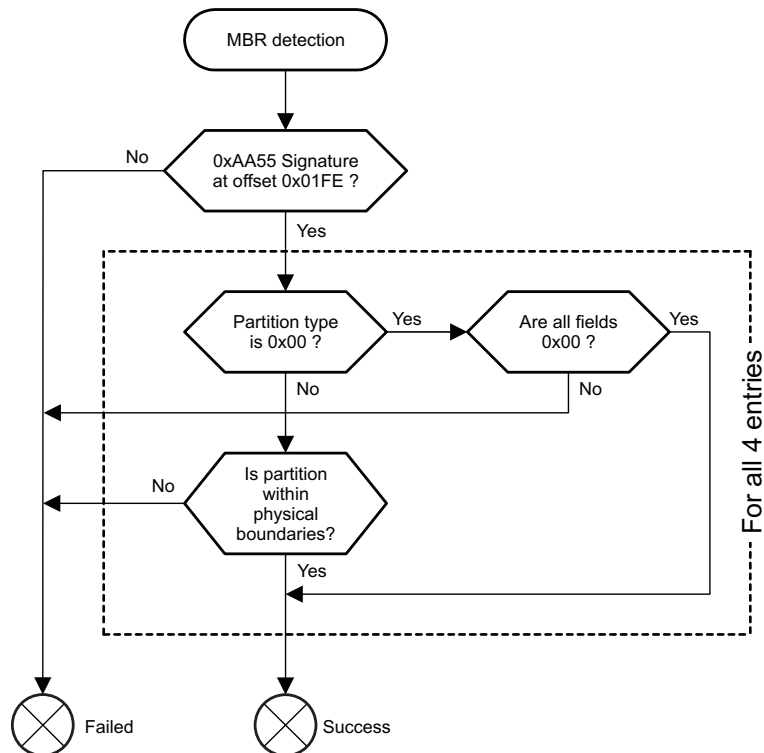

**Table 5-28. Partition Types**

Partition Type	Description
04h, 06h, 0Eh	FAT16
0Bh, 0Ch, 0Fh	FAT32

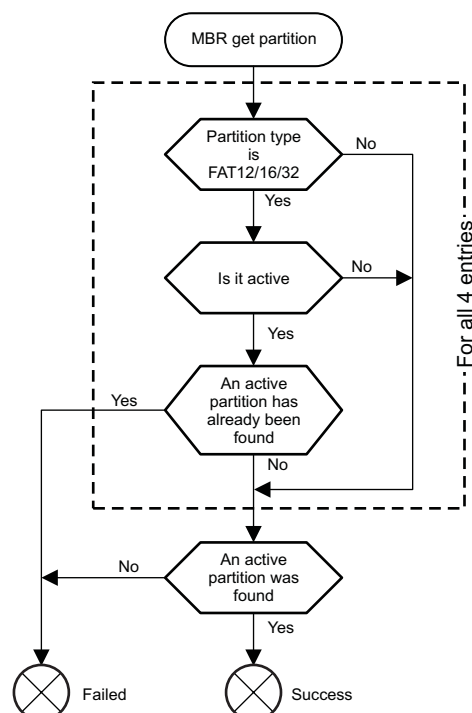

[Figure 5-21](#) shows whether the ROM Code detects a sector is the 1st sector of an MBR.

The ROM Code first checks if the signature is present. Each partition entry is checked:

- If the type is 00h then all fields in the entry must be 00h.
- The partition is checked to be within physical boundaries, that is, the partition is located inside and its size fits the total physical sectors.

**Figure 5-21. MBR Detection Procedure**

Once identified, the ROM Code gets the partition using the procedure shown in [Figure 5-22](#). The partition type is checked to be FAT16 or FAT32. Its state must be 00h or 80h. If than one active partition exists, the test fails. The ROM Code returns FAIL if no active primary FAT16/32 is found.

**Figure 5-22. MBR, Get Partition**

### 5.2.6.5.7.2 FAT16/32 Boot Sector

The FAT file system includes:

- Boot sector which holds the BIOS Parameter Block (BPB)
- File Allocation Table (FAT) which describes the use of each cluster of the partition
- Data area which holds the files, directories and root directory (for FAT16, the root directory has a specific fixed location).

[Table 5-29](#) describes the boot sector. For more details, refer to [12]. **Note:** In the following description, all the fields whose names start with BPB\_ are part of the BPB. All the fields whose names start with BS\_ are part of the Boot Sector. They are not part of the BPB (not mandatory) and they are not used by the ROM Code.

**Table 5-29. FAT Boot Sector**

Offset		Length (bytes)	Name	Description
0000h		3	BS_impBoot	Jump Instruction to Boot Code (not used)
0003h		8	BS_OEMName	Name of the System which created the partition
000Bh		2	BPB_BytsPerSec	Bytes per sector (usually 512)
000Dh		1	BPB_SecPerClus	Number of sectors per allocation unit
000Eh		2	BPB_RsvdSecCnt	Number of reserved sectors for the Boot Sector. For FAT16 is 1, for FAT32, usually 32
0010h		1	BPB_NumFATs	Number of copies of FAT, usually 2
0011h		2	BPB_RootEntCnt	For FAT16, number of 32-byte entries in the Root Directory (multiple of BPB_BytsPerSec/32). For FAT32 this value is 0.
0013h		2	BPB_TotSec16	Total Count of sectors on the volume. If the size is bigger than 10000h or for FAT32, this field is 0 and BPB_TotSec32 holds the value
0015h		1	BPB_Media	Media Type, usually F8h: fixed, non-removable
0016h		2	BPB_FATSz16	For FAT16, size in sectors of one FAT. For FAT32, holds 0
0018h		2	BPB_SecPerTrk	Number of sectors per track, 63 for SD/MMC
001Ah		2	BPB_NumHeads	Number of heads, 255 for SD/MMC
001Ch		4	BPB_HiddSec	Number of sectors preceding the partition
0020h		4	BPB_TotSec32	Total Count of sectors on the volume. If the size is smaller than 10000h (for FAT16), this field is 0 and BPB_TotSec16 is valid
FAT16	0024h	1	BS_DrvNum	Drive Number
	0025h	1	BS_Reserved1	00h
	0026h	1	BS_BootSig	Extended Boot Signature 29h. Indicates that the following three fields are present
	0027h	4	BS_VolID	Volume Serial Number
	002Bh	11	BS_VolLab	Volume Label
	0036h	8	BS_FilSysType	File system Type: "FAT16", "FAT32". Note: This field is not mandatory (BS_) and cannot identify the partition type.

**Table 5-29. FAT Boot Sector (continued)**

Offset		Length (bytes)	Name	Description
FAT32	0024h	4	BPB_FATSz32	Size in sectors of one FAT. Field BPB_FATSz16 must be 0
	0028h	2	BPB_ExtFlags	FAT Flags: [7]: 0=FAT is mirrored; 1=Only one FAT is used [3:0]: Number of used FAT if no mirroring used
	002Ah	2	BPB_FSVer	File system Version Number
	002Ch	4	BPB_RootClus	First Cluster number of the Root Directory
	0030h	2	BPB_FSInfo	Sector number of FSINFO Structure in the reserved-area, usually 1
	0032h	2	BPB_BkBootSec	If non-zero, indicates the sector number in the reserved-area of a copy of the Boot Sector
	0034h	12	BPB_Reserved	Reserved, set to 00h
	0040h	1	BS_DrvNum	Drive Number
	0041h	1	BS_Reserved1	00h
	0042h	1	BS_BootSig	Extended Boot Signature 29h. Indicates that the following 3 fields are present
	0043h	4	BS_VolID	Volume Serial Number
	0047h	11	BS_VolLab	Volume Label
	0052h	8	BS_FilSysType	File system Type: "FAT16", "FAT32". Note: This field is not mandatory (BS_) and cannot identify the partition type.
01FEh		2	BPB_Signature	AA55h

To check whether a sector holds a valid FAT16/32 partition, only fields starting with BPB can be checked because they are mandatory. The fields starting from offset 0024h to 01FDh cannot be used for the check because they differ when using FAT16 or FAT32. [Figure 5-23](#) describes the procedure.

1. The ROM Code checks if the BPB\_Signature is equal to AA55h.
2. The ROM Code checks some fields which must have some values: BPB\_BytsPerSec, BPB\_SecPerClus, BPB\_RsvdSecCnt, BPB\_NumFATs, BPB\_RootEntCnt
3. If the geometry of the device is known (valid CHS for device size < 4GB) then it is compared against BPB\_SecPerTrk and BPB\_NumHeads fields
4. If an MBR was found before, the partition size is also checked:  

$$\text{BPB\_TotSec16} = \text{MBR\_Partition\_Size}$$
or  

$$\text{BPB\_TotSec32} = \text{MBR\_Partition\_Size}$$
5. The field BPB\_ToSec16 is used if the total number of sectors is below 65518 (in this case BPB\_TotSec32 = 0). Otherwise, BPB\_TotSec32 is used (BPB\_TotSec16=0).
6. The partition sector offset is also checked: BPB\_HiddSec = MBR\_Partition\_Offset (if this value is not 0 as some operating systems do not update this field correctly).
7. The last step is to decide the type of FAT file system. The ROM Code computes the number of clusters in the Data Area part of the partition:  

$$\text{Nb\_clusters} < 4085 \Rightarrow \text{FAT12}$$

$$4085 \leq \text{Nb\_clusters} < 65525 \Rightarrow \text{FAT16}$$

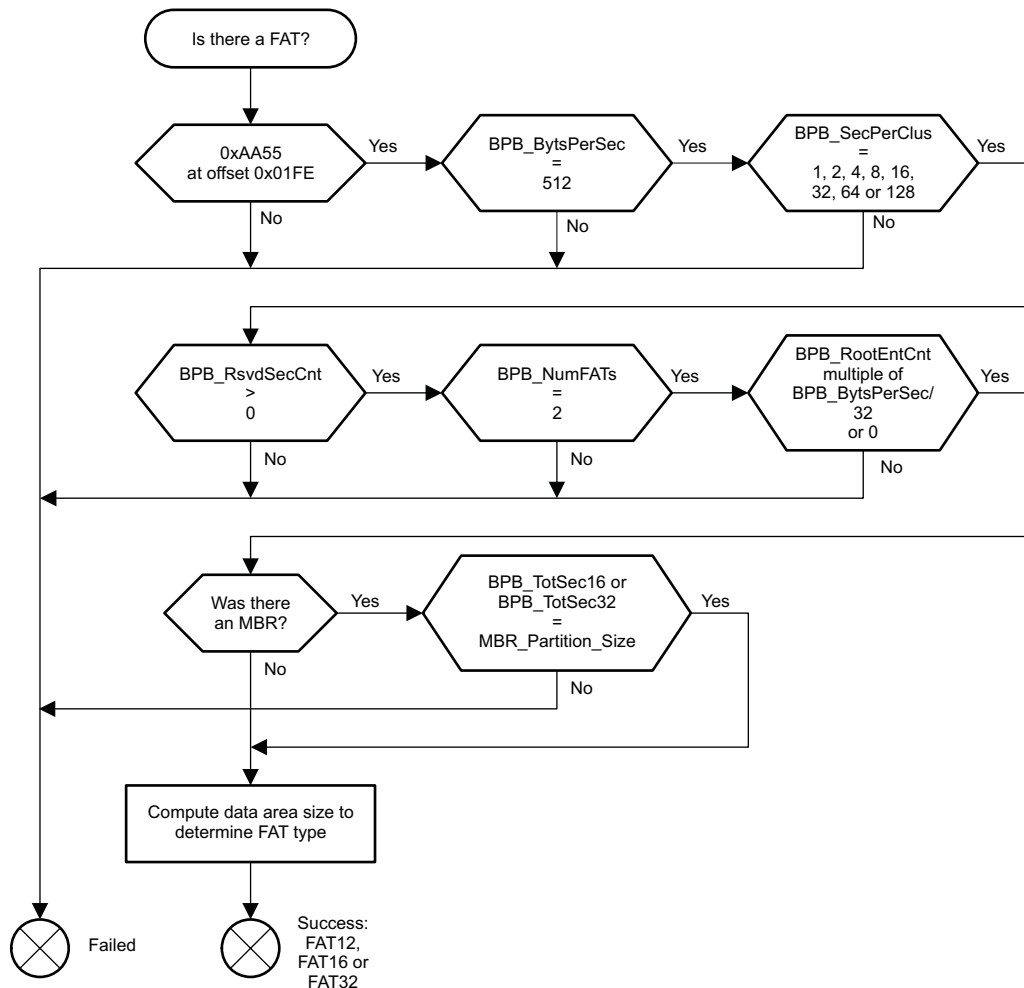

$$65525 \leq \text{Nb\_clusters} \Rightarrow \text{FAT32}$$

(1)

where  $\text{Nb\_clusters}$  is given by the size of the data area:

$$\begin{aligned} \text{RootDirSectors} &= \frac{\text{BPB\_RootEntCnt} \times 32}{\text{BPB\_BytesPerSec}} \\ \text{DataSec} &= \text{BPB\_TotSec} - (\text{BPB\_RsvdSecCnt} + (\text{BPB\_NumFATs} \times \text{BPB\_FATSz}) + \text{RootDirSectors}) \\ \text{Nb\_clusters} &= \frac{\text{DataSec}}{\text{BPB\_SecPerClus}} \end{aligned}$$

(2)

**Figure 5-23. FAT Detection Procedure**

### 5.2.6.5.7.3 FAT16/32 Root Directory

Next, the ROM Code finds the booting file named “MLO” inside the root directory of the FAT16/32 file system. The file is not searched in any other location.

For a FAT16 file system, the root directory has a fixed location which is cluster 0. For a FAT32 file system, its cluster location is given by BPB\_RootClus. The general formulae to find the sector number (relative to device sector 0, not partition sector 0) of a cluster is given by:

$$\text{Cluster}_{\text{sector}} = \text{BPB\_HiddSec} + \text{BPB\_RsvdSecCnt} + \text{BPB\_NumFATs} \times \text{BPB\_FATSz} + \text{Cluster} \times \text{BPB\_SecPerClus} \quad (3)$$

**Note:** the BPB\_HiddSec field can contain 0 even if the FAT file system is located somewhere other than on sector 0 (floppy-like). The ROM Code actually uses the partition offset taken from the MBR instead of this field, which can be wrong. If no MBR is found (floppy-like), the value 0 is used.

Each entry in the root directory is 32 bytes long and holds information about the file such as filename, date of creation, rights, and cluster location. [Table 5-30](#) describes more.

The ROM Code checks each entry in the root directory until either the booting file is found or the entry is empty (first byte is 00h), or when the end of the root directory is reached. Entries with an ATTR\_LONG\_NAME attribute (LFN) and with first byte at E5h (erased file) are ignored. When found, the first cluster offset of the file is read from the DIR\_FstClusHi and DIR\_FstClusLo fields.

There is a slight difference between FAT16 and FAT32 when handling the Root Directory. On FAT16, this directory has a fixed location and length fixed by BPB\_RootEntCnt which is the total number of 32-byte entries. Handling this directory is therefore straightforward. On FAT32, the root directory is like a standard file. The File Allocation Table (FAT) must retrieve each sector of the directory.

**Table 5-30. FAT Directory Entry**

Offset	Length (bytes)	Name	Description
0000h	11	DIR_Name	Short Name (8+3)
000Bh	1	DIR_Attr	File Attributes: ATTR_READ_ONLY 01h ATTR_HIDDEN 02h ATTR_SYSTEM 04h ATTR_VOLUME_ID 08h ATTR_DIRECTORY 10h ATTR_ARCHIVE 20h ATTR_LONG_NAME ATTR_READ_ONLY   ATTR_HIDDEN   ATTR_SYSTEM   ATTR_VOLUME_ID
000Ch	1	DIR_NTRes	Reserved, set to 00h
000Dh	1	DIR_CrtTimeTenth	Millisecond stamp at file creation
000Eh	2	DIR_CrtTime	Time file was created
0010h	2	DIR_CrtDate	Date file was created
0012h	2	DIR_LstAccDate	Last Access date
0014h	2	DIR_FstClusHi	High word of this entry's first cluster number
0016h	2	DIR_WrtTime	Time of last write
0018h	2	DIR_WrtDate	Date of last write
001Ah	2	DIR_FstClusLo	Low word of this entry's first cluster number
001Ch	4	DIR_FileSize	File size in bytes

#### 5.2.6.5.7.4 FAT16/32 File Allocation Table

The ROM Code must read the FAT to retrieve sectors either for the booting file or for the root directory (if the file system is FAT32). There can be multiple copies of the FAT inside the file system (ROM Code supports only 2) located after the boot sector:

$$\text{FATn}_{\text{sector}} = \text{BPB\_HiddSec} + \text{BPB\_RsvdSecCnt} + \text{BPB\_FATSz} \times n \quad (4)$$

Its size is given by BPB\_FATSz16 or BPB\_FATSz32. The ROM Code checks each copy of the FAT if identical. If the values are different, the ROM Code uses the value from the last FAT copy. With the FAT32 file system, the copy system can be disabled according to a flag located in BPB\_ExtFlags[7]. If this flag is set, then FAT BPB\_ExtFlags[3:0] is used and the ROM Code verifies no other copies of FAT.

The FAT is a simple array of values each referring to a cluster located in the data area. One entry of the array is 16- or 32-bit depending on the file system.

The value inside an entry defines whether the cluster is being used and if another cluster must be taken into account. This creates a single-linked chain of clusters defining the file. The meaning of an entry is described in [Table 5-31](#).

**Note:** For compatibility reasons, clusters 0 and 1 are not used for files and those entries must contain FFF8h and FFFFh (for FAT16) and ?FFFFFF8h and ?FFFFFFFh (for FAT32).

**Table 5-31. FAT Entry Description**

FAT16	FAT32	Description
0000h	?0000000h	Free Cluster
0001h	?0000001h	Reserved Cluster
0002h-FFEFh	00000002h-?FFFFFFEFh	Used Cluster; value points to next cluster
FFF0h-FFF6h	?FFFFFF0h-?FFFFFF6h	Reserved values
FFF7h	?FFFFFF7h	Bad Cluster
FFF8h-FFFFh	?FFFFFF8h-?FFFFFFFh	Last Cluster in File

**Note:** FAT32 uses only bits [27:0]. The upper 4 bits are usually 0 and should be left untouched. When accessing the root directory for FAT32, the ROM Code starts from the root directory cluster entry and follows the linked chain to retrieve the clusters.

When the booting file is found, the ROM Code buffers each FAT entry corresponding to the file in a sector way. This means each cluster is translated to one or several sectors depending on the number of sectors in a cluster (BPB\_SecPerClus). This buffer is used later by the booting procedure to access the file.

#### 5.2.6.5.8 Pins Used

Table 5-32 and Table 5-33 list the device pins configured by the ROM for MMC boot mode. Not all pins are driven at boot time.

**Table 5-32. Pins Used for MMC0 Boot**

Signal name	Pin used	CTRL_CONF Register	Register Setting
clk	mmc0_clk	CTRL_CONF_MMC0_CLK	0x08050000
cmd	mmc0_cmd	CTRL_CONF_MMC0_CMD	0x08060000
dat0	mmc0_dat0	CTRL_CONF_MMC0_DAT0	0x08060000
dat1	mmc0_dat1	CTRL_CONF_MMC0_DAT1	0x08060000
dat2	mmc0_dat2	CTRL_CONF_MMC0_DAT2	0x08060000
dat3	mmc0_dat3	CTRL_CONF_MMC0_DAT3	0x08060000

**Table 5-33. Pins Used for MMC1 Boot**

Signal name	Pin used	CTRL_CONF Register	Register Setting
clk	gpmc_cs1	CTRL_CONF_GPMC_CS1	0x08050002
cmd	gpmc_cs2	CTRL_CONF_GPMC_CS2	0x08060002
dat0	gpmc_ad8	CTRL_CONF_GPMC_AD8	0x08060002
dat1	gpmc_ad9	CTRL_CONF_GPMC_AD9	0x08060002
dat2	gpmc_ad10	CTRL_CONF_GPMC_AD10	0x08060002
dat3	gpmc_ad11	CTRL_CONF_GPMC_AD11	0x08060002

## 5.2.6.6 SPI

SPI EEPROMs or SPI flashes have an EEPROM or NOR flash backend and they connect to the device using the serial SPI protocol.

These devices operate in three stages: the command stage, the address stage, and the data transfer stage. The command is usually an 8-bit value followed by the address (depending on the size of the device) followed by the data to be read or written.

Because fewer pins are required, these devices are comparatively inexpensive, easy for board layout, and are the devices of choice when cost, complexity and form factor are critical considerations.

### 5.2.6.6.1 Features

- Supports 12 MHz clock (50% duty cycle)
- Supports only SPI Mode 3 (clock polarity = 1, clock phase = 1, chip select is active low)
- Supports only 24-bit addressable EEPROMs
- Supports only 4-pin SPI mode (CS, CLK, Serial Input, Serial Output)
- The boot devices must be connected to chip select 0 and must support the read command (03h)
- The boot image is copied into internal memory and then executed

### 5.2.6.6.2 Initialization and Detection

The ROM Code initializes the SPI controller, pin muxing, and clocks to communicate with the SPI device. The controller is initialized in Mode 3 and the clock is set to operate at 12 MHz. There is no specific device identification routine that is executed by the ROM code to identify whether a boot device is preset. If no SPI device is present, the sector read will return only 0xFFFFFFFF and the SPI boot will be treated as failed.

### 5.2.6.6.3 SPI Read Sector Procedure

The ROM Code reads SPI data from the boot device in 512-byte sectors. For each call to the SPI Read Sector routine, the SPI Read Command (0x03) is sent with the 24-bit start address of the data to be read.

Form the next iteration, a dummy value transmits on the master out line and the data is received on the master in line. This is a required process because SPI protocol always operates in full duplex mode. The dummy data transmitted by the ROM is the read command appended to the start address. The data from the boot device is received MSB first.

### 5.2.6.6.4 SPI Boot Image Requirement

Because this Cortex is a little-endian processor and SPI operates in a big-endian format, the boot image must be in a big-endian format while writing to the flash to avoid the endian conversion at boot time and improve boot performance.

### 5.2.6.6.5 Pins Used

[Table 5-34](#) lists the device pins configured by the ROM for SPI boot mode. Not all pins are driven at boot time.

**Table 5-34. Pins Used for SPI Boot**

Signal Name	Pin Used	CTRL_CONF Register	Register Setting
Cs	spi0_cs0	CTRL_CONF_SPI0_CS0	0x08060000
Miso	spi0_d0	CTRL_CONF_SPI0_D0	0x08040000
mosi	spi0_d1	CTRL_CONF_SPI0_D1	0x08040000
Clk	spi0_sclk	CTRL_CONF_SPI0_SCLK	0x08060000

### 5.2.6.7 QSPI

QSPI EEPROMs or QSPI flashes have an EEPROM or NOR flash backend and they connect to the device using the serial QSPI protocol.

The device will operate in memory mapped mode.

ROM Code will execute ISW directly from QSPI Flash because it is configured in memory mapped mode

#### 5.2.6.7.1 Features

- Supports only QSPI Mode 3 (clock polarity = 1, clock phase = 1, data delay = 0)
- Supports 12 MHz clock (50% duty cycle)
- Supports only 24-bit addressable EEPROMs
- Supports memory mapped mode
- Supports only 6-pin SPI mode (CS, CLK, D0, D1,D2, D3)
- Supports quad read mode
- The boot devices must be connected to chip select 0 and must support both the READ (03h) and QOR (6Bh) commands
- Image must be flashed in little endian format
- The boot device must default to quad mode, if quad-read support is desired

#### 5.2.6.7.2 Initialization and Detection

The ROM Code initializes the QSPI controller, pin muxing, and clocks to communicate with the QSPI device. The controller is initialized in Mode 3 and the clock is set to operate at 12 MHz. There is no specific device identification routine executed by the ROM code to identify whether a boot device is preset. If no QSPI device is present, the QSPI read will return only 0xFFFFFFFF and the QSPI boot will be treated as failed.

The ROM code uses the Quad Read command (0x6B) to read from the flash, so the ROM expects the QSPI flash to be in quad mode right after reset. This configuration is typically be done at flashing time by writing to the non-volatile Quad Enable (QE) bit of the flash.

If the ROM detects SYSBOOT[7] as 1, it will read from the QSPI flash using the Single Line Read command (0x03).

#### 5.2.6.7.3 Pins Used

[Table 5-35](#) lists the device pins configured by the ROM for the QSPI boot mode. Not all pins are driven at boot time.

**Table 5-35. Pins Used for QSPI Boot**

Signal Name	Pin Used Pinmux Option 0	CTRL_CONF Register	Register Setting	Pin Used Pinmux Option 1	CTRL_CONF Register	Register Setting
Clk	gpmc_csn3	CTRL_CONF_ CSN3	0x08460002	cam0_data2	CTRL_CONF_ CAM0_DATA2	0x08040003
Csn0	gpmc_csn0	CTRL_CONF_ CSN0	0x08060003	cam0_data3	CTRL_CONF_ CAM0_DATA3	0x08060003
D0	gpmc_advn_ale	CTRL_CONF_ ADV_N_ALE	0x08060003	cam0_data4	CTRL_CONF_ CAM0_DATA4	0x08060003
D1	gpmc_oen_ren	CTRL_CONF_ OEN_REN	0x08060003	cam0_data5	CTRL_CONF_ CAM0_DATA5	0x08060003
D2	gpmc_wen	CTRL_CONF_ GPMC_WEN	0x08060003	cam0_data6	CTRL_CONF_ CAM0_DATA6	0x08060003
D3	gpmc_be0n_cle	CTRL_CONF_ GPMC_BE0N_ CLE	0x08060003	cam0_data7	CTRL_CONF_ CAM0_DATA7	0x08060003

#### 5.2.6.7.4 SYSBOOT Signals

Table 5-36 lists the SYSBOOT signals for QSPI boot.

**Table 5-36. SYSBOOT Signals for QSPI Boot**

SYSBOOT[7]	Used to select QSPI bus width. 0b – 4 bits (D3-D0) used. ROM uses Quad Read command (0x6B). 1b – 1 bit (D0) used. ROM uses Single Read command (0x03).
SYSBOOT[6]	Used for Pinmux option selection in QSPI. 0b – pinmux option 0 is selected for QSPI. 1b – pinmux option 1 is selected for QSPI.

### 5.2.6.8 USB Mass Storage (USB\_MS) Device

#### 5.2.6.8.1 Device Initialization

The ROM Code supports booting from the USB interface in host mode under the following conditions:

- Using the USB1 interface.
- USB operates in High-Speed, Host mode.
- Supports Mass Storage Class device with SCSI command set.
- ROM does not support hubs.
- Data transfer is performed using the USB core's DMA, so the boot image can be loaded only from 0x40300000 because the internal memory of the ARM is not accessible to the DMA. This restricts the maximum image size to 220KB.
- ROM code used the value of DATA POLARITY inversion feature for USB based on SYSBOOT[16] (silicon revision PG1.2 only)

#### 5.2.6.8.2 Overview

If USB boot is chosen by the SYSBOOT pin configuration:

- The USB hardware and PRCM clocks are configured.
- The ROM code implements the SCSI command set.

#### 5.2.6.8.3 Enumeration and Detection

1. Enables the USB module by programming the PRCM to turn on the functional clocks.
2. Powers on the USB integrated Transceiver.
3. The ROM code detects that the USB is a USB A-device through the USB-ID pin pulled low.
4. The ROM code sets host mode.
5. When the ROM detects a device is connected, it performs a USB Reset to the device.
6. The ROM performs USB enumeration.

#### 5.2.6.8.4 Device Detection Parameters

1. If the interface descriptor of the device has bInterfaceClass specified as 08h for Mass Storage Class, the ROM code checks the bInterfaceProtocol field of the USB interface descriptor for Bulk Only Transport mode, having two Bulk Endpoints(BULK -IN and BULK OUT)
2. If the bInterfaceSubclass is set to 06, SCSI transparent command set is supported by the device  
Other types of subclasses are not supported.
3. The BootROM communicates with the device per the Mass storage Protocol using the SCSI command set to read the sectors from the USB device.
4. The BootROM sends a standard SCSI enquiry command to the device to know the capabilities of the

device.

5. The BootROM parses the boot table and partition information to retrieve the boot image.

#### 5.2.6.8.5 Boot Procedure

The USB Mass Storage device connected for booting should hold FAT file system which ROM code reads and processes. The image the booting procedure uses is taken from a specific booting file named "MLO". This file must be located in the root directory on an active primary partition of type FAT16 or FAT32.

An MBR must be present in the first sector of the card. This MBR holds a table of partitions, one of which must be FAT16/32, primary and active.

The ROM Code retrieves a map of the booting file from the FAT table. The booting file map is a collection of all FAT entries related to the booting file (a FAT entry points to a cluster holding part of the file). The booting procedure uses this map to access any 512-byte sector within the booting file without involving the ROM Code FAT module.

The sector read procedure uses a standard SCSI READ10 function.

The sector address generates based on the booting memory file map collected during the initialization. Hence the ROM Code can address sectors freely within the booting file space.

#### 5.2.6.8.6 Pins Used

[Table 5-37](#) lists the device pins configured by the ROM for the USB boot mode. Not all pins are driven at boot time.

**Table 5-37. Pins Used for USB\_MS Boot**

Signal Name	Pin Used	Register Setting
dm	usb1_dm	Not written by ROM
dp	usb1_dp	Not written by ROM
id	usb1_id	Not written by ROM
vbus	usb1_vbus	Not written by ROM

#### 5.2.6.8.7 SYSBOOT Signals

[Table 5-38](#) lists the SYSBOOT signals for USB mass storage boot.

**Table 5-38. SYSBOOT Signals for USB\_MS Boot**

SYSBOOT[16] <sup>(1)</sup>	Used to select swapping of USB signals. 0b – USB DP/DM is not swapped. 1b – USB DP/DM is swapped.
----------------------------	---

<sup>(1)</sup> The functionality provided by SYSBOOT[16] is only available on silicon revision PG1.2

#### 5.2.6.9 Blocks and Sectors Search Summary for the Redundant Images

[Table 5-39](#) summarizes numbers of blocks and sectors which are searched during the memory booting from devices requiring image shadowing. NAND is organized with blocks, which are erasable units.

**Table 5-39. Blocks and Sectors Searched on non-XIP Memories**

Memory	Maximum Number of Blocks Checked	Number of Sectors Searched
NAND	first 4	1 <sup>(1)</sup>
SPI, eMMC/eSD and MMC/SD cards (raw mode)	first 4	1

<sup>(1)</sup> Depends on NAND geometry

For MMC/SD card booting in FAT mode, the file system area is searched for one file.

## 5.2.7 Peripheral Booting

### 5.2.7.1 Overview

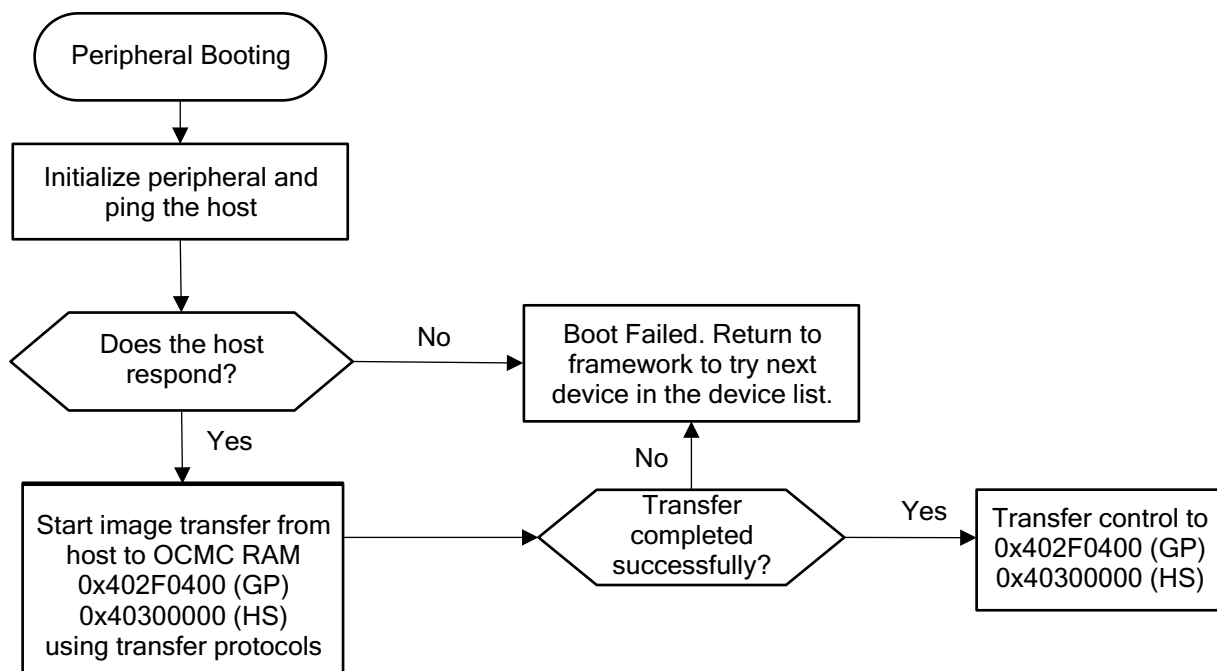

The ROM Code boots from three different peripheral interfaces:

- EMAC: 100/10 Mbps Ethernet, using standard TCP/IP network boot protocols BOOTP and TFTP
- USB: Full-speed, client mode
- UART: 115.2Kbps, 8-bit, no parity, 1 stop bit, no flow control

The purpose of booting from a peripheral interface is to download a boot image from an external host (typically a PC). This booting method is mostly used for programming flash memories connected to the device (for example, in the case of initial flashing, or for firmware updates or servicing).

### 5.2.7.2 Peripheral Boot Procedure Overview

**Figure 5-24. Peripheral Booting Procedure**

### 5.2.7.3 EMAC Boot Procedure

#### 5.2.7.3.1 Device Initialization

- EMAC boot uses the CPGMAC port 1 of the device.
- Supports connection to external Ethernet PHY using the MII, RMII, RGMII and MDIO pins.
- In dual-port configurations, the ROM code assumes the Ethernet PHY with the lowest MDIO address (0–31) is connected to CPGMAC port 1.
- Device uses EFUSE register MAC\_ID0 for Ethernet MAC address of the device.
- EMAC boot assumes that PHY will do auto-negotiation at power on.
- On a warm reset, if Ethernet reset isolation is enabled, the ROM will skip configuring the EMAC and directly issue the BOOTP request.
- ROM code expects an external 50-MHz reference clock requirement when using RMII PHY Interface.
- When booting using RGMII PHY interface, ROM only supports internal delay mode (delay on the Tx path with respect to clock) enabled in the device.
- Device detects if the PHY is alive on the MDIO interface and
  - Reads the STATUS register to check if Ethernet link is active
  - Waits 5 seconds for auto-negotiation to complete before timing out.
  - Reads the STATUS register to check if the PHY supports Gigabit Mode.
  - Reads the PHY registers No. 4,5,9,10 to detect the auto-negotiated mode of operation.
    - Is the mode full-duplex or half duplex
    - Speed of operation: 100/10 Mbps

#### 5.2.7.3.2 BOOTP (RFC 951)

The device obtains the IP and boot information using the BOOTP protocol. The device prepares and broadcasts the BOOTP message with the following information:

- Device MAC address in "chaddr" field to uniquely identify the device to the server.
- "vender-class-identifier" option number 60 (RFC 1497, RFC 1533). Servers use this information to identify the device type. The value present is "AM43xx ROM v1.0"
- "Client-identifier" option number 61 (RFC 1497, RFC 1533). This has the ASIC-ID structure (see [Section 5.2.7.6](#)), which contains additional information for the device.

The device then expects a BOOTP response that provides the following information for the booting to proceed:

- Device IP address from "yiaddr" field
  - Subnetmask from extended option 1 (RFC 1497, RFC 1533)
  - Gateway IP from extended option number 3 (RFC 1497, RFC 1533) or from "giaddr" field of BOOTP response.
  - Boot image filename from "file" field
  - TFTP server IP address from the "siaddr" field
- Timeouts and retries
- Exponentially increasing timeouts starting from 4 seconds, doubling for each retry.
  - 3 retries

### 5.2.7.3.3 TFTP (RFC 1350)

After a successful BOOTP completion, the device initiates the TFTP download of the boot image into SRAM. The device can reach the TFTP server within the local subnet or outside through the gateway.

Timeouts and retries:

- Timeout of 1 second to receive a response for the READ request
- 5 retries for the READ request
- Retries are managed by a server once the data transfer starts (server re-sends a data packet if the ACK was not received within a timeout value)
- Device has a 60 second timeout to complete the data transfer and handle the scenario if the server dies in the middle of a data transfer

### 5.2.7.3.4 Pins Used

Table 5-40, Table 5-41, and Table 5-42 list the device pins configured by the ROM for the EMAC boot mode. Not all pins are driven at boot time.

**Table 5-40. Pins Used for EMAC Boot in MII Mode**

Signal Name	Pin Used in Device	Pin Mux Mode	CTRL_CONF Register	Register Setting
gmii1_col	MII1_COL	0	CTRL_CONF_MII1_COL	0x000c0000
gmii1_crs	MII1_CRCS	0	CTRL_CONF_MII1_CRCS	0x000c0000
gmii1_rxe	MII1_RX_ER	0	CTRL_CONF_MII1_RXERR	0x000c0000
gmii1_txen	MII1_TX_EN	0	CTRL_CONF_MII1_TXEN	0x00040000
gmii1_rxdv	MII1_RX_DV	0	CTRL_CONF_MII1_RXDV	0x00040000
gmii1_txd[3:0]	MII1_TXD[3:0]	0	CTRL_CONF_MII1_TXD3 to CTRL_CONF_MII1_TXD0	0x000c0000
gmii1_txclk	MII1_TX_CLK	0	CTRL_CONF_MII1_TXCLK	0x000c0000
gmii1_rxclk	MII1_RX_CLK	0	CTRL_CONF_MII1_RXCLK	0x00000000

### 5.2.7.3.5 SYSBOOT Signals

Some of the SYSBOOT pins have special meanings when EMAC boot is selected. SYSBOOT[5] returns the EMAC PHY interface being used (**Note:** RGMII is automatically detected). [Table 5-43](#) details more.

**Table 5-43. Ethernet PHY Mode Selection**

SYSBOOT[5]	PHY Mode
0b	MII
1b	RMII

SYSBOOT[18] provides a way to select a clock that can be generated by the device and output on CLKOUT2. This can be used to connect to an external ethernet PHY to eliminate the need for an external crystal or oscillator for the PHY. The frequency will differ depending on the PHY mode chosen with SYSBOOT[5]. More details in [Table 5-44](#).

**Table 5-44. Ethernet Clock Selection**

SYSBOOT[18] <sup>(1)</sup>	CLKOUT2
0	CLKOUT2 not used
1	CLKOUT2 = 25MHz if SYSBOOT[5] = 0 CLKOUT2 = 50MHz if SYSBOOT[5] = 1

<sup>(1)</sup> The functionality provided by SYSBOOT[18] is only available on silicon revision PG1.2.

### 5.2.7.4 UART Boot Procedure

#### 5.2.7.4.1 Device Initialization

- UART boot uses UART0.
- UART0 is configured to run at 115200 baud, 8-bit, no parity, 1 stop bit and no flow control.

#### 5.2.7.4.2 Boot Image Download

- UART boot uses x-modem client protocol to receive the boot image.
- Utilities such as hyperterm, teraterm, minicom can be used on the PC side to download the boot image to the board
- With x-modem packet size of 1K throughout is roughly about 4KB/s.
- The ROM code will ping the host 10 times in 3s to start x-modem transfer. If host does not respond, UART boot will time out.
- Once the transfer starts, if the host does not send any packet for 3 seconds, UART boot will time out

- If the delay between two consecutive bytes of the same packet is more than 2 ms, the host is requested to re-transmit the entire packet again
- Error checking using the CRC-16 support in x-modem. If an error is detected, the host is requested to re-transmit the packet again.

#### 5.2.7.4.3 Pins Used

[Table 5-45](#) lists the device pins configured by the ROM for the UART boot. Not all pins are driven at boot time.

**Table 5-45. Pins Used for UART Boot**

Signal Name	Pin Used	CTRL_CONF Register	Register Setting
Rx	uart0_rxd	CTRL_CONF_UART0_RXD	0x080e0000
Tx	uart0_txd	CTRL_CONF_UART0_TXD	0x080b0000

## 5.2.7.5 USB Client (USB\_CL) Boot Procedure

### 5.2.7.5.1 Device Initialization

The ROM Code supports booting from the USB interface in client (peripheral) mode under the following conditions:

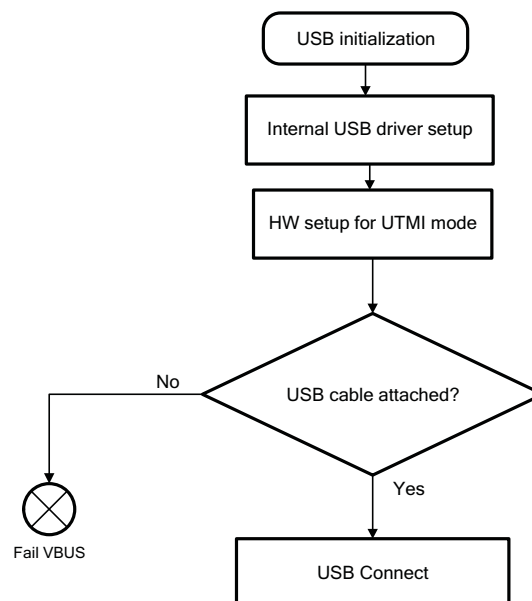

- Using the USB0 interface.
- USB operates in Full Speed, Client mode.
- USB will operate only in device powered mode with maximum power rating of 100mA.
- USB cable should be plugged in within 20 sec of powering up the device.
- ROM code uses the value of DATA POLARITY inversion feature for USB based on SYSBOOT[16].

### 5.2.7.5.2 Overview

If USB\_CL boot is chosen by the SYSBOOT pin configuration:

- The USB hardware and PRCM clocks are configured for UTMI mode.
- The ROM Code continues with the USB procedure only if the USB cable is detected present (that is, VBUS is detected at transceiver level and communicated as such through the UTMI traffic). If not, the initialization procedure is aborted.
- The ROM code implements the RNDIS class driver.
- From user's perspective, USB boot is indistinguishable from Ethernet boot.
- The USB initialization procedure is shown in [Figure 5-25](#).

**Figure 5-25. USB Initialization Procedure**

### 5.2.7.5.3 Enumeration Descriptors

[Table 5-46](#) lists the device descriptor parameters used during enumeration. The default Vendor ID and Product ID can be automatically overridden by the customer by programming the EFUSE that stores these values.

**Table 5-46. Customized Descriptor Parameters**

Parameter	Size (bytes)	TI Default Values
Device Class	1	02h (Communication Class)
Device Id Vendor (VID)	String	"Texas Instruments" (0x0451)

**Table 5-46. Customized Descriptor Parameters (continued)**

Parameter	Size (bytes)	TI Default Values
Device IProduct	String	"AM43xx 1.0"
Device Id Product (PID)	2	0x6142

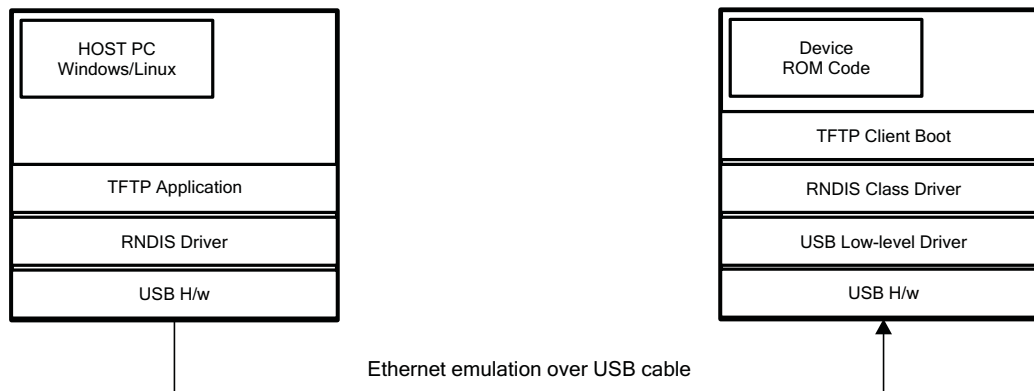

Four endpoints are configured for USB:

- One control endpoint (default)
- Two bulk endpoints: Data transmit and receive having interface class as "Communication Data"
- One interrupt endpoint used for RNDIS notifications

The interface class for USB is "Communication Control" and interface sub-class is "Abstract Line Control Model".

#### 5.2.7.5.4 Image Download Procedure

- The ROM implements as RNDIS class driver, so it enumerates as an Ethernet port.
- Standard RNDIS drivers present on Linux and Windows are picked up during the enumeration, no special drivers need to be installed.
- Once the enumeration is complete, the customer can download the boot image using any standard TFTP server application.

**Figure 5-26. Image Transfer for USB Boot**

### 5.2.7.5.5 Pins Used

[Table 5-47](#) lists the device pins configured by the ROM for the USB boot mode. Not all pins are driven at boot time.

**Table 5-47. Pins Used for USB\_CL Boot**

Signal Name	Pin Used	CTRL_CONF Register Setting
dm	usb0_dm	Not written by ROM
dp	usb0_dp	Not written by ROM
id	usb0_id	Not written by ROM
vbus	usb0_vbus	Not written by ROM

### 5.2.7.5.6 SYSBOOT Signals

[Table 5-48](#) lists the SYSBOOT signals for USB client boot.

**Table 5-48. SYSBOOT Signals for USB\_CL Boot**

SYSBOOT[16] <sup>(1)</sup>	Used to select swapping of USB signals. 0b – USB DP/DM is not swapped. 1b – USB DP/DM is swapped.
----------------------------	---

<sup>(1)</sup> The functionality provided by SYSBOOT[16] is only available on silicon revision PG1.2.

### 5.2.7.6 ASIC ID Structure

The ASIC ID size is 81 bytes for Ethernet and USB. All fields of this structure are reserved.

## 5.2.8 Low Latency NOR Booting

### 5.2.8.1 Overview

The low latency NOR boot features:

- Possible only on GP Device
- ROM only supports connection to 16-bit memory
- Consists of a blind jump in ARM mode to a code located in an external NOR device connected to CS0
- The jump is performed with minimum on-chip ROM Code execution, without configuring any PLL
- Allows the customer to create its own booting code
- Set up by means of the configuration pins, see [Table 5-10](#)

### 5.2.8.2 Settings

The NOR device requires the following settings:

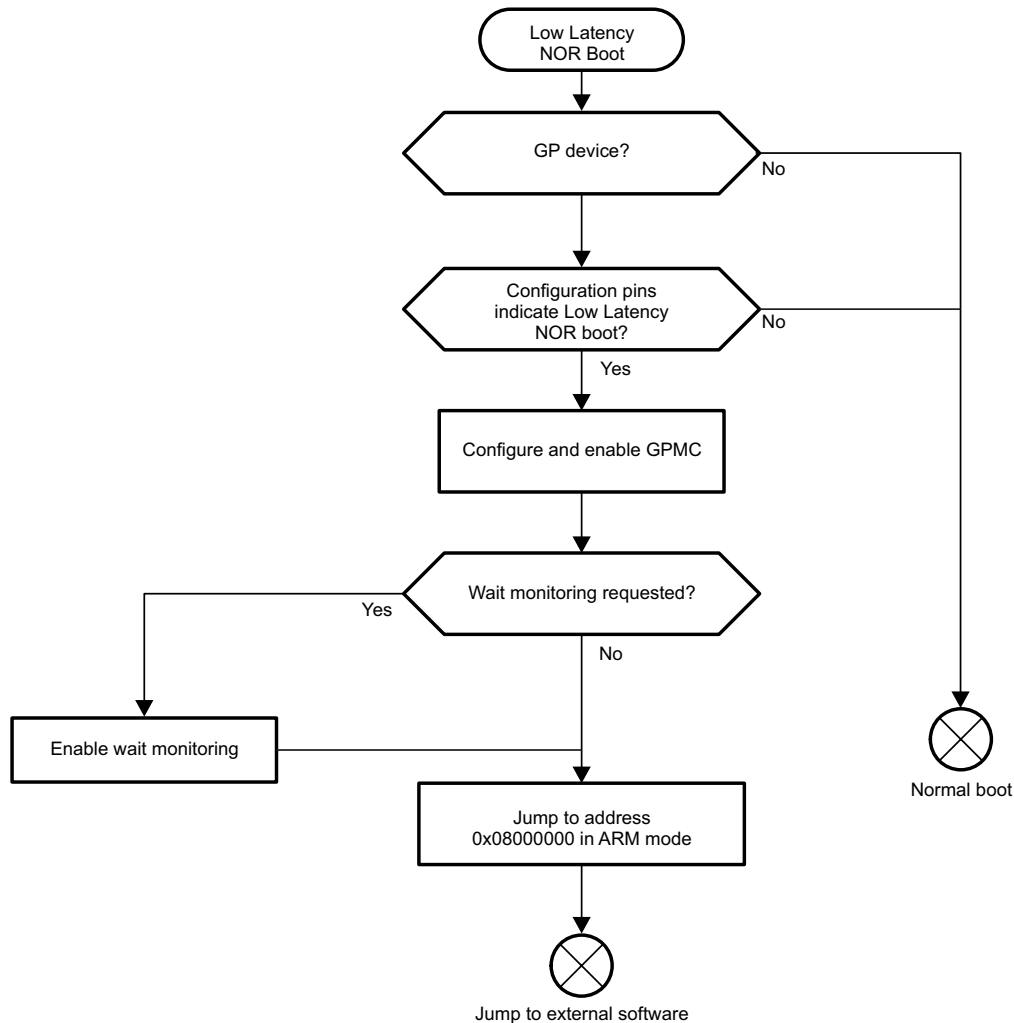

- Addr/Data muxed device or a non-muxed (selected using SYSBOOT[11] ) device is connected in pinmux option 0 configuration (except for be1n), as mentioned in the [Table 5-14](#) and [Table 5-15](#), respectively. The be1n pin on the flash device needs to be connected to gpmc\_csn2.
- Only 16-bit mode is supported <sup>(2)</sup>
- CS0 chip select
- Device wait signal connected to the WAIT0 mux config 0 GPMC signal (if used)
- The wait monitoring enable/disable is based on the value of SYSBOOT[9]

<sup>(2)</sup> See [Table 5-10](#), *SYSBOOT Configuration Pins*.

### 5.2.8.3 External Booting

Figure 5-27 shows the Low Latency NOR boot procedure. The code does not use RAM and is designed for fast execution.

**Figure 5-27. Low Latency NOR Boot**

### 5.2.8.4 SYSBOOT Signals

Table 5-49 describes the SYSBOOT signals relevant to Low Latency NOR Boot (fast NOR)

**Table 5-49. SYSBOOT Signals for Low Latency NOR Boot**

SYSBOOT[8]	Must be set to 1 (only 16-bit device is supported)
SYSBOOT[9]	Used to determine if Wait is enabled. 0b – Ignore WAIT input 1b – Use WAIT input
SYSBOOT[11]	0b – Non-muxed device 1b – A/D-muxed device

## 5.2.9 Image Format

### 5.2.9.1 Overview

All preceding sections describe how the ROM Code searches and detects a boot image from a memory or a peripheral device type. This section describes the format of the boot image itself.

A boot image includes two major parts:

- The software to execute.
- A header containing the destination address and size of the image for non-XIP memory devices.

The mandatory section of a boot image contains the software loaded into the memory and executed. An overview of the image formats is shown in [Figure 5-28](#):

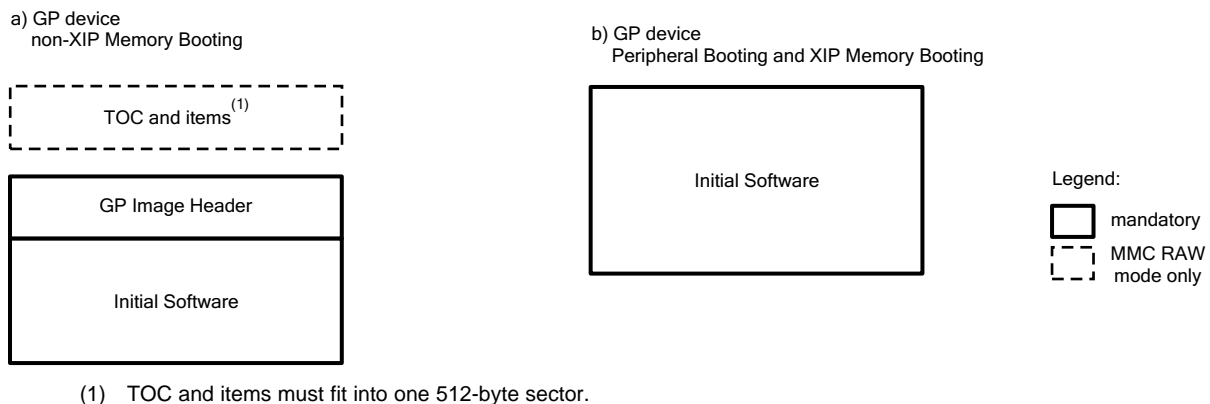

#### (a) GP non-XIP Memory Booting:

It is used for memories which require shadowing (for example, MMC). Image must begin with a GP header which contains information on image size and destination address. Only when MMC RAW mode is used must the image contain a TOC, in addition to the GP header.

#### (b) GP Peripheral Booting and XIP Memory Booting:

When memory device is of XIP type (for example, NOR) the GP header is not needed and the image can contain code for direct execution. The same image format is used for peripheral booting (where the code is transferred to internal RAM).

**Figure 5-28. Image Formats on GP Devices**

### 5.2.9.2 Image format for GP Device

A GP device involves no security, so keys and certificates are not required in the boot image.

When the booting memory device is non-XIP (for example, MMC) the image must contain a small header (referred as GP header) with the size of the image and the destination address where to store it.

The GP header is not required when booting from an XIP memory device (for example, NOR) or if peripheral booting. In this case, the peripheral or memory booting image starts directly with executable code.

**Table 5-50. GP Device Image Format**

Field	non-XIP Device (offset)	XIP Device (offset)	Size (bytes)	Description
Size	0000h	-	4	Size of the executable code plus 8-byte header
Destination	0004h	-	4	Address where to store the image / code entry point
Image	0008h	0000h	X	Executable code

**Note:** the “Destination” address field stands for both:

- Target address for the image copy from the non-XIP storage to the target XIP location (for example, internal RAM or SDRAM)
- Entry point for image code

The user must locate the code entry point to the target address for image copy.

### 5.2.10 Table of Contents

The Table of Contents (TOC) is a header needed only in GP devices while using MMC RAW mode. This must not be confused with the TOC used in HS devices. The TOC is 512 bytes long and consists of a maximum of 2 TOC items (32 bytes long each), located one after the other. The second TOC item must be filled by FFh. Each TOC item contains information required by the ROM Code to find a valid image in RAW mode, as illustrated in [Table 5-51](#). To detect RAW mode, the ROM also needs the magic values mentioned in [Table 5-52](#). Other than the TOC item fields and magic values, all the other bytes in the 512-byte TOC must be zero.

**Table 5-51. The TOC Item Fields**

Offset	Field	Size (bytes)	Description
0000h	Start	4	0x000000A0
0004h	Size	4	0x00000050
0008h	Flags	4	Not used, should be zero.
000Ch	Align	4	Not used, should be zero.
0010h	Load Address	4	Not used, should be zero.
0014h	Filename	12	12 character long name of sub image, including the zero ('\0') terminator.

**Table 5-52. Magic Values for MMC RAW Mode**

Offset	Value
A0h	0xC0C0C0C1
A4h	0x00000100

The ROM Code recognizes the TOC based on the filename described in [Table 5-53](#).

**Table 5-53. Filenames in TOC for GP Device**

Filename	Description
CHSETTINGS	Magic string used by ROM

### 5.2.11 Services for HLOS Support – API

This Cortex core restricts accesses to few ARM coprocessor registers to the secure mode only. The GP Device forbids entering the secure mode and hence do not provide any secure services. However HLOS need to access secure registers for L2 cache maintenance.

For these purposes the ROM Code provides different primitives that can be called on GP or HS Device type. These services are implemented in monitor mode (service must be called by writing function ID into R12 register and using the SMC instruction) and do not use any resources like RAM/stack or hardware outside the MPU. The caller must save R0-R5 before using these APIs because the ROM code overwrites R0-R5.

The services include:

- L2 cache set debug register
- L2 cache clean and invalidate range of physical address
- L2 cache set control register
- L2 cache set auxiliary control
- L2 cache get control
- L2 cache set latency

**Table 5-54. L2 Cache Set Debug Register**

Function ID	Description	
R12 = 0x100	This function writes the PL310 Debug Control Register with the input given value in r0.	
Parameters		
Type	Field	Description
Input	32-bit unsigned integer – R0	Debug register value to set

**Table 5-55. L2 Cache Clean and Invalidate Range of Physical Address**

Function ID	Description	
R12 = 0x101	This function cleans and invalidates the range of the physical address given.	
Parameters		
Type	Field	Description
Input	32-bit unsigned integer – R0	Physical Start Address of range.
Input	32-bit unsigned integer – R1	Size of the range to invalidate.

**Table 5-56. L2 Cache Set Control Register**

Function ID	Description	
R12 = 0x102	This function writes the PL310 Control Register which enables and disables the L2 Cache.	
Parameters		
Type	Field	Description
Input	32-bit unsigned integer – R0	Control register value to set

**Table 5-57. L2 Cache Set Auxiliary Control Register**

Function ID	Description	
R12 = 0x109	This function writes a given input value into the PL310 Auxiliary Control Register.	
Parameters		
Type	Field	Description
Input	32-bit unsigned integer – R0	Auxiliary control register value to set

**Table 5-58. L2 Cache Set Latency Control Register**

Function ID	Description	
R12 = 0x112	This function writes the input values in the PL310 Tag and Data RAM Latency Control Register.	
Parameters		
Type	Field	Description
Input	32-bit unsigned integer – R0	TAG RAM Latency control register value to be set.
Input	32-bit unsigned integer – R1	Data RAM Latency to be set.

**Table 5-59. L2 Cache Set Pre-fetch Control Register**

Function ID	Description	
R12 = 0x113	This function sets the given input value in the L2 Cache Pre-fetch Control Register.	
Parameters		
Type	Field	Description
Input	32-bit unsigned integer – R0	Value to set in the Pre-fetch Control Register.

**Table 5-60. L2 Cache Set Address Filtering Register**

Function ID	Description	
R12 = 0x114	Writes the given input values to the PL130 Address Filtering Start and Address Filtering End registers.	
Parameters		
Type	Field	Description
Input	32-bit unsigned integer – R0	Value to set in address filtering start register.
Input	32-bit unsigned integer – R1	Value to be set in address filtering end register.

**Table 5-61. L2 Cache Clean Set Way**

Function ID	Description	
R12 = 0x115	Cleans the L2 cache by Set and Way.	
Parameters		
Type	Field	Description
Input	None	

**Table 5-62. L1 Cache Set Pre-fetch Enable**

Function ID	Description	
R12 = 0x116	Enable and disable L1 pre-fetch.	
Parameters		
Type	Field	Description
Input	32-bit unsigned integer – R0	0x0 = Disable pre-fetch. 0x1 = Enable pre-fetch.

**Table 5-63. SCTLR Round-Robin Enable**

Function ID	Description	
R12 = 0x117	Enable and disable round-robin replacement strategy for caches, BTAC, and micro TLBs.	
Parameters		
Type	Field	Description
Input	32-bit unsigned integer – R0	0x0 = Disable round-robin. 0x1 = Enable round-robin.

**Table 5-64. CP15 Set ACTLR Register**

Function ID	Description	
R12 = 0x118	This function sets the given input value in the CP15 ACTLR register.	
Parameters		
Type	Field	Description
Input	32-bit unsigned integer – R0	Value to set in the CP15 ACTLR register.

## 5.2.12 Tracing

Tracing in the Public ROM Code includes five 32-bit vectors for which each bit corresponds to a particular “way point” in the ROM Code execution sequence (see [Table 5-6](#)). Tracing vectors are initialized at the very beginning of the startup phase and updated all along the boot process.

**Table 5-65. Tracing Vectors**

Trace Vector	Bit	Group	Meaning
1	0	General	Passed the public reset vector
1	1	General	Entered main function
1	2	General	Running after the cold reset
1	3	Boot	Main booting routine entered
1	4	Memory Boot	Memory booting started
1	5	Peripheral Boot	Peripheral booting started
1	6	Reserved	Reserved
1	7	Boot	Header found

## 6.1 Introduction

The device power-management architecture ensures maximum performance and operation time for user satisfaction (audio/video support) while offering versatile power-management techniques for maximum design flexibility, depending on application requirements. This introduction contains the following information:

- Power-management architecture building blocks for the device
- State-of-the-art power-management techniques supported by the power-management architecture of the device

## 6.2 Device Power-Management Architecture Building Blocks

To provide a versatile architecture supporting multiple power-management techniques, the power-management framework is built with three levels of resource management: clock, power, and voltage management.

These management levels are enforced by defining the managed entities or building blocks of the power-management architecture, called the clock, power, and voltage domains. A domain is a group of modules or subsections of the device that share a common entity (for example, common clock source, common voltage source, or common power switch). The group forming the domain is managed by a policy manager. For example, a clock for a clock domain is managed by a dedicated clock manager within the power, reset, and clock management (PRCM) module. The clock manager considers the joint clocking constraints of all the modules belonging to that clock domain (and, hence, receiving that clock).

## 6.3 Clock Management

The PRCM module along with the control module manages the gating (that is, switching off) and enabling of the clocks to the device modules. The clocks are managed based on the requirement constraints of the associated modules. The following sections identify the module clock characteristics, management policy, clock domains, and clock domain management

### 6.3.1 Module Interface and Functional Clocks

Each module within the device has specific clock input characteristic requirements. Based on the characteristics of the clocks delivered to the modules, the clocks are divided into two categories: interface clocks and functional clocks

**Figure 6-1. Functional and Interface Clocks**

The interface clocks have the following characteristics:

- They ensure proper communication between any module/subsystem and interconnect.
- In most cases, they supply the system interconnect interface and registers of the module.
- A typical module has one interface clock, but modules with multiple interface clocks may also exist (that is, when connected to multiple interconnect buses).
- Interface clock management is done at the device level.
- From the standpoint of the PRCM module, an interface clock is identified by an \_ICLK suffix.

Functional clocks have the following characteristics:

- They supply the functional part of a module or subsystem.
- A module can have one or more functional clocks. Some functional clocks are mandatory, while others are optional. A module needs its mandatory clock(s) to be operational. The optional clocks are used for specific features and can be shut down without stopping the module activity
- From the standpoint of the PRCM module, a functional clock is distributed directly to the related modules through a dedicated clock tree. It is identified with an \_FCLK suffix

### 6.3.2 Module-Level Clock Management

Each module in the device may also have specific clock requirements. Certain module clocks must be active when operating in specific modes, or may be gated otherwise. Globally, the activation and gating of the module clocks are managed by the PRCM module. Hence, the PRCM module must be aware of when to activate and when to gate the module clocks. The PRCM module differentiates the clock-management behavior for device modules based on whether the module can initiate transactions on the device interconnect (called master module or initiators) or cannot initiate transactions and only responds to the transactions initiated by the master (called slave module or targets). Thus, two hardware-based power-management protocols are used:

- Master standby protocol: Clock-management protocol between the PRCM and master modules.
- Slave idle protocol: Clock-management protocol between the PRCM and slave modules.

#### 6.3.2.1 Master Standby Protocol

Master standby protocol is used to indicate that a master module must initiate a transaction on the device interconnect and requests specific (functional and interface) clocks for the purpose. The PRCM module ensures that the required clocks are active when the master module requests the PRCM module to enable them. This is called a module wake-up transition and the module is said to be functional after this transition completes. Similarly, when the master module no longer requires the clocks, it informs the PRCM module, which can then gate the clocks to the module. The master module is then said to be in standby mode. Although the protocol is completely hardware-controlled, software must configure the clock-management behavior for the module. This is done by setting the module register bit field <Module>\_SYSCONFIG.MIDLEMODE or <Module>\_SYSCONFIG.STANDBYMODE. The behavior, identified by standby mode values, must be configured.

**Table 6-1. Master Module Standby-Mode Settings**

Standby Mode Value	Selected Mode	Description
0x0	Force-standby	The module unconditionally asserts the standby request to the PRCM module, regardless of its internal operations. The PRCM module may gate the functional and interface clocks to the module. This mode must be used carefully because it does not prevent the loss of data at the time the clocks are gated.
0x1	No-standby	The module never asserts the standby request to the PRCM module. This mode is safe from a module point of view because it ensures that the clocks remain active. However, it is not efficient from a power-saving perspective because it never allows the output clocks of the PRCM module to be gated
0x2	Smart-standby	The module asserts the standby request based on its internal activity status. The standby signal is asserted only when all ongoing transactions are complete and the module is idled. The PRCM module can then gate the clocks to the module.

**Table 6-1. Master Module Standby-Mode Settings (continued)**

Standby Mode Value	Selected Mode	Description
0x3	Smart-standby wakeup-capable mode	The module asserts the standby request based on its internal activity status. The standby signal is asserted only when all ongoing transactions are complete and the module is idle. The PRCM module can then gate the clocks to the module. The module may generate (master-related) wake-up events when in STANDBY state. The mode is relevant only if the appropriate module mwakeup output is implemented.

The standby status of a master module is indicated by the CM\_<Power\_domain>\_<Module>\_CLKCTRL[x]. STBYST bit in the PRCM module.

**Table 6-2. Master Module Standby Status**

STBYST Bit Value	Description
0x0	The module is functional.
0x1	The module is in standby mode

### 6.3.2.2 Slave Idle Protocol

This hardware protocol allows the PRCM module to control the state of a slave module. The PRCM module informs the slave module, through assertion of an idle request, when its clocks (interface and functional) can be gated. The slave can then acknowledge the request from the PRCM module and the PRCM module is then allowed to gate the clocks to the module. A slave module is said to be in IDLE state when its clocks are gated by the PRCM module. Similarly, an idled slave module may need to be awakened because of a service request from a master module or as a result of an event (called a wake-up event; for example, interrupt or DMA request) received by the slave module. In this situation the PRCM module enables the clocks to the module and then deasserts the idle request to signal the module to wake up. Although the protocol is completely hardware-controlled, software must configure the clock-management behavior for the slave module. This is done by setting the module register bit field <Module>\_SYSCONFIG. SIDLEMODE or <Module>\_SYSCONFIG. IDLEMODE. The behavior, listed in the Idle Mode Value column, must be configured by software.

**Table 6-3. Module Idle Mode Settings**

Idle Mode Value	Selected Mode	Description
0x0	Force-idle	The module unconditionally acknowledges the idle request from the PRCM module, regardless of its internal operations. This mode must be used carefully because it does not prevent the loss of data at the time the clock is switched off.
0x1	No-idle	The module never acknowledges any idle request from the PRCM module. This mode is safe from a module point of view because it ensures that the clocks remain active. However, it is not efficient from a power-saving perspective because it does not allow the PRCM module output clock to be shut off, and thus the power domain to be set to a lower power state.

**Table 6-3. Module Idle Mode Settings (continued)**

Idle Mode Value	Selected Mode	Description
0x2	Smart-idle	The module acknowledges the idle request basing its decision on its internal activity. Namely, the acknowledge signal is asserted only when all pending transactions, interrupts, or direct memory access (DMA) requests are processed. This is the best approach to efficient system power management.
0x3	Smart-idle wakeup-capable mode	The module acknowledges the idle request basing its decision on its internal wakeup-capable mode activity. Namely, the acknowledge signal is asserted only when all pending transactions, interrupts, or DMA requests are processed. This is the best approach to efficient system power management. The module may generate (IRQ- or DMA-request-related) wake-up events when in IDLE state. The mode is relevant only if the appropriate module wakeup output(s) is implemented.

The idle status of a slave module is indicated by the CM\_<Powerdomain>\_<Module>\_CLKCTRL[x] IDLEST bit field in the PRCM module.

**Table 6-4. Idle States for a Slave Module**

IDLEST Bit VALUE	Idle Status	Description
0x0	Functional	The module is fully functional. The interface and functional clocks are active.
0x1	In transition	The module is performing a wake-up or a sleep transition.
0x2	Interface idle	The module interface clock is idled. The module may remain functional if using a separate functional clock.
0x3	Full idle	The module is fully idle. The interface and functional clocks are gated in the module.

For the idle protocol management on the PRCM module side, the behavior of the PRCM module is configured in the CM\_<Power domain>\_<module>\_CLKCTRL[x] MODULEMODE bit field. Based on the configured behavior, the PRCM module asserts the idle request to the module unconditionally (that is, immediately when the software requests).

**Table 6-5. Slave Module Mode Settings in PRCM**

MODULEMODE Bit VALUE	Selected Mode	Description
0x0	Disabled	The PRCM module unconditionally asserts the module idle request. This request applies to the gating of the functional and interface clocks to the module. If acknowledged by the module, the PRCM module can gate all clocks to the module (that is, the module is completely disabled)..
0x1	Reserved	NA

**Table 6-5. Slave Module Mode Settings in PRCM (continued)**

MODULEMODE Bit VALUE	Selected Mode	Description
0x2	Enabled	This mode applies to a module when the PRCM module manages its interface and functional clocks. The functional clock to the module remains active unconditionally, while the PRCM module automatically asserts/deasserts the module idle request based on the clock-domain transitions. If acknowledged by the module, the PRCM module can gate only the interface clock to the module.
0x3	Reserved	NA

In addition to the IDLE and STANDBY protocol, PRCM offers also the possibility to manage optional clocks, through a direct SW control: “OptFclken” bit from programming register.

**Table 6-6. Module Clock Enabling Condition**

Clock Enabling			
Clock associated with STANDBY protocol	AND	Clock Domain is 'ACTIVE'	
		OR	MStandby is de-asserted
			Mwakeup is asserted
Clock associated with IDLE protocol, as interface clock	AND	Clock Domain is 'ACTIVE'	
		OR	Idle status = FUNCT
			Idle status = TRANS
			SWakeup is asserted
Clock associated with IDLE protocol, as functional clock	AND	Clock Domain is 'ACTIVE'	
		OR	Idle status = FUNCT
			Idle status = IDLE
			Idle status = TRANS
			SWakeup is asserted
Optional clock	AND	Clock domain is ready	
		OptFclken=Enabled ('1')	

### 6.3.3 Clock Domain

A clock domain is a group of modules fed by clock signals controlled by the same clock manager in the PRCM module. By gating the clocks in a clock domain, the clocks to all the modules belonging to that clock domain can be cut to lower their active power consumption (that is, the device is on and the clocks to the modules are dynamically switched to ACTIVE or INACTIVE (GATED) states). Thus, a clock domain allows control of the dynamic power consumption of the device. The device is partitioned into multiple clock domains, and each clock domain is controlled by an associated clock manager within the PRCM module. This allows the PRCM module to individually activate and gate each clock domain of the device.

Figure 6-2. Generic Clock Domain

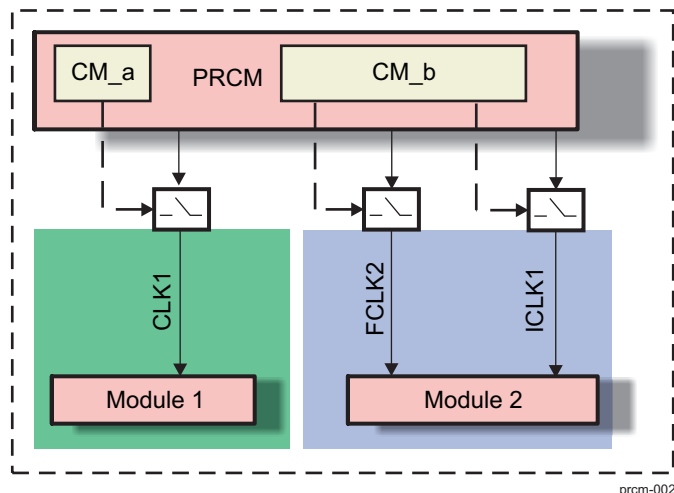

Figure above is an example of two clock managers: CM\_a and CM\_b. Each clock manager manages a clock domain. The clock domain of CM\_b is composed of two clocks: a functional clock (FCLK2) and an interface clock (ICLK1), while the clock domain of CM\_a consists of a clock (CLK1) that is used by the module as a functional and interface clock. The clocks to Module 2 can be gated independently of the clock to Module 1, thus ensuring power savings when Module 2 is not in use. The PRCM module lets software check the status of the clock domain functional clocks. The CM\_<Clock domain>\_CLKSTCTRL[x] CLKACTIVITY\_<FCLK/Clock name\_FCLK> bit in the PRCM module identifies the state of the functional clock(s) within the clock domain. Table shows the possible states of the functional clock.

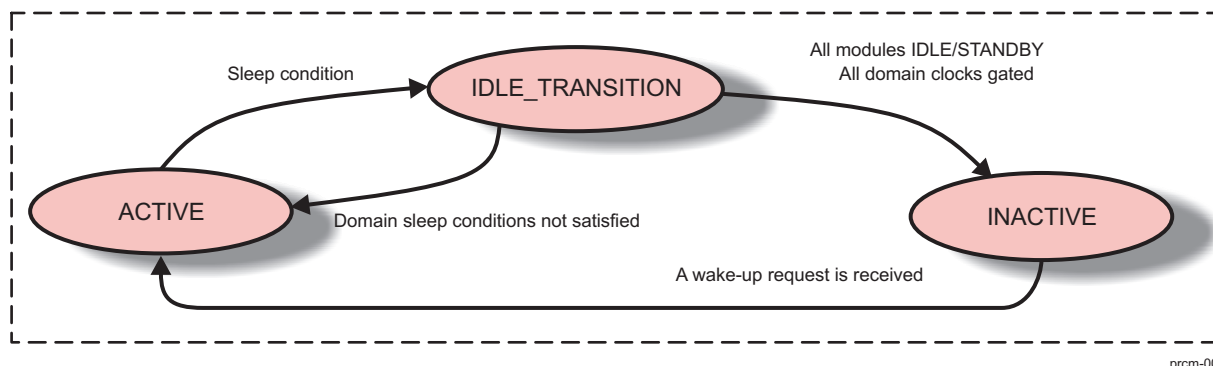

Table 6-7. Clock Domain Functional Clock States

CLKACTIVITY BIT Value	Status	Description
0x0	Gated	The functional clock of the clock domain is inactive
0x1	Active	The functional clock of the clock domain is running

### 6.3.3.1 Clock Domain-Level Clock Management

The domain clock manager can automatically (that is, based on hardware conditions) and jointly manage the interface clocks within the clock domain. The functional clocks within the clock domain are managed through software settings. A clock domain can switch between three possible states: ACTIVE, IDLE\_TRANSITION, and INACTIVE. Figure 6-3 shows the sleep and wake-up transitions of the clock domain between ACTIVE and INACTIVE states.

Figure 6-3. Clock Domain State Transitions

**Table 6-8. Clock Domain States**

State	Description
ACTIVE	<p>Every nondisabled slave module (that is, those whose MODULEMODE value is not set to disabled) is put out of IDLE state.</p> <p>All interface clocks to the nondisabled slave modules in the clock domain are provided. All functional and interface clocks to the active master modules (that is, not in STANDBY) in the clock domain are provided. All enabled optional clocks to the modules in the clock domain are provided.</p>
IDLE_TRANSITION	<p>This is a transitory state.</p> <p>Every master module in the clock domain is in STANDBY state. Every idle request to all the slave modules in the clock domain is asserted. The functional clocks to the slave module in enabled state (that is, those whose MODULEMODE values are set to enabled) remain active.</p> <p>All enabled optional clocks to the modules in the clock domain are provided.</p>
INACTIVE	<p>All clocks within the clock domain are gated.</p> <p>Every slave module in the clock is in IDLE state and set to disabled.</p> <p>Every slave module in the clock domain (that is, those whose MODULEMODE is set to disabled) is in IDLE state and set to disabled.</p> <p>Every optional functional clock in the clock domain is gated</p>

Each clock domain transition behavior is managed by an associated register bit field in the CM\_<Clock domain>\_CLKSTCTRL[x] CLKTRCTRL PRCM module

**Table 6-9. Clock Transition Mode Settings**

CLKTRCTRL Bit Value	Selected Mode	Description
0x0	NO_SLEEP	Sleep transition cannot be initiated. Wakeup transition may however occur.
0x1	SW_SLEEP	A software-forced sleep transition. The transition is initiated when the associated hardware conditions are satisfied
0x2	SW_WKUP	A software-forced clock domain wake-up transition is initiated
0x3	Reserved	NA

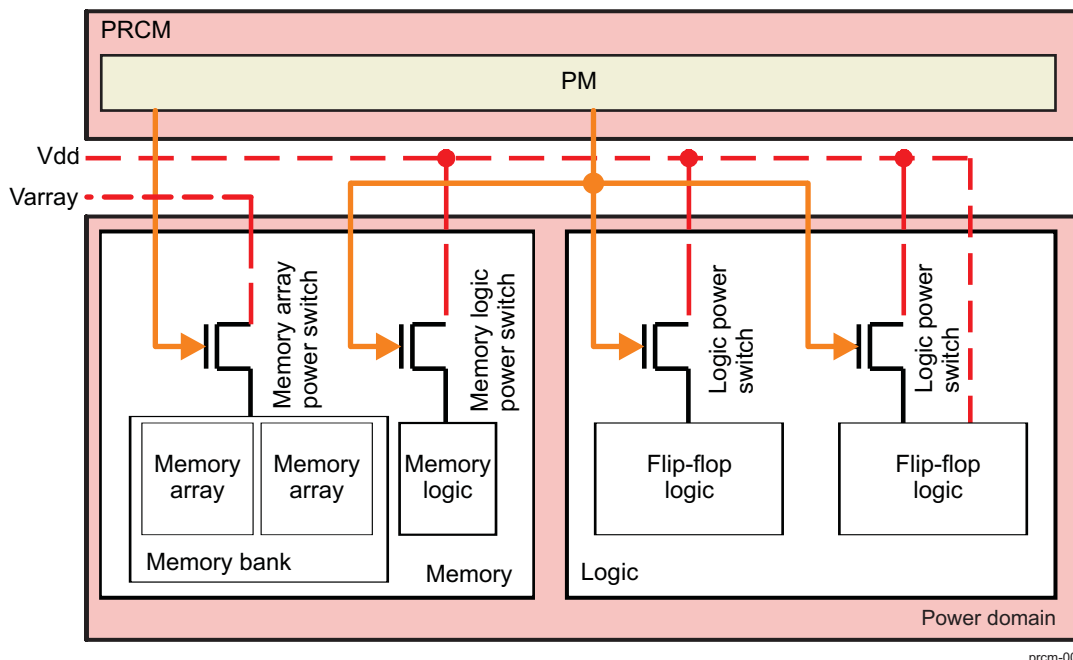

## 6.4 Power Management

The PRCM module manages the switching on and off of the power supply to the device modules. To minimize device power consumption, the power to the modules can be switched off when they are not in use. Independent power control of sections of the device allows the PRCM module to turn on and off specific sections of the device without affecting the others.

### 6.4.1 Power Domain

A power domain is a section (that is, a group of modules) of the device with an independent and dedicated power manager (see [Figure 6-4](#)). A power domain can be turned on and off without affecting the other parts of the device.

Figure 6-4. Generic Power Domain Architecture

To minimize device power consumption, the modules are grouped into power domains. A power domain can be split into a logic area and a memory area.

Table 6-10. States of a Memory Area in a Power Domain

State	Description
ON	The memory array is powered and fully functional
OFF	The memory array is powered down

Table 6-11. States of a Logic Area in a Power Domain

State	Description
ON	Logic is fully powered
OFF	Logic power switches are off. All the logic (DFF) is lost

## 6.4.2 Power Domain Management

The power manager associated with each power domain is assigned the task of managing the domain power transitions. It ensures that all hardware conditions are satisfied before it can initiate a power domain transition from a source to a target power state

Table 6-12. Power Domain Control and Status Registers

Register/Bit Field	Type	Description
PM_<Power domain>_PWRSTCTRL[1:0] POWERSTATE	Control	Selects the target power state of the power domain among OFF, ON, or RETENTION.
PM_<Power domain>_PWRSTST[1:0] POWERSTATEST	Status	Identifies the current state of the power domain. It can be OFF, ON, or RETENTION.
PM_<Power domain>_PWRSTST[2] LOGICSTATEST	Status	Identifies the current state of the logic area in the power domain. It can be OFF or ON.

**Table 6-12. Power Domain Control and Status Registers (continued)**

Register/Bit Field	Type	Description
PM_<Power domain>_PWRSTST[5:4] MEMSTATEST	Status	Identifies the current state of the memory area in the power domain. It can be OFF, ON, or RETENTION

### 6.4.2.1 Power Management Techniques

The following section describes the state-of-the-art power management techniques supported by the device.

#### 6.4.2.1.1 Dynamic Voltage Frequency Scaling (DVFS)

DVFS is a power management technique where the operating voltage and frequency are dynamically scaled across device Operating Performance Points (OPP). An OPP is a voltage/frequency pair that defines a specific power state. For each OPP, software sends control signals to external regulators in order to set the minimum voltage.

##### 6.4.2.1.1.1 Switching and Sequencing

DVFS switching primarily involves the following aspects:

- DVFS switching must always be ensured that the voltage of the external regulator is always changed to the right OPP voltage.
  - When moving from higher to lower OPP: Frequency changes first and then voltage
  - When moving from lower to higher OPP: Voltage changes first and then frequency

#### 6.4.2.1.2 MPU DPS and DCG

The MPU supports dynamic clock gating (DCG / HW\_AUTO) feature as part of the PRCM's Clock Domain Management. For active usecase sensitive to power, this feature can be used to save power. MPU will automatically be clock gated when it enters WFI state. Wakeup will be via interrupts. Having DCG feature enables dynamic power switching (DPS) using the power domain management of PRCM.

### 6.4.3 Power Modes

The following is a high-level description of the different power modes of the device. They are listed in order from highest power consumption, lowest wakeup latency (Standby), to lowest power consumption, highest wakeup latency (RTC-only). If your application requires some sort of power management, you must determine which power mode level described below satisfies your requirements. Each level must be evaluated based on power consumed and latency (the time it takes to wakeup to Active mode). Specific values are detailed in the device-specific data sheet. Note that not all modes are supported by software packages supplied by Texas Instruments.

**Table 6-13. Typical Power Modes**

Power Modes	Application State	Power Domains, Clocks, and Voltage Supply States
Active	All Features	<b>Power supplies:</b> All power supplies are ON. VDD_MPU = 1.1 V (nom) VDD_CORE = 1.1 V (nom) <b>Clocks:</b> Main Oscillator (OSC0) = ON All DPLLs are locked. <b>Power domains:</b> PD_PER = ON PD_MPU = ON PD_GFX = ON or OFF (depending on use case) PD_WKUP = ON DDR is active.
Standby	DDR memory is in self-refresh and contents are preserved. Wakeup from any GPIO. Cortex-A9 context/register contents are lost and must be saved before entering standby. On exit, context must be restored from DDR. For wakeup, boot ROM executes and branches to system resume.	<b>Power supplies:</b> All power supplies are ON. VDD_MPU = 0.95 V (nom) VDD_CORE = 0.95 V (nom) <b>Clocks:</b> Main Oscillator (OSC0) = ON All DPLLs are in bypass. <b>Power domains:</b> PD_PER = ON PD_MPU = OFF PD_GFX = OFF PD_WKUP = ON DDR is in self-refresh.
Deepsleep	PD_PER peripheral and Cortex-A9/MPU register information will be lost. On-chip peripheral register (context) information of PD_PER domain needs to be saved by application to SDRAM before entering this mode. DDR is in self-refresh. For wakeup, boot ROM executes and branches to peripheral context restore followed by system resume.	<b>Power supplies:</b> All power supplies are ON. VDD_MPU = 0.95 V (nom) VDD_CORE = 0.95 V (nom) <b>Clocks:</b> Main Oscillator (OSC0) = OFF All DPLLs are in bypass. <b>Power domains:</b> PD_PER = OFF (except 64KB L3 OCMC retained) PD_MPU = OFF (except MPU OCMC RAM retained) PD_GFX = OFF PD_WKUP = ON DDR is in self-refresh.

**Table 6-13. Typical Power Modes (continued)**

Power Modes	Application State	Power Domains, Clocks, and Voltage Supply States
RTC-Only	RTC timer remains active and all other device functionality is disabled.	<b>Power supplies:</b> All power supplies are OFF except VDDS_RTC. VDD_MPU = 0 V VDD_CORE = 0 V <b>Clocks:</b> Main Oscillator (OSC0) = OFF <b>Power domains:</b> All power domains are OFF.

#### 6.4.3.1 Active

In Active mode, the supply to all voltage rails must be maintained. All power domains come up in ON state and the device is fully functional.

#### 6.4.3.2 Standby

The device can be placed in Standby mode to reduce power consumption during low activity levels. This first level of power management allows you to maintain the device context for fast resume times. The main characteristics of this mode which distinguish it from Active mode are:

- All modules are clock gated except GPIOs
- PLLs may be placed in bypass mode if downstream clocking does not require full performance
- Voltage domains VDD\_MPU and VDD\_CORE voltage levels can be reduced to OPP50 levels because the required performance of the entire device is reduced
- MPU power domain (PD\_MPU) is in OFF state
- DDR memory is in low power self-refresh mode.

Further power reduction can be achieved in this mode if the RTC function is not required. See [Section 6.4.3.5, Internal RTC LDO](#).

The above conditions result in lower power consumption than Active mode but require the user to save the MPU context to OCMC RAM or DDR to resume properly upon wakeup. Contents of the internal SRAM are lost because PD\_MPU is turned OFF. Wakeup in Standby mode is achieved using any GPIO. GPIO wakeup is possible by switching the pad to GPIO mode and configuring the corresponding GPIO bank for generating an interrupt to the MPUSS. Note that pads that do not have a GPIO muxmode (for example, ADC or USB), cannot cause these wakeups. If additional or other wakeup sources are required, the associated peripheral module clock and interconnect clock domain should remain enabled (this may require the associated PLL to remain locked) and the module must be configured appropriately for wakeup by configuring it to generate an interrupt to the MPUSS.

#### 6.4.3.3 DeepSleep

DeepSleep mode enables lower power consumption than Standby. The main characteristics of the mode which distinguish it from other higher power modes are:

- All on-chip power domains are shut off (except PD\_WKUP and PD\_RTC remain ON) to reduce power leakage
- VDD\_CORE power (except VDDA analog) to DPLLs is turned OFF using CTRL\_DPLL\_PWR\_SW register
- VDDS\_SRAM\_CORE\_BG is in retention using CTRL\_VSLDO.vslldo\_core\_auto\_ramp\_en

DeepSleep mode is typically used during periods of inactivity when the user requires very low power while waiting for an event that requires processing or higher performance. This is the lowest power mode which still includes DDR in self-refresh, so wakeup events do not require a full cold boot, which greatly reduces wakeup latencies over RTC-only mode.

Further power reduction can be achieved in this mode if the RTC function is not required. See [Section 6.4.3.5, Internal RTC LDO](#).

The contents of the internal SRAM are lost because PD\_MPU is turned OFF.

Before entering DeepSleep mode, peripheral and MPU context must be saved in the DDR. Upon wakeup, the boot ROM executes and checks to see if it has resumed from a DeepSleep state. If so, it redirects to the DDR to continue the resume process. Because power to PD\_WKUP is ON throughout DeepSleep, power to key modules such as GPIO0, I2C, and others is maintained to allow wakeup events to exit out of this mode. In addition, power to OCMC RAM is maintained to preserve information internally during DeepSleep.

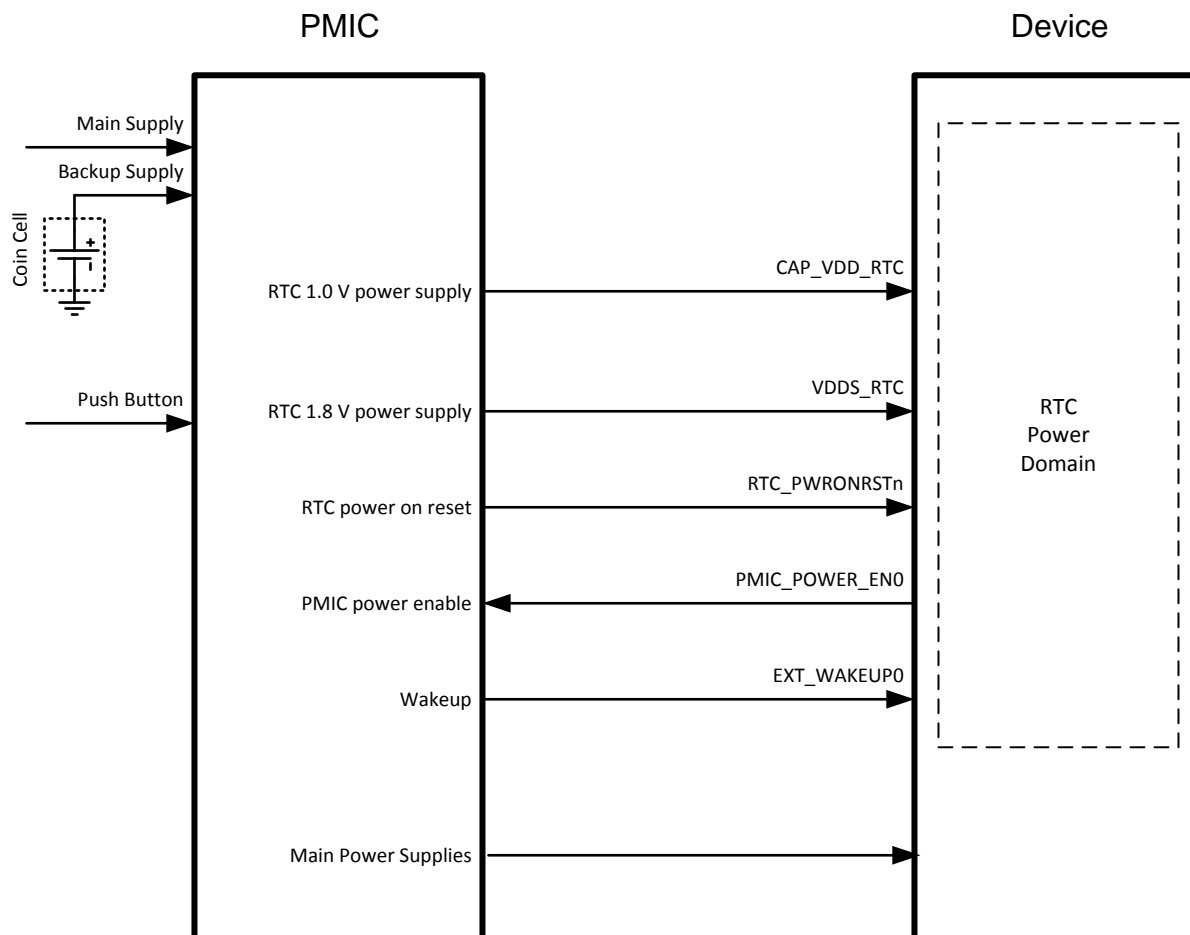

Activity on wakeup peripherals via wakeup events enables the master crystal oscillator using the oscillator control circuit. The wakeup events also interrupt the wakeup processor, which controls proper enabling of power domains and clocks in the PRCM. See [Section 6.4.5, Wakeup Sources/Events](#), for details on wakeup sources during DeepSleep and other low power modes mentioned.

#### 6.4.3.4 RTC-Only

RTC-only mode is an ultra-low power mode which allows the user to maintain power and clocks to the real-time clock (RTC) domain while the rest of the device is powered down. All context and memories will be lost, and the only portion of the chip that will be maintained is the RTC. Only the RTC power supply must be ON. All the remaining supplies must be OFF. The RTC battery backup domain consists of the RTC subsystem (RTCSS), a dedicated on-chip 32.768 Hz crystal oscillator, and I/Os associated with the RTCSS: pmic\_power\_enable0 and ext\_wakeup0.

[Figure 6-5](#) gives a high level view of system which implements the RTC-only mode.

**Figure 6-5. High Level System View for RTC-only Mode**

Wakeup from RTC-only mode can only be achieved using the `ext_wakeup0` signal. Once a wakeup is triggered using this signal, the device drives `pmic_pwr_enable0` to initiate a power-up sequence by the PMIC. The device must go through a full cold boot upon wakeup from RTC-only mode.

#### 6.4.3.5 Internal RTC LDO

The device contains an internal LDO (low dropout) regulator which powers the RTC digital core. Depending on your application, you may be able to disable this regulator to save power in low power use cases.

If your application never uses the RTC functionality, connect `RTC_KALDO_ENn` to `VDDS_RTC`, `CAP_VDD_RTC` to `VDD_CORE`, and `RTC_PWRONRSTn` to ground. These connections disable the internal RTC LDO because `RTC_KALDO_ENn` is high, and they use the external `VDD_CORE` supply to power the RTC digital core. The RTC LDO must be disabled for internal power sequencing even though the RTC is not used. Grounding the reset signal will ensure the RTC stays in reset. Disabling the internal LDO will allow the application to achieve lower power consumption in all the low power modes.

If your application uses the RTC functionality and never needs RTC-only mode, the hardware scenario is similar to the previous description, but the RTC reset signal can be connected to the device `PWRONRSTn`. Note that `PWRONRSTn` and `RTC_PWRONRSTn` may be at different voltage levels, so `PWRONRSTn` may require level shifting before connecting to `RTC_PWRONRSTn`. This connection allows full functionality of the RTC subsystem without the internal RTC LDO consuming power.

If your application uses the RTC functionality and requires RTC-only mode, the internal LDO is required to enable proper wakeup signaling from the RTC domain. The proper wakeup signaling requires the following connections:

- `RTC_KALDO_ENn` is grounded
- `CAP_VDD_RTC` is connected to 1uF decoupling capacitor to ground
- `RTC_PWRONRSTn` is connected to 1.8V RTC power on reset
- `PMIC_POWER_EN` is connected to power input of PMIC
- `EXT_WAKEUP0` is connected to a wakeup source

See the device datasheet for more information on these signals.

#### 6.4.3.6 Supported Low Power USB Wakeup Scenarios

Table 6-14 summarizes different USB wakeup use cases which are supported in each system sleep state (DeepSleep or Standby). Three use case scenarios exist:

- USB Connect: Wakeup is caused by physically inserting the USB cable.
- USB Disconnect: Wakeup is caused by physically removing the USB cable.
- USB Suspend/Resume: Wakeup is caused by a USB suspend or resume command. For example, a USB mouse click can cause a USB resume command.

Within each wakeup use case, each row describes whether or not that type of wakeup is supported in each system sleep mode. USB mode (host or device) is also considered.

There are two possible Wakeup events that are generated:

- PHY WKUP: this is an internal wakeup signal to the wakeup processor that is generated by the USB PHY based off of USB signaling.
- VBUS2GPIO: this is an external wakeup signal coming from a level change on VBUS voltage. This event requires an external board solution which routes VBUS to a GPIO on the device. Ensure you level shift the voltage to conform to the I/O requirements. When VBUS transitions from 0V to 5V (or vice versa), the transition on a GPIO will trigger a wakeup.

**Table 6-14. USB Wakeup Use Cases Supported in System Sleep States**

No.	USB Wakeup Use Case	System Sleep State	USB Controller State	USB Mode	Supported	USB Wakeup Event
1	USB Connect	DS	POWER OFF	Host	No	N/A
2		DS	POWER OFF	Device	Yes	VBUS2GPIO
3		Standby	Clock Gated	Host	Yes	PHY WKUP
4		Standby	Clock Gated	Device	Yes	VBUS2GPIO
5	USB Suspend / Resume	DS	POWER OFF	Host	No	N/A
6		DS	POWER OFF	Device	No	N/A
7		Standby	Clock Gated	Host	Yes	PHY WKUP
8		Standby	Clock Gated	Device	Yes	PHY WKUP
9	USB Disconnect	DS	POWER OFF	Host	No	N/A
10		DS	POWER OFF	Device	No	N/A
11		Standby	Clock Gated	Host	Yes	PHY WKUP
12		Standby	Clock Gated	Device	Yes	VBUS2GPIO

#### 6.4.4 Main Oscillator Control During DeepSleep

The DeepSleep oscillator circuit is used to control the main oscillator by disabling it during deep sleep and enabling during active/wakeup. By default during reset, the oscillator is enabled and the oscillator control circuit comes up disabled (in-active). In order to activate the oscillator control circuit for deepsleep, DSEN bit of CTRL\_DEEPSLEEP register must set. Once this is set and whenever the wakeup processor enters standby, the oscillator control will disable the oscillator causing the clock to be shut OFF. Any async event from the wakeup sources will cause the oscillator control to re-enable the oscillator after a period of DSCOUNT configured in CTRL\_DEEPSLEEP register.

For use cases where an external oscillator is used, the CLKREQ pin provides a similar function to shut off the oscillator. The CLKREQ will be active high. Typically, polarity control is expected at the destination device. In the absence of polarity control and polarity mismatch, an inverter has to be put on the board.

The wakeup processor will always be powered up. But when the main oscillator is in power down / OFF state, the wakeup processor will not receive any clock.

### 6.4.5 Wakeup Sources/Events

Following are the wake sources when the main oscillator is in OFF state. These are part of the Wakeup Power domain and remain always ON.

- DMTimer0
- DMTimer\_1ms (timer-based wakeup)
- ADC0: Touchscreen Controller (TSC, ADC monitor functions)
- UART0 (Infra-red support)
- I2C0
- RTCSS
- IOs via daisy chaining
- Debug
- Warm reset pin

### 6.4.6 Functional Sequencing for Power Management with Wakeup Processor

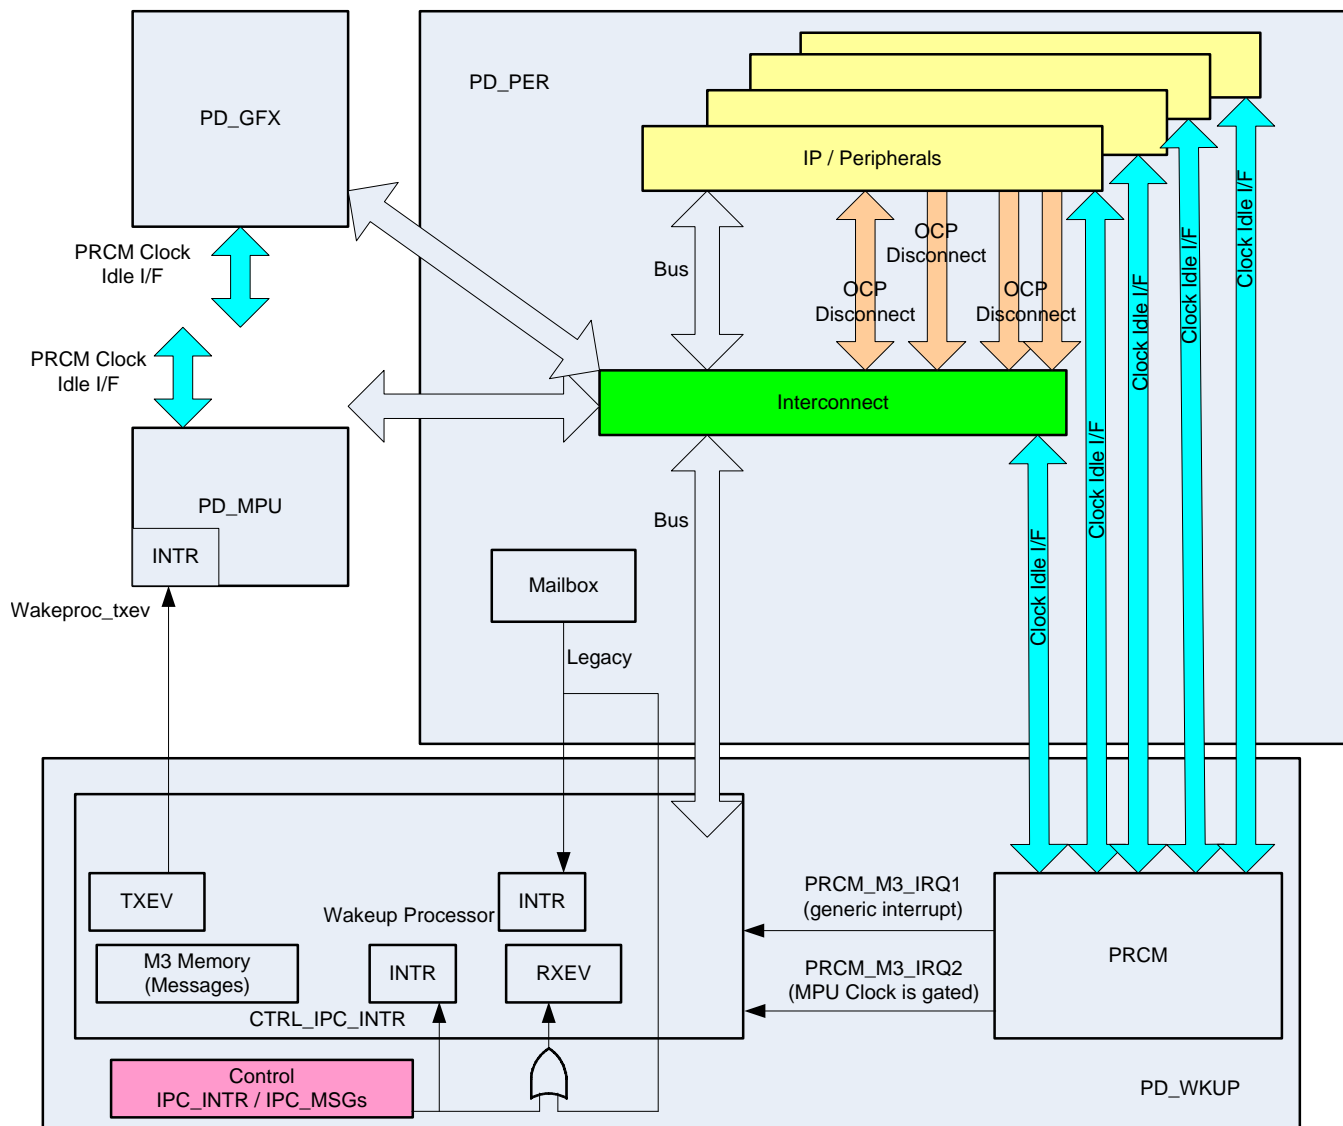

The device contains a dedicated wakeup processor to handle the power management transitions. It is part of the Wake up Power domain (PD\_WKUP).

The power management sequence kicks off with the MPU executing a WFI instruction with the following steps:

1. During Active power mode, the MPU executes a WFI instruction to enter IDLE mode.
2. The wakeup processor receives an interrupt and becomes active.
3. The processor then powers down the MPU power domain (if required).
4. Interrupt registers are configured for the wakeup source.
5. The wakeup processor executes WFI and goes into idle state.
6. The wakeup event triggers an interrupt to the wakeup processor and it wakes up the MPU.

Generally, the MPU and wakeup processor are not expected to be active at the same time. The wakeup processor along with the PRCM is the power manager primarily for PD\_MPU and PD\_PER. Other power domains (such as PD\_GFX) may be handled directly using the MPU software. [Figure 6-6](#) gives a system level view of the Power management system between the MPU and wakeup processor.

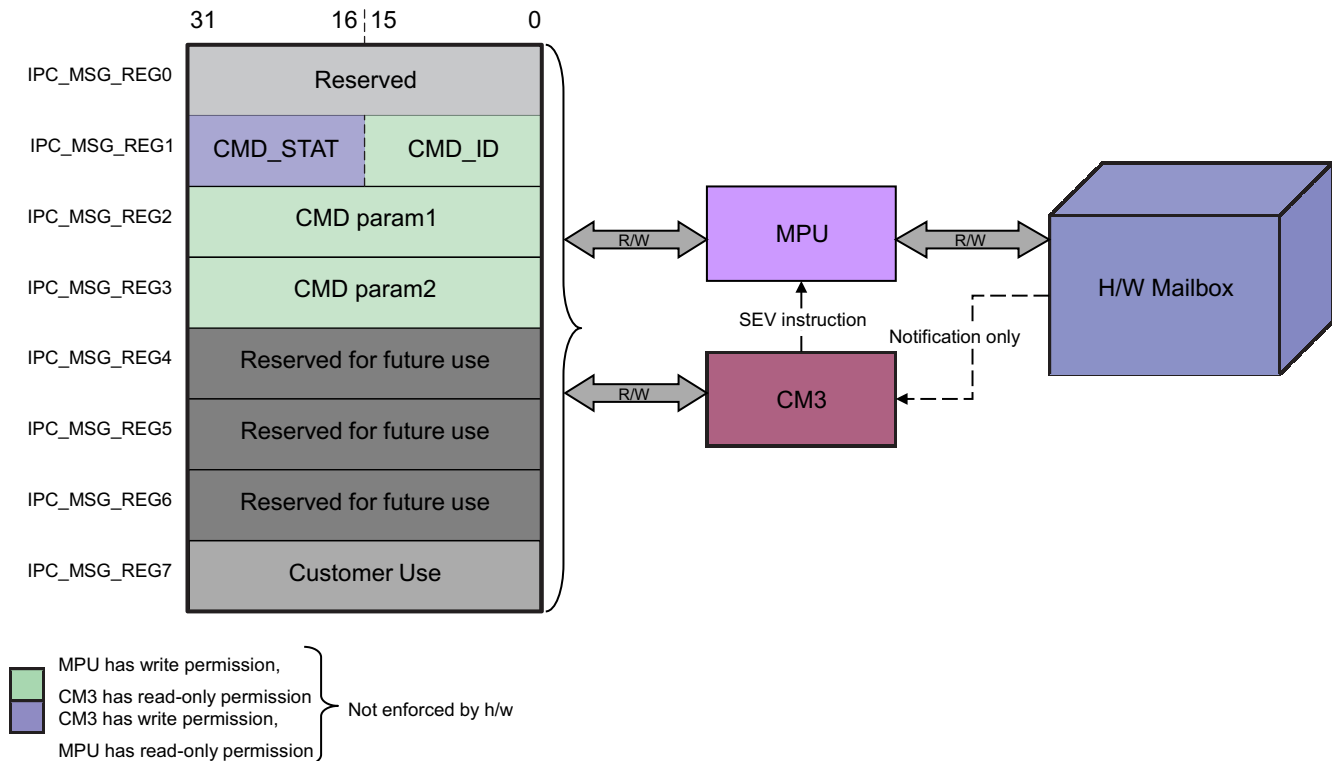

Figure 6-6. DeepSleep System View

As Figure 6-6 shows, a graceful shutdown of power domains PD\_PER and PD\_MPU involves:

1. Software to shutdown the peripheral
2. PRCM power idle interface with each peripheral
3. OCP disconnect interface between peripherals
4. Wakeup processor to shut down the Interconnect infrastructure
5. Interprocessor communication (IPC) between MPU and wakeup processor

The wakeup processor handles all of the low-level power management control of the device. A firmware binary is provided by Texas Instruments that includes all of the necessary functions to achieve low power modes. Inter-Processor Communication (IPC) registers (ipc\_msg\_regx, located in the control module registers) are available to communicate with the wakeup processor so the user can provide certain configuration parameters based on the level of low power that is required. Figure 6-7 provides a mapping of these registers.

**Figure 6-7. IPC Mechanism**

IPC\_MSG\_REG1 contains the CMD\_STAT and CMD\_ID parameters as described in [Table 6-15](#) and [Table 6-16](#).

**Table 6-15. CMD\_STAT Field**

CMD_STAT	Value	Description
PASS	0x1	In the initialization phase, PASS (0x1) denotes that the CM3 was successfully initialized.
IN_PROGRESS	0x2	Early indication of command being carried out.
FAIL	0x3	In the initialization phase, 0x2 denotes CM3 could not properly initialize. When other tasks are to be done, FAIL (0x3) indicates some error in carrying out the task. Check trace vector for details.
WAIT4OK	0x4	CM3 INTC will catch the next WFI of A9 and continue with the pre-defined sequence.

**Table 6-16. CMD\_ID Field**

CMD_ID	Value	Description
CMD_RTC	0x1	1. Initiates force_sleep on interconnect clocks. 2. Turns off MPU and PER power domains. 3. Programs the RTC alarm register for deasserting pmic_pwr_enable.
CMD_RTC_FAST	0x2	Programs the RTC alarm register for deasserting pmic_pwr_enable.
CMD_DS0	0x3	1. Initiates force_sleep on interconnect clocks. 2. Turns off the MPU and PER power domains. 3. Configures the system for disabling MOSC when CM3 executes WFI.
CMD_DS1	0x5	1. Initiates force_sleep on interconnect clocks. 2. Turns off the MPU power domains. 3. Configures the system for disabling MOSC when CM3 executes WFI.

#### 6.4.6.1 Sleep Sequencing

This section gives the system level guidelines for sleep sequencing. The guidelines can serve as an example for implementing the sleep mode sequencing. The user can opt to implement a sequence with certain steps interchanged between the MPU and the wakeup processor.

1. Application saves context of peripherals to memories supporting retention and DDR – this step is only required for DeepSleep.
2. MPU OCMC\_RAM goes into retention.
3. Unused power domains are turned OFF: program clock/power domains PWRSTCTRL, save contexts, and so forth.
4. Software populates L3\_OCMC\_RAM for wakeup restoration viz Save EMIF settings, public restoration pointers, and so forth.
5. Execute WFI from SRAM.
6. Any peripheral interrupt will trigger a wake interrupt to the wakeup processor through the MPU's WKUP signal, INTR2.
7. After the MPU power domain is clock-gated, the PRCM provides an interrupt to the wakeup processor using INTR1.
8. The wakeup processor performs low-level power sequencing to turn off certain power domain and eventually executes WFI.
9. When the wakeup processor goes into WFI, the hardware oscillator control circuit disables the master oscillator.

#### 6.4.6.2 Wakeup Sequencing

This section gives the guidelines for Wakeup sequencing.

1. One of the wakeup event triggers (which was configured during the sleep sequencing) initiates a wakeup sequence
2. The wakeup event switches ON the oscillator, which was configured to go OFF during DeepSleep.
3. The wakeup event also triggers an interrupt to the wakeup processor.
4. On the wakeup event interrupt, the wakeup processor executes the following:
  - Restore the voltages to normal Operating voltage.
  - Enable PLL locking.
  - Switch ON the power domains and/or enable clocks for PD\_PER.
  - Switch ON the power domains and/or enable clocks for PD\_MPU.
  - Execute WFI.
5. The MPU executes from ROM reset vector.
6. Restore the application context (required only for Deep sleep 0).

#### 6.4.7 I/O Power Management and Daisy Chaining

I/O power management is useful when the main oscillator is clock gated and the PER power domain is OFF (power-gated state). Since the I/Os are controlled by modules in power-gated state, I/O power management is required to have flexibility when interfacing with external devices. During DeepSleep, the wakeup feature is active, described in **Wakeup** below. Isolation is required to be activated and de-activated during sleep and wakeup sequencing, respectively (see following description of **Isolation**).

Three aspects comprise I/O cell power management.

**Isolation**— Isolation from power state transitions.

When ISOLATED, the I/Os will hold their previous state (0,1, tristate) until the ISOLATION is released. The controls for the ISOLATION travel through the chain. Isolation is controlled during sleep and wakeup sequencing.

Note: The PRCM must have the optional feature to remove isolation from DDR I/Os while allowing rest of the I/O isolation to be removed later. This allows for software to restore any critical peripherals from DDR and ensure the peripheral is in a required or valid state (like GPIO) before the remaining I/Os are removed from Isolation.

**Wakeup**— I/O PAD can be individually enabled for wakeup using PADCONFx.WUEN register bit.

The wakeup controls and events (as well as enable and disable controls) travels through asynchronously through the chain during DeepSleep. The global wakeup chain is enabled/controlled by the PRCM. This is global control is achieved by qualifying each of the I/O PAD wakeup enables with global wakeup daisy chain control coming from PRCM.

**PADCONFIG**— Individual control on what will be the IO state during Isolation using DS-PADCONFIG control register bits.

The DS-PADCONFIG registers must be used only if the default state of the I/O during the low power state does not meet system requirements.

The following pins are special and will be kept out of Isolation and wakeup chains:

- System pins (named under section GLUE in pinmux mode0 column)
- Two xdma\_event\_intr pins are part of this GLUE section. Leaving out of daisy chain for having at least couple of GPIO0 pins with direct wakeup connectivity
- JTAG interface (named under DEBUGSS in pinmux mode0 column)
- I2C0
- spi0\_cs1 and eCAP0\_in\_PWM0\_out: These pins are muxed with timer0 and timer1 which can be used to toggle the external LED during low power states. They are also muxed with GPIO0 to be used as a backup for a direct wakeup event.

## 6.5 PRCM Module Overview

The PRCM is structured using the architectural concepts presented in the 5000x Power Management Framework. This framework provides:

A set of modular, re-usable FSM blocks to be assembled into the full clock and power management mechanism. A register set and associated programming model. Functional sub-block definitions for clock management, power management, system clock source generation, and master clock generation.

The device supports an enhanced power management scheme based on four functional power domains:

### Generic Domains

- WAKEUP
- MPU
- PER
- RTC

The PRCM provides the following functional features:

- Software configurable for direct, automatic, or a combination thereof, functional power domain state transition control
- Device power-up sequence control
- Device sleep / wake-up sequence control
- Centralized reset generation and management
- Centralized clock generation and management

The PRCM modules implement these general functional interfaces:

- OCP configuration ports
- Direct interface to device boundary
- Power switch control signals
- Device control signals

- Clocks control signals
- Resets signals
- A set of power management protocol signals for each module to control and monitor standby, idle and wake-up modes (CM and PRM)
- Emulation signals

### 6.5.1 Interface Descriptions

This section lists and shortly describes the different interfaces that allow PRCM to communicate with other modules or external devices.

#### 6.5.1.1 OCP Interfaces

The PRCM has 1 target OCP interfaces, compliant with respect to the OCP/IP2 standard. The OCP port, for the PRCM module is used to control power, reset and wake-up Management.

#### 6.5.1.2 OCP Slave Interfaces

PRCM implements a 32-bit OCP target interface compliant to the OCP/IP2.0 standard.

#### 6.5.1.3 Power Control Interface

The Device does has power domain switches over the device, this interface provides PRCM control over power domain switches and receives responses from the power domains which indicate the switch status. It also controls the isolation signals. The control for power domain switches will be latched in PRCM Status Registers

#### 6.5.1.4 Device Control Interface

This interface provides PRM management of several device-level features which are not specific to any single power domain. This PRM interface controls signals to/from the device for global control:

- Device Type coding
- IOs isolation control

#### 6.5.1.5 Clocks Interface

This interface gathers all clock inputs and outputs managed by PRCM modules.

#### 6.5.1.6 Resets Interface

This interface gathers all resets inputs and outputs managed by PRCM module.

#### 6.5.1.7 Modules Power Management Control Interface

Modules or subsystems in the device are split over 2 categories:

- Initiator: an initiator is a module able to generate traffic on the device interconnects (typically: processors, MMU, EDMA).
- Target: a target is a module that cannot generate traffic on the device interconnects, but that can generate interrupts or DMA request to the system (typically: peripherals). PRCM handles a power management handshake protocol with each module or sub-system. This protocol allows performing proper clock and power transition taking into account each module activity or state.

#### 6.5.1.8 Initiator Modules Interface

PRCM module handle all initiator modules power management interfaces: MStandby signal MWait signal

### 6.5.1.9 Targets Modules Interface

PRCM module handle all target modules power management interfaces: SIdleReq signal SIdleAck signal FCLKEN signal

**Note:** USB Support for SWakeUp

## 6.6 Clock Generation and Management

PRCM provides a centralized control for the generation, distribution and gating of most clocks in the device. PRCM gathers external clocks and internally generated clocks for distribution to the other modules in the device. PRCM manages the system clock generation

### 6.6.1 Terminology

The PRCM produces 2 types of clock:

**Interface clocks:** these clocks primarily provide clocking for the system interconnect modules and the portions of device's functional modules which interface to the system interconnect modules. In most cases, the interface clock supplies the functional module's system interconnect interface and registers. For some modules, interface clock is also used as functional clock. In this document, interface clocks are represented by blue lines.

**Functional clock:** this clock supplies the functional part of a module or a sub-system. In some cases, a module or a subsystem may require several functional clocks: 1 or several main functional clock(s), 1 or several optional clock(s). A module needs its main clock(s) to be operational. Optional clocks are used for specific features and can be shutdown without stopping the module

### 6.6.2 Clock Structure

To generate high-frequency clocks, the device supports multiple on-chip DPLLs controlled directly by the PRCM module. They are of two types of PLLs, referred to ADPLLS and ADPLLLJ throughout this document.

The ADPLLS module is used for the Core, Display, ARM Subsystem and DDR PLLs

The ADPLLLJ module is used for the peripheral functional clocks

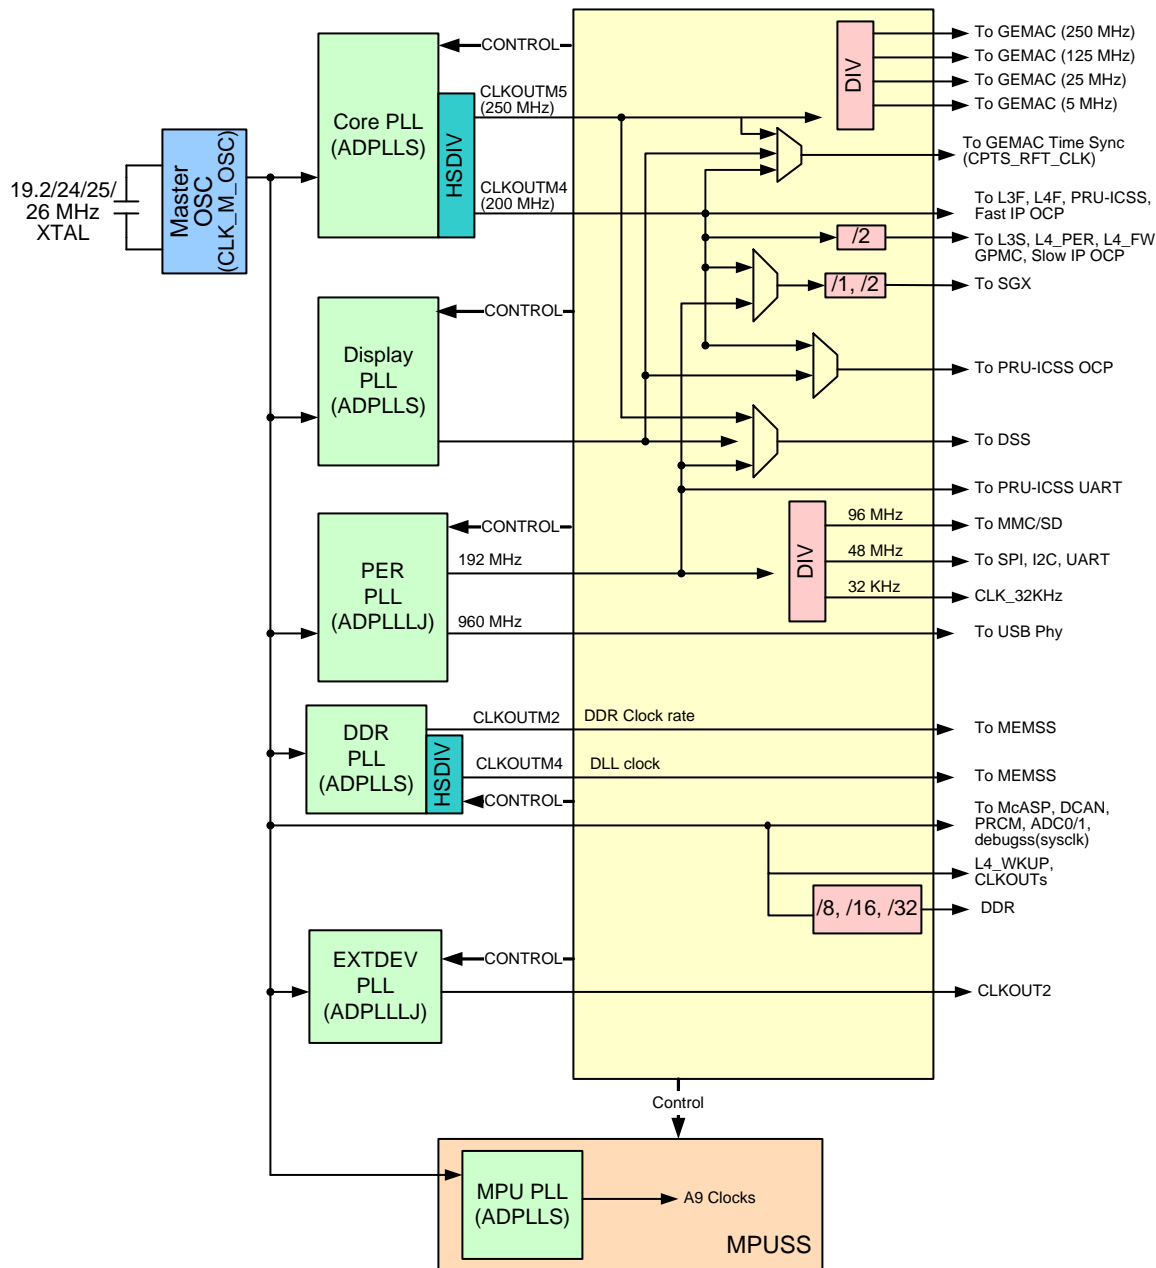

The device has two reference clocks which are generated by on-chip oscillators or externally. These are for the main clock tree and RTC block, respectively.

In the case of an external oscillator, a clock can directly be connected to XTALIN pin and the oscillator will be put in bypass mode. The 32-Khz crystal oscillator is controlled and configurable by the RTC. This device also contains an on-chip RC oscillator. This oscillator is not configurable and is always on.

The main oscillator on the device (see [Chapter 5, Initialization](#), for possible frequencies) produces the master high frequency clock CLK\_M\_OSC.

[Figure 6-8](#) shows a high-level overview of the device clock architecture. The diagram shows only the peripheral functional clocks, and the frequency values shown are typical (OPP100) values. See each DPLL section for a more detailed clocking structure.

Figure 6-8. Internal Clocking Architecture

### 6.6.3.1 Clock Functions

**Table 6-17. Output Clocks in Locked Condition**

Pin Name	Frequency	Comments
<b>REGM4XEN='0'</b>		
CLKOUT	$[M / (N+1)] * CLKINP * [1/M2]$	
CLKOUTX2	$2 * [M / (N+1)] * CLKINP * [1/M2]$	
CLKDCOLDO	$2 * [M / (N+1)] * CLKINP$	
CLKOUTHIF	CLKINPHIF / M3	CLKINPHIFSEL='1'
	$2 * [M / (N+1)] * CLKINP * [1/M3]$	CLKINPHIFSEL='0'
<b>REGM4XEN='1'</b>		
CLKOUT	$[4M / (N+1)] * CLKINP * [1/M2]$	
CLKOUTX2	$2 * [4M / (N+1)] * CLKINP * [1/M2]$	
CLKDCOLDO	$2 * [4M / (N+1)] * CLKINP$	
CLKOUTHIF	CLKINPHIF / M3	CLKINPHIFSEL='1'
	$2 * [4M / (N+1)] * CLKINP * [1/M3]$	CLKINPHIFSEL='0'

**Table 6-18. Output Clocks Before Lock and During Relock Modes**

Pin Name	Frequency	Comments
CLKOUT	CLKINP / (N2+1)	ULOWCLKEN='0'
	CLKINPULOW	ULOWCLKEN='1'
CLKOUTX2	CLKINP / (N2+1)	ULOWCLKEN='0'
	CLKINPULOW	ULOWCLKEN='1'
CLKDCOLDO	Low	
CLKOUTHIF	CLKINPHIF/M3	ULOWCLKEN='1'
	Low	ULOWCLKEN='0'

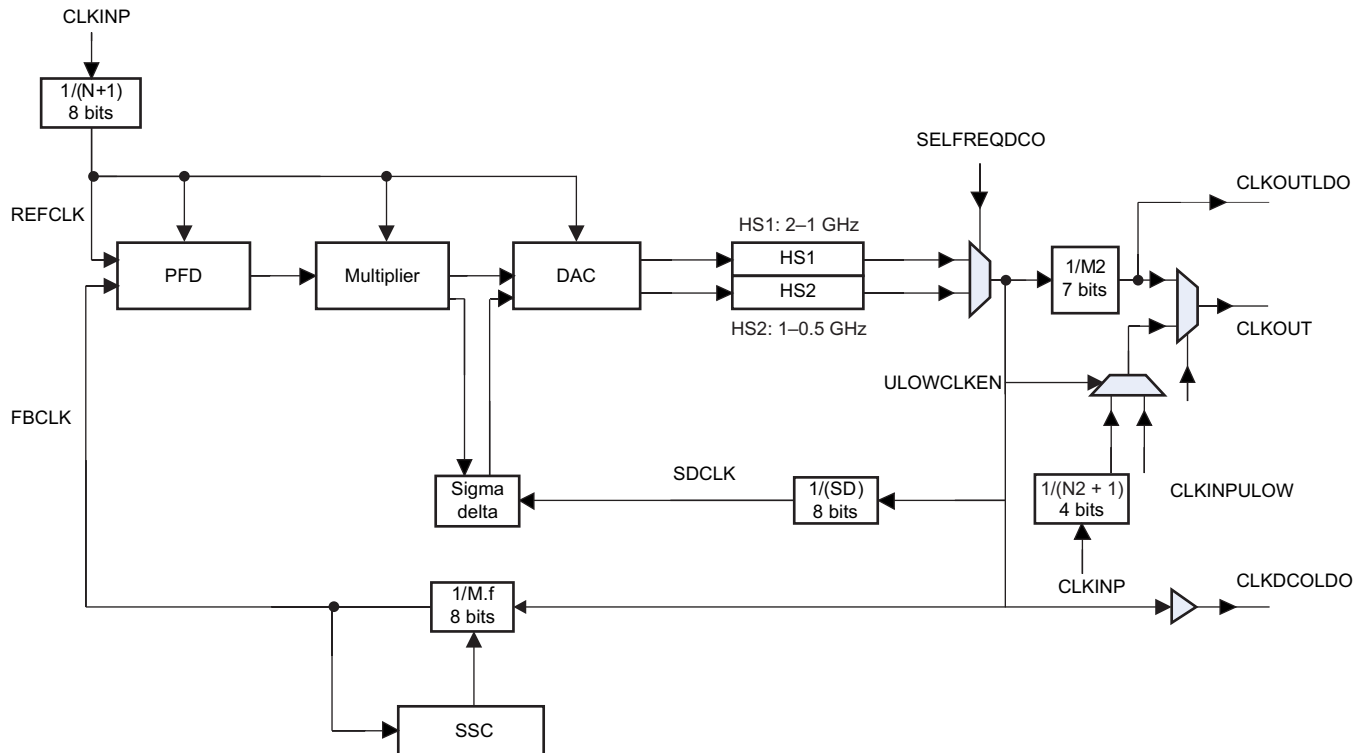

**Note:** Since M3 divider is running on the internal LDO domain, in the case when CLKINPHIFSEL='1', CLKOUTHIF could be active only when internal LDO is ON. Hence, whenever LDOPWDN goes low to high to powerdown LDO (happens when TINITZ activated / when entering slow relock bypass mode), output CLKOUTHIF will glitch and stop. To avoid this glitch, it is recommended to gate CLKOUTHIF using control CLKOUTHIFEN before asserting TINITZ / entering any slow relock bypass mode Frequency Range (MHz)

See the device-specific data manual for details on operating performance points (OPPs) supported by your device.

### 6.6.4 ADPLLJ (Low Jitter DPLL)

The ADPLLJ is a low jitter PLL with a 2-GHz maximum output. ADPLLJ has a predivide feature which allows user to divide, for instance, a 24-MHz or 26-MHz reference clock to 1 MHz and then multiply up to 2 GHz maximum.

All PLLs will come-up in bypass mode at reset. SW needs to program all the PLL settings appropriately and then wait for PLL to be locked. For more details, see the configuration procedure for each PLL.

**Figure 6-10. Basic Structure of the ADPLLJ**

The peripheral PLL and EXTDEV PLL belong to type ADPLLJ:

The DPLL has two input clocks:

- CLKINP: Reference input clock
- CLKINPULOW: Bypass input clock.

The DPLL has two internal clocks:

- REFCLK (Internal reference clock): This is generated by dividing the input clock CLKINP by the programmed value N+1. The entire loop of the PLL runs on the REFCLK.  
Here,  $REFCLK = CLKINP / (N+1)$ .
- CLKDCO (Internal Oscillator clock.): This is the raw clock directly out of the digitally controlled oscillator (DCO) before the post-divider. The PLL output clock is synthesized by an internal oscillator which is phase locked to the refclk. There are two oscillators built within ADPLLJ. The oscillators are user selectable based on the synthesized output clock frequency requirement. In locked condition,  $CLKDCO = CLKINP * [M / (N+1)]$ .

The ADPLLJ lock frequency is defined as follows:  $f_{DPLL} = CLKDCOOUT$

The DPLL has three external output clocks:

- CLKOUTLDO: Primary output clock in VDDLDOOUT domain. Bypass option not available on this output.  
 $CLKOUTLDO = (M / (N+1)) * CLKINP * (1/M2)$
- CLKOUT:  
Primary output clock on digital core domain  
 $CLKOUT = (M / (N+1)) * CLKINP * (1/M2)$
- CLKDCOLDO:  
Oscillator (DCO) output clock before post-division in VDDLDOOUT domain. Bypass option is not available on this output.  
 $CLKDCOLDO = (M / (N+1)) * CLKINP$ .

All clock outputs of the DPLL can be gated. The Control module provides the DPLL with a clock gating control signal to enable or disable the clock, and the DPLL provides the PRCM module with a clock activity status signal to let the PRCM module hardware know when the clock is effectively running or effectively gated. Output clock gating control for various clockouts:  
CLKOUTEN/CLKOUTLDOEN/CLKDCOLDOEN.

#### 6.6.4.1 Clock Functions

**Table 6-19. Output Clocks in Locked Condition**

Pin Name	Frequency
CLKOUT	$[M / (N+1)] * CLKINP * [1/M2]$
CLKOUTLDO	$[M / (N+1)] * CLKINP * [1/M2]$
CLKDCOOUT	$[M / (N+1)] * CLKINP$

**Table 6-20. Output Clocks Before Lock and During Relock Modes**

Pin Name	Frequency	Comments
CLKOUT	$CLKINP/(N2+1)$	ULOWCLKEN='0'
	CLKINPLOW	ULOWCLKEN='1'
CLKDCOLDO	LOW	
CLKOUTLDO	LOW	

#### 6.6.5 M2 and N2 Change On-the-Fly

The dividers M2 and N2 are designed to change on the fly and provide a glitch-free frequency switch from the old to new frequencies. In other words, they can be changed while the PLL is in a locked condition, without having to switch to bypass mode. A status toggle bit will give an indication if the new divisor was accepted. These dividers can also be changed in bypass mode, and the new divisor value will be reflected on output after the PLL rellocks. For more details, see the PLL configuration procedures for each PLL.

#### 6.6.6 Spread Spectrum Clocking (SSC)

The module supports spread spectrum clocking (SSC) on its output clocks. SSC is used to spread the spectral peaking of the clock to reduce any electromagnetic interference (EMI) that may be caused due to the clock's fundamental or any of its harmonics. When SSC is enabled the clock's spectrum is spread by the amount of frequency spread, and the attenuation is given by the ratio of the frequency spread ( $\Delta f$ ) and the modulation frequency ( $f_m$ ), i.e.,  $[10 \cdot \log_{10}(\Delta f / f_m)] - 10$  dB.

SSC is performed by changing the feedback divider (M) in a triangular pattern. Implying, the frequency of the output clock would vary in a triangular pattern. The frequency of this pattern would be modulation frequency ( $f_m$ ). The peak ( $\Delta M$ ) or the amplitude of the triangular pattern as a percent of M would be equal to the percent of the output frequency spread ( $\Delta f$ ); that is,  $\Delta M / M = \Delta f / f_c$ . Next mark with  $F_{inP}$  the frequency of the clock signal at the input of the DPLL. Because it is divided to N+1 before entering the phase detector, so the internal reference frequency is  $F_{ref} = F_{inP} / (N + 1)$ .

Assume the central frequency  $f_c$  to be equal to the DPLL output frequency  $F_{out}$ , or  $f_c = F_{out} = (F_{inP} / (N + 1)) * (M / M2)$ . Since this is in band modulation for the DPLL, the modulation frequency is required to be within the DPLL's loop bandwidth (lowest BW of  $F_{ref} / 70$ ). A higher modulation frequency would result in lesser spreading in the output clock.

SSC can be enabled/disabled using bit CM\_CLKMODE\_DPLL\_xxx.DPLL\_SSC\_EN (where xxx can be any one of the following DPLLs: MPU, DDR, DISP, CORE, PER). An acknowledge signal CM\_CLKMODE\_DPLL\_xxx.DPLL\_SSC\_ACK notifies the exact start and end of SSC. When SSC\_EN is de-asserted, SSC is disabled only after completion of one full cycle of the triangular pattern given by the modulation frequency. This is done in order to maintain the average frequency.

Modulation frequency ( $f_m$ ) can be programmed as a ratio of  $F_{ref} / 4$ ; that is, the value that needs to be programmed  $ModFreqDivider = F_{ref} / (4 * f_m)$ . The  $ModFreqDivider$  is split into Mantissa and  $2^{Exponent}$  ( $ModFreqDivider = ModFreqDividerMantissa * 2^{ModFreqDividerExponent}$ ). The mantissa is controlled by 7-bit signal  $ModFreqDividerMantissa$  through  $CM\_SSC\_MODFREQDIV\_DPLL\_xxx.MODFREQDEV\_MANTISSA$  bit field. The exponent is controlled by 3-bit signal  $ModFreqDividerExponent$  through the  $CM\_SSC\_MODFREQDIV\_DPLL\_xxx.MODFREQDEV\_EXPONENT$  bit field.

**Note:** Although the same value of  $ModFreqDivider$  can be obtained by different combinations of mantissa and exponent values, it is recommended to get the target  $ModFreqDivider$  by programming maximum mantissa and a minimum exponent. To define the Frequency spread ( $\Delta f$ ),  $\Delta M$  must be controlled as explained previously. To define  $\Delta M$ , the step size of  $M$  for each  $F_{ref}$  during the triangular pattern must be programmed; that is,

$$\Delta M = (2^{ModFreqDividerExponent}) * ModFreqDividerMantissa * DeltaMStep \text{ IF } ModFreqDividerExponent \leq 3$$

$$\Delta M = 8 * ModFreqDividerMantissa * DeltaMStep \text{ IF } ModFreqDividerExponent > 3$$

$\Delta MStep$  is split into integer part and fractional part. Integer part is controlled by 2-bit signal  $\Delta MStepInteger$  through the  $CM\_SSC\_DELTAMSTEP\_DPLL\_xxx.DELTAMSTEP\_INTEGER$  bit field. Fractional part is controlled by 18-bit signal  $\Delta MStepFraction$  through the  $CM\_SSC\_DELTAMSTEP\_DPLL\_xxx.DELTAMSTEP\_FRACTION$  bit field.

The frequency spread achieved has an overshoot of 20 percent or an inaccuracy of +20 percent. If the  $CM\_CLKMODE\_DPLL.DPLL\_SSC\_DOWNSPREAD$  is set to 1, the frequency spread on lower side is twice the programmed value. The frequency spread on higher side is 0 (except for the overshoot as described previously).

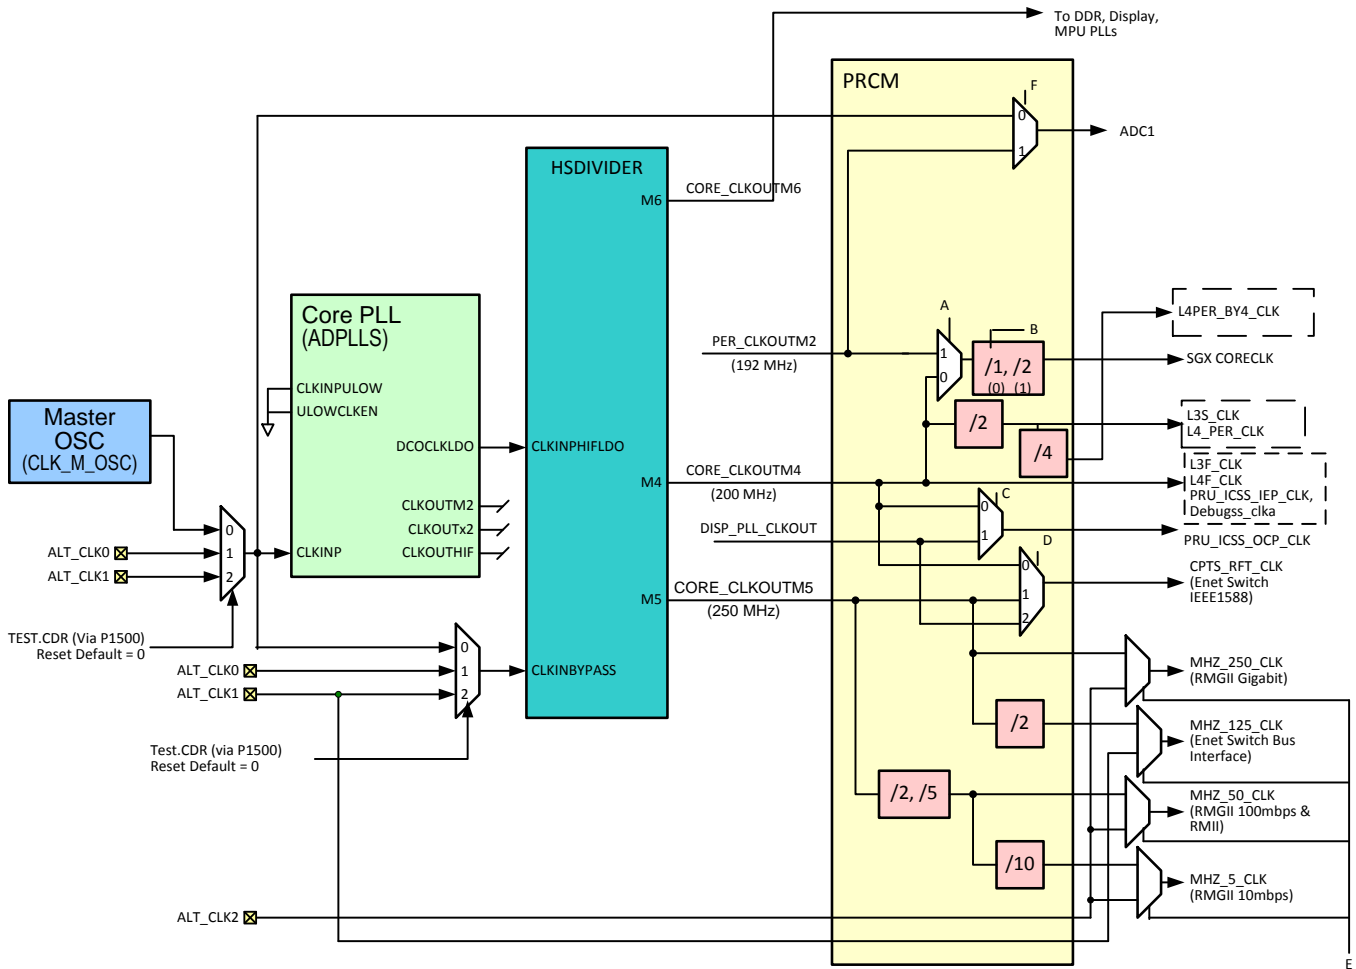

There is restriction of range of  $M$  values. The restriction is  $M - \Delta M$  should be  $\geq 20$ . Also,  $M + \Delta M$  should be  $\leq 2045$ . In case the downspread feature is enabled,  $M - 2 * \Delta M$  should be  $\geq 20$  and  $M \leq 2045$ .

### 6.6.7 Core PLL Description

The Core PLL provides the source for a majority of the device infrastructure and peripheral clocks. The Core PLL comprises an ADPLLs with HSDIVIDER and additional dividers and muxes located in the PRCM as shown in [Figure 6-11](#).

**Figure 6-11. Core PLL Structure**

ALT\_CLKs are to be used for internal test purpose and should not be used in functional mode.

**Table 6-21. PLL and Clock Frequencies**

Mux Select	Register BitSection 7.2.3.4
A	PRCM.CLKSEL_GFX_FCLK[1]
B	PRCM.CLKSEL_GFX_FCLK[0]
C	PRCM.CLKSEL_PRU_ICSS_OCP_CLK[0]
D	PRCM.CM_CPTS_RFT_CLKSEL[0]
F	PRCM.CLKSEL_ADC1_CLK[0]

Table 6-22 gives the typical PLL and clock frequencies. The HSDIVIDER is used to generate three divided clocks M4, M5, and M6. M4 and M5 are nominally 200 and 250 MHz, respectively.

**Table 6-22. Core PLL Typical Frequencies (MHz)**

CLOCK	Source	Power-On-Reset / HSDIVIDER Bypass		OPP100		OPP50 <sup>(1)</sup>	
		DIV	Freq	DIV Value	Freq (MHz)	DIV Value	Freq (MHz)
CLKDCOLDO (PLL Lock frequency)	APLLS	-	-	-	2000	-	100
CORE_CLKOUTM4	HSDIVIDER-M4	-	Mstr Xtal	10	200	1	100

<sup>(1)</sup> Not all interfaces and peripheral modules are available in OPP50. For more information, see the device-specific datasheet.

**Table 6-23. Bus Interface Clocks**

L3F_CLK	SGX530 (MEMCLK and SYSCLK), MPU Subsystem, GEMAC Switch (Ethernet), DAP, PRU-ICSS, EMIF, TPTC, TPCC, OCMC RAM, DEBUGSS, DSS, EDMA, VPFE
L3S_CLK	USB, ADC0, GPMC, MMCSD2, McASP0, McASP1, QSPI, ADC1
L4_PER_CLK	DCAN0, DCAN1 DMTIMER2, DMTIMER3, DMTIMER4, DMTIMER5, DMTIMER6, DMTIMER7, DMTIMER8, DMTIMER9, DMTIMER10, DMTIMER11 eCAP/eQEP/ePWM0, eCAP/eQEP/ePWM1, eCAP/eQEP/ePWM2, eFuse ELM, GPIO1, GPIO2, GPIO3, GPIO4, GPIO5 I2C1, I2C2, IEEE1500, Mailbox0 HDQ1W, McASP0, McASP1 MMCSD0, MMCSD1, OCP Watchpoint, SPI0, SPI1, Spinlock UART1, UART2, UART3, UART4, UART5
L4_WKUP_CLK	Clock Manager, Control Module DMTIMER0, DMTIMER_1MS, SyncTimer32k, RTCSS, GPIO0 I2C0, UART0, WDT1

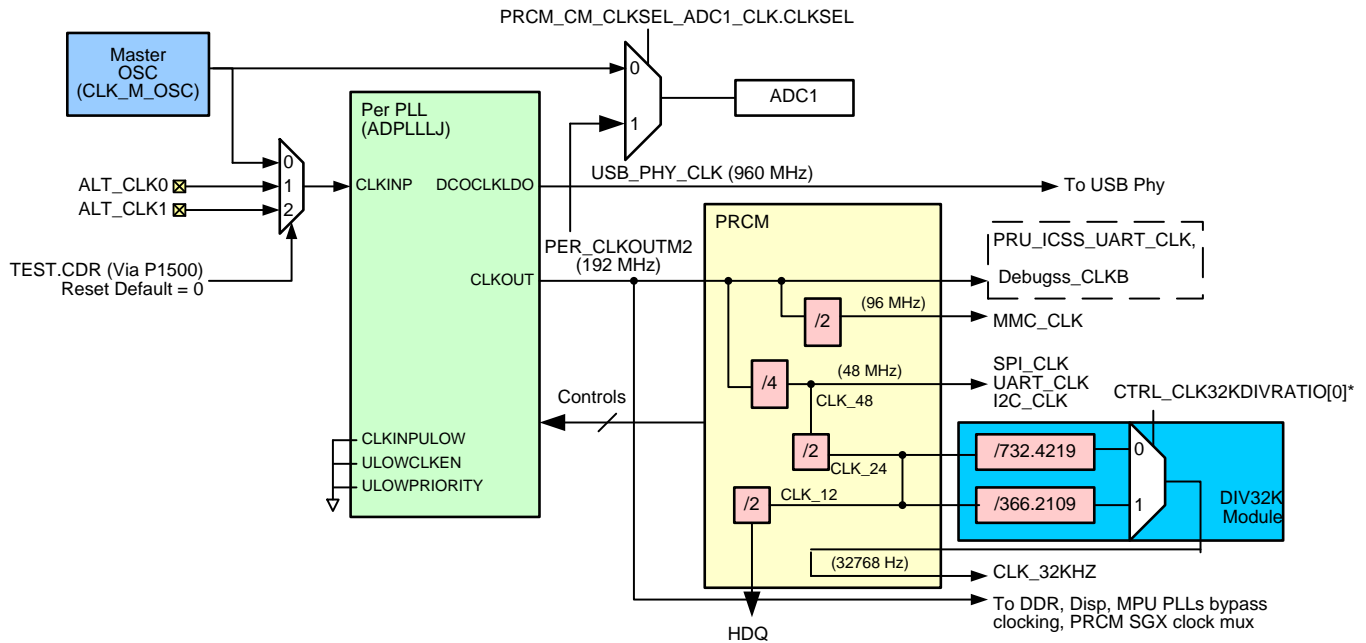

#### 6.6.7.1 Configuring the Core PLL

1. Switch PLL to bypass mode by setting CM\_CLKMODE\_DPLL\_CORE.DPLL\_EN to 0x4.
2. Wait for CM\_IDLEST\_DPLL\_CORE.ST\_MN\_BYPASS = 1 to ensure PLL is in bypass (CM\_IDLEST\_DPLL\_CORE.ST\_DPLL\_CLK should also change to 0 to denote the PLL is unlocked).
3. Configure Multiply and Divide values by setting CM\_CLKSEL\_DPLL\_CORE.DPLL\_MULT and DPLL\_DIV to the desired values.
4. Configure M4, M5 and M6 dividers by setting HSDIVIDER\_CLKOUT1\_DIV bits in CM\_DIV\_M4\_DPLL\_CORE, CM\_DIV\_M5\_DPLL\_CORE, and CM\_DIV\_M6\_DPLL\_CORE to the desired values.
5. Switch over to lock mode by setting CM\_CLKMODE\_DPLL\_CORE.DPLL\_EN to 0x7.
6. Wait for CM\_IDLEST\_DPLL\_CORE.ST\_DPLL\_CLK = 1 to ensure PLL is locked (CM\_IDLEST\_DPLL\_CORE.ST\_MN\_BYPASS should also change to 0 to denote the PLL is out of bypass mode).

**Note:** M4, M5, and M6 dividers can also be changed on-the-fly so that there is no need to put the PLL in bypass and back to lock mode. After changing CM\_DIV\_Mx\_DPLL\_CORE.DPLL\_CLKOUT\_DIV, check CM\_DIV\_Mx\_DPLL\_CORE.DPLL\_HSDIVIDER\_CLKOUT1\_DIVCHACK for a toggle (a change from 0 to 1 or 1 to 0) to see if the change was acknowledged by the PLL.

#### 6.6.8 Peripheral PLL Description

The Per PLL provides the source for peripheral functional clocks. The Per PLL comprises an ADPLLJ and additional dividers and muxes located in the PRCM as shown

**Figure 6-12. Peripheral PLL Structure**

\* Reset default zero

ALT\_CLKs are to be used for internal test purpose and should not be used in functional mode.

The PLL is locked at 960 MHz. The PLL output is divided by the M2 divider to generate a 192-MHz CLKOUT. This clock is gated in the PRCM to form the PRU-ICSS UART clock. There is a /2 divider to create 96 MHz for MMC\_CLK. The clock is also divided within the PRCM by a fixed /4 divider to create a 48-MHz clock for the SPI, UART and I2C modules. The 48-MHz clock is further divided by a fixed /2 divider and a fixed /732.4219 divider to create an accurate 32.768-KHz clock for Timer and debounce use.

**Table 6-24. Per PLL Typical Frequencies (MHz)**

Clock	Source	Power-On-Reset / PLL Bypass		OPP100		OPP50 <sup>(1)(2)</sup>	
		DIV Value	Freq	DIV Value	Freq (MHz)	DIV Value	Freq (MHz)
PLL Lock frequency	PLL	-	-	-	960	-	960
USB_PHY_CLK	CLKDCOLDO	-	Held Low	-	960	-	960
PER_CLKOUTM2	CLKOUT of ADPLLJ CLKOUT uses PLL's M2 Divider when PLL is locked and PLL's N2 divider when PLL Bypass	N2 is 0 on power-on-reset	Mstr Xtal/ (N2+1)	5	192	10	96
MMC_CLK	PER_CLKOUTM2	2	Mstr Xtal/ ((N2+1)*2)	2	96	2	48
SPI_CLK, UART_CLK, I2C_CLK	PER_CLKOUTM2	4	Mstr Xtal/ ((N2+1)*4)	4	48	4	24
CLK_24	CLK_48	2	CLK_48 /2	2	24	2	12
CLK_32KHZ	CLK_24 (output of CLK_48/2)	732.4219	CLK_24 / <CLK32_DIV>	732.4219	0.032768	366.2109	0.032768

<sup>(1)</sup> For limitations using OPP50, see the device-specific errata.

<sup>(2)</sup> Not all interfaces and peripheral modules are available in OPP50. For more information, see the device-specific errata.

### 6.6.8.1 Configuring the Peripheral PLL

The following steps detail how to configure the peripheral PLL.

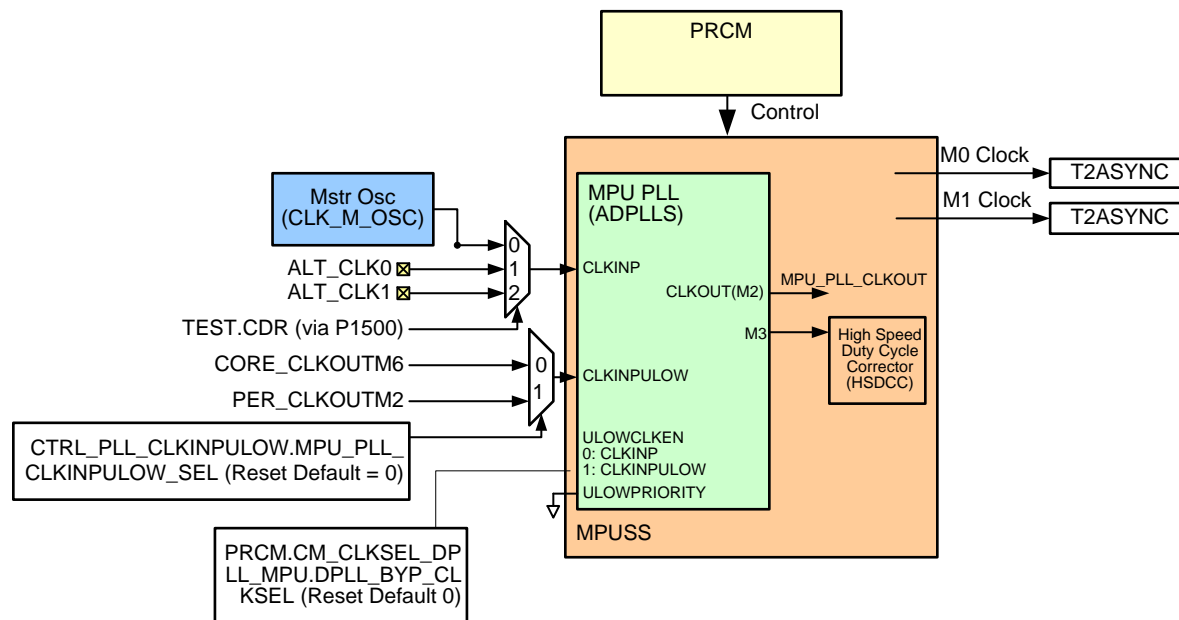

1. Switch PLL to bypass mode by setting CM\_CLKMODE\_DPLL\_PER.DPLL\_EN to 0x4.
2. Wait for CM\_IDLEST\_DPLL\_PER.ST\_MN\_BYPASS = 1 to ensure PLL is in bypass (CM\_IDLEST\_DPLL\_PER.ST\_DPLL\_CLK should also change to 0 to denote the PLL is unlocked).
3. Configure Multiply and Divide values by setting CM\_CLKSEL\_DPLL\_PER.DPLL\_MULT and DPLL\_DIV to the desired values.
4. Configure M2 divider by setting CM\_DIV\_M2\_DPLL\_PER.DPLL\_CLKOUT\_DIV to the desired value.
5. Switch over to lock mode by setting CM\_CLKMODE\_DPLL\_PER.DPLL\_EN to 0x7.
6. Wait for CM\_IDLEST\_DPLL\_PER.ST\_DPLL\_CLK = 1 to ensure PLL is locked (CM\_IDLEST\_DPLL\_PER.ST\_MN\_BYPASS should also change to 0 to denote the PLL is out of bypass mode).

**Note:** M2 divider can also be changed on-the-fly (ie., there is no need to put the PLL in bypass and back to lock mode). After changing CM\_DIV\_M2\_DPLL\_PER.DPLL\_CLKOUT\_DIV, check CM\_DIV\_M2\_DPLL\_PER.DPLL\_CLKOUT\_DIVCHACK for a toggle (a change from 0 to 1 or 1 to 0) to see if the change was acknowledged by the PLL.

### 6.6.9 MPU PLL Description

The MPU subsystem includes an internal ADPLLs for generating the required MPU clocks. This PLL is driven by the master oscillator output with control provided by PRCM registers.

**Figure 6-13. MPU Subsystem PLL Structure**

For example:

For a frequency for MPU, say 600 MHz, the ADPLLs is configured (PLL locked at 1200 MHz and M2 Divider =1) so as to expect CLKOUT = 600 MHz .

The ULOWCLKEN input from a programmable PRCM register selects whether CLKINP or CLKINPULOW is the bypass clock source. This is a glitch free switch. When CLKINP is selected it is sourced through the ADPLLs 1/(N2+1) divider. The PRCM register defaults to 0 on power-up to select the CLKINP source.

The CLKINPULOW input may be sourced from the CORE\_CLKOUTM6 from the Core PLL, or PER\_CLKOUTM2 from the Per PLL. These PLL output clocks can be used as alternate clock sources in low power active use cases for the MPU Subsystem clock when the PLL is in bypass mode.

### 6.6.9.1 Configuring the MPU PLL

The following steps detail how to configure the MPU PLL.

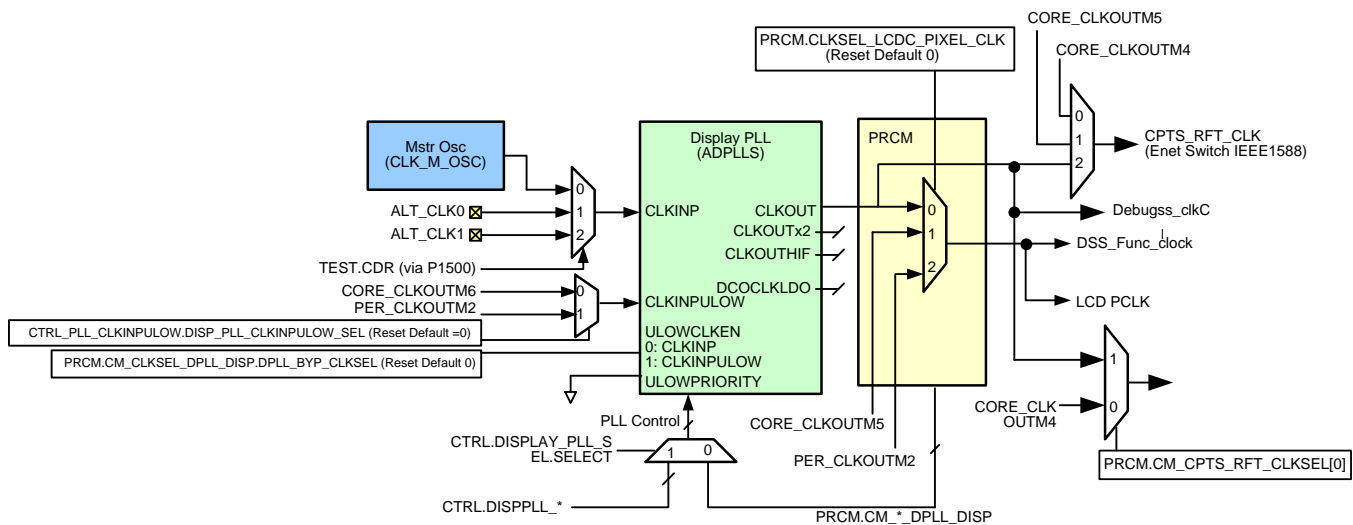

1. Switch PLL to bypass mode by setting CM\_CLKMODE\_DPLL\_MPU.DPLL\_EN to 0x4.
2. Wait for CM\_IDLEST\_DPLL\_MPU.ST\_MN\_BYPASS = 1 to ensure PLL is in bypass (CM\_IDLEST\_DPLL\_MPU.ST\_DPLL\_CLK should also change to 0 to denote the PLL is unlocked).
3. Configure Multiply and Divide values by setting CM\_CLKSEL\_DPLL\_MPU.DPLL\_MULT and DPLL\_DIV to the desired values.
4. Configure M2 divider by setting CM\_DIV\_M2\_DPLL\_MPU.DPLL\_CLKOUT\_DIV to the desired value.
5. Switch over to lock mode by setting CM\_CLKMODE\_DPLL\_MPU.DPLL\_EN to 0x7.
6. Wait for CM\_IDLEST\_DPLL\_MPU.ST\_DPLL\_CLK = 1 to ensure PLL is locked (CM\_IDLEST\_DPLL\_MPU.ST\_MN\_BYPASS should also change to 0 to denote the PLL is out of bypass mode).

**Note:** M2 divider can also be changed on-the-fly (ie., there is no need to put the PLL in bypass and back to lock mode). After changing CM\_DIV\_M2\_DPLL\_MPU.DPLL\_CLKOUT\_DIV, check CM\_DIV\_M2\_DPLL\_MPU.DPLL\_CLKOUT\_DIVCHACK for a toggle (a change from 0 to 1 or 1 to 0) to see if the change was acknowledged by the PLL.

### 6.6.10 Display PLL Description

The Display PLL provides the pixel clock required for the LCD display and is independent from the other peripheral and infrastructure clocks. The PLL is clocked from the Master Oscillator. The ADPLLs M2 divider determines the output clock frequency which is clock gated by the PRCM as shown in Figure 6-14.

**Figure 6-14. Display PLL Structure**

The display PLL also provides a clock to the time sync module clock of the Ethernet switch (CPTS\_RFT\_CLK). This PLL can be optionally controlled using the control module registers (CTRL\_DISPPLL\_i) for on-the-fly fine tuning of the time sync clock frequency using the fractional M multiplier. This synchronizes the frequency with the external master clock in an Ethernet IEEE 1588-compliant system. The clock frequency would be fine tuned up to  $\pm 3\%$  of the nominal clock frequency of 250 MHz, that is, effectively the time sync module is required to run up to a maximum frequency of 258 MHz.

For example: say frequency for pixel clock 100 MHz, the ADPLLs is configured (PLL locked at 200 MHz and M2 Divider =1) so as to expect CLKOUT = 100 MHz.

The ULOWCLKEN input from a programmable PRCM register selects whether CLKINP or CLKINPULOW is the bypass clock source. This is a glitch free switch. When CLKINP is selected it is sourced through the ADPLLs  $1/(N2+1)$  divider. The PRCM register defaults to 0 on power-up to select the CLKINP source.

The CLKINPULOW input is sourced from the CORE\_CLKOUTM6 from the Core PLL or PER\_CLKOUTM2 from the Per PLL. This PLL output clock can be used as an alternate clock source in low power active use cases for the pixel clock when the Display PLL is in bypass mode.

### 6.6.10.1 Configuring the Display PLL

The following steps detail how to configure the display PLL.

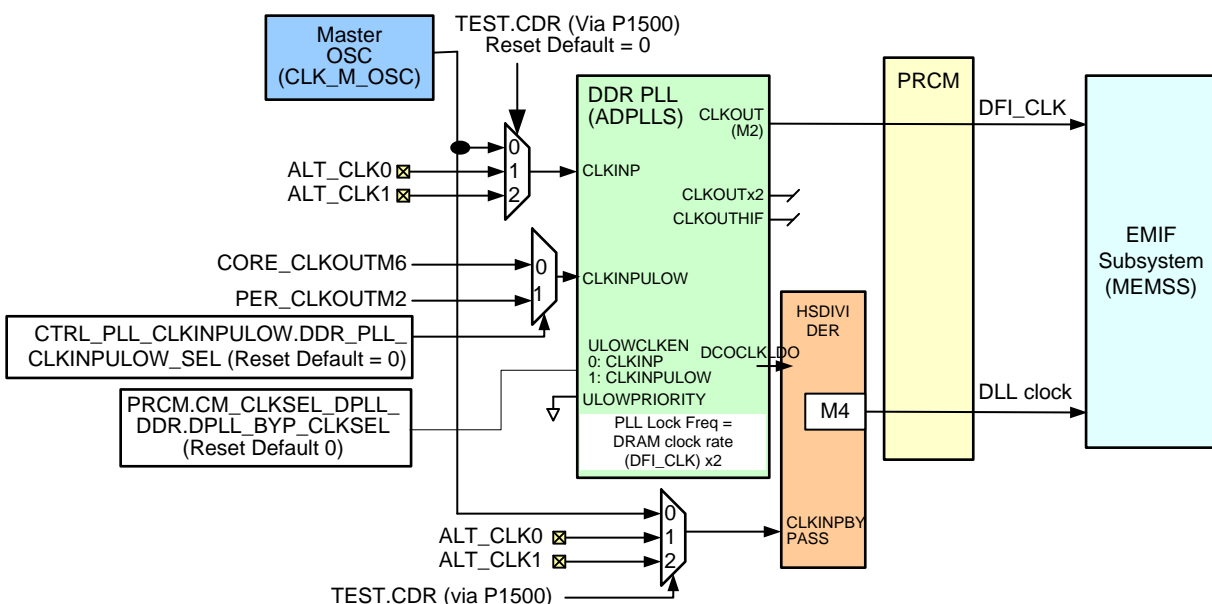

1. Switch PLL to bypass mode by setting CM\_CLKMODE\_DPLL\_DISP.DPLL\_EN to 0x4.
2. Wait for CM\_IDLEST\_DPLL\_DISP.ST\_MN\_BYPASS = 1 to ensure PLL is in bypass (CM\_IDLEST\_DPLL\_DISP.ST\_DPLL\_CLK should also change to 0 to denote the PLL is unlocked).
3. Configure Multiply and Divide values by setting CM\_CLKSEL\_DPLL\_DISP.DPLL\_MULT and DPLL\_DIV to the desired values.
4. Configure M2 divider by setting CM\_DIV\_M2\_DPLL\_DISP.DPLL\_CLKOUT\_DIV to the desired value.
5. Switch over to lock mode by setting CM\_CLKMODE\_DPLL\_DISP.DPLL\_EN to 0x7.
6. Wait for CM\_IDLEST\_DPLL\_DISP.ST\_DPLL\_CLK = 1 to ensure PLL is locked (CM\_IDLEST\_DPLL\_DISP.ST\_MN\_BYPASS should also change to 0 to denote the PLL is out of bypass mode).

**Note:** M2 divider can also be changed on-the-fly (ie., there is no need to put the PLL in bypass and back to lock mode). After changing CM\_DIV\_M2\_DPLL\_DISP.DPLL\_CLKOUT\_DIV, check CM\_DIV\_M2\_DPLL\_DISP.DPLL\_CLKOUT\_DIVCHACK for a toggle (a change from 0 to 1 or 1 to 0) to see if the change was acknowledged by the PLL.

### 6.6.11 DDR PLL Description

The DDR PLL provides the clocks required by the DDR macros and the EMIF and is independent from the other peripheral and infrastructure clocks. The PLL is clocked from the Master Oscillator. The ADPLLs M2 divider determines the output clock frequency which is connected to the EMIF subsystem (MEMSS) for clocking the memory interfaces. An HSDIVIDER, clocked by DCOCLKLDO, provides the DLL clock, which is an integer ratio with the DFI\_CLK (going to MEMSS and DRAM), as Figure 6-15 shows.

Figure 6-15. DDR PLL Structure

For OPP information, see the device-specific data manual.

For example:

- The PLL lock frequency is 666 MHz.

- M2 Divider equals 1, so as to expect CLKOUT/DFI\_CLK is 333 MHz.
- The DDR pin clock will be 333 MHz.

The ULOWCLKEN input from a programmable PRCM register selects whether CLKINP or CLKINPULOW is the bypass clock source. This is a glitch free switch. When CLKINP is selected it is sourced through the ADPLLs 1/(N2+1) divider. The PRCM register defaults to 0 on power-up to select the CLKINP source.

The CLKINPULOW input may be sourced from the CORE\_CLKOUTM6 from the Core PLL, or PER\_CLKOUTM2 from the Per PLL. These PLL output clocks can be used as alternate clock sources in low power active use cases for the DDR clocks when PLL is in bypass mode

#### 6.6.11.1 Configuring the DDR PLL

The following steps detail how to configure the DDR PLL.

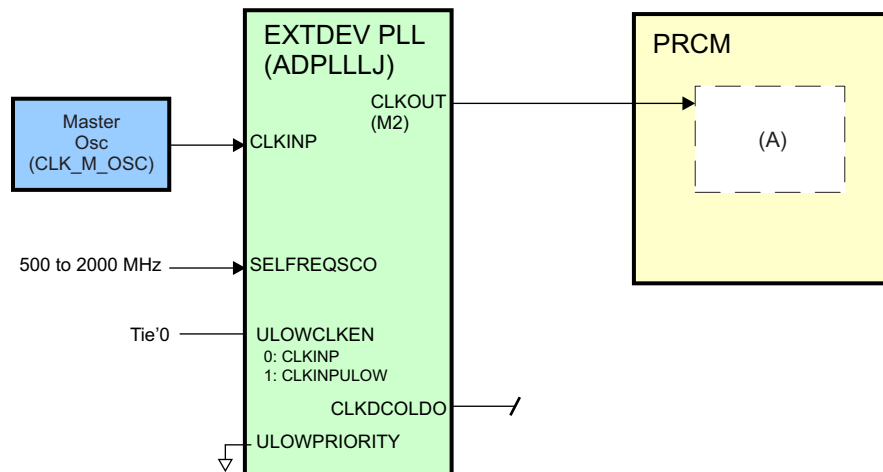

1. Switch PLL to bypass mode by setting CM\_CLKMODE\_DPLL\_DDR.DPLL\_EN to 0x4.
2. Wait for CM\_IDLEST\_DPLL\_DDR.ST\_MN\_BYPASS = 1 to ensure PLL is in bypass (CM\_IDLEST\_DPLL\_DDR.ST\_DPLL\_CLK should also change to 0 to denote the PLL is unlocked).
3. Configure Multiply and Divide values by setting CM\_CLKSEL\_DPLL\_DDR.DPLL\_MULT and DPLL\_DIV to the desired values.
4. Configure M2 divider by setting CM\_DIV\_M2\_DPLL\_DDR.DPLL\_CLKOUT\_DIV to the desired value.
5. Switch over to lock mode by setting CM\_CLKMODE\_DPLL\_DDR.DPLL\_EN to 0x7.
6. Wait for CM\_IDLEST\_DPLL\_DDR.ST\_DPLL\_CLK = 1 to ensure PLL is locked (CM\_IDLEST\_DPLL\_DDR.ST\_MN\_BYPASS should also change to 0 to denote the PLL is out of bypass mode).

**Note:** M2 divider can also be changed on-the-fly (i.e., there is no need to put the PLL in bypass and back to lock mode). After changing CM\_DIV\_M2\_DPLL\_DDR.DPLL\_CLKOUT\_DIV, check CM\_DIV\_M2\_DPLL\_DDR.DPLL\_CLKOUT\_DIVCHACK for a toggle (a change from 0 to 1 or 1 to 0) to see if the change was acknowledged by the PLL.

#### 6.6.12 EXTDEV PLL Description

This PLL output feeds to CLKOUTs. It will generate clocks for external devices such as a modem. The lock frequency depends on the external clock device. The PRCM must support a fractional multiplier for this PLL.

**Figure 6-16. EXTDEV PLL Structure**

(A): CLKOUT mux logic. See [Section 6.6.14, CLKOUT Signals](#).

#### 6.6.12.1 Configuring the EXTDEV PLL

The SELFREQSCO tieoff value must be defined in the range of 500 to 2000 MHz to give the best jitter.

### 6.6.13 PLL Bypass Modes

When an active PLL is not required, the PLL can be configured into a bypass mode to reduce power consumption. Each bypass mode has unique power and latency characteristics, which should be considered when selecting the appropriate operating mode. The supported modes are handled through the CLKMODE\_DPLL\_X.DPLL\_EN register bitfield.

The ADPLL module supports three different bypass modes through their internal MNBypass mode, external Low Power Idle bypass mode, and Fast Relock bypass mode. The PLLs are in the MNBypass mode after power-on-reset and can be configured by software to enter the other bypass modes for power-down. The MNBypass and Low Power Idle bypass modes gate internal clocks and turn off the analog blocks of the DPLL to reduce power consumption, but at a cost to relock latency. The Fast Relock bypass mode keeps the DPLL analog bias and LDO active and provides the lowest latency relock period. When the Core PLL is configured in bypass mode, the HSDIVIDER enters bypass mode and the CLKINBYPASS input is driven on the M4, M5, and M6 outputs. CLKINBYPASS defaults to the master oscillator input (typically 24 MHz).

The ADPLLJ module supports two different bypass modes through their internal MNBypass mode and their external Low Power Idle bypass mode. Fast Relock bypass is not supported for ADPLLJ. The PER PLL can use the Low Power Idle bypass mode. When the internal bypass mode is selected, the CLKOUT output is driven by CLKINP/(N2+1) where N2 is driven by the PRCM. CLKINP defaults to the master oscillator input (typically 24 MHz).

[Table 6-25](#) describes the relock times and power consumption for the PLL bypass modes, for nominal process at 30°C. Frequency Lock Time is the maximum latency from the bypass mode to when the internal normal clk frequency is within +/-1% of the final output frequency, of Active and Locked mode. Phase Lock Time is the maximum latency from the bypass mode to when, internally, the phase difference between FBCLK and REFCLK is less than 6–12% of the REFCLK period for 96 continuous REFCLKs, of Active and Locked mode.

**Table 6-25. Latency and Power for PLL Bypass Modes**

	MN Bypass	Low Power Bypass	Fast Relock Bypass
Frequency Relock Time	1.9us + 350REFCLKs	1.9us + 70REFCLKs	0.05us + 70REFCLKs
Phase Relock Time	1.9us + 500REFCLKs	1.9us + 120REFCLKs	0.05us + 120REFCLKs

If temperature is steady when entering into and coming out of the bypass modes, the lock time for relock is significantly lower compared to the initial lock time. However, if the temperature drift exceeds 10°C, the frequency and phase relock times increase (see [Table 6-26](#)). Once the module is locked, it can tolerate any amount of change in temperature within the operating temperature range. Because the typical rate of change in temperature is very slow compared to the loop BW (~REFCLK/50), the loop will be able to track changes in temperature.

Additional relock time will be taken if exit of bypass mode is triggered without the DPLL being fully in bypass mode.

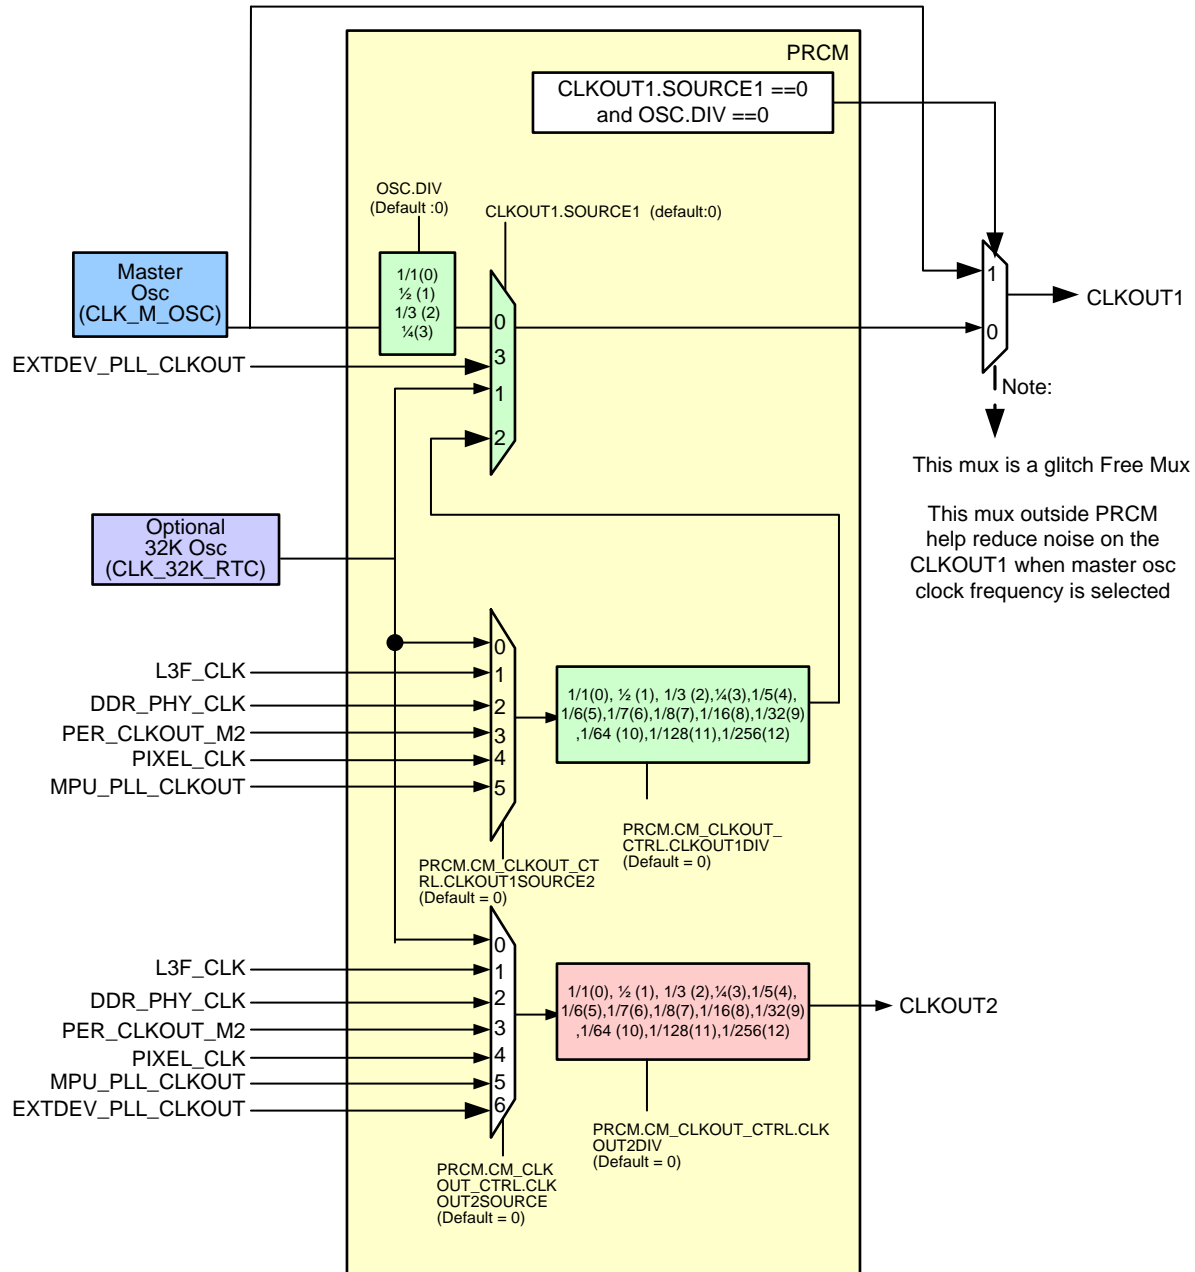

**Table 6-26. Effects of Temperature Drift on Relock**

Temperature Drift (°C)	Low Power Bypass		Fast Relock Bypass	
	Frequency Relock	Phase Relock	Frequency Relock	Phase Relock
$\Delta T \leq 10$	1.9us + 70REFCLKs	1.9us + 120REFCLKs	0.05us + 70REFCLKs	0.05us + 120REFCLKs
$\Delta T > 10$	1.9us + 100REFCLKs	1.9us + 150REFCLKs	0.05us + 100REFCLKs	0.05us + 150REFCLKs

### 6.6.14 CLKOUT Signals

The CLKOUT1 and CLKOUT2 signals go device pads and should mainly be used as debug testpoints.

[Figure 6-17](#) shows the different clock sources coming from the PLL or master oscillator and their routing to CLKOUT1 and CLKOUT2 pads. The CLKOUT1 and CLKOUT2 signals go to device pads and can be used as source clocks for FPGAs or other system devices.

**Figure 6-17. CLKOUT Architecture**

### 6.6.15 32-kHz Clock Structure

The 32-kHz crystal oscillator is used by the RTCSS. The device also contains an on-chip RC oscillator. The RC oscillator is not configurable but may be enabled or disabled through the Control Module RCOSC\_CTRL register. The 32-kHz clocks are summarized in [Table 6-27](#).

**Table 6-27. 32-kHz Clock Summary**

Clock Name	Source	Accuracy
CLK_32KHZ	Divide down of PER PLL output (PLL uses Master Osc).	32768 Hz Precise
CLK_32K_RC	Internal RC Oscillator.	16 to 60 kHz
CLK_32K_RTC	External 32768 Hz crystal with internal 32K Osc or external 32768-Hz clock.	32768 Hz Precise
CLK_32K_MOSC	Divide down of Master Oscillator Crystal Frequency	~ 32768 Hz

#### 6.6.15.1 Watchdog Timer Clocking

The RC oscillator is inaccurate and can vary in frequency from 16 to 60 kHz. The clock options for watchdog1 are shown in [Figure 6-18](#).

**Figure 6-18. Watchdog Timer Clock Selection**

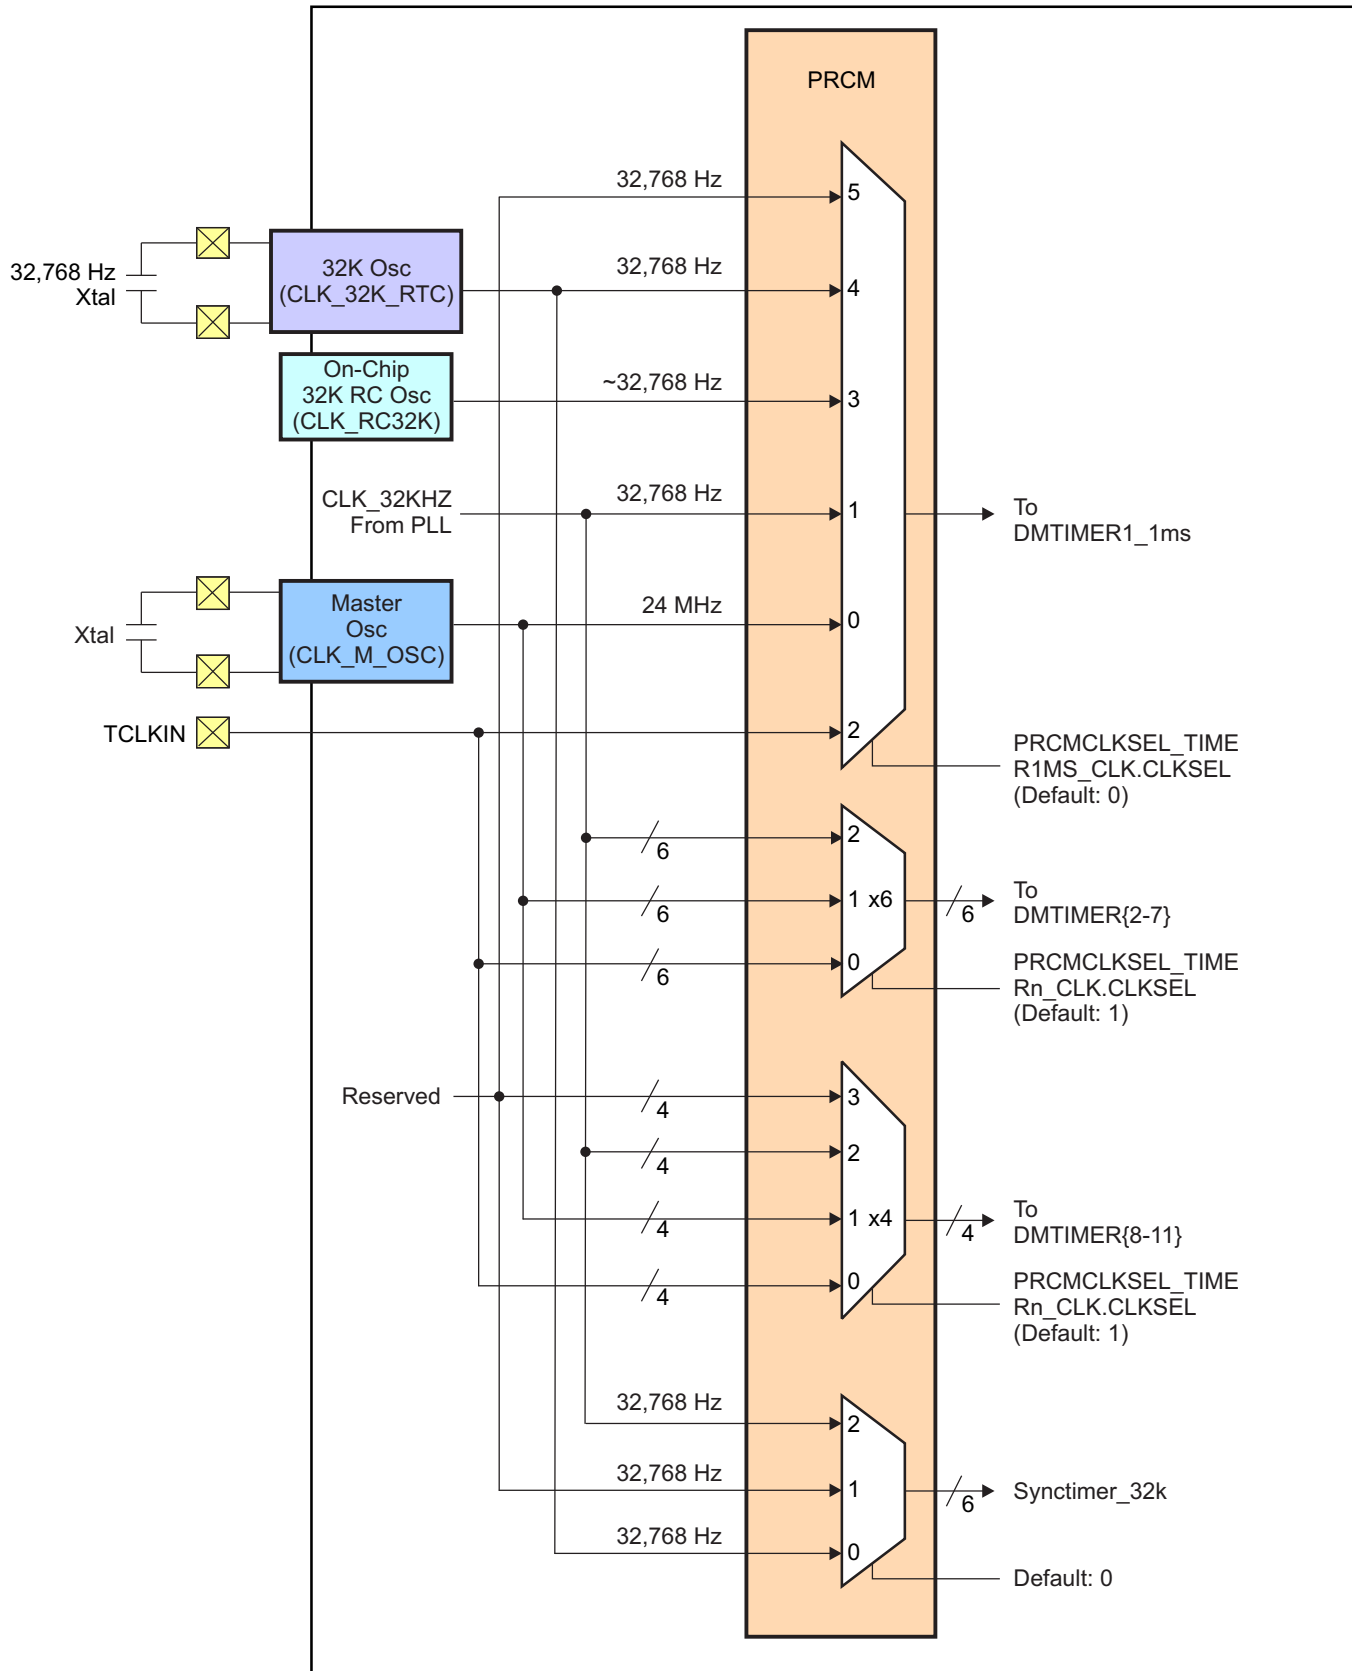

#### 6.6.15.2 Timer Clocking

The clock selections for the other Timer modules are shown in [Figure 6-19](#). CLK\_32KHZ, the master oscillator, and the external pin (TCLKIN) are optional clocks available for all timers, which may be selected based on end use application.

DMTIMER1 is implemented using the dmtimer\_1ms module, which is capable of generating an accurate 1ms tick using a 32.768-kHz clock. During low power modes, the master oscillator is disabled. CLK\_32KHZ is not available in this scenario since it is sourced from the master oscillator-based PER PLL. Hence, in low power modes, DMTIMER1 in the WKUP domain can use the 32K clock sources from the one of the 32-kHz oscillators for timer-based wakeup. The synctimer32K is a free running timer which can be used for time reference by the operating system.

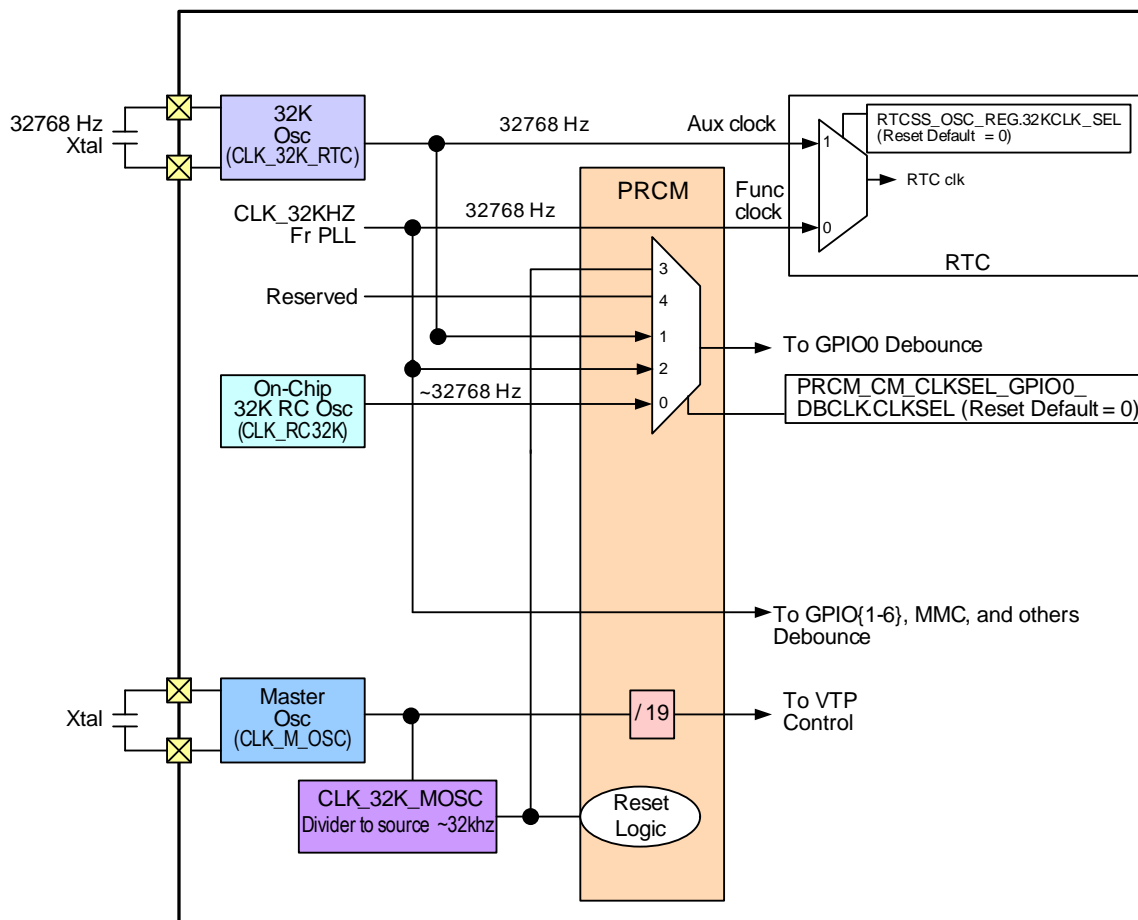

Figure 6-19. Timer Clock Selection

### 6.6.15.3 RTC, VTP, Debounce and Reset Clocking

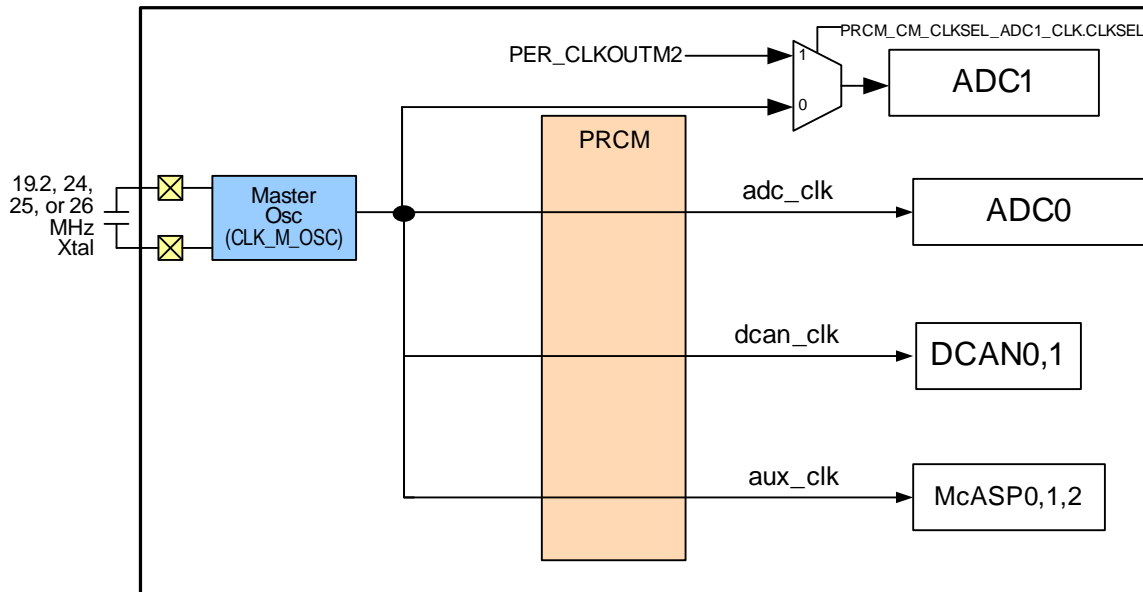

Figure 6-20 shows the clocking for RTC, DDR VTP macro, debounce clocks for GPIO, and the reset logic of PRCM. In low power modes, the debounce for GPIO0 in WKUP domain can use the accurate 32768-Hz crystal oscillator or the inaccurate (16 to 60 kHz) 32K RC oscillator when the master oscillator is powered down.

Figure 6-20. RTC, VTP and Debounce Clock Selection

### 6.6.16 ADC0, ADC1, DCAN, and McASP Clocking

Figure 6-21 shows the functional clock sources for ADC0, ADC1, DCAN, and McASP.

**Figure 6-21. ADC0, ADC1, DCAN, and McASP Clock Selection**

## 6.7 Reset Management

### 6.7.1 Overview

The PRCM manages the resets to all power domains inside the device and generates a single reset output signal through device pin, WARMRSTn, for external use. The PRCM has no knowledge of or control over resets generated locally within a module, e.g., via the OCP configuration register bit: PeripheralName\_SYSCONFIG.SoftReset.

All PRM reset outputs are asynchronously asserted. These outputs are active-low except for the PLL resets. Deassertion is synchronous to the clock which runs a counter used to stall, or delay, reset deassertion upon source deactivation. This clock will be CLK\_M\_OSC used by all the reset managers. All modules receiving a PRCM generated reset are expected to treat the reset as asynchronous and implement local re-synchronization upon de-activation as needed.

One or more Reset Managers are required per power domain. Independent management of multiple reset domains is required to meet the reset sequencing requirements of all modules in the power domain

### 6.7.2 Reset Concepts and Definitions

The PRCM collects many sources of reset. Here below is a list of qualifiers of the source of reset:

- Cold reset: it affects all the logic in a given entity
- Warm reset: it is a partial reset which doesn't affect all the logic in a given entity
- Global reset: it affects the entire device
- Local reset: it affects part of the device (1 power domain for example)
- S/W reset: it is initiated by software
- H/W reset: it is hardware driven

Each reset source is specified as being a cold or warm type. Cold types are synonymous with power-on-reset (POR) types. Such sources are applied globally within each receiving entity (i.e., sub-system, module, macro-cell) upon assertion. Cold reset events include: device power-up, power-domain power-up, and eFuse programming failures.

Warm reset types are not necessarily applied globally within each receiving entity. A module may use a warm reset to reset a subset of its logic. This is often done to speed-up reset recovery time, i.e., the time to transition to a safe operating state, compared to the time required upon receipt of a cold reset. Warm reset events include: software initiated per power-domain, watchdog timeout, externally triggered, and emulation initiated.

Reset sources, warm or cold types, intended for device-wide effect are classified as global sources. Reset sources intended for regional effect are classified as local sources.

Each Reset Manager provides two reset outputs. One is a cold reset generated from the group of global and local cold reset sources it receives. The other is a warm+cold reset generated from the combined groups of, global and local, cold and warm reset sources it receives.

The Reset Manager asserts one, or both, of its reset outputs asynchronously upon reset source assertion. Reset deassertion is extended beyond the time the source gets de-asserted. The reset manager will then extend the active period of the reset outputs beyond the release of the reset source, according to the PRCM's internal constraints and device's constraints. Some reset durations can be software-configured. Most (but not all) reset sources are logged by PRCM's reset status registers. The same reset output can generally be activated by several reset sources and the same reset source can generally activate several reset outputs. All the reset signals output of the PRCM are active low. Several conventions are used in this document for signal and port names. They include:

- "\_RST" in a signal or port name is used to denote reset signal.
- "\_PWRON\_RST" in a signal or port name is used to denote a cold reset source

### 6.7.3 Global Power On Reset (Cold Reset)

There are several cold reset sources. See [Table 6-28](#) for a summary of the different reset sources.

#### 6.7.3.1 Power On Reset (PORz)

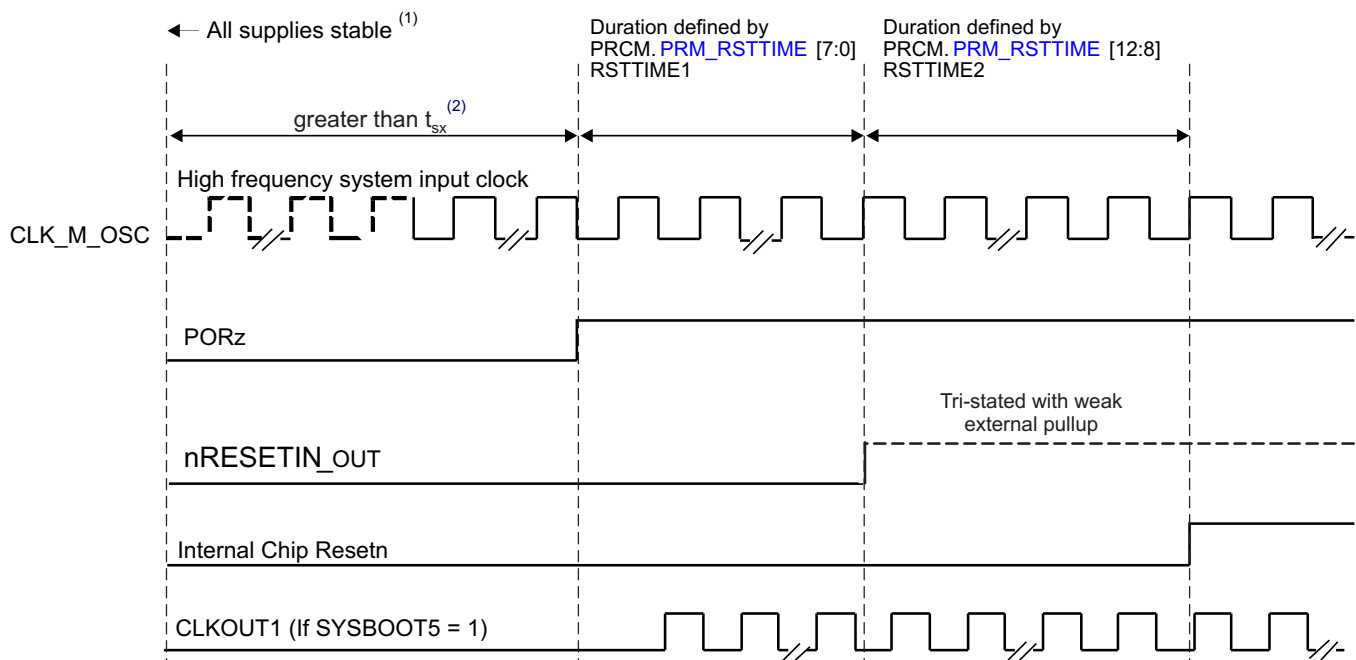

The source of power on reset is PORz signal on the device. Everything on device is reset with assertion of power on reset. This reset is non-blockable. PORz can be driven by external power management devices or power supervisor circuitry. During power-up, when power supplies to the device are ramping up, PORz needs to be driven Low. When the ramp-up is complete and supplies reach their steady-state values, PORz need to be driven High. During normal operation when any of the device power supplies are turned OFF, PORz must be driven Low.

#### 6.7.3.2 PORz Sequence

1. PORz pin at chip boundary gets asserted (goes low). Note: The state of nRESETIN\_OUT during PORz assertion should be a don't care, it should not affect PORz (only implication is if they are both asserted and nRESETIN\_OUT is deasserted after PORz you will get re-latching of boot config pins and may see warm nRESETIN\_OUT flag set in PRCM versus POR).
2. The processor drives Warm Reset Out (nRESETIN\_OUT pin) to Low. All other IOs are tristated with pull values, as defined in the device datasheet.
3. When power comes up, PORz value will propagate to the PRCM.
4. PRCM will fan out reset to the complete chip and all logic which uses async reset will get reset. nRESETIN\_OUT will go low to indicate reset-in-progress.
5. External clocks will start toggling and the PRCM will propagate these clocks to the chip while keeping PLLs in bypass mode.
6. All logic using sync reset will be reset.
7. When all power and clocks to the chip are stable, PORz must be de-asserted (this is handled externally by the PMIC or Supervisor Circuitry).
8. Boot configuration pins are latched when PORz is de-asserted (on rising edge of PORz). <sup>(1)</sup>
9. IO cell controls from peripherals for all the IOs with a few exceptions (see datasheet for details) are driven by the GPIO peripheral. GPIO puts all IOs in input mode with a few exceptions (see datasheet).

<sup>(1)</sup> In order to simplify end system design, it is desired that SysBoot configuration inputs have no hold time requirement relative the the PORz riding edge. In order to achieve this 0 ns hold time, the inputs need to be sampled continuously during the PORz active period and the final sampled value prior to the (last) rising edge latched in the register.

10. PRCM internal state machines will be released after RSTTIME1 (based on 32K MOSC divided clock).
11. FuseFarms reset will be de-asserted to start eFuse scanning.
12. nRESETIN\_OUT is de-asserted after PRCM.RSTTIME1 time is met.
13. As soon as nRESETIN\_OUT is de-asserted (system warm reset out):
  - (a) The RSTTIME2 count starts for other domain resets.
  - (b) The RSTTIME2 count starts for MPU pwron reset release. After the counter expires, MPU pwron reset is released. This is followed by Reset done from the MPU and then the MPU\_RST is de-asserted.
14. Internal Resets to all peripherals without local reset will be de-asserted.
15. Once the device finishes booting, all remaining peripherals will see reset de-assertion.

**Figure 6-22. PORz**

- (1) nRESETIN\_OUT is not defined (can either be driven low or pulled up high) until all supplies are fully ramped up. For nRESETIN\_OUT to maintain a valid low state until the supplies are ramped, an external buffer should be implemented, as shown in [Figure 6-23](#).
- (2) For information on  $t_{sx}$ , see *AM437x ARM Cortex-A9 Processors* (literature number [SPRS851](#))

**Figure 6-23. External Buffer for nRESETIN\_OUT**

### 6.7.3.3 Bad Device Reset (BAD\_DEVICE\_RST)

This reset is asserted whenever the DEVICE\_TYPE encodes an unsupported device type, such as the code for a "bad" device.

### 6.7.3.4 Global Cold Software Reset (GLOBAL\_COLD\_SW\_RST)

The source for GLOBAL\_COLD\_SW\_RST is generated internally by the PRM. It is activated upon setting the PRM\_RSTCTRL.RST\_GLOBAL\_COLD\_SW bit in the PRM memory map. This bit is self-clearing, i.e., it is automatically cleared by the hardware.

## 6.7.4 Global Warm Reset

All warm reset events must be logged in a register (PRCM.PRM\_RSTST), which is isolated from warm reset. After reboot, software can identify the source of the reset and clear the bit.

### 6.7.4.1 External Warm Reset

nRESETIN\_OUT is a bidirectional warm reset signal. As an input, it is typically used by an external source as a device reset. Refer to Table 8-24 for a summary of the differences between a warm reset and cold reset. Some of these differences are:

- The warm reset can be blocked to the EMAC switch and its reference clock source PLL using the RESET\_ISO register in the Control Module.
- The warm reset assumes that clocks and power to the chip are stable from assertion through deassertion, whereas during the cold reset, the power supplies can become stable during assertion
- Some PRCM and Control module registers are warm reset insensitive and maintain their value throughout a warm reset
- SYSBOOT pins are not latched with a warm reset. The device will boot with the SYSBOOT values from the previous cold reset.
- Most debug subsystem logic is not affected by warm reset. This allows you to maintain any debug sessions throughout a warm reset event.
- PLLs are not affected by warm reset

As an output, nRESETIN\_OUT can be used to reset external devices. nRESET\_OUT will drive low during a cold reset or an internally generated warm reset. After completion of a cold or warm reset, nRESETIN\_OUT will continue to drive low for a period defined by PRM\_RSTTIME.RSTTIME1. RSTTIME1 is a timer that counts down to zero at a rate equal to the high frequency system input clock CLK\_M\_OSC. This allows external devices to be held in reset for some time after the device comes out of reset.

Caution must be used when implementing the nRESETIN\_OUT as an bi-directional reset signal. Because of the short maximum time allowed using RSTTIME1, it does not supply an adequate debounce time for an external push button circuit. The processor could potentially start running while external components are still in reset. It is recommended that this signal be used as input only (do not connect to other devices as a reset) to implement a push button reset circuit to the device, or an output only to be able to reset other devices after an device reset completes.

#### 6.7.4.1.1 Warm Reset Input/Reset Output (nRESETIN\_OUT)

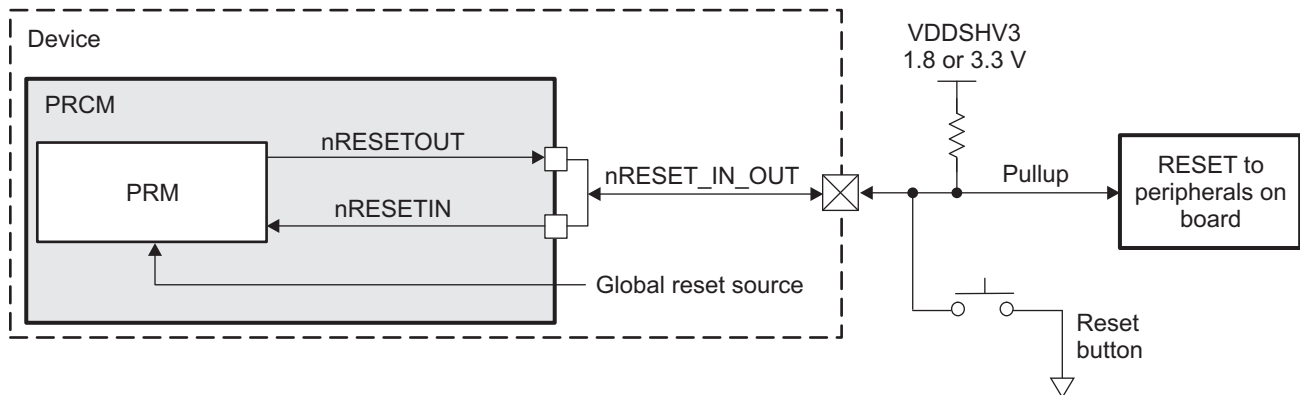

Any global reset source (internal or external) causes nRESETIN\_OUT to be driven and maintained at the boundary of the device for at least the amount of time configured in the PRCM.PRM\_RSTTIME.RSTTIME1 bit field. This ensures that the device and its related peripherals are reset together.

The RSTTIME1 counter must use a slower clock (such as 32-kHz clock) and the default count value is set to a 6-clock period. Software can later change the default value to a desirable setting based on the system requirements. This new value will be effective for subsequent global warm resets. However, if there is a global cold reset, the RSTTIME1 default count value will be reset to a 6-clock period.

The nRESETIN\_OUT output buffer is configured as an open-drain; consequently, an external pull-up resistor is required.

After the de-assertion, the bi-directional pin nRESETIN\_OUT is tri-stated to allow for assertion from off chip source (externally).

**Figure 6-24. External System Reset**

Note: It is recommended to implement warm reset as an input only (for example, push button) or an output only (to reset external peripherals), not both.

The device will have one pin nRESETIN\_OUT which reflects chip reset status. This output will always assert asynchronously when any chip watchdog timer reset occurs if any of the following reset events occurs:

- POR (only internal stretched portion of reset event after bootstrap is latched)
- External Warm reset (nRESETIN\_OUT pin, only internal stretched portion of reset event after bootstrap is latched)
- Emulation reset (Cold or warm from ICEPICK)
- Reset requestor
- SW cold/warm reset

This output will remain asserted as long as PRCM keeps reset to the host processor asserted.

**Note:** TRST does not cause RSTOUTn assertion

#### 6.7.4.1.2 Warm Reset Sequence

1. nRESETIN\_OUT pin at chip boundary gets asserted (goes low). NOTE: For Warm Reset sequence to work as described, it is expected that PORz pin is always inactive, otherwise you will get PORz functionality as described in previous section.
2. All IOs (except test and emulation) will go to tri-state immediately.
3. Chip clocks are not affected as both PLL and dividers are intact.
4. After the programmable timer expires, nRESETIN\_OUT is de-asserted and tri-stated. At this point, if nRESETIN\_OUT is still active (driven LOW) by an external source, then the devices continues to be in warm reset until nRESETIN\_OUT is de-asserted (Pulled HIGH) externally.
5. After external warm-reset source is de-asserted, all internal reset to the chip will be released after PRCM.RSTTIME2 time is met.
6. Note that all peripherals with local CPUs will have local reset asserted by default at Warm Reset and reset de-assertion would require host processor to write to respective registers in PRCM.

Figure 6-25 shows the nRESETIN\_OUT waveform when using nRESETIN\_OUT as warm reset source. For the duration when external warm reset switch is closed, both the device and chip will be driving zero.

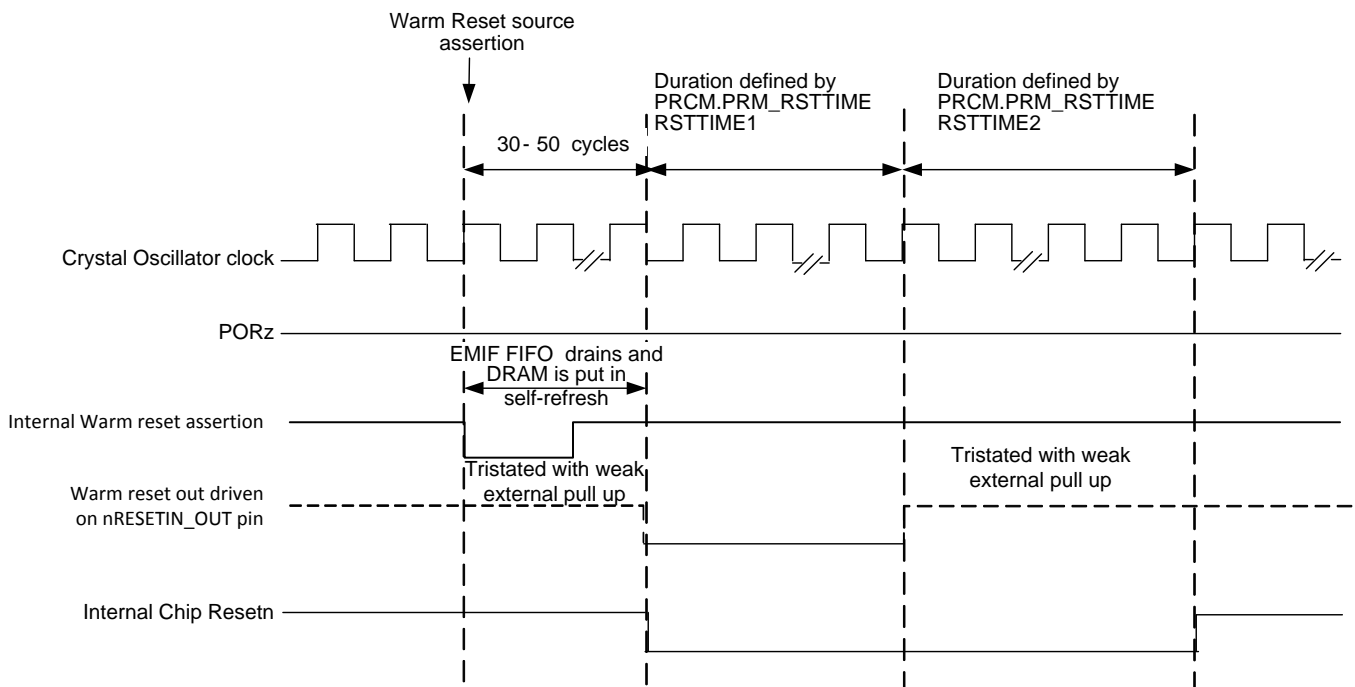

**Figure 6-25. Warm Reset Sequence (External Warm Reset Source)**

Figure 6-26 shows the nRESETIN\_OUT waveform when any one of the warm reset sources captured except using nRESETIN\_OUT itself as warm reset source.

Note: PRCM.PRM\_RSTTIME1 and PRCM.PRM\_RSTTIME2 use a 32-kHz clock derived from the master crystal oscillator clock.

**Figure 6-26. Warm Reset Sequence (Internal Warm Reset Source)**

For applications not needing a warm reset input function, the warm reset input can be disabled by a software programmable MMR bit. During device boot-up, software can program this MMR bit to mask/disable Warm reset input function.

#### 6.7.4.2 Watchdog Timer (WDT\_RST)

WDT\_RST is generated from internal watchdog timer modules. Activation is triggered by a timeout event. The reset is not blockable.

#### 6.7.4.3 Global Warm Software Reset (GLOBAL\_SW\_WARM\_RST)

GLOBAL\_WARM\_SW\_RST is internally generated by the PRCM. Activation is triggered upon setting memory-mapped register bit, PRM\_RSTCTRL. RST\_GLOBAL\_WARM\_SW. This bit is self-clearing, which means it is automatically cleared by the hardware.

#### 6.7.4.4 Test Reset (TRSTz)

This reset is triggered from TRSTz pin on JTAG interface. This is a non-blockable reset and it resets test and emulation logic.

**NOTE:** A PORz reset assertion should cause entire device to reset including all test and emulation logic regardless of the state of TRSTz. Therefore, PORz assertion will achieve full reset of the device even if TRSTz pin is pulled permanently high and no special toggling of TRSTz pin is required during power ramp to achieve full POR reset to the device. Further, it is acceptable for TRSTz input to be pulled permanently low during normal functional usage of the device in the end-system to ensure that all test and emulation logic is kept in reset.

#### 6.7.5 Reset Characteristics

The following table shows characteristic of each reset source.

**Table 6-28. Reset Sources**

Characteristic	Cold Reset Sources			Warm Reset sources			
	Pin PORz	SW Cold Reset	Bad Device	Pin Warm Reset	Watchdog Timer	SW Warm Reset	TRSTz
Boot pins latched	Y	N	N	N	N	N	N
Resets Standard Efuses	Y	N	N	N	N	N	N
Resets Customer Efuses	Y	Y	Y	Y	Y	Y	N
DRAM contents preserved	N	N	N	N <sup>(1)</sup>	N <sup>(1)</sup>	N <sup>(1)</sup>	Y
Resets PLLs	Y	Y	Y	N	N	N	N
Resets Clock Dividers	Y	Y	Y	N	N	N	N
PLLs enter bypass mode <sup>(2)</sup>	Y	Y	Y	Y	Y	Y	N
Reset source blockable by emulation	N	N	N	Y	Y	Y	N
Resets test and emulation logic	Y	Y	Y	N	Y	N	Y
Resets Chip Functional Logic	Y	Y	Y	Y	Y	Y	N
Puts IOs in Tri-state	Y	Y	Y	Y	Y	Y	N
Resets Pinmux Registers	Y	Y	Y <sup>(3)</sup>	Y <sup>(3)</sup>	Y	Y <sup>(3)</sup>	N
Reset out Assertion (nRESETIN_OUT Pin)	Y	Y	Y <sup>(3)</sup>	Y <sup>(3)</sup>	Y	Y <sup>(3)</sup>	N

<sup>(1)</sup> DRAM contents are not guaranteed to be preserved across all Warm resets. The ROM software does not utilize this feature of DRAM content preservation, hence, the processor reboots like a cold boot for warm resets.

<sup>(2)</sup> CORE PLL is an exception when EMAC switch reset isolation is enabled

<sup>(3)</sup> Some special IOs/Muxing registers like test, emulation, GEMAC Switch (when under reset isolation mode), and more related will not be affected under warm reset conditions.

### 6.7.6 EMAC Switch Reset Isolation

The device will support reset isolation for the Ethernet Switch peripheral. This allows the device to undergo a warm reset without disrupting the switch or traffic being routed through the switch during the reset condition.

If configured by registers in the control module (CPSW Reset Isolation Register: RESET\_ISO[0]) that EMAC reset isolation is active, then behavior is as follows:

Any warm reset source (except the software warm reset) will be blocked to the EMAC switch logic in the peripheral (the peripheral has ISO\_MAIN\_ARST\_N input to support such isolation) and to PLL (and its control bits) which is sourcing the EMAC switch clocks as required by the peripheral (50- or 125 MHz reference clocks). Also, the EMAC switch related IO pins must retain their pin muxing and not glitch (continuously controlled by the EMAC switch peripheral) by blocking reset to the controlling MMR bits.

If configured by registers in the control module that EMAC reset isolation is NOT active (default state), then the warm reset sources are allowed to propagate as normal including to the EMAC Switch peripheral (both reset inputs to the peripheral).

All cold or POR resets will always propagate to the EMAC switch peripheral as normal (as otherwise defined in this document).

### 6.7.7 Reset Priority

If more than one of these reset sources are asserted simultaneously then the following priority order should be used:

1. POR
2. TRSTz
3. External warm reset
4. Emulation
5. Reset requestors
6. Software resets

### 6.7.8 Trace Functionality Across Reset

Other than the Cold Reset Sources shown and TRSTz, no other resets (such as global warm resets and local resets) affect trace functionality. The debug subsystem must implement required reset isolation for the trace logic. The I/Os and muxing control (if any) for trace I/Os should not get affected by any other reset (all DebugSS EMU pins). Since PLLs are reset only on Global Cold Resets and are isolated with other resets (such as global warm resets and local resets), clocks are ensured to be stable.

### 6.7.9 RTC PORz

This processor supports RTC-only mode by supplying dedicated power to the RTC module. The RTC module has a dedicated PORz signal (RTC\_PORz) to reset RTC logic and circuitry during powerup. RTC\_PORz is expected to be driven low when the RTC power supply is ramping up. After the power supply reaches its stable value, the RTC\_PORz can be de-asserted. The RTC module is not affected by the device PORz. Similarly RTC\_PORz does not affect the device reset.

If RTC-only mode is not required, then PORz and RTC\_PORz need to be shorted. For power-up sequencing with respect to RTC\_PORz, see the device datasheet.

## 6.8 Power-Up/Down Sequence

Each power domain has a dedicated warm and cold reset. Warm reset gets asserted each time there is any warm reset source requesting a reset. Warm reset is also asserted when the power domain moves from ON to OFF state. Cold reset for the power domain is asserted in response to cold reset sources. When the domain moves from ON to OFF state, then a cold reset also gets asserted as this is similar to a power-up condition for that domain.

## 6.9 IO State

All IOs except for JTAG i/f and Reset output (and any special cases mentioned in pinlist) should have their output drivers tri-state and internal pulls enabled during assertion of all reset sources. JTAG i/f IO is affected only by TRSTz.

**Note:** The PRU-ICSS and wakeup processor are held under reset after global warm reset by assertion of software source of reset. Other domains are held under reset after global warm reset until the MPU software enables their respective interface clock.

## 6.10 Voltage and Power Domains

The following table shows how the device core logic is partitioned into two core logic voltage domains and four power domains. The table lists which voltage and power domain a functional module belongs.

**Table 6-29. Core Logic Voltage and Power Domains**

Logic Voltage Domain Name	Module
CORE	All Core Modules
RTC	RTC

### 6.10.1 Voltage Domains

The core logic is divided into two voltage domains: VDD\_CORE and VDD\_RTC.

### 6.10.2 Power Domains

In order to reduce power due to leakage, the core logic supply voltage to the power domains can be turned OFF with internal power switches. The internal power switches are controlled through memory mapped registers in the control module.

If all the modules within a power domain are not used, that power domain can be placed in the OFF state.

The following table shows the allowable combination power domain ON/OFF states and which power domains are switched via internal power switches. At power-on-reset, all domains except always-on will be in the power domain OFF state.

**Table 6-30. Power Domain State Table**

MODE	POWER DOMAIN					
	WAKEUP	MPU	GFX	PER	RTC	EFUSE
No Voltage Supply	N/A	N/A	N/A	N/A	N/A	N/A
Power On Reset	ON	OFF	OFF	OFF	OFF	OFF
ALL OTHER FUNCTIONAL MODES	ON	DON'T CARE	DON'T CARE	DON'T CARE	DON'T CARE	DON'T CARE
Internal Power Switch	NO	YES	YES	YES	YES	YES

## 6.11 Device Modules and Power Management Attributes List

		VDD for IO for the alarm pin

### 6.11.1 Power Domain Power Down Sequence

The following sequence of steps happen during the power down of a power domain

All peripherals (belonging to a power domain) with STANDBY interface will assert STANDBY. STANDBY assertion should get triggered by a peripheral based on its activity on OCP initiator port. The peripheral should assert STANDBY whenever initiator port is IDLE. Some of the peripherals may not have this feature and they will require SW write to standby-mode register to get STANDBY assertion from the peripheral.

1. SW will request all modules in given power domain to go to disable state by programming module control register inside PRCM.
2. PRCM will start and wait for completion of power management handshake with peripherals (IdleReq/IdleAck).
3. PRCM will gate-off all the clocks to the power domain.
4. SW will request all clock domains in given power domain to go to “force sleep” mode by programming functional clock domain register in PRCM. Note that PRCM has already gated-off clocks and this register programming may look redundant.
5. SW will request PRCM to take this power domain to OFF state by programming PWRSTCTRL register. Note that this step can be skipped if PWRSTCTRL is permanently programmed to OFF state. When this is done, functional clock domain register decides when power domain will be taken to OFF state. Only reason not to have OFF state in PWRSTCTRL is to take power domain to just clock gate state without power gating.
6. PSCON specific to this power domain will assert isolation enable for the domain.
7. PRCM will assert warm and cold reset to the power domain.
8. PSCON will assert control signals to switch-off power using on-die switches.
9. On-die switches will send acknowledge back to PSCON.

### 6.11.2 Power Domain Power-Up Sequence

The following sequence of steps occurs during power-up of a power domain. This sequence is not relevant to always-on domain as this domain will never go to OFF state as long as the device is powered. This sequence will be repeated each time a domain is taken to ON state from OFF (including first time power-up). Note that some of the details are intentionally taken out here to simplify things.

There can be multiple reasons to start power-up sequence for a domain. For example it can be due to an interrupt from one of the peripherals which is powered-up.

1. SW will request required clock domains inside this power domain to go to force wake-up state by programming functional clock domain register.
2. PRCM will enable clocks to the required clock domains.
3. PSCON specific to this power domain will assert control signal to un-gate the power.
4. Once power is un-gated, on die switches will send acknowledge back to PSCON.
5. PRCM will de-assert cold and warm reset to the power domain.
6. PRCM will turn-off isolation cells.
7. SW will request PRCM to enable required module in the power domain by programming module control register.
8. PRCM will initiate and wait for completion of PM protocol to enable the modules (IdleReq/IdleAck).

## 6.12 Power Management Registers

### 6.12.1 PRCM\_PRM\_CEFUSE Registers

[Table 6-32](#) lists the memory-mapped registers for the PRCM\_PRM\_CEFUSE. All register offset addresses not listed in [Table 6-32](#) should be considered as reserved locations and the register contents should not be modified.

**Table 6-32. PRCM\_PRM\_CEFUSE REGISTERS**

Offset	Acronym	Register Name	Section
0h	PRCM_PM_CEFUSE_PWRSTCTRL		<a href="#">Section 6.12.1.1</a>
4h	PRCM_PM_CEFUSE_PWRSTST		<a href="#">Section 6.12.1.2</a>
24h	PRCM_RM_CEFUSE_CONTEXT		<a href="#">Section 6.12.1.3</a>

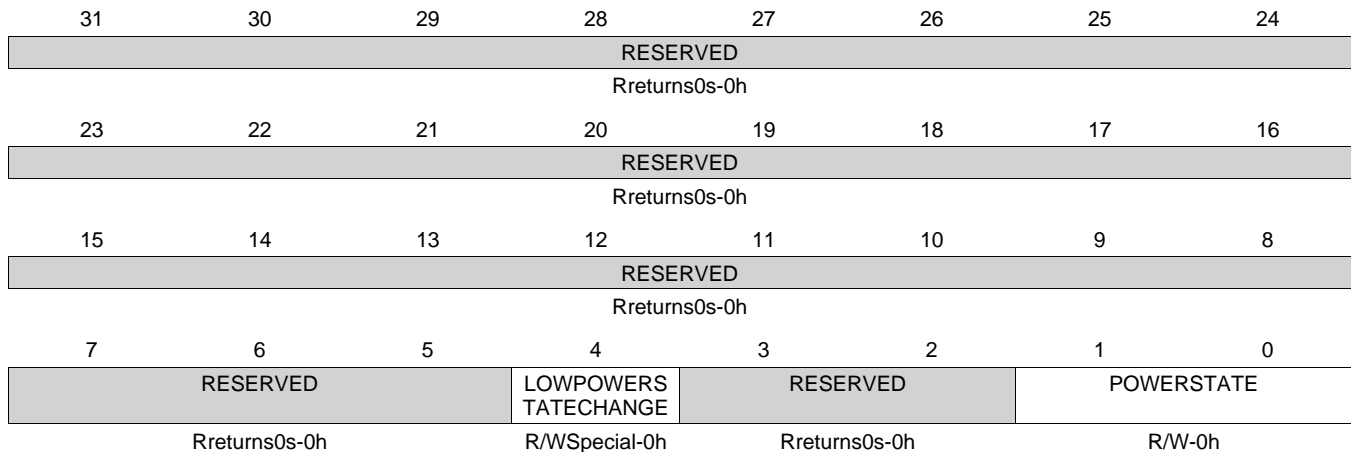

### 6.12.1.1 PRCM\_PM\_CEFUSE\_PWRSTCTRL Register (offset = 0h) [reset = 0h]

Register mask: FFFFFFFFh

PRCM\_PM\_CEFUSE\_PWRSTCTRL is shown in [Figure 6-27](#) and described in [Table 6-33](#).

This register controls the CEFUSE power state to reach upon a domain sleep transition

**Figure 6-27. PRCM\_PM\_CEFUSE\_PWRSTCTRL Register**

**Table 6-33. PRCM\_PM\_CEFUSE\_PWRSTCTRL Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-5	RESERVED	Rreturns0s	0h	
4	LOWPOWERSTATECHANGE	R/WSpecial	0h	Power state change request when domain has already performed a sleep transition. Allows going into deeper low power state without waking up the power domain. 0h (R/W) = Do not request a low power state change. 1h (R/W) = Request a low power state change. This bit is automatically cleared when the power state is effectively changed or when power state is ON.
3-2	RESERVED	Rreturns0s	0h	
1-0	POWERSTATE	R/W	0h	Power state control 0h (R/W) = OFF state 1h (R/W) = RESERVED 2h (R/W) = RESERVED 3h (R/W) = ON State

### 6.12.1.2 PRCM\_PM\_CEFUSE\_PWRSTST Register (offset = 4h) [reset = 7h]

Register mask: FFFFFFFFh

PRCM\_PM\_CEFUSE\_PWRSTST is shown in [Figure 6-28](#) and described in [Table 6-34](#).

This register provides a status on the current CEFUSE power domain state. [warm reset insensitive]

**Figure 6-28. PRCM\_PM\_CEFUSE\_PWRSTST Register**

**Table 6-34. PRCM\_PM\_CEFUSE\_PWRSTST Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-26	RESERVED	Rreturns0s	0h	
25-24	LASTPOWERSTATEENTERED	R/W1toSet	0h	Last low power state entered. Set to 0x3 upon write of the same only. This register is intended for debug purpose only. 0h (R) = Power domain was previously OFF 1h (R) = Power domain was previously ON-ACTIVE
23-21	RESERVED	Rreturns0s	0h	
20	INTRANSITION	R	0h	Domain transition status 0h (R) = No on-going transition on power domain 1h (R) = Power domain transition is in progress.
19-3	RESERVED	Rreturns0s	0h	
2	LOGICSTATEST	R	1h	Logic state status 0h (R) = Logic in domain is OFF 1h (R) = Logic in domain is ON
1-0	POWERSTATEST	R	3h	Current power state status 0h (R) = Power domain is OFF 3h (R) = Power domain is ON-ACTIVE

### 6.12.1.3 PRCM\_RM\_CEFUSE\_CONTEXT Register (offset = 24h) [reset = 1h]

Register mask: FFFFFFFFh

PRCM\_RM\_CEFUSE\_CONTEXT is shown in [Figure 6-29](#) and described in [Table 6-35](#).

This register contains dedicated CEFUSE module context statuses. [warm reset insensitive]

**Figure 6-29. PRCM\_RM\_CEFUSE\_CONTEXT Register**

### 6.12.2.1 PRCM\_PRM\_RSTCTRL Register (offset = 0h) [reset = 0h]

Register mask: FFFFFFFFh

PRCM\_PRM\_RSTCTRL is shown in [Figure 6-30](#) and described in [Table 6-37](#).

Global software cold and warm reset control. This register is auto-cleared. Only write 1 is possible. A read returns 0 only.

**Figure 6-30. PRCM\_PRM\_RSTCTRL Register**

**Table 6-37. PRCM\_PRM\_RSTCTRL Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-2	RESERVED	Rreturns0s	0h	
1	RST_GLOBAL_COLD_SW	Rreturns0s/W	0h	Global COLD software reset control. This bit is reset only upon a global cold source of reset. 0h (R/W) = 0X0 : Global COLD software reset is cleared. 1h (R/W) = 0X1 : Asserts a global COLD software reset. The software must ensure the SDRAM is properly put in self-refresh mode before applying this reset.
0	RST_GLOBAL_WARM_SW	Rreturns0s/W	0h	Global WARM software reset control. This bit is reset upon any global source of reset (warm and cold). 0h (R/W) = 0X0 : Global warm software reset is cleared. 1h (R/W) = 0X1 : Asserts a global warm software reset.

### 6.12.2.2 PRCM\_PRM\_RSTST Register (offset = 4h) [reset = 1h]

Register mask: FFFFFFFFh

PRCM\_PRM\_RSTST is shown in [Figure 6-31](#) and described in [Table 6-38](#).

This register logs the global reset sources. Each bit is set upon release of the domain reset signal. Must be cleared by software. [warm reset insensitive]

31-10	RESERVED	Rreturns0s	0h	
9	ICEPICK_RST	R/W1toClr	0h	IcePick reset event. This is a source of global warm reset initiated by the emulation. [warm reset insensitive] 0h (R/W) = 0X0 : No ICEPICK reset. 1h (R/W) = 0X1 : IcePick reset has occurred.
8-6	RESERVED	Rreturns0s	0h	
5	EXTERNAL_WARM_RST	R/W1toClr	0h	External warm reset event [warm reset insensitive] 0h (R/W) = 0X0 : No global warm reset. 1h (R/W) = 0X1 : Global external warm reset has occurred.
4	WDT1_RST	R/W1toClr	0h	Watchdog1 timer reset event. This is a source of global WARM reset. [warm reset insensitive] 0h (R/W) = 0X0 : No watchdog reset. 1h (R/W) = 0X1 : watchdog reset has occurred.
3-2	RESERVED	R/W	0h	
1	GLOBAL_WARM_SW_RST	R/W1toClr	0h	Global warm software reset event [warm reset insensitive] 0h (R/W) = 0X0 : No global warm SW reset 1h (R/W) = 0X1 : Global warm SW reset has occurred.
0	GLOBAL_COLD_RST	R/W1toClr	1h	Power-on (cold) reset event [warm reset insensitive] 0h (R/W) = 0X0 : No power-on reset. 1h (R/W) = 0X1 : Power-on reset has occurred.

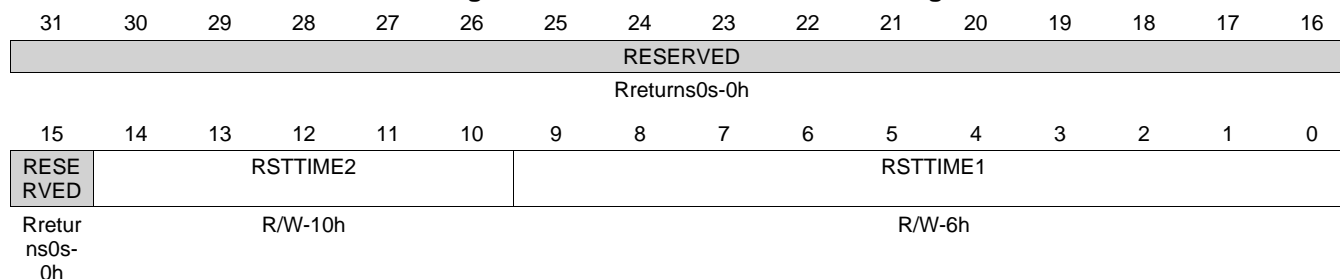

### 6.12.2.3 PRCM\_PRM\_RSTTIME Register (offset = 8h) [reset = 4006h]

Register mask: FFFFFFFFh

PRCM\_PRM\_RSTTIME is shown in [Figure 6-32](#) and described in [Table 6-39](#).

Reset duration control. [warm reset insensitive]

**Figure 6-32. PRCM\_PRM\_RSTTIME Register**

**Table 6-39. PRCM\_PRM\_RSTTIME Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-15	RESERVED	Rreturns0s	0h	
14-10	RSTTIME2	R/W	10h	(Power domain) reset duration 2 (number of RM.SYSCLK clock cycles)
9-0	RSTTIME1	R/W	6h	(Global) reset duration 1 (number of SYS_CLK clock cycles)

#### 6.12.2.4 PRCM\_PRM\_SRAM\_COUNT Register (offset = Ch) [reset = 78000017h]

Register mask: FFFFFFFFh

PRCM\_PRM\_SRAM\_COUNT is shown in [Figure 6-33](#) and described in [Table 6-40](#).

Common setup for SRAM LDO transition counters. Applies to all voltage domains. [warm reset insensitive]

**Figure 6-33. PRCM\_PRM\_SRAM\_COUNT Register**

Bit	Field	Type	Reset	Description
31-24	STARTUP_COUNT	R/W	78h	Determines the start-up duration of SRAM and ABB LDO. The duration is computed as 16 x NbCycles of system clock cycles. Target is 50us.
23-16	SLPCNT_VALUE	R/W	0h	Delay between retention/off assertion of last SRAM bank and SRAMALLRET signal to LDO is driven high. Counting on system clock. Target is 2us.
15-8	VSETUPCNT_VALUE	R/W	0h	SRAM LDO rampup time from retention to active mode. The duration is computed as 8 x NbCycles of system clock cycles. Target is 30us.
7-6	RESERVED	Rreturns0s	0h	
5-0	PCHARGE CNT_VALUE	R/W	17h	Delay between de-assertion of standby_rta_ret_on and standby_rta_ret_good. Counting on system clock. Target is 600ns.

### 6.12.2.5 PRCM\_PRM\_LDO\_SRAM\_CORE\_SETUP Register (offset = 10h) [reset = 1h]

Register mask: FFFFFFFFh

PRCM\_PRM\_LDO\_SRAM\_CORE\_SETUP is shown in [Figure 6-34](#) and described in [Table 6-41](#).

Setup of the SRAM LDO for CORE voltage domain. [warm reset insensitive]

**Figure 6-34. PRCM\_PRM\_LDO\_SRAM\_CORE\_SETUP Register**

Bit	Field	Type	Reset	Description
31-9	RESERVED	Rreturns0s	0h	
8	AIPOFF	R/W	0h	Override on AIPOFF input of SRAM LDO. 0h (R/W) = AIPOFF signal is not overridden 1h (R/W) = AIPOFF signal is overridden to '1'. Corresponding SRAM LDO is disabled and in HZ mode.
7	ENFUNC5	R/W	0h	ENFUNC5 input of SRAM LDO. 0h (R/W) = Active to retention is a one step transfer 1h (R/W) = Active to retention is a two steps transfer
6	ENFUNC4	R/W	0h	ENFUNC4 input of SRAM LDO. 0h (R/W) = One external clock is supplied 1h (R/W) = No external clock is supplied
5	ENFUNC3_EXPORT	R/WSpecial	0h	ENFUNC3 input of SRAM LDO. After PowerOn reset and Efuse sensing, this bitfield is automatically loaded with an Efuse value from control module. Bitfield remains writable after this. 0h (R/W) = Sub regulation is disabled 1h (R/W) = Sub regulation is enabled
4	ENFUNC2_EXPORT	R/WSpecial	0h	ENFUNC2 input of SRAM LDO. After PowerOn reset and Efuse sensing, this bitfield is automatically loaded with an Efuse value from control module. Bitfield remains writable after this. 0h (R/W) = External cap is used 1h (R/W) = External cap is not used
3	ENFUNC1_EXPORT	R/WSpecial	0h	ENFUNC1 input of SRAM LDO. After PowerOn reset and Efuse sensing, this bitfield is automatically loaded with an Efuse value from control module. Bitfield remains writable after this. 0h (R/W) = Short circuit protection is disabled 1h (R/W) = Short circuit protection is enabled

**Table 6-41. PRCM\_PRM\_LDO\_SRAM\_CORE\_SETUP Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
2	ABBOFF_SLEEP_EXPOR T	R/WSpecial	0h	Determines whether SRAMNWA is supplied by VDDS or VDDAR during deep-sleep. After PowerOn reset and Efuse sensing, this bitfield is automatically loaded with an Efuse value from control module. Bitfield remains writable after this. 0h (R/W) = SRAMNWA supplied with VDDS 1h (R/W) = SRAMNWA supplied with VDDAR
1	ABBOFF_ACT_EXPORT	R/WSpecial	0h	Determines whether SRAMNWA is supplied by VDDS or VDDAR during active mode. After PowerOn reset and Efuse sensing, this bitfield is automatically loaded with an Efuse value from control module. Bitfield remains writable after this. 0h (R/W) = SRAMNWA supplied with VDDS 1h (R/W) = SRAMNWA supplied with VDDAR
0	DISABLE_RTA_EXPORT	R/WSpecial	1h	Control for HD memory RTA feature. After PowerOn reset and Efuse sensing, this bitfield is automatically loaded with an Efuse value from control module. Bitfield remains writable after this. Note : This feature is not used. 0h (R/W) = HD memory RTA feature is enabled 1h (R/W) = HD memory RTA feature is disabled

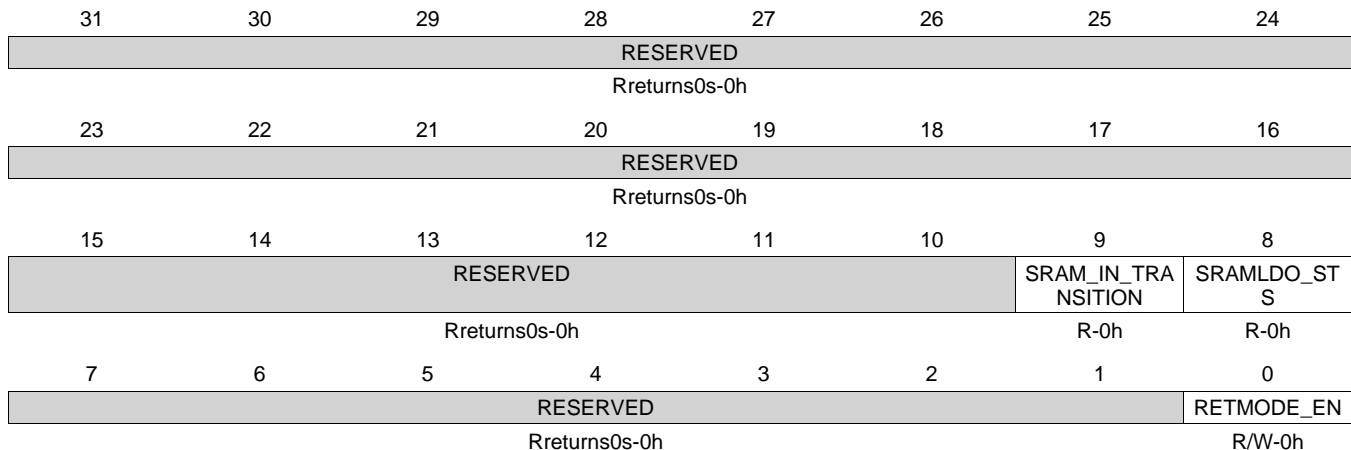

### 6.12.2.6 PRCM\_PRM\_LDO\_SRAM\_CORE\_CTRL Register (offset = 14h) [reset = 0h]

Register mask: FFFFFFFFh

PRCM\_PRM\_LDO\_SRAM\_CORE\_CTRL is shown in [Figure 6-35](#) and described in [Table 6-42](#).

Control and status of the SRAM LDO for CORE voltage domain. [warm reset insensitive]

**Figure 6-35. PRCM\_PRM\_LDO\_SRAM\_CORE\_CTRL Register**

31-9	RESERVED	Rreturns0s	0h	
8	AIPOFF	R/W	0h	Override on AIPOFF input of SRAM LDO. 0h (R/W) = AIPOFF signal is not overridden 1h (R/W) = AIPOFF signal is overridden to '1'. Corresponding SRAM LDO is disabled and in HZ mode.
7	ENFUNC5	R/W	0h	ENFUNC5 input of SRAM LDO. 0h (R/W) = Active to retention is a one step transfer 1h (R/W) = Active to retention is a two steps transfer
6	ENFUNC4	R/W	0h	ENFUNC4 input of SRAM LDO. 0h (R/W) = One external clock is supplied 1h (R/W) = No external clock is supplied
5	ENFUNC3_EXPORT	R/WSpecial	0h	ENFUNC3 input of SRAM LDO. After PowerOn reset and Efuse sensing, this bitfield is automatically loaded with an Efuse value from control module. Bitfield remains writable after this. 0h (R/W) = Sub regulation is disabled 1h (R/W) = Sub regulation is enabled
4	ENFUNC2_EXPORT	R/WSpecial	0h	ENFUNC2 input of SRAM LDO. After PowerOn reset and Efuse sensing, this bitfield is automatically loaded with an Efuse value from control module. Bitfield remains writable after this. 0h (R/W) = External cap is used 1h (R/W) = External cap is not used
3	ENFUNC1_EXPORT	R/WSpecial	0h	ENFUNC1 input of SRAM LDO. After PowerOn reset and Efuse sensing, this bitfield is automatically loaded with an Efuse value from control module. Bitfield remains writable after this. 0h (R/W) = Short circuit protection is disabled 1h (R/W) = Short circuit protection is enabled

**Table 6-43. PRCM\_PRM\_LDO\_SRAM\_MPU\_SETUP Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
2	ABBOFF_SLEEP_EXPOR T	R/WSpecial	0h	Determines whether SRAMNWA is supplied by VDDS or VDDAR during deep-sleep. After PowerOn reset and Efuse sensing, this bitfield is automatically loaded with an Efuse value from control module. Bitfield remains writable after this. 0h (R/W) = SRAMNWA supplied with VDDS 1h (R/W) = SRAMNWA supplied with VDDAR
1	ABBOFF_ACT_EXPORT	R/WSpecial	0h	Determines whether SRAMNWA is supplied by VDDS or VDDAR during active mode. After PowerOn reset and Efuse sensing, this bitfield is automatically loaded with an Efuse value from control module. Bitfield remains writable after this. 0h (R/W) = SRAMNWA supplied with VDDS 1h (R/W) = SRAMNWA supplied with VDDAR
0	DISABLE_RTA_EXPORT	R/WSpecial	0h	Control for HD memory RTA feature. After PowerOn reset and Efuse sensing, this bitfield is automatically loaded with an Efuse value from control module. Bitfield remains writable after this. 0h (R/W) = HD memory RTA feature is enabled 1h (R/W) = HD memory RTA feature is disabled

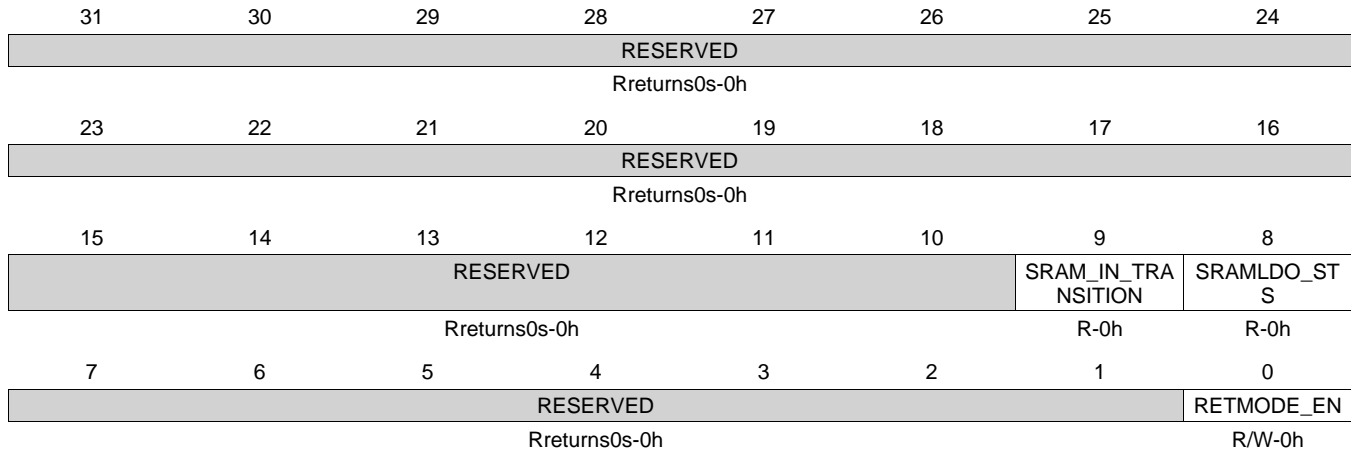

### 6.12.2.8 PRCM\_PRM\_LDO\_SRAM\_MPU\_CTRL Register (offset = 1Ch) [reset = 0h]

Register mask: FFFFFFFFh

PRCM\_PRM\_LDO\_SRAM\_MPU\_CTRL is shown in [Figure 6-37](#) and described in [Table 6-44](#).

Control and status of the SRAM LDO for MPU voltage domain. [warm reset insensitive]

**Figure 6-37. PRCM\_PRM\_LDO\_SRAM\_MPU\_CTRL Register**

**Table 6-44. PRCM\_PRM\_LDO\_SRAM\_MPU\_CTRL Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-10	RESERVED	Rreturns0s	0h	
9	SRAM_IN_TRANSITION	R	0h	Status indicating SRAM LDO state machine state. 0h (R) = SRAM LDO state machine is stable 1h (R) = SRAM LDO state machine is in transition state
8	SRAMLDO_STS	R	0h	SRAMLDO status 0h (R) = SRAMLDO is in ACTIVE mode. 1h (R) = SRAMLDO is on RETENTION mode.
7-1	RESERVED	Rreturns0s	0h	
0	RETMODE_EN	R/W	0h	Control if the SRAM LDO retention mode is used or not. 0h (R/W) = SRAM LDO is not allowed to go to RET mode 1h (R/W) = SRAM LDO go to RET mode when all memory of voltage domain are OFF or RET

### 6.12.2.9 PRCM\_PRM\_IO\_COUNT Register (offset = 20h) [reset = 3Ah]

Register mask: FFFFFFFFh

PRCM\_PRM\_IO\_COUNT is shown in [Figure 6-38](#) and described in [Table 6-45](#).

This register allows controlling EMIF IO isolation removal setup. [warm reset insensitive]

**Figure 6-38. PRCM\_PRM\_IO\_COUNT Register**

**Table 6-45. PRCM\_PRM\_IO\_COUNT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-8	RESERVED	Rreturns0s	0h	
7-0	ISO_2_ON_TIME	R/W	3Ah	Determines the setup time of the DDR IOs going out of isolation. Counting on the system clock. Target is 1.5us.

### 6.12.2.10 PRCM\_PRCM\_IO\_PMCTRL Register (offset = 24h) [reset = 20h]

Register mask: FFFFFFFFh

PRCM\_PRCM\_IO\_PMCTRL is shown in [Figure 6-39](#) and described in [Table 6-46](#).

This register allows controlling power management features of the IOs.

**Figure 6-39. PRCM\_PRCM\_IO\_PMCTRL Register**

31	30	29	28	27	26	25	24
RESERVED						IO_ISO_STS	IO_ISO_CTRL
Rreturns0s-0h						R-0h	R/W-0h
23	22	21	20	19	18	17	16
RESERVED							GLOBAL_WUEN
Rreturns0s-0h							R/W-0h
15	14	13	12	11	10	9	8
RESERVED						WUCLK_STS	WUCLK_CTRL
Rreturns0s-0h						R-0h	R/W-0h

RESERVED		IO_ON_STS	ISOOVR_EXTEND	RESERVED		ISOCK_STS	ISOCK_OVERRIDE
Rreturns0s-0h		R-1h	R/W-0h	Rreturns0s-0h		R-0h	R/W-0h

**Table 6-46. PRCM\_PRCM\_IO\_PMCTRL Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-26	RESERVED	Rreturns0s	0h	
25	IO_ISO_STS	R	0h	IO ISO Status. 0h (R) = IO isolation not active. 1h (R) = IO isolation active
24	IO_ISO_CTRL	R/W	0h	IO ISO control. writing this bit to '1' will kick off IO isolation. 0h (R/W) = Turn off the IO isolation. 1h (R/W) = Turn ON the IO isolation
23-17	RESERVED	Rreturns0s	0h	
16	GLOBAL_WUEN	R/W	0h	Global IO wakeup enable. This is a gating condition to all individual IO WUEN coming from control module. Gating is done in the Spinner logic. 0h (R/W) = All individual IO WUEN are gated in the Spinner logic (overridden to 0). 1h (R/W) = All individual IO WUEN from control module are going to IOs.
15-10	RESERVED	Rreturns0s	0h	
9	WUCLK_STS	R	0h	Gives value of WUCLKOUT signal coming back from IO pad ring.
8	WUCLK_CTRL	R/W	0h	Direct control on WUCLKIN signal to IO pad ring. 0h (R/W) = WUCLKIN signal is driven to 0. IO wakeup daisy chain is functional as well as IO whose wakeup feature is enabled. 1h (R/W) = WUCLKIN signal is driven to 1. IO wakeup daisy chain is reset and is latching current pad states and WUEN inputs.
7-6	RESERVED	Rreturns0s	0h	
5	IO_ON_STS	R	1h	Gives the functional status of the IO ring. 0h (R) = Part or all of the IOs are not in the ON state, that is are in isolation state. 1h (R) = All IOs are in the ON state.

**Table 6-46. PRCM\_PRM\_IO\_PMCTRL Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
4	ISOOVR_EXTEND	R/W	0h	Control non-EMIF IO isolation extension. 0h (R/W) = Non-EMIF IO isolation is not extended. "EMIF_ON" IO transition happens as soon as automatic restore is completed. 1h (R/W) = Non-EMIF IO isolation is extended. "EMIF_ON" IO transition is stalled.
3-2	RESERVED	Rreturns0s	0h	
1	ISOCLK_STS	R	0h	Gives value of ISOCLKOUT signal coming back from IO pad ring.
0	ISOCLK_OVERRIDE	R/W	0h	Override control on ISOCLKIN signal to IO pad ring. When not overridden, this signal is controlled by hardware only. 0h (R/W) = ISOCLKIN signal is not overridden. 1h (R/W) = ISOCLKIN signal is overridden to active value ('1').

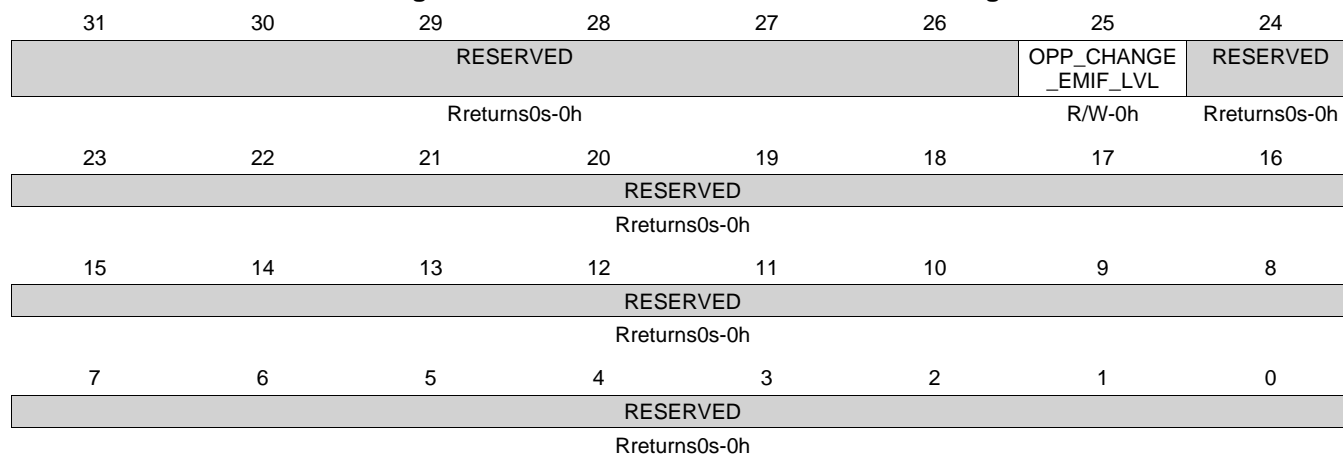

### 6.12.2.11 PRCM\_PRCM\_VC\_VAL\_BYPASS Register (offset = 28h) [reset = 0h]

Register mask: FFFFFFFFh

PRCM\_PRCM\_VC\_VAL\_BYPASS is shown in [Figure 6-40](#) and described in [Table 6-47](#).

This MMR has flag to indicate OPP change to EMIF to allow read/write leveling.

**Figure 6-40. PRCM\_PRCM\_VC\_VAL\_BYPASS Register**

**Table 6-47. PRCM\_PRCM\_VC\_VAL\_BYPASS Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-26	RESERVED	Rreturns0s	0h	
25	OPP_CHANGE_EMIF_LVL	R/W	0h	This bit controls read-write leveling of EMIF memories (DDR3). It must be set in case OPP voltage change is done. 0h (R/W) = Enable leveling 1h (R/W) = disable leveling
24-0	RESERVED	Rreturns0s	0h	

### 6.12.2.12 PRCM\_PRCM\_EMIF\_CTRL Register (offset = 30h) [reset = 0h]

Register mask: FFFFFFFFh

PRCM\_PRCM\_EMIF\_CTRL is shown in [Figure 6-41](#) and described in [Table 6-48](#).

This register controls EMIF controller low power configurations.

**Figure 6-41. PRCM\_PRCM\_EMIF\_CTRL Register**

Bit	Field	Type	Reset	Description
31-1	RESERVED	Rreturns0s	0h	Reserved
0	EMIF_DEVOFF	R/W	0h	EMIF Controller DeepSleep Mode Enable. This bit should be programmed to '1' (ON) before going into DeepSleep. Must be cleared to '0' (OFF) after wakeup and EMIF configuration is completed. 0h (R/W) = EMIF Controller DeepSleep Mode is Disabled. 1h (R/W) = EMIF Controller DeepSleep Mode is Enabled.

### 6.12.3 PRCM\_PRCM\_GFX Registers

[Table 6-49](#) lists the memory-mapped registers for the PRCM\_PRCM\_GFX. All register offset addresses not listed in [Table 6-49](#) should be considered as reserved locations and the register contents should not be modified.

**Table 6-49. PRCM\_PRCM\_GFX REGISTERS**

Offset	Acronym	Register Name	Section
0h	PRCM_PRCM_PM_GFX_PWRSTCTRL		<a href="#">Section 6.12.3.1</a>
4h	PRCM_PRCM_PM_GFX_PWRSTST		<a href="#">Section 6.12.3.2</a>
10h	PRCM_PRCM_RM_GFX_RSTCTRL		<a href="#">Section 6.12.3.3</a>

Rreturns0s-0h			R/WSpecial-0h	Rreturns0s-0h		R/W-0h	

**Table 6-50. PRCM\_PRM\_PM\_GFX\_PWRSTCTRL Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-18	RESERVED	Rreturns0s	0h	
17-16	GFX_MEM_ONSTATE	Rreturns1s	3h	GFX memory state when domain is ON. 3h (R) = Memory bank is on when the domain is ON.
15-9	RESERVED	Rreturns0s	0h	
8	GFX_MEM_RETSTATE	R/W	1h	GFX_MEM bank state when domain is retention 0h (R/W) = Memory is off when the domain is in the RETENTION state. 1h (R/W) = Memory is retained when domain is in RETENTION state.
7-5	RESERVED	Rreturns0s	0h	
4	LOWPOWERSTATECHANGE	R/WSpecial	0h	Power state change request when domain has already performed a sleep transition. Allows going into deeper low power state without waking up the power domain. 0h (R/W) = Do not request a low power state change. 1h (R/W) = Request a low power state change. This bit is automatically cleared when the power state is effectively changed or when power state is ON.
3-2	RESERVED	Rreturns0s	0h	
1-0	POWERSTATE	R/W	0h	Power state control 0h (R/W) = OFF State 1h (R) = RESERVED 2h (R) = RESERVED 3h (R/W) = ON State

### 6.12.3.2 PRCM\_PRM\_PM\_GFX\_PWRSTST Register (offset = 4h) [reset = 17h]

Register mask: FFFFFFFFh

PRCM\_PRM\_PM\_GFX\_PWRSTST is shown in [Figure 6-43](#) and described in [Table 6-51](#).

This register provides a status on the current GFX power domain state. [warm reset insensitive]

**Figure 6-43. PRCM\_PRM\_PM\_GFX\_PWRSTST Register**

**Table 6-51. PRCM\_PRM\_PM\_GFX\_PWRSTST Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-26	RESERVED	Rreturns0s	0h	
25-24	LASTPOWERSTATEENTERED	R/W1toSet	0h	Last low power state entered. Set to 0x3 upon write of the same only. This register is intended for debug purpose only. 0h (R) = Power domain was previously OFF 1h (R) = Power domain was previously in RETENTION 2h (R) = Power domain was previously ON-INACTIVE 3h (R) = Power domain was previously ON-ACTIVE
23-21	RESERVED	Rreturns0s	0h	
20	INTRANSITION	R	0h	Domain transition status 0h (R) = No on-going transition on power domain 1h (R) = Power domain transition is in progress.
19-6	RESERVED	Rreturns0s	0h	
5-4	GFX_MEM_STATEST	R	1h	GFX memory state status 0h (R) = Memory is OFF 1h (R) = Memory is in RETENTION. 2h (R) = Reserved 3h (R) = Memory is ON
3	RESERVED	Rreturns0s	0h	
2	LOGICSTATEST	R	1h	Logic state status 0h (R) = Logic in domain is OFF 1h (R) = Logic in domain is ON
1-0	POWERSTATEST	R	3h	Current Power State Status 0h (R) = OFF State [warm reset insensitive] 3h (R) = ON State [warm reset insensitive]

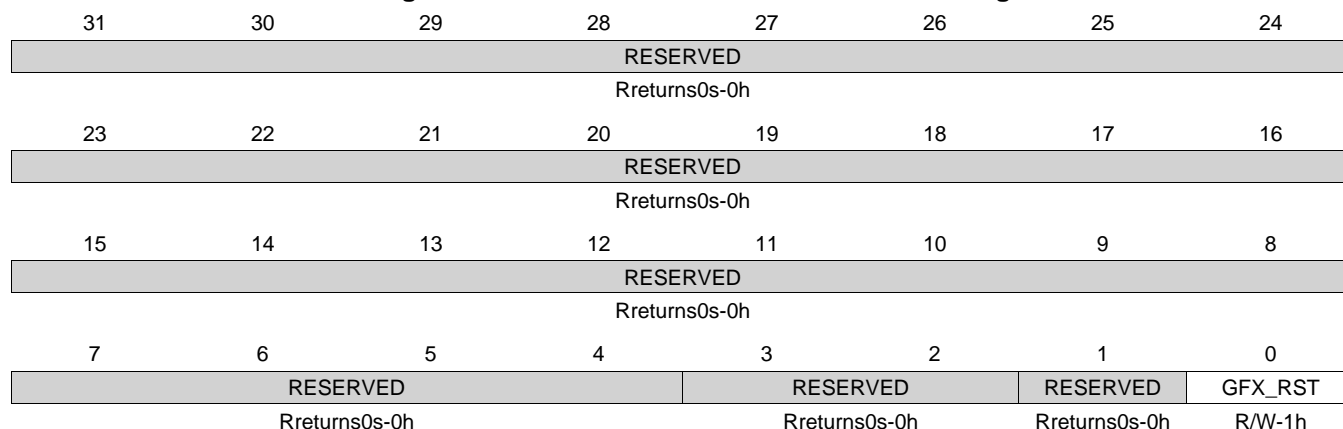

### 6.12.3.3 PRCM\_PRM\_RM\_GFX\_RSTCTRL Register (offset = 10h) [reset = 1h]

Register mask: FFFFFFFFh

PRCM\_PRM\_RM\_GFX\_RSTCTRL is shown in [Figure 6-44](#) and described in [Table 6-52](#).

This register controls the release of the GFX Domain resets.

**Figure 6-44. PRCM\_PRM\_RM\_GFX\_RSTCTRL Register**

**Table 6-52. PRCM\_PRM\_RM\_GFX\_RSTCTRL Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-4	RESERVED	Rreturns0s	0h	
3-2	RESERVED	Rreturns0s	0h	
1	RESERVED	Rreturns0s	0h	
0	GFX_RST	R/W	1h	GFX domain local reset control 0h (R/W) = Reset is cleared for the GFX Domain (SGX530) 1h (R/W) = Reset is asserted for the GFX Domain (SGX 530)

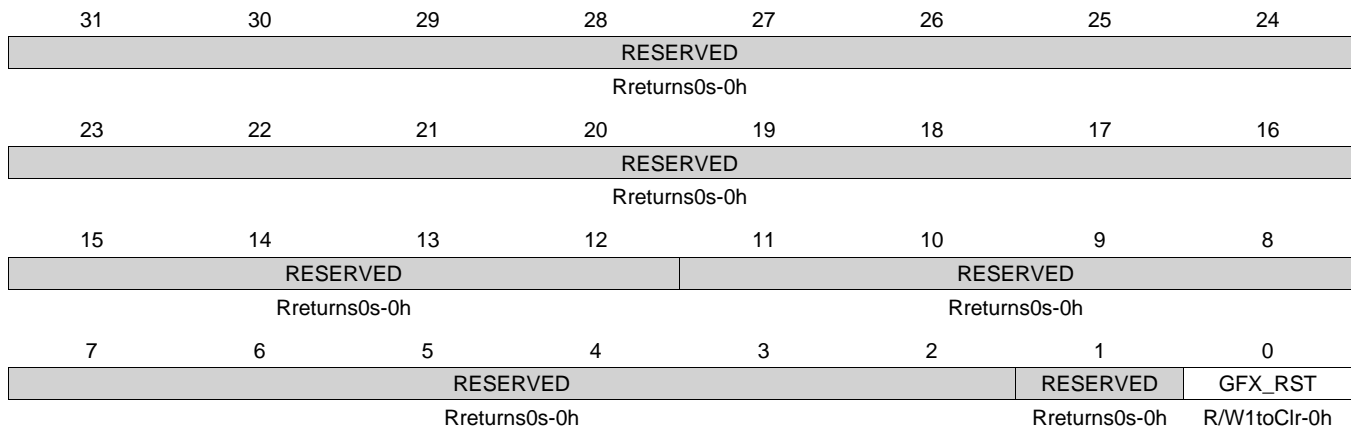

### 6.12.3.4 PRCM\_PRM\_RM\_GFX\_RSTST Register (offset = 14h) [reset = 0h]

Register mask: FFFFFFFFh

PRCM\_PRM\_RM\_GFX\_RSTST is shown in [Figure 6-45](#) and described in [Table 6-53](#).

This register logs the different reset sources of the GFX domain. Each bit is set upon release of the domain reset signal. Must be cleared by software. [warm reset insensitive]

**Figure 6-45. PRCM\_PRM\_RM\_GFX\_RSTST Register**

**Table 6-53. PRCM\_PRM\_RM\_GFX\_RSTST Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-12	RESERVED	Rreturns0s	0h	
11-2	RESERVED	Rreturns0s	0h	
1	RESERVED	Rreturns0s	0h	
0	GFX_RST	R/W1toClr	0h	GFX Domain Logic Reset 0h (R/W) = No SW reset occurred 1h (R/W) = GFX Domain Logic has been reset upon SW reset

### 6.12.3.5 PRCM\_PRCM\_RM\_GFX\_CONTEXT Register (offset = 24h) [reset = 101h]

Register mask: FFFFFFFFh

PRCM\_PRCM\_RM\_GFX\_CONTEXT is shown in [Figure 6-46](#) and described in [Table 6-54](#).

This register contains dedicated GFX context statuses. [warm reset insensitive]

**Figure 6-46. PRCM\_PRCM\_RM\_GFX\_CONTEXT Register**

Bit	Field	Type	Reset	Description
31-9	RESERVED	Rreturns0s	0h	
8	LOSTMEM_GFX_MEM	R/W1toClr	1h	Specify if memory-based context in GFX_MEM memory bank has been lost due to a previous power transition or other reset source. 0h (R/W) = Context has been maintained 1h (R/W) = Context has been lost
7-1	RESERVED	Rreturns0s	0h	
0	LOSTCONTEXT_DFF	R/W1toClr	1h	Specify if DFF-based context has been lost due to a previous power transition or other reset source. (set upon assertion of GFX_RST signal) 0h (R/W) = Context has been maintained 1h (R/W) = Context has been lost

### 6.12.4 PRM\_MPU Registers

[Table 6-55](#) lists the memory-mapped registers for the PRM\_MPU. All register offset addresses not listed in [Table 6-55](#) should be considered as reserved locations and the register contents should not be modified.

**Table 6-55. PRM\_MPU Registers**

Offset	Acronym	Register Name	Section
0h	PRCM_PM_MPU_PWRSTCTRL		<a href="#">Section 6.12.4.1</a>
4h	PRCM_PM_MPU_PWRSTST		<a href="#">Section 6.12.4.2</a>
14h	PRCM_RM_MPU_RSTST		<a href="#">Section 6.12.4.3</a>
24h	PRCM_RM_MPU_CONTEXT		<a href="#">Section 6.12.4.4</a>

#### 6.12.4.1 PRCM\_PM\_MPU\_PWRSTCTRL Register (offset = 0h) [reset = 3F0707h]

Register mask: FFFFFFFFh

PRCM\_PM\_MPU\_PWRSTCTRL is shown in [Figure 6-47](#) and described in [Table 6-56](#).

This register controls the MPU power state to reach upon mpu domain sleep transition

**Figure 6-47. PRCM\_PM\_MPU\_PWRSTCTRL Register**

### 6.12.4.3 PRCM\_RM\_MPU\_RSTST Register (offset = 14h) [reset = 0h]

Register mask: FFFFFFFFh

PRCM\_RM\_MPU\_RSTST is shown in [Figure 6-49](#) and described in [Table 6-58](#).

This register logs the different reset sources of the ALWON domain. Each bit is set upon release of the domain reset signal. Must be cleared by software. [warm reset insensitive]

### 6.12.5.3 PRCM\_RM\_PER\_RSTCTRL Register (offset = 10h) [reset = 3h]

Register mask: FFFFFFFFh

PRCM\_RM\_PER\_RSTCTRL is shown in [Figure 6-53](#) and described in [Table 6-63](#).

This register controls the release of the PER Domain resets.

**Figure 6-53. PRCM\_RM\_PER\_RSTCTRL Register**

**Table 6-63. PRCM\_RM\_PER\_RSTCTRL Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-6	RESERVED	Rreturns0s	0h	
5-3	RESERVED	Rreturns0s	0h	
2	ASSERT	Rreturns0s	0h	
1	PRU_ICSS_LRST	R/W	1h	PER domain PRU-ICSS local reset control 0h (R/W) = Reset is cleared for the PRU-ICSS 1h (R/W) = Reset is asserted for the PRU-ICSS
0	RESERVED	Rreturns0s	1h	

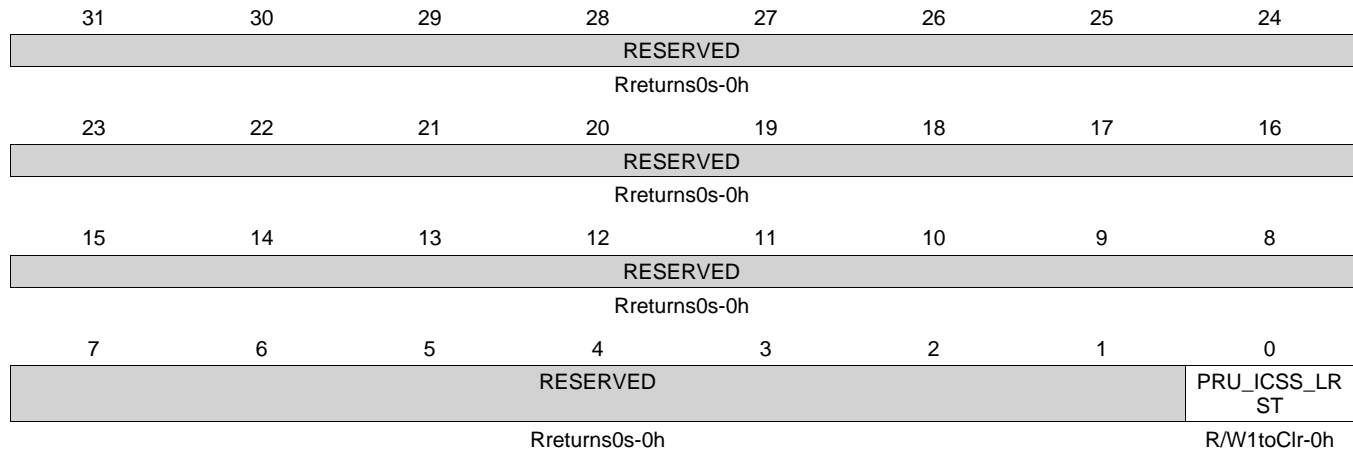

#### 6.12.5.4 PRCM\_RM\_PER\_RSTST Register (offset = 14h) [reset = 0h]

Register mask: FFFFFFFFh

PRCM\_RM\_PER\_RSTST is shown in [Figure 6-54](#) and described in [Table 6-64](#).

This register logs the different reset sources of the PER domain. Each bit is set upon release of the domain reset signal. Must be cleared by software. [warm reset insensitive]

**Figure 6-54. PRCM\_RM\_PER\_RSTST Register**

**Table 6-64. PRCM\_RM\_PER\_RSTST Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	RESERVED	Rreturns0s	0h	
0	PRU_ICSS_LRST	R/W1toClr	0h	PRU-ICSS Processor software reset status. 0h (R/W) = No reset 1h (R/W) = PRU-ICSS Processor has been reset upon SW reset

### 6.12.5.5 PRCM\_RM\_PER\_L3\_CONTEXT Register (offset = 24h) [reset = 1h]

Register mask: FFFFFFFFh

PRCM\_RM\_PER\_L3\_CONTEXT is shown in [Figure 6-55](#) and described in [Table 6-65](#).

This register contains dedicated L3 module context statuses. [warm reset insensitive]

**Figure 6-55. PRCM\_RM\_PER\_L3\_CONTEXT Register**

**Table 6-65. PRCM\_RM\_PER\_L3\_CONTEXT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	RESERVED	Rreturns0s	0h	
0	LOSTCONTEXT_DFF	R/W1toClr	1h	Specify if DFF-based context has been lost due to a previous power transition or other reset source. (set upon assertion of PER_DOM_RST signal) 0h (R/W) = Context has been maintained 1h (R/W) = Context has been lost

### 6.12.5.6 PRCM\_RM\_PER\_L3\_INSTR\_CONTEXT Register (offset = 44h) [reset = 1h]

Register mask: FFFFFFFFh

PRCM\_RM\_PER\_L3\_INSTR\_CONTEXT is shown in [Figure 6-56](#) and described in [Table 6-66](#).

This register contains dedicated L3\_INSTR module context statuses. [warm reset insensitive]

**Figure 6-56. PRCM\_RM\_PER\_L3\_INSTR\_CONTEXT Register**

**Table 6-66. PRCM\_RM\_PER\_L3\_INSTR\_CONTEXT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	RESERVED	Rreturns0s	0h	
0	LOSTCONTEXT_DFF	R/W1toClr	1h	Specify if DFF-based context has been lost due to a previous power transition or other reset source. (set upon assertion of PER_DOM_RST signal) 0h (R/W) = Context has been maintained 1h (R/W) = Context has been lost

### 6.12.5.7 PRCM\_RM\_PER\_OCMCRAM\_CONTEXT Register (offset = 54h) [reset = 301h]

Register mask: FFFFFFFFh

PRCM\_RM\_PER\_OCMCRAM\_CONTEXT is shown in [Figure 6-57](#) and described in [Table 6-67](#).

This register contains dedicated OCMCRAM module context statuses. [warm reset insensitive]

#### 6.12.5.14 PRCM\_RM\_PER\_DLL\_AGING\_CONTEXT Register (offset = 9Ch) [reset = 1h]

Register mask: FFFFFFFFh

PRCM\_RM\_PER\_DLL\_AGING\_CONTEXT is shown in [Figure 6-64](#) and described in [Table 6-74](#).

This register contains dedicated DLL\_AGING module context statuses. [warm reset insensitive]

**Figure 6-64. PRCM\_RM\_PER\_DLL\_AGING\_CONTEXT Register**

**Table 6-74. PRCM\_RM\_PER\_DLL\_AGING\_CONTEXT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	RESERVED	Rreturns0s	0h	
0	LOSTCONTEXT_DFF	R/W1toClr	1h	Specify if DFF-based context has been lost due to a previous power transition or other reset source. (set upon assertion of PER_DOM_RST signal) 0h (R/W) = Context has been maintained 1h (R/W) = Context has been lost

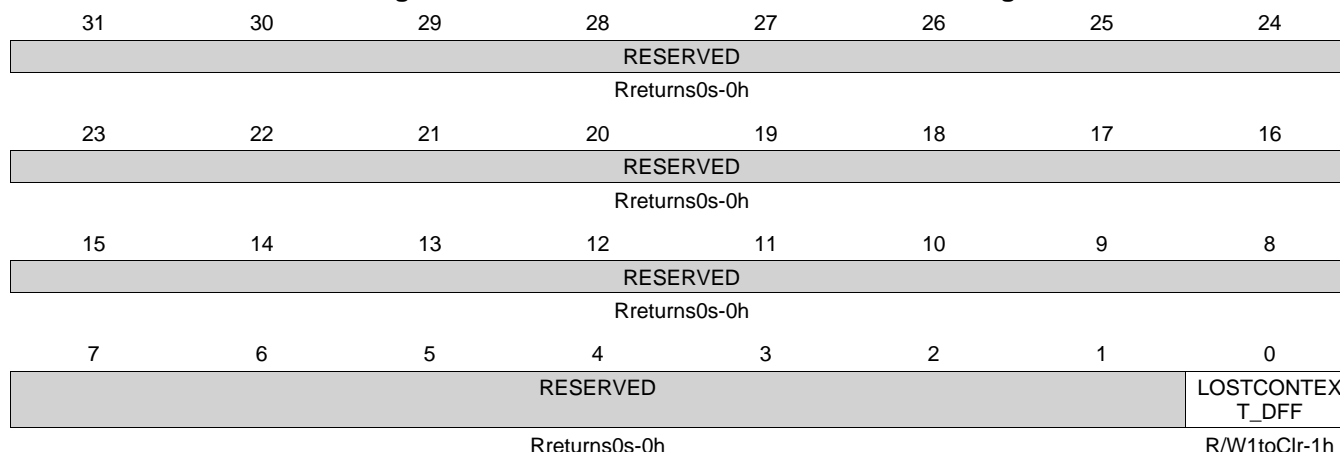

### 6.12.5.15 PRCM\_RM\_PER\_L4HS\_CONTEXT Register (offset = A4h) [reset = 1h]

Register mask: FFFFFFFFh

PRCM\_RM\_PER\_L4HS\_CONTEXT is shown in [Figure 6-65](#) and described in [Table 6-75](#).

This register contains dedicated L4HS module context statuses. [warm reset insensitive]

**Figure 6-65. PRCM\_RM\_PER\_L4HS\_CONTEXT Register**

**Table 6-75. PRCM\_RM\_PER\_L4HS\_CONTEXT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	RESERVED	Rreturns0s	0h	
0	LOSTCONTEXT_DFF	R/W1toClr	1h	Specify if DFF-based context has been lost due to a previous power transition or other reset source. (set upon assertion of PER_DOM_RST signal) 0h (R/W) = Context has been maintained 1h (R/W) = Context has been lost

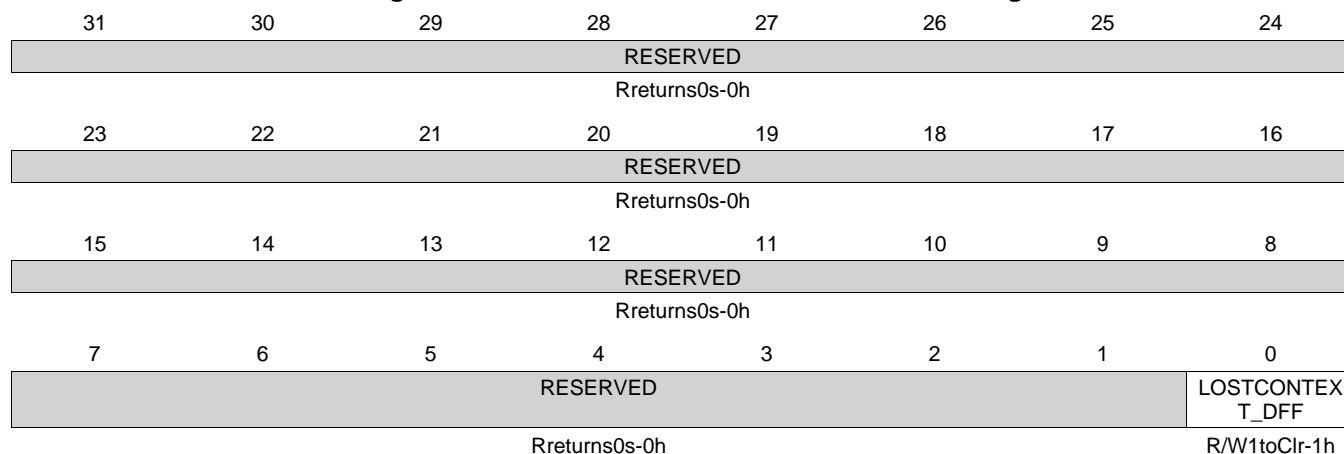

### 6.12.5.16 PRCM\_RM\_PER\_GPMC\_CONTEXT Register (offset = 224h) [reset = 1h]

Register mask: FFFFFFFFh

PRCM\_RM\_PER\_GPMC\_CONTEXT is shown in [Figure 6-66](#) and described in [Table 6-76](#).

This register contains dedicated GPMC module context statuses. [warm reset insensitive]

**Figure 6-66. PRCM\_RM\_PER\_GPMC\_CONTEXT Register**

**Table 6-76. PRCM\_RM\_PER\_GPMC\_CONTEXT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	RESERVED	Rreturns0s	0h	
0	LOSTCONTEXT_DFF	R/W1toClr	1h	Specify if DFF-based context has been lost due to a previous power transition or other reset source. (set upon assertion of PER_DOM_RST signal) 0h (R/W) = Context has been maintained 1h (R/W) = Context has been lost

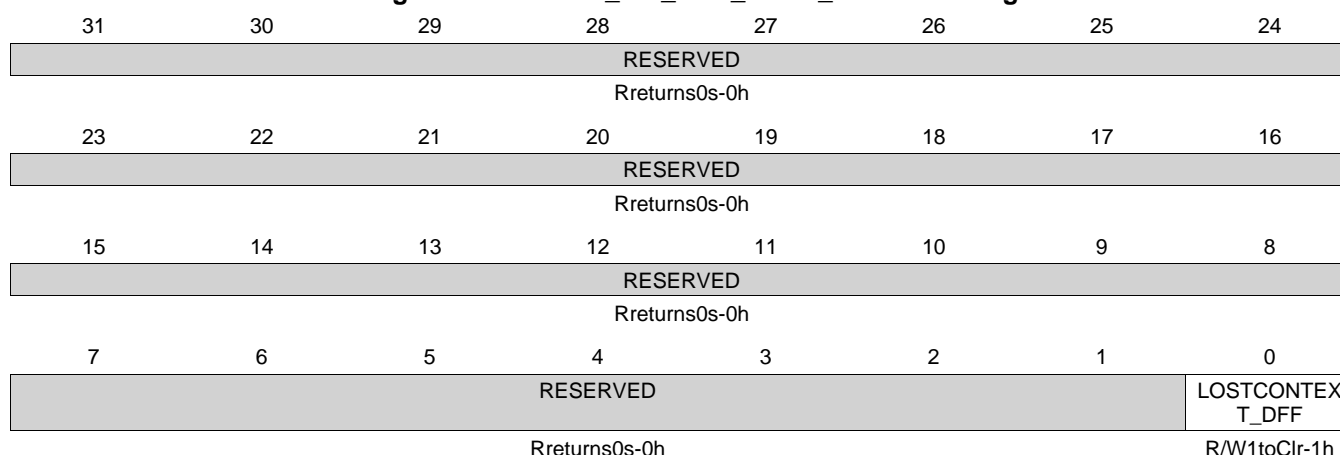

### 6.12.5.17 PRCM\_RM\_PER\_ADC1\_CONTEXT Register (offset = 234h) [reset = 1h]

Register mask: FFFFFFFFh

PRCM\_RM\_PER\_ADC1\_CONTEXT is shown in [Figure 6-67](#) and described in [Table 6-77](#).

This register contains dedicated ADC1 module context statuses. [warm reset insensitive]

**Figure 6-67. PRCM\_RM\_PER\_ADC1\_CONTEXT Register**

**Table 6-77. PRCM\_RM\_PER\_ADC1\_CONTEXT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	RESERVED	Rreturns0s	0h	
0	LOSTCONTEXT_DFF	R/W1toClr	1h	Specify if DFF-based context has been lost due to a previous power transition or other reset source. (set upon assertion of PER_DOM_RST signal) 0h (R/W) = Context has been maintained 1h (R/W) = Context has been lost

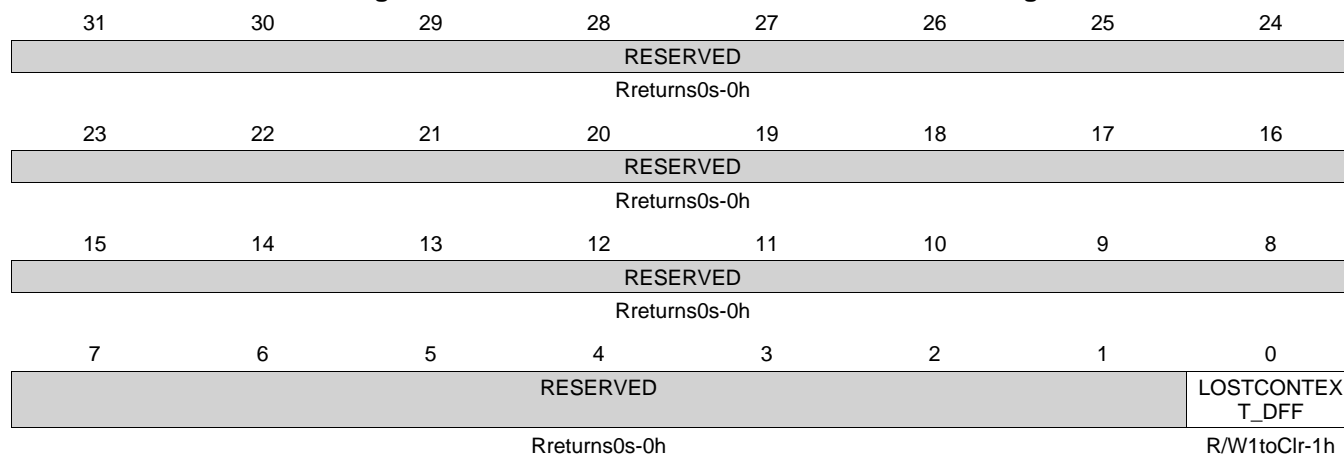

### 6.12.5.18 PRCM\_RM\_PER\_MCASP0\_CONTEXT Register (offset = 23Ch) [reset = 1h]

Register mask: FFFFFFFFh

PRCM\_RM\_PER\_MCASP0\_CONTEXT is shown in [Figure 6-68](#) and described in [Table 6-78](#).

This register contains dedicated MCASP0 module context statuses. [warm reset insensitive]

**Figure 6-68. PRCM\_RM\_PER\_MCASP0\_CONTEXT Register**

**Table 6-78. PRCM\_RM\_PER\_MCASP0\_CONTEXT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	RESERVED	Rreturns0s	0h	
0	LOSTCONTEXT_DFF	R/W1toClr	1h	Specify if DFF-based context has been lost due to a previous power transition or other reset source. (set upon assertion of PER_DOM_RST signal) 0h (R/W) = Context has been maintained 1h (R/W) = Context has been lost

### 6.12.5.19 PRCM\_RM\_PER\_MCASP1\_CONTEXT Register (offset = 244h) [reset = 1h]

Register mask: FFFFFFFFh

PRCM\_RM\_PER\_MCASP1\_CONTEXT is shown in [Figure 6-69](#) and described in [Table 6-79](#).

This register contains dedicated MCASP1 module context statuses. [warm reset insensitive]

**Figure 6-69. PRCM\_RM\_PER\_MCASP1\_CONTEXT Register**

**Table 6-79. PRCM\_RM\_PER\_MCASP1\_CONTEXT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	RESERVED	Rreturns0s	0h	
0	LOSTCONTEXT_DFF	R/W1toClr	1h	Specify if DFF-based context has been lost due to a previous power transition or other reset source. (set upon assertion of PER_DOM_RST signal) 0h (R/W) = Context has been maintained 1h (R/W) = Context has been lost

### 6.12.5.20 PRCM\_RM\_PER\_MMC2\_CONTEXT Register (offset = 24Ch) [reset = 101h]

Register mask: FFFFFFFFh

PRCM\_RM\_PER\_MMC2\_CONTEXT is shown in [Figure 6-70](#) and described in [Table 6-80](#).

This register contains dedicated MMC2 module context statuses. [warm reset insensitive]

### 6.12.5.25 PRCM\_RM\_PER\_L4LS\_CONTEXT Register (offset = 424h) [reset = 1h]

Register mask: FFFFFFFFh

PRCM\_RM\_PER\_L4LS\_CONTEXT is shown in [Figure 6-75](#) and described in [Table 6-85](#).

This register contains dedicated L4LS module context statuses. [warm reset insensitive]

**Figure 6-75. PRCM\_RM\_PER\_L4LS\_CONTEXT Register**

**Table 6-85. PRCM\_RM\_PER\_L4LS\_CONTEXT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	RESERVED	Rreturns0s	0h	
0	LOSTCONTEXT_DFF	R/W1toClr	1h	Specify if DFF-based context has been lost due to a previous power transition or other reset source. (set upon assertion of PER_DOM_RST signal) 0h (R/W) = Context has been maintained 1h (R/W) = Context has been lost

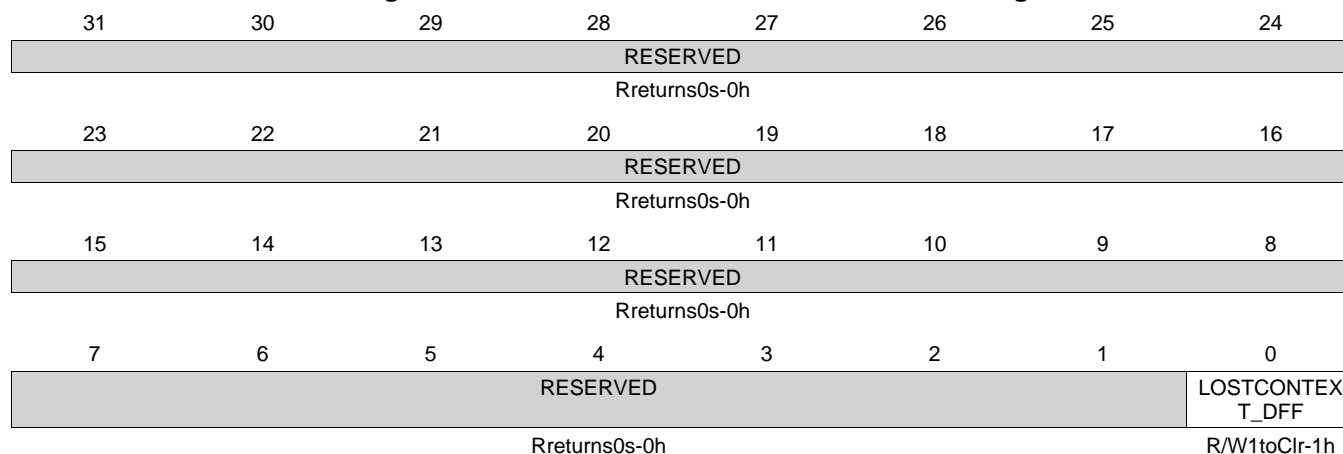

### 6.12.5.26 PRCM\_RM\_PER\_DCAN0\_CONTEXT Register (offset = 42Ch) [reset = 1h]

Register mask: FFFFFFFFh

PRCM\_RM\_PER\_DCAN0\_CONTEXT is shown in [Figure 6-76](#) and described in [Table 6-86](#).

This register contains dedicated DCAN0 module context statuses. [warm reset insensitive]

**Figure 6-76. PRCM\_RM\_PER\_DCAN0\_CONTEXT Register**

**Table 6-86. PRCM\_RM\_PER\_DCAN0\_CONTEXT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	RESERVED	Rreturns0s	0h	
0	LOSTCONTEXT_DFF	R/W1toClr	1h	Specify if DFF-based context has been lost due to a previous power transition or other reset source. (set upon assertion of PER_DOM_RST signal) 0h (R/W) = Context has been maintained 1h (R/W) = Context has been lost

### 6.12.5.27 PRCM\_RM\_PER\_DCAN1\_CONTEXT Register (offset = 434h) [reset = 1h]

Register mask: FFFFFFFFh

PRCM\_RM\_PER\_DCAN1\_CONTEXT is shown in [Figure 6-77](#) and described in [Table 6-87](#).

This register contains dedicated DCAN1 module context statuses. [warm reset insensitive]

**Figure 6-77. PRCM\_RM\_PER\_DCAN1\_CONTEXT Register**

**Table 6-87. PRCM\_RM\_PER\_DCAN1\_CONTEXT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	RESERVED	Rreturns0s	0h	
0	LOSTCONTEXT_DFF	R/W1toClr	1h	Specify if DFF-based context has been lost due to a previous power transition or other reset source. (set upon assertion of PER_DOM_RST signal) 0h (R/W) = Context has been maintained 1h (R/W) = Context has been lost

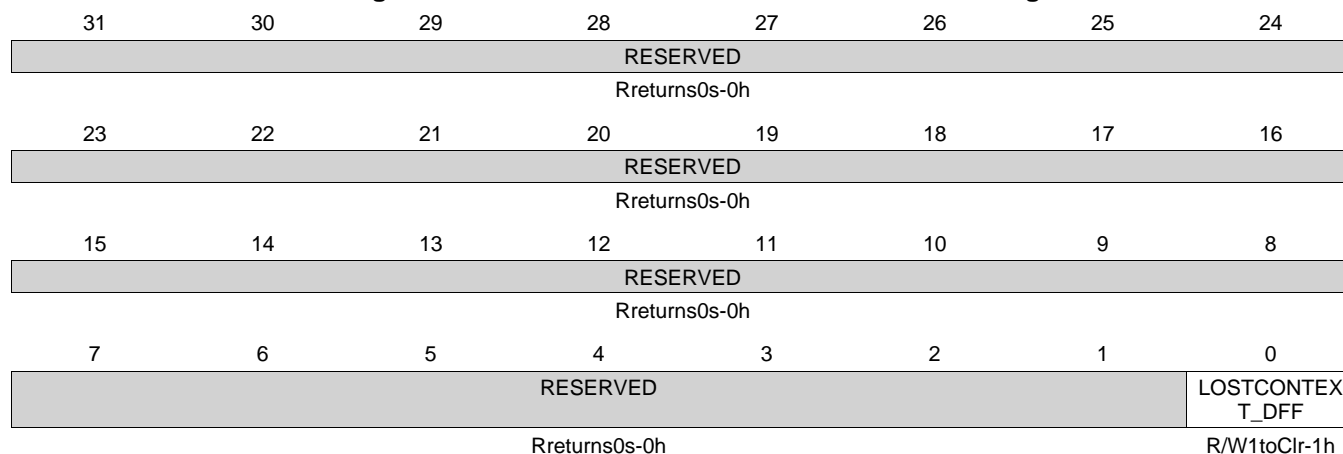

### 6.12.5.28 PRCM\_RM\_PER\_PWMSS0\_CONTEXT Register (offset = 43Ch) [reset = 1h]

Register mask: FFFFFFFFh

PRCM\_RM\_PER\_PWMSS0\_CONTEXT is shown in [Figure 6-78](#) and described in [Table 6-88](#).

This register contains dedicated PWMSS0 module context statuses. [warm reset insensitive]

**Figure 6-78. PRCM\_RM\_PER\_PWMSS0\_CONTEXT Register**

**Table 6-88. PRCM\_RM\_PER\_PWMSS0\_CONTEXT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	RESERVED	Rreturns0s	0h	
0	LOSTCONTEXT_DFF	R/W1toClr	1h	Specify if DFF-based context has been lost due to a previous power transition or other reset source. (set upon assertion of PER_DOM_RST signal) 0h (R/W) = Context has been maintained 1h (R/W) = Context has been lost

### 6.12.5.29 PRCM\_RM\_PER\_PWMSS1\_CONTEXT Register (offset = 444h) [reset = 1h]

Register mask: FFFFFFFFh

PRCM\_RM\_PER\_PWMSS1\_CONTEXT is shown in [Figure 6-79](#) and described in [Table 6-89](#).

This register contains dedicated PWMSS1 module context statuses. [warm reset insensitive]

**Figure 6-79. PRCM\_RM\_PER\_PWMSS1\_CONTEXT Register**

**Table 6-89. PRCM\_RM\_PER\_PWMSS1\_CONTEXT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	RESERVED	Rreturns0s	0h	
0	LOSTCONTEXT_DFF	R/W1toClr	1h	Specify if DFF-based context has been lost due to a previous power transition or other reset source. (set upon assertion of PER_DOM_RST signal) 0h (R/W) = Context has been maintained 1h (R/W) = Context has been lost

### 6.12.5.30 PRCM\_RM\_PER\_PWMSS2\_CONTEXT Register (offset = 44Ch) [reset = 1h]

Register mask: FFFFFFFFh

PRCM\_RM\_PER\_PWMSS2\_CONTEXT is shown in [Figure 6-80](#) and described in [Table 6-90](#).

This register contains dedicated PWMSS2 module context statuses. [warm reset insensitive]

**Figure 6-80. PRCM\_RM\_PER\_PWMSS2\_CONTEXT Register**

**Table 6-90. PRCM\_RM\_PER\_PWMSS2\_CONTEXT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	RESERVED	Rreturns0s	0h	
0	LOSTCONTEXT_DFF	R/W1toClr	1h	Specify if DFF-based context has been lost due to a previous power transition or other reset source. (set upon assertion of PER_DOM_RST signal) 0h (R/W) = Context has been maintained 1h (R/W) = Context has been lost

### 6.12.5.31 PRCM\_RM\_PER\_PWMSS3\_CONTEXT Register (offset = 454h) [reset = 1h]

Register mask: FFFFFFFFh

PRCM\_RM\_PER\_PWMSS3\_CONTEXT is shown in [Figure 6-81](#) and described in [Table 6-91](#).

This register contains dedicated PWMSS3 module context statuses. [warm reset insensitive]

**Figure 6-81. PRCM\_RM\_PER\_PWMSS3\_CONTEXT Register**

**Table 6-91. PRCM\_RM\_PER\_PWMSS3\_CONTEXT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	RESERVED	Rreturns0s	0h	
0	LOSTCONTEXT_DFF	R/W1toClr	1h	Specify if DFF-based context has been lost due to a previous power transition or other reset source. (set upon assertion of PER_DOM_RST signal) 0h (R/W) = Context has been maintained 1h (R/W) = Context has been lost

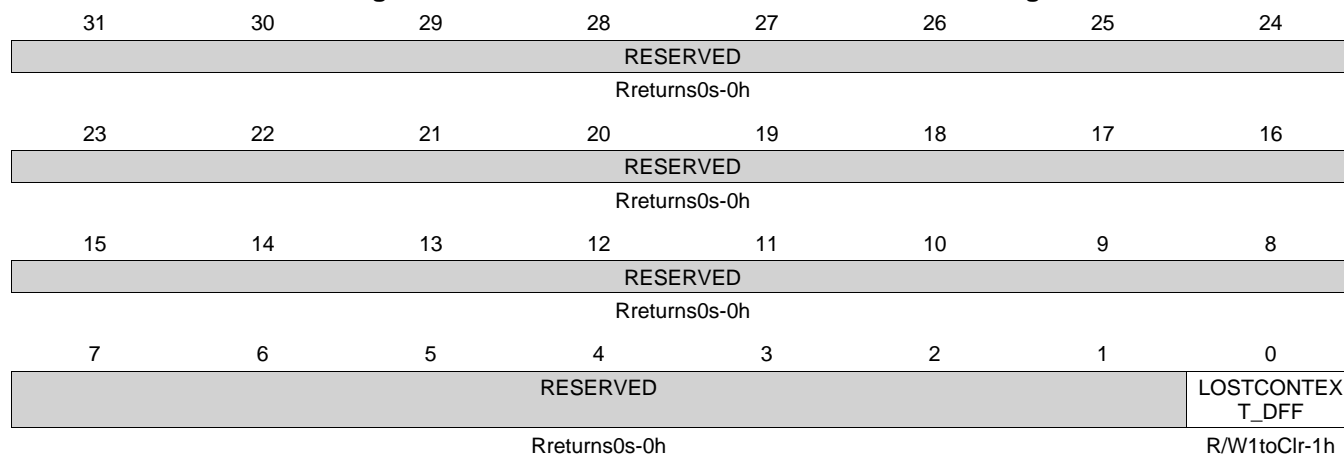

### 6.12.5.32 PRCM\_RM\_PER\_PWMSS4\_CONTEXT Register (offset = 45Ch) [reset = 1h]

Register mask: FFFFFFFFh

PRCM\_RM\_PER\_PWMSS4\_CONTEXT is shown in [Figure 6-82](#) and described in [Table 6-92](#).

This register contains dedicated PWMSS4 module context statuses. [warm reset insensitive]

**Figure 6-82. PRCM\_RM\_PER\_PWMSS4\_CONTEXT Register**

**Table 6-92. PRCM\_RM\_PER\_PWMSS4\_CONTEXT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	RESERVED	Rreturns0s	0h	
0	LOSTCONTEXT_DFF	R/W1toClr	1h	Specify if DFF-based context has been lost due to a previous power transition or other reset source. (set upon assertion of PER_DOM_RST signal) 0h (R/W) = Context has been maintained 1h (R/W) = Context has been lost

### 6.12.5.33 PRCM\_RM\_PER\_PWMSS5\_CONTEXT Register (offset = 464h) [reset = 1h]

Register mask: FFFFFFFFh

PRCM\_RM\_PER\_PWMSS5\_CONTEXT is shown in [Figure 6-83](#) and described in [Table 6-93](#).

This register contains dedicated PWMSS5 module context statuses. [warm reset insensitive]

**Figure 6-83. PRCM\_RM\_PER\_PWMSS5\_CONTEXT Register**

**Table 6-93. PRCM\_RM\_PER\_PWMSS5\_CONTEXT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	RESERVED	Rreturns0s	0h	
0	LOSTCONTEXT_DFF	R/W1toClr	1h	Specify if DFF-based context has been lost due to a previous power transition or other reset source. (set upon assertion of PER_DOM_RST signal) 0h (R/W) = Context has been maintained 1h (R/W) = Context has been lost

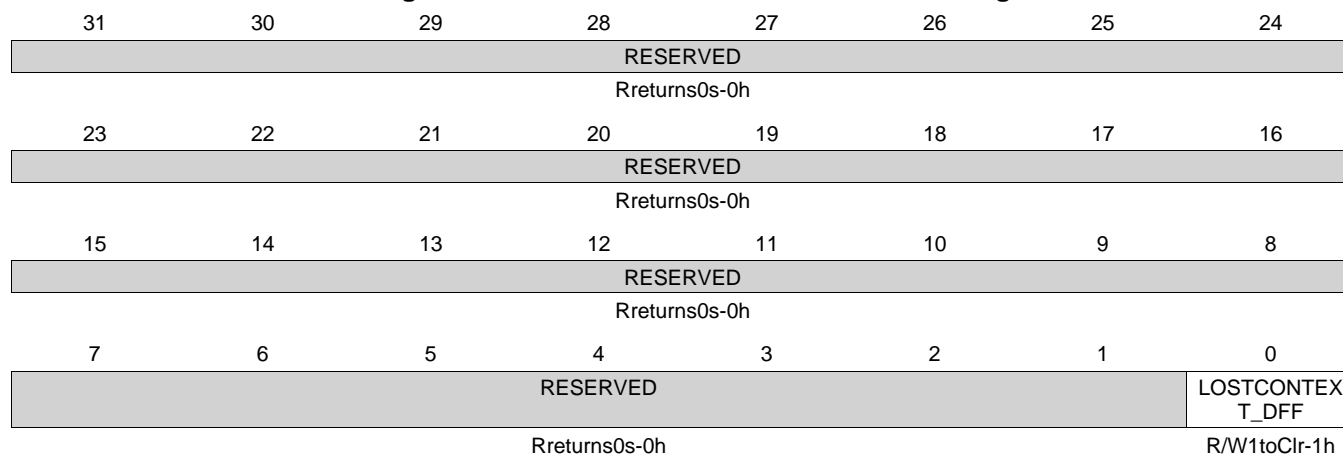

### 6.12.5.34 PRCM\_RM\_PER\_ELM\_CONTEXT Register (offset = 46Ch) [reset = 1h]

Register mask: FFFFFFFFh

PRCM\_RM\_PER\_ELM\_CONTEXT is shown in [Figure 6-84](#) and described in [Table 6-94](#).

This register contains dedicated ELM module context statuses. [warm reset insensitive]

**Figure 6-84. PRCM\_RM\_PER\_ELM\_CONTEXT Register**

**Table 6-94. PRCM\_RM\_PER\_ELM\_CONTEXT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	RESERVED	Rreturns0s	0h	
0	LOSTCONTEXT_DFF	R/W1toClr	1h	Specify if DFF-based context has been lost due to a previous power transition or other reset source. (set upon assertion of PER_DOM_RST signal) 0h (R/W) = Context has been maintained 1h (R/W) = Context has been lost

### 6.12.5.35 PRCM\_RM\_PER\_GPIO1\_CONTEXT Register (offset = 47Ch) [reset = 1h]

Register mask: FFFFFFFFh

PRCM\_RM\_PER\_GPIO1\_CONTEXT is shown in [Figure 6-85](#) and described in [Table 6-95](#).

This register contains dedicated GPIO1 module context statuses. [warm reset insensitive]

**Figure 6-85. PRCM\_RM\_PER\_GPIO1\_CONTEXT Register**

**Table 6-95. PRCM\_RM\_PER\_GPIO1\_CONTEXT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	RESERVED	Rreturns0s	0h	
0	LOSTCONTEXT_DFF	R/W1toClr	1h	Specify if DFF-based context has been lost due to a previous power transition or other reset source. (set upon assertion of PER_DOM_RST signal) 0h (R/W) = Context has been maintained 1h (R/W) = Context has been lost

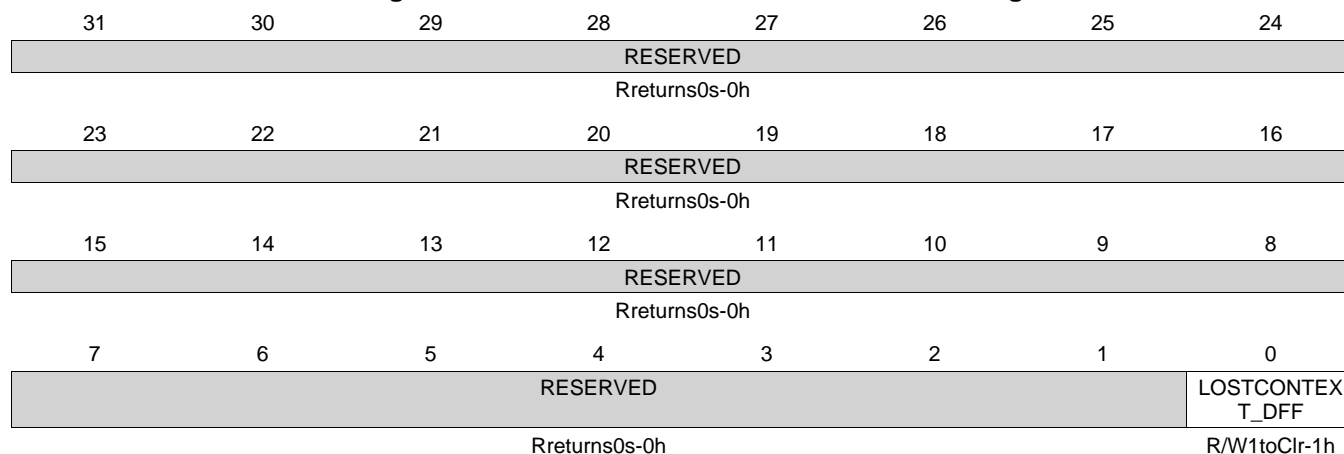

### 6.12.5.36 PRCM\_RM\_PER\_GPIO2\_CONTEXT Register (offset = 484h) [reset = 1h]

Register mask: FFFFFFFFh

PRCM\_RM\_PER\_GPIO2\_CONTEXT is shown in [Figure 6-86](#) and described in [Table 6-96](#).

This register contains dedicated GPIO2 module context statuses. [warm reset insensitive]

**Figure 6-86. PRCM\_RM\_PER\_GPIO2\_CONTEXT Register**

**Table 6-96. PRCM\_RM\_PER\_GPIO2\_CONTEXT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	RESERVED	Rreturns0s	0h	
0	LOSTCONTEXT_DFF	R/W1toClr	1h	Specify if DFF-based context has been lost due to a previous power transition or other reset source. (set upon assertion of PER_DOM_RST signal) 0h (R/W) = Context has been maintained 1h (R/W) = Context has been lost

### 6.12.5.37 PRCM\_RM\_PER\_GPIO3\_CONTEXT Register (offset = 48Ch) [reset = 1h]

Register mask: FFFFFFFFh

PRCM\_RM\_PER\_GPIO3\_CONTEXT is shown in [Figure 6-87](#) and described in [Table 6-97](#).

This register contains dedicated GPIO3 module context statuses. [warm reset insensitive]

**Figure 6-87. PRCM\_RM\_PER\_GPIO3\_CONTEXT Register**

**Table 6-97. PRCM\_RM\_PER\_GPIO3\_CONTEXT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	RESERVED	Rreturns0s	0h	
0	LOSTCONTEXT_DFF	R/W1toClr	1h	Specify if DFF-based context has been lost due to a previous power transition or other reset source. (set upon assertion of PER_DOM_RST signal) 0h (R/W) = Context has been maintained 1h (R/W) = Context has been lost

### 6.12.5.38 PRCM\_RM\_PER\_GPIO4\_CONTEXT Register (offset = 494h) [reset = 1h]

Register mask: FFFFFFFFh

PRCM\_RM\_PER\_GPIO4\_CONTEXT is shown in [Figure 6-88](#) and described in [Table 6-98](#).

This register contains dedicated GPIO4 module context statuses. [warm reset insensitive]

**Figure 6-88. PRCM\_RM\_PER\_GPIO4\_CONTEXT Register**

**Table 6-98. PRCM\_RM\_PER\_GPIO4\_CONTEXT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	RESERVED	Rreturns0s	0h	
0	LOSTCONTEXT_DFF	R/W1toClr	1h	Specify if DFF-based context has been lost due to a previous power transition or other reset source. (set upon assertion of PER_DOM_RST signal) 0h (R/W) = Context has been maintained 1h (R/W) = Context has been lost

### 6.12.5.39 PRCM\_RM\_PER\_GPIO5\_CONTEXT Register (offset = 49Ch) [reset = 1h]

Register mask: FFFFFFFFh

PRCM\_RM\_PER\_GPIO5\_CONTEXT is shown in [Figure 6-89](#) and described in [Table 6-99](#).

This register contains dedicated GPIO5 module context statuses. [warm reset insensitive]

**Figure 6-89. PRCM\_RM\_PER\_GPIO5\_CONTEXT Register**

**Table 6-99. PRCM\_RM\_PER\_GPIO5\_CONTEXT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	RESERVED	Rreturns0s	0h	
0	LOSTCONTEXT_DFF	R/W1toClr	1h	Specify if DFF-based context has been lost due to a previous power transition or other reset source. (set upon assertion of PER_DOM_RST signal) 0h (R/W) = Context has been maintained 1h (R/W) = Context has been lost

#### 6.12.5.40 PRCM\_RM\_PER\_HDQ1W\_CONTEXT Register (offset = 4A4h) [reset = 1h]

Register mask: FFFFFFFFh

PRCM\_RM\_PER\_HDQ1W\_CONTEXT is shown in [Figure 6-90](#) and described in [Table 6-100](#).

This register contains dedicated HDQ1W module context statuses. [warm reset insensitive]

**Figure 6-90. PRCM\_RM\_PER\_HDQ1W\_CONTEXT Register**

**Table 6-100. PRCM\_RM\_PER\_HDQ1W\_CONTEXT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	RESERVED	Rreturns0s	0h	
0	LOSTCONTEXT_DFF	R/W1toClr	1h	Specify if DFF-based context has been lost due to a previous power transition or other reset source. (set upon assertion of PER_DOM_RST signal) 0h (R/W) = Context has been maintained 1h (R/W) = Context has been lost

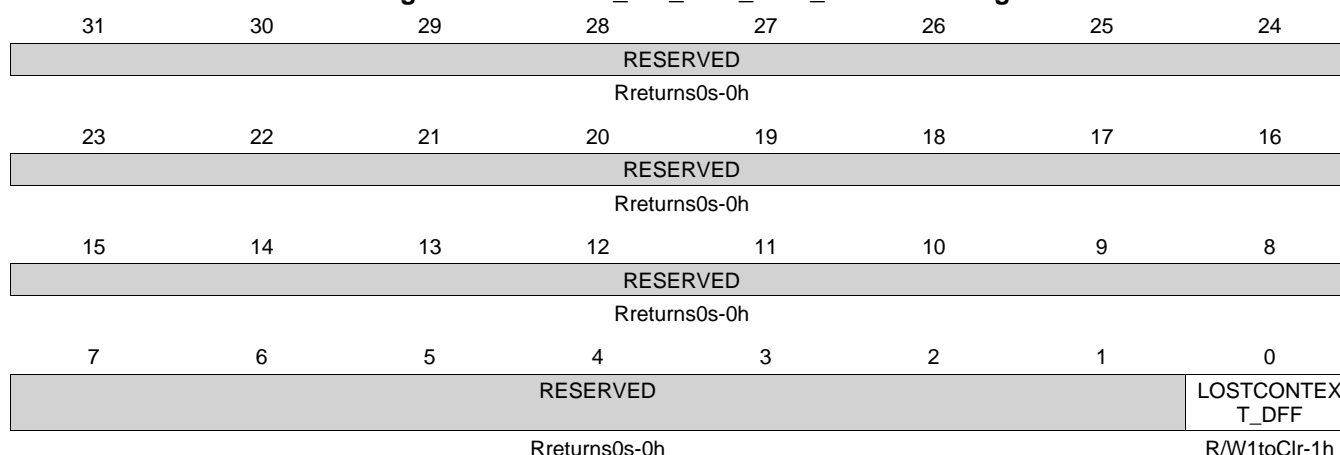

### 6.12.5.41 PRCM\_RM\_PER\_I2C1\_CONTEXT Register (offset = 4ACh) [reset = 1h]

Register mask: FFFFFFFFh

PRCM\_RM\_PER\_I2C1\_CONTEXT is shown in [Figure 6-91](#) and described in [Table 6-101](#).

This register contains dedicated I2C1 module context statuses. [warm reset insensitive]

**Figure 6-91. PRCM\_RM\_PER\_I2C1\_CONTEXT Register**

**Table 6-101. PRCM\_RM\_PER\_I2C1\_CONTEXT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	RESERVED	Rreturns0s	0h	
0	LOSTCONTEXT_DFF	R/W1toClr	1h	Specify if DFF-based context has been lost due to a previous power transition or other reset source. (set upon assertion of PER_DOM_RST signal) 0h (R/W) = Context has been maintained 1h (R/W) = Context has been lost

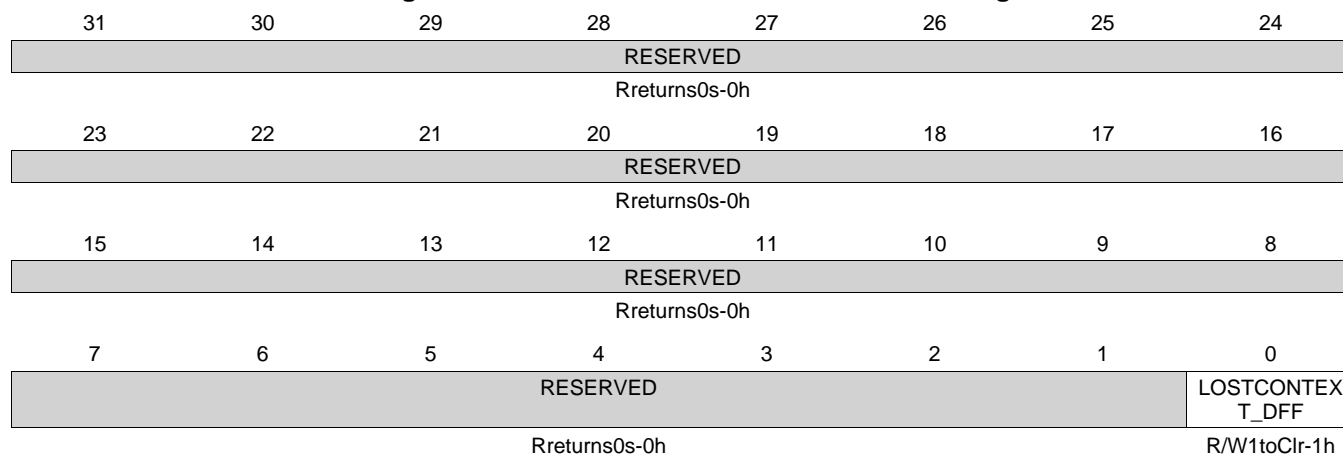

#### 6.12.5.42 PRCM\_RM\_PER\_I2C2\_CONTEXT Register (offset = 4B4h) [reset = 1h]

Register mask: FFFFFFFFh

PRCM\_RM\_PER\_I2C2\_CONTEXT is shown in [Figure 6-92](#) and described in [Table 6-102](#).

This register contains dedicated I2C2 module context statuses. [warm reset insensitive]

**Figure 6-92. PRCM\_RM\_PER\_I2C2\_CONTEXT Register**

**Table 6-102. PRCM\_RM\_PER\_I2C2\_CONTEXT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	RESERVED	Rreturns0s	0h	
0	LOSTCONTEXT_DFF	R/W1toClr	1h	Specify if DFF-based context has been lost due to a previous power transition or other reset source. (set upon assertion of PER_DOM_RST signal) 0h (R/W) = Context has been maintained 1h (R/W) = Context has been lost

### 6.12.5.43 PRCM\_RM\_PER\_MAILBOX0\_CONTEXT Register (offset = 4BCh) [reset = 1h]

Register mask: FFFFFFFFh

PRCM\_RM\_PER\_MAILBOX0\_CONTEXT is shown in [Figure 6-93](#) and described in [Table 6-103](#).

This register contains dedicated MAILBOX0 module context statuses. [warm reset insensitive]

**Figure 6-93. PRCM\_RM\_PER\_MAILBOX0\_CONTEXT Register**

**Table 6-103. PRCM\_RM\_PER\_MAILBOX0\_CONTEXT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	RESERVED	Rreturns0s	0h	
0	LOSTCONTEXT_DFF	R/W1toClr	1h	Specify if DFF-based context has been lost due to a previous power transition or other reset source. (set upon assertion of PER_DOM_RST signal) 0h (R/W) = Context has been maintained 1h (R/W) = Context has been lost

#### 6.12.5.44 PRCM\_RM\_PER\_MMC0\_CONTEXT Register (offset = 4C4h) [reset = 101h]

Register mask: FFFFFFFFh

PRCM\_RM\_PER\_MMC0\_CONTEXT is shown in [Figure 6-94](#) and described in [Table 6-104](#).

This register contains dedicated MMC0 module context statuses. [warm reset insensitive]

**Figure 6-94. PRCM\_RM\_PER\_MMC0\_CONTEXT Register**

Bit	Field	Type	Reset	Description
31-9	RESERVED	Rreturns0s	0h	
8	LOSTMEM_RETAINED_BANK	R/W1toClr	1h	Specify if memory-based context in RETAINED_BANK memory bank has been lost due to a previous power transition or other reset source. 0h (R/W) = Context has been maintained 1h (R/W) = Context has been lost
7-1	RESERVED	Rreturns0s	0h	
0	LOSTCONTEXT_DFF	R/W1toClr	1h	Specify if DFF-based context has been lost due to a previous power transition or other reset source. (set upon assertion of PER_DOM_RST signal) 0h (R/W) = Context has been maintained 1h (R/W) = Context has been lost

#### 6.12.5.45 PRCM\_RM\_PER\_MMC1\_CONTEXT Register (offset = 4CCh) [reset = 101h]

Register mask: FFFFFFFFh

PRCM\_RM\_PER\_MMC1\_CONTEXT is shown in [Figure 6-95](#) and described in [Table 6-105](#).

This register contains dedicated MMC1 module context statuses. [warm reset insensitive]

**Figure 6-95. PRCM\_RM\_PER\_MMC1\_CONTEXT Register**

**Table 6-105. PRCM\_RM\_PER\_MMC1\_CONTEXT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-9	RESERVED	Rreturns0s	0h	
8	LOSTMEM_RETAINED_BANK	R/W1toClr	1h	Specify if memory-based context in RETAINED_BANK memory bank has been lost due to a previous power transition or other reset source. 0h (R/W) = Context has been maintained 1h (R/W) = Context has been lost
7-1	RESERVED	Rreturns0s	0h	
0	LOSTCONTEXT_DFF	R/W1toClr	1h	Specify if DFF-based context has been lost due to a previous power transition or other reset source. (set upon assertion of PER_DOM_RST signal) 0h (R/W) = Context has been maintained 1h (R/W) = Context has been lost

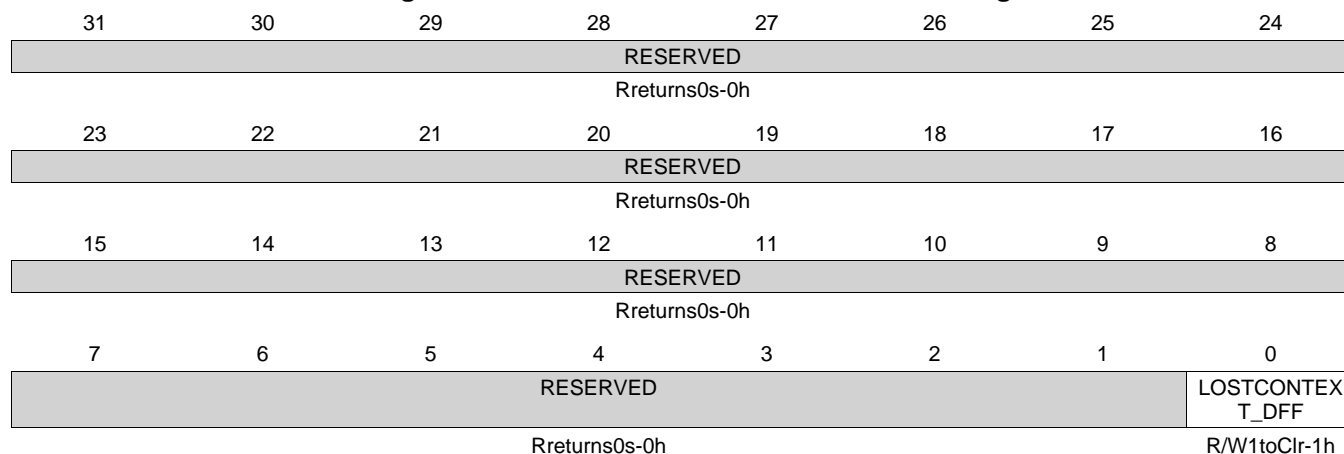

### 6.12.5.46 PRCM\_RM\_PER\_SPI0\_CONTEXT Register (offset = 504h) [reset = 1h]

Register mask: FFFFFFFFh

PRCM\_RM\_PER\_SPI0\_CONTEXT is shown in [Figure 6-96](#) and described in [Table 6-106](#).

This register contains dedicated SPI0 module context statuses. [warm reset insensitive]

**Figure 6-96. PRCM\_RM\_PER\_SPI0\_CONTEXT Register**

**Table 6-106. PRCM\_RM\_PER\_SPI0\_CONTEXT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	RESERVED	Rreturns0s	0h	
0	LOSTCONTEXT_DFF	R/W1toClr	1h	Specify if DFF-based context has been lost due to a previous power transition or other reset source. (set upon assertion of PER_DOM_RST signal) 0h (R/W) = Context has been maintained 1h (R/W) = Context has been lost

### 6.12.5.47 PRCM\_RM\_PER\_SPI1\_CONTEXT Register (offset = 50Ch) [reset = 1h]

Register mask: FFFFFFFFh

PRCM\_RM\_PER\_SPI1\_CONTEXT is shown in [Figure 6-97](#) and described in [Table 6-107](#).

This register contains dedicated SPI1 module context statuses. [warm reset insensitive]

**Figure 6-97. PRCM\_RM\_PER\_SPI1\_CONTEXT Register**

**Table 6-107. PRCM\_RM\_PER\_SPI1\_CONTEXT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	RESERVED	Rreturns0s	0h	
0	LOSTCONTEXT_DFF	R/W1toClr	1h	Specify if DFF-based context has been lost due to a previous power transition or other reset source. (set upon assertion of PER_DOM_RST signal) 0h (R/W) = Context has been maintained 1h (R/W) = Context has been lost

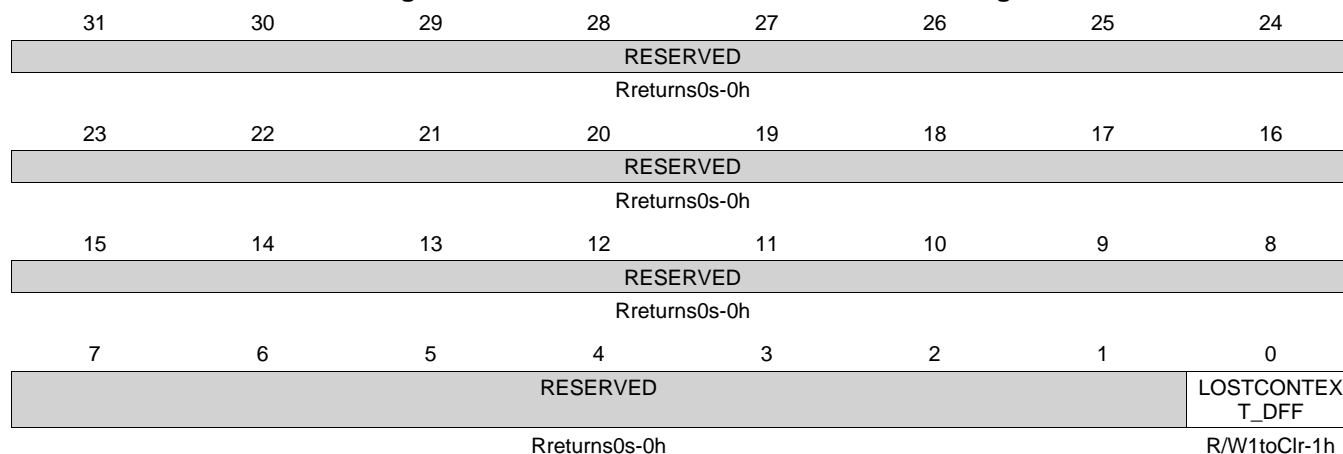

### 6.12.5.48 PRCM\_RM\_PER\_SPI2\_CONTEXT Register (offset = 514h) [reset = 1h]

Register mask: FFFFFFFFh

PRCM\_RM\_PER\_SPI2\_CONTEXT is shown in [Figure 6-98](#) and described in [Table 6-108](#).

This register contains dedicated SPI2 module context statuses. [warm reset insensitive]

**Figure 6-98. PRCM\_RM\_PER\_SPI2\_CONTEXT Register**

**Table 6-108. PRCM\_RM\_PER\_SPI2\_CONTEXT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	RESERVED	Rreturns0s	0h	
0	LOSTCONTEXT_DFF	R/W1toClr	1h	Specify if DFF-based context has been lost due to a previous power transition or other reset source. (set upon assertion of PER_DOM_RST signal) 0h (R/W) = Context has been maintained 1h (R/W) = Context has been lost

#### 6.12.5.49 PRCM\_RM\_PER\_SPI3\_CONTEXT Register (offset = 51Ch) [reset = 1h]

Register mask: FFFFFFFFh

PRCM\_RM\_PER\_SPI3\_CONTEXT is shown in [Figure 6-99](#) and described in [Table 6-109](#).

This register contains dedicated SPI3 module context statuses. [warm reset insensitive]

**Figure 6-99. PRCM\_RM\_PER\_SPI3\_CONTEXT Register**

**Table 6-109. PRCM\_RM\_PER\_SPI3\_CONTEXT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	RESERVED	Rreturns0s	0h	
0	LOSTCONTEXT_DFF	R/W1toClr	1h	Specify if DFF-based context has been lost due to a previous power transition or other reset source. (set upon assertion of PER_DOM_RST signal) 0h (R/W) = Context has been maintained 1h (R/W) = Context has been lost

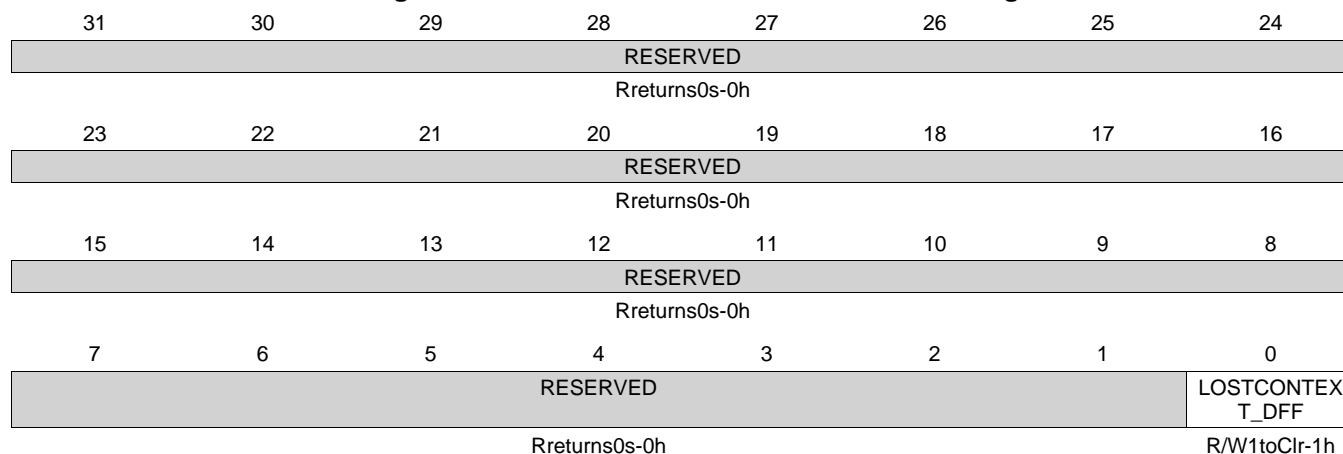

### 6.12.5.50 PRCM\_RM\_PER\_SPI4\_CONTEXT Register (offset = 524h) [reset = 1h]

Register mask: FFFFFFFFh

PRCM\_RM\_PER\_SPI4\_CONTEXT is shown in [Figure 6-100](#) and described in [Table 6-110](#).

This register contains dedicated SPI4 module context statuses. [warm reset insensitive]

**Figure 6-100. PRCM\_RM\_PER\_SPI4\_CONTEXT Register**

**Table 6-110. PRCM\_RM\_PER\_SPI4\_CONTEXT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	RESERVED	Rreturns0s	0h	
0	LOSTCONTEXT_DFF	R/W1toClr	1h	Specify if DFF-based context has been lost due to a previous power transition or other reset source. (set upon assertion of PER_DOM_RST signal) 0h (R/W) = Context has been maintained 1h (R/W) = Context has been lost

### 6.12.5.51 PRCM\_RM\_PER\_SPINLOCK\_CONTEXT Register (offset = 52Ch) [reset = 101h]

Register mask: FFFFFFFFh

PRCM\_RM\_PER\_SPINLOCK\_CONTEXT is shown in [Figure 6-101](#) and described in [Table 6-111](#).

This register contains dedicated SPINLOCK module context statuses. [warm reset insensitive]

**Figure 6-101. PRCM\_RM\_PER\_SPINLOCK\_CONTEXT Register**

**Table 6-111. PRCM\_RM\_PER\_SPINLOCK\_CONTEXT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-9	RESERVED	Rreturns0s	0h	
8	LOSTMEM_RETAINED_BANK	R/W1toClr	1h	Specify if memory-based context in RETAINED_BANK memory bank has been lost due to a previous power transition or other reset source. 0h (R/W) = Context has been maintained 1h (R/W) = Context has been lost
7-1	RESERVED	Rreturns0s	0h	
0	LOSTCONTEXT_DFF	R/W1toClr	1h	Specify if DFF-based context has been lost due to a previous power transition or other reset source. (set upon assertion of PER_DOM_RST signal) 0h (R/W) = Context has been maintained 1h (R/W) = Context has been lost

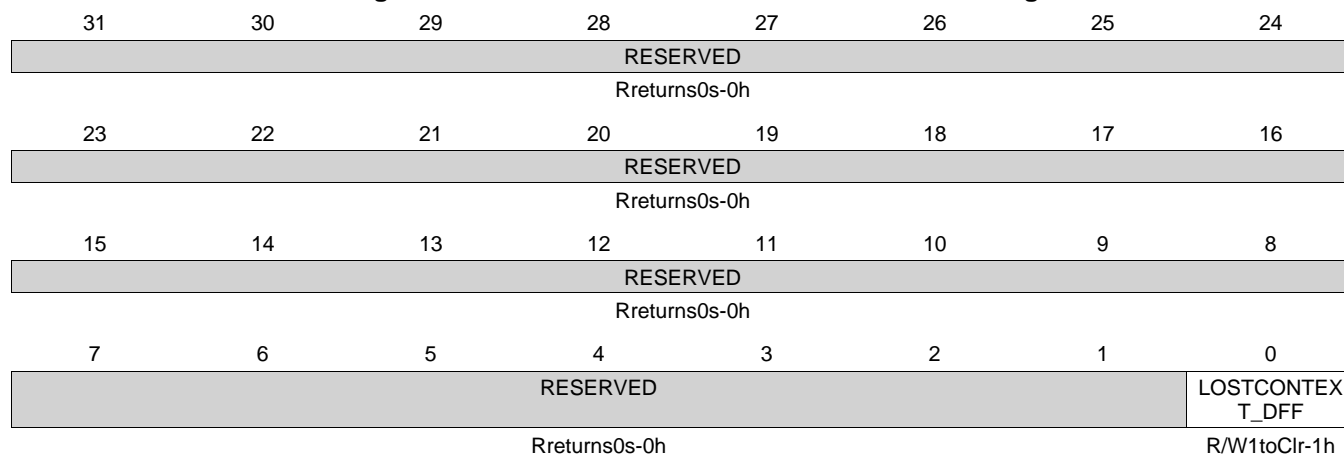

### 6.12.5.52 PRCM\_RM\_PER\_TIMER2\_CONTEXT Register (offset = 534h) [reset = 1h]

Register mask: FFFFFFFFh

PRCM\_RM\_PER\_TIMER2\_CONTEXT is shown in [Figure 6-102](#) and described in [Table 6-112](#).

This register contains dedicated TIMER2 module context statuses. [warm reset insensitive]

**Figure 6-102. PRCM\_RM\_PER\_TIMER2\_CONTEXT Register**

**Table 6-112. PRCM\_RM\_PER\_TIMER2\_CONTEXT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	RESERVED	Rreturns0s	0h	
0	LOSTCONTEXT_DFF	R/W1toClr	1h	Specify if DFF-based context has been lost due to a previous power transition or other reset source. (set upon assertion of PER_DOM_RST signal) 0h (R/W) = Context has been maintained 1h (R/W) = Context has been lost

### 6.12.5.53 PRCM\_RM\_PER\_TIMER3\_CONTEXT Register (offset = 53Ch) [reset = 1h]

Register mask: FFFFFFFFh

PRCM\_RM\_PER\_TIMER3\_CONTEXT is shown in [Figure 6-103](#) and described in [Table 6-113](#).

This register contains dedicated TIMER3 module context statuses. [warm reset insensitive]

**Figure 6-103. PRCM\_RM\_PER\_TIMER3\_CONTEXT Register**

**Table 6-113. PRCM\_RM\_PER\_TIMER3\_CONTEXT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	RESERVED	Rreturns0s	0h	
0	LOSTCONTEXT_DFF	R/W1toClr	1h	Specify if DFF-based context has been lost due to a previous power transition or other reset source. (set upon assertion of PER_DOM_RST signal) 0h (R/W) = Context has been maintained 1h (R/W) = Context has been lost

#### 6.12.5.54 PRCM\_RM\_PER\_TIMER4\_CONTEXT Register (offset = 544h) [reset = 1h]

Register mask: FFFFFFFFh

PRCM\_RM\_PER\_TIMER4\_CONTEXT is shown in [Figure 6-104](#) and described in [Table 6-114](#).

This register contains dedicated TIMER4 module context statuses. [warm reset insensitive]

**Figure 6-104. PRCM\_RM\_PER\_TIMER4\_CONTEXT Register**

**Table 6-114. PRCM\_RM\_PER\_TIMER4\_CONTEXT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	RESERVED	Rreturns0s	0h	
0	LOSTCONTEXT_DFF	R/W1toClr	1h	Specify if DFF-based context has been lost due to a previous power transition or other reset source. (set upon assertion of PER_DOM_RST signal) 0h (R/W) = Context has been maintained 1h (R/W) = Context has been lost

### 6.12.5.55 PRCM\_RM\_PER\_TIMER5\_CONTEXT Register (offset = 54Ch) [reset = 1h]

Register mask: FFFFFFFFh

PRCM\_RM\_PER\_TIMER5\_CONTEXT is shown in [Figure 6-105](#) and described in [Table 6-115](#).

This register contains dedicated TIMER5 module context statuses. [warm reset insensitive]

**Figure 6-105. PRCM\_RM\_PER\_TIMER5\_CONTEXT Register**

**Table 6-115. PRCM\_RM\_PER\_TIMER5\_CONTEXT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	RESERVED	Rreturns0s	0h	
0	LOSTCONTEXT_DFF	R/W1toClr	1h	Specify if DFF-based context has been lost due to a previous power transition or other reset source. (set upon assertion of PER_DOM_RST signal) 0h (R/W) = Context has been maintained 1h (R/W) = Context has been lost

### 6.12.5.56 PRCM\_RM\_PER\_TIMER6\_CONTEXT Register (offset = 554h) [reset = 1h]

Register mask: FFFFFFFFh

PRCM\_RM\_PER\_TIMER6\_CONTEXT is shown in [Figure 6-106](#) and described in [Table 6-116](#).

This register contains dedicated TIMER6 module context statuses. [warm reset insensitive]

**Figure 6-106. PRCM\_RM\_PER\_TIMER6\_CONTEXT Register**

**Table 6-116. PRCM\_RM\_PER\_TIMER6\_CONTEXT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	RESERVED	Rreturns0s	0h	
0	LOSTCONTEXT_DFF	R/W1toClr	1h	Specify if DFF-based context has been lost due to a previous power transition or other reset source. (set upon assertion of PER_DOM_RST signal) 0h (R/W) = Context has been maintained 1h (R/W) = Context has been lost

### 6.12.5.57 PRCM\_RM\_PER\_TIMER7\_CONTEXT Register (offset = 55Ch) [reset = 1h]

Register mask: FFFFFFFFh

PRCM\_RM\_PER\_TIMER7\_CONTEXT is shown in [Figure 6-107](#) and described in [Table 6-117](#).

This register contains dedicated TIMER7 module context statuses. [warm reset insensitive]

**Figure 6-107. PRCM\_RM\_PER\_TIMER7\_CONTEXT Register**

**Table 6-117. PRCM\_RM\_PER\_TIMER7\_CONTEXT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	RESERVED	Rreturns0s	0h	
0	LOSTCONTEXT_DFF	R/W1toClr	1h	Specify if DFF-based context has been lost due to a previous power transition or other reset source. (set upon assertion of PER_DOM_RST signal) 0h (R/W) = Context has been maintained 1h (R/W) = Context has been lost

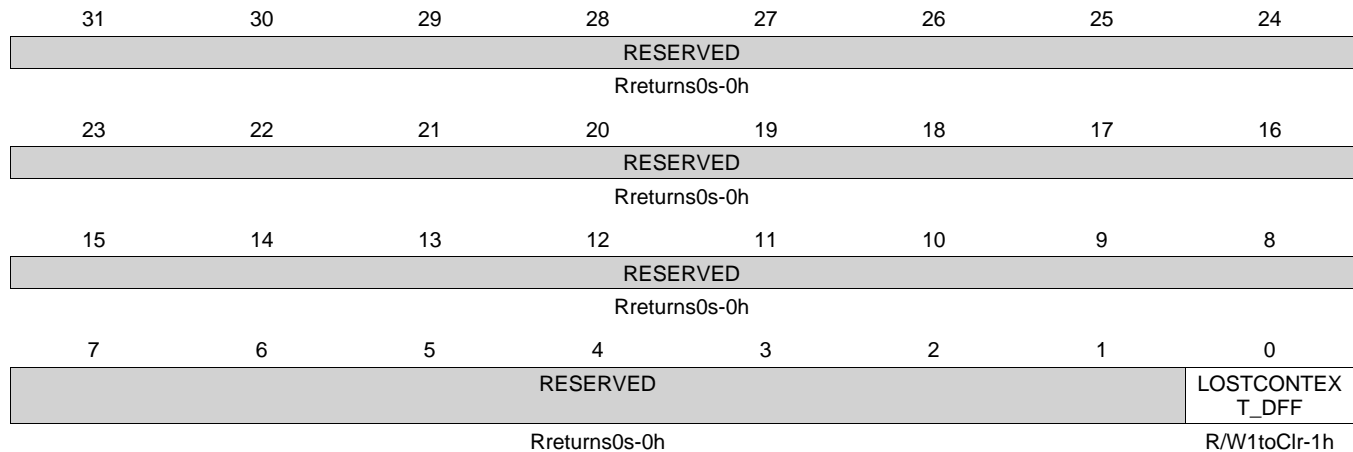

### 6.12.5.58 PRCM\_RM\_PER\_TIMER8\_CONTEXT Register (offset = 564h) [reset = 1h]

Register mask: FFFFFFFFh

PRCM\_RM\_PER\_TIMER8\_CONTEXT is shown in [Figure 6-108](#) and described in [Table 6-118](#).

This register contains dedicated TIMER8 module context statuses. [warm reset insensitive]

**Figure 6-108. PRCM\_RM\_PER\_TIMER8\_CONTEXT Register**

**Table 6-118. PRCM\_RM\_PER\_TIMER8\_CONTEXT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	RESERVED	Rreturns0s	0h	
0	LOSTCONTEXT_DFF	R/W1toClr	1h	Specify if DFF-based context has been lost due to a previous power transition or other reset source. (set upon assertion of PER_DOM_RST signal) 0h (R/W) = Context has been maintained 1h (R/W) = Context has been lost

### 6.12.5.59 PRCM\_RM\_PER\_TIMER9\_CONTEXT Register (offset = 56Ch) [reset = 1h]

Register mask: FFFFFFFFh

PRCM\_RM\_PER\_TIMER9\_CONTEXT is shown in [Figure 6-109](#) and described in [Table 6-119](#).

This register contains dedicated TIMER9 module context statuses. [warm reset insensitive]

**Figure 6-109. PRCM\_RM\_PER\_TIMER9\_CONTEXT Register**

**Table 6-119. PRCM\_RM\_PER\_TIMER9\_CONTEXT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	RESERVED	Rreturns0s	0h	
0	LOSTCONTEXT_DFF	R/W1toClr	1h	Specify if DFF-based context has been lost due to a previous power transition or other reset source. (set upon assertion of PER_DOM_RST signal) 0h (R/W) = Context has been maintained 1h (R/W) = Context has been lost

### 6.12.5.60 PRCM\_RM\_PER\_TIMER10\_CONTEXT Register (offset = 574h) [reset = 1h]

Register mask: FFFFFFFFh

PRCM\_RM\_PER\_TIMER10\_CONTEXT is shown in [Figure 6-110](#) and described in [Table 6-120](#).

This register contains dedicated TIMER10 module context statuses. [warm reset insensitive]

**Figure 6-110. PRCM\_RM\_PER\_TIMER10\_CONTEXT Register**

**Table 6-120. PRCM\_RM\_PER\_TIMER10\_CONTEXT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	RESERVED	Rreturns0s	0h	
0	LOSTCONTEXT_DFF	R/W1toClr	1h	Specify if DFF-based context has been lost due to a previous power transition or other reset source. (set upon assertion of PER_DOM_RST signal) 0h (R/W) = Context has been maintained 1h (R/W) = Context has been lost

### 6.12.5.61 PRCM\_RM\_PER\_TIMER11\_CONTEXT Register (offset = 57Ch) [reset = 1h]

Register mask: FFFFFFFFh

PRCM\_RM\_PER\_TIMER11\_CONTEXT is shown in [Figure 6-111](#) and described in [Table 6-121](#).

This register contains dedicated TIMER11 module context statuses. [warm reset insensitive]

**Figure 6-111. PRCM\_RM\_PER\_TIMER11\_CONTEXT Register**

**Table 6-121. PRCM\_RM\_PER\_TIMER11\_CONTEXT Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	RESERVED	Rreturns0s	0h	
0	LOSTCONTEXT_DFF	R/W1toClr	1h	Specify if DFF-based context has been lost due to a previous power transition or other reset source. (set upon assertion of PER_DOM_RST signal) 0h (R/W) = Context has been maintained 1h (R/W) = Context has been lost

### 6.12.5.62 PRCM\_RM\_PER\_UART1\_CONTEXT Register (offset = 584h) [reset = 101h]

Register mask: FFFFFFFFh

PRCM\_RM\_PER\_UART1\_CONTEXT is shown in [Figure 6-112](#) and described in [Table 6-122](#).

This register contains dedicated UART1 module context statuses. [warm reset insensitive]

**Figure 6-112. PRCM\_RM\_PER\_UART1\_CONTEXT Register**

### 6.12.6 PRCM\_PRM\_RTC Registers

[Table 6-134](#) lists the memory-mapped registers for the PRCM\_PRM\_RTC. All register offset addresses not listed in [Table 6-134](#) should be considered as reserved locations and the register contents should not be modified.

**Table 6-134. PRCM\_PRM\_RTC REGISTERS**

Offset	Acronym	Register Name	Section
24h	PRCM_RM_RTC_CONTEXT		<a href="#">Section 6.12.6.1</a>

### 6.12.6.1 PRCM\_RM\_RTC\_CONTEXT Register (offset = 24h) [reset = 1h]

Register mask: FFFFFFFFh

PRCM\_RM\_RTC\_CONTEXT is shown in [Figure 6-124](#) and described in [Table 6-135](#).

This register contains dedicated RTC module context statuses. [warm reset insensitive]

### 6.12.7 PRM\_WKUP Registers

[Table 6-136](#) lists the memory-mapped registers for the PRM\_WKUP. All register offset addresses not listed in [Table 6-136](#) should be considered as reserved locations and the register contents should not be modified.

**Table 6-136. PRM\_WKUP Registers**

Offset	Acronym	Register Name	Section
10h	PRCM_RM_WKUP_RSTCTRL		<a href="#">Section 6.12.7.1</a>
14h	PRCM_RM_WKUP_RSTST		<a href="#">Section 6.12.7.2</a>

### 6.12.7.1 PRCM\_RM\_WKUP\_RSTCTRL Register (offset = 10h) [reset = 8h]

Register mask: FFFFFFFFh

PRCM\_RM\_WKUP\_RSTCTRL is shown in [Figure 6-125](#) and described in [Table 6-137](#).

This register controls the release of the ALWAYS ON Domain resets.

**Figure 6-125. PRCM\_RM\_WKUP\_RSTCTRL Register**

31-6	RESERVED	Rreturns0s	0h	
5-4	RESERVED	Rreturns0s	0h	
3	WKUP_PROC_LRST	R/W	1h	Assert Reset to WKUP_PROC 0h (R/W) = Reset is cleared for the Wakeup Processor 1h (R/W) = Reset is asserted for the Wakeup Processor by the A9
2-0	RESERVED	Rreturns0s	0h	

### 6.12.7.2 PRCM\_RM\_WKUP\_RSTST Register (offset = 14h) [reset = 0h]

Register mask: FFFFFFFFh

PRCM\_RM\_WKUP\_RSTST is shown in [Figure 6-126](#) and described in [Table 6-138](#).

This register logs the different reset sources of the ALWON domain. Each bit is set upon release of the domain reset signal. Must be cleared by software. [warm reset insensitive]

7	ICECRUSHER_WKUP_PROC_RST	R/W1toClr	0h	Wakeup Processor has been reset due to Wakeup Processor ICECRUSHER1 reset event 0h (R/W) = No reset 1h (R/W) = Wakeup Processor has been reset
6	EMULATION_WKUP_PROC_RST	R/W1toClr	0h	Wakeup Processor has been reset due to emulation reset source e.g. assert reset command initiated by the icepick module 0h (R/W) = No reset 1h (R/W) = Wakeup Processor has been reset
5	WKUP_PROC_LRST	R/W1toClr	0h	Wakeup Processor has been reset 0h (R/W) = No reset 1h (R/W) = Wakeup Processor has been reset
4-0	RESERVED	Rreturns0s	0h	

### 6.12.7.3 PRCM\_RM\_WKUP\_DBGSS\_CONTEXT Register (offset = 24h) [reset = 101h]

Register mask: FFFFFFFFh

PRCM\_RM\_WKUP\_DBGSS\_CONTEXT is shown in [Figure 6-127](#) and described in [Table 6-139](#).

This register contains dedicated DEBUGSS module context statuses.

[warm reset insensitive]

**Table 6-151. PRCM\_REVISION Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-30	SCHEME	Rreturns	1h	Used to distinguish between old scheme and current. 0h (R) = Legacy ASP or WTBUS scheme 1h (R) = Highlander 0.8 scheme
29-28	RESERVED	Rreturns0s	0h	
27-16	FUNC	Rreturns0s	0h	Function indicates a software compatible module family.
15-11	R_RTL	Rreturns0s	0h	RTL Version (R), maintained by IP design owner.
10-8	X_MAJOR	Rreturns	4h	Major Revision (X), maintained by IP specification owner. 0h (R) = Reserved 1h (R) = Reserved
7-6	CUSTOM	Rreturns0s	0h	Indicates a special version for a particular device. 0h (R) = Non custom (standard) revision
5-0	Y_MINOR	Rreturns	0h	Minor Revision (Y), maintained by IP specification owner. 0h (R) = ES1.0 and similar versions

### 6.12.8.2 PRCM\_PRM\_IRQSTS\_MPU Register (offset = 4h) [reset = 0h]

Register mask: FFFFFFFFh

PRCM\_PRM\_IRQSTS\_MPU is shown in [Figure 6-139](#) and described in [Table 6-152](#).

This register provides status on MPU interrupt events. An event is logged whether interrupt generation for the event is enabled or not. SW is required to clear a set bit by writing a '1' into the bit-position to be cleared.

**Figure 6-139. PRCM\_PRM\_IRQSTS\_MPU Register**

#### 6.12.8.4 PRCM\_PRM\_IRQSTS\_WKUP\_PROC Register (offset = Ch) [reset = 0h]

Register mask: FFFFFFFFh

PRCM\_PRM\_IRQSTS\_WKUP\_PROC is shown in [Figure 6-141](#) and described in [Table 6-154](#).

This register provides status on Wakeup Processor interrupt events. An event is logged whether interrupt generation for the event is enabled or not. SW is required to clear a set bit by writing a '1' into the bit-position to be cleared.

## 6.13 Clock Module Registers

### 6.13.1 PRCM\_CM\_CEFUSE Registers

[Table 6-156](#) lists the memory-mapped registers for the PRCM\_CM\_CEFUSE. All register offset addresses not listed in [Table 6-156](#) should be considered as reserved locations and the register contents should not be modified.

**Table 6-156. PRCM\_CM\_CEFUSE REGISTERS**

Offset	Acronym	Register Name	Section
0h	PRCM_CM_CEFUSE_CLKSTCTRL		<a href="#">Section 6.13.1.1</a>
20h	PRCM_CM_CEFUSE_CLKCTRL		<a href="#">Section 6.13.1.2</a>

### 6.13.1.1 PRCM\_CM\_CEFUSE\_CLKSTCTRL Register (offset = 0h) [reset = 2h]

Register mask: FFFFFFFFh

PRCM\_CM\_CEFUSE\_CLKSTCTRL is shown in [Figure 6-143](#) and described in [Table 6-157](#).

This register enables the domain power state transition. It controls the HW supervised domain power state transition between ON-ACTIVE and ON-INACTIVE states. It also hold one status bit per clock input of the domain.

**Figure 6-143. PRCM\_CM\_CEFUSE\_CLKSTCTRL Register**

Bit	Field	Type	Reset	Description
31-10	RESERVED	Rreturns0s	0h	
9	CLKACTIVITY_CUST_EFUSE_SYS_CLK	R	0h	This field indicates the state of the Cust_Efuse_SYSCLK clock input of the domain. [warm reset insensitive] 0h (R) = Corresponding clock is gated 1h (R) = Corresponding clock is active
8	CLKACTIVITY_L4_CEFUSE_GICLK	R	0h	This field indicates the state of the L4_CEFUSE_GCLK clock input of the domain. [warm reset insensitive] 0h (R) = Corresponding clock is gated 1h (R) = Corresponding clock is active
7-2	RESERVED	Rreturns0s	0h	
1-0	CLKTRCTRL	R/W	2h	Controls the clock state transition of the clock domain in customer efuse power domain. 0h (R/W) = NO_SLEEP: Sleep transition cannot be initiated. Wakeup transition may however occur. 1h (R/W) = SW_SLEEP: Start a software forced sleep transition on the domain. 2h (R/W) = SW_WKUP: Start a software forced wake-up transition on the domain. 3h (R/W) = Reserved

### 6.13.1.2 PRCM\_CM\_CEFUSE\_CLKCTRL Register (offset = 20h) [reset = 30000h]

Register mask: FFFFFFFFh

PRCM\_CM\_CEFUSE\_CLKCTRL is shown in [Figure 6-144](#) and described in [Table 6-158](#).

This register manages the CEFUSE clocks.

**Figure 6-144. PRCM\_CM\_CEFUSE\_CLKCTRL Register**

31	30	29	28	27	26	25	24
RESERVED

Bit	Field	Type	Reset	Description
31-18	RESERVED	Rreturns0s	0h	
17-16	IDLEST	R	3h	Module idle status. [warm reset insensitive] 0h (R) = Module is fully functional, including OCP 1h (R) = Module is performing transition: wakeup, or sleep, or sleep abortion 2h (R) = Module is in Idle mode (only OCP part). It is functional if using separate functional clock 3h (R) = Module is disabled and cannot be accessed
15-2	RESERVED	Rreturns0s	0h	
1-0	MODULEMODE	R/W	0h	Control the way mandatory clocks are managed. 0h (R/W) = Module is disable by SW. Any OCP access to module results in an error, except if resulting from a module wakeup (asynchronous wakeup). 1h (R) = Reserved 2h (R/W) = Module is explicitly enabled. Interface clock (if not used for functions) may be gated according to the clock domain state. Functional clocks are guarantied to stay present. As long as in this configuration, power domain sleep transition cannot happen. 3h (R) = Reserved

### 6.13.2 PRCM\_CM\_DEVICE Registers

Table 6-159 lists the memory-mapped registers for the PRCM\_CM\_DEVICE. All register offset addresses not listed in Table 6-159 should be considered as reserved locations and the register contents should not be modified.

**Table 6-159. PRCM\_CM\_DEVICE REGISTERS**

Offset	Acronym	Register Name	Section

Bit	Field	Type	Reset	Description
31-3	RESERVED	Rreturns0s	0h	
2	DLL_READYST	R	0h	Gives the DLL ready status. It is the AND of individual DLL_READY signals. 0h (R) = 0 1h (R) = 1
1	DLL_RESET	R/W	0h	Controls DLL Reset. Applicable only for DVFS. This reset is to be used only during DVFS when DLL frequency is being changed 0h (R/W) = No Reset to DLL 1h (R/W) = Reset DLL
0	DLL_OVERRIDE	R/W	1h	Control if DLL lock and code outputs are overridden or not 0h (R/W) = Lock and code outputs are not overridden 1h (R/W) = Lock output is overridden to '1' and code output is overridden with a value coming from control module.

### 6.13.2.3 PRCM\_CM\_CLKOUT2\_CTRL Register (offset = 8h) [reset = 0h]

Register mask: FFFFFFFFh

PRCM\_CM\_CLKOUT2\_CTRL is shown in [Figure 6-147](#) and described in [Table 6-162](#).

This register provides the control over CLKOUT2 output

**Figure 6-147. PRCM\_CM\_CLKOUT2\_CTRL Register**

### 6.13.3.1 PRCM\_CM\_DPLL\_DPLL\_CLKSEL\_TIMER1\_CLK Register (offset = 0h) [reset = 0h]

Register mask: FFFFFFFFh

PRCM\_CM\_DPLL\_DPLL\_CLKSEL\_TIMER1\_CLK is shown in [Figure 6-148](#) and described in [Table 6-164](#).

Selects the Mux select line for TIMER1 clock [warm reset insensitive]

**Figure 6-148. PRCM\_CM\_DPLL\_DPLL\_CLKSEL\_TIMER1\_CLK Register**

**Table 6-164. PRCM\_CM\_DPLL\_DPLL\_CLKSEL\_TIMER1\_CLK Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-3	RSVD	Rreturns0s	0h	
2-0	CLKSEL	R/W	0h	<p>Selects the Mux select line for DMTIMER_1MS clock [warm reset insensitive]</p> <p>0h (R/W) = Select CLK_M_OSC clock</p> <p>1h (R/W) = Select CLK_32KHZ clock from PER_PLL divided clock</p> <p>2h (R/W) = Select TCLKIN clock</p> <p>3h (R/W) = Select CLK_RC32K clock</p> <p>4h (R/W) = Selects the 32KHz clock from RTC 32KHz Crystal Osc</p> <p>5h (R/W) = Reserved</p>

### 6.13.3.2 PRCM\_CM\_DPLL\_CLKSEL\_TIMER2\_CLK Register (offset = 4h) [reset = 1h]

Register mask: FFFFFFFFh

PRCM\_CM\_DPLL\_CLKSEL\_TIMER2\_CLK is shown in [Figure 6-149](#) and described in [Table 6-165](#).

Selects the Mux select line for TIMER2 clock [warm reset insensitive]

**Figure 6-149. PRCM\_CM\_DPLL\_CLKSEL\_TIMER2\_CLK Register**

**Table 6-165. PRCM\_CM\_DPLL\_CLKSEL\_TIMER2\_CLK Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-2	RESERVED	Rreturns0s	0h	
1-0	CLKSEL	R/W	1h	Selects the Mux select line for TIMER2 clock [warm reset insensitive] 0h (R/W) = Select TCLKIN clock 1h (R/W) = Select CLK_M_OSC clock 2h (R/W) = Select CLK_32KHZ clock 3h (R/W) = Reserved

### 6.13.3.3 PRCM\_CM\_DPLL\_CLKSEL\_TIMER3\_CLK Register (offset = 8h) [reset = 1h]

Register mask: FFFFFFFFh

PRCM\_CM\_DPLL\_CLKSEL\_TIMER3\_CLK is shown in [Figure 6-150](#) and described in [Table 6-166](#).

Selects the Mux select line for TIMER3 clock [warm reset insensitive]

**Figure 6-150. PRCM\_CM\_DPLL\_CLKSEL\_TIMER3\_CLK Register**

**Table 6-166. PRCM\_CM\_DPLL\_CLKSEL\_TIMER3\_CLK Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-2	RESERVED	Rreturns0s	0h	
1-0	CLKSEL	R/W	1h	Selects the Mux select line for TIMER3 clock [warm reset insensitive] 0h (R/W) = Select TCLKIN clock 1h (R/W) = Select CLK_M_OSC clock 2h (R/W) = Select CLK_32KHZ clock 3h (R/W) = Reserved

### 6.13.3.4 PRCM\_CM\_DPLL\_CLKSEL\_TIMER4\_CLK Register (offset = Ch) [reset = 1h]

Register mask: FFFFFFFFh

PRCM\_CM\_DPLL\_CLKSEL\_TIMER4\_CLK is shown in [Figure 6-151](#) and described in [Table 6-167](#).

Selects the Mux select line for TIMER4 clock [warm reset insensitive]

**Figure 6-151. PRCM\_CM\_DPLL\_CLKSEL\_TIMER4\_CLK Register**

**Table 6-167. PRCM\_CM\_DPLL\_CLKSEL\_TIMER4\_CLK Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-2	RESERVED	Rreturns0s	0h	
1-0	CLKSEL	R/W	1h	Selects the Mux select line for TIMER4 clock [warm reset insensitive] 0h (R/W) = Select TCLKIN clock 1h (R/W) = Select CLK_M_OSC clock 2h (R/W) = Select CLK_32KHZ clock 3h (R/W) = Reserved

### 6.13.3.5 PRCM\_CM\_DPLL\_CLKSEL\_TIMER5\_CLK Register (offset = 10h) [reset = 1h]

Register mask: FFFFFFFFh

PRCM\_CM\_DPLL\_CLKSEL\_TIMER5\_CLK is shown in [Figure 6-152](#) and described in [Table 6-168](#).

Selects the Mux select line for TIMER5 clock [warm reset insensitive]

**Figure 6-152. PRCM\_CM\_DPLL\_CLKSEL\_TIMER5\_CLK Register**

**Table 6-168. PRCM\_CM\_DPLL\_CLKSEL\_TIMER5\_CLK Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-2	RESERVED	Rreturns0s	0h	
1-0	CLKSEL	R/W	1h	Selects the Mux select line for TIMER5 clock [warm reset insensitive] 0h (R/W) = Select TCLKIN clock 1h (R/W) = Select CLK_M_OSC clock 2h (R/W) = Select CLK_32KHZ clock 3h (R/W) = Reserved

### 6.13.3.6 PRCM\_CM\_DPLL\_CLKSEL\_TIMER6\_CLK Register (offset = 14h) [reset = 1h]

Register mask: FFFFFFFFh

PRCM\_CM\_DPLL\_CLKSEL\_TIMER6\_CLK is shown in [Figure 6-153](#) and described in [Table 6-169](#).

Selects the Mux select line for TIMER6 clock [warm reset insensitive]

**Figure 6-153. PRCM\_CM\_DPLL\_CLKSEL\_TIMER6\_CLK Register**

**Table 6-169. PRCM\_CM\_DPLL\_CLKSEL\_TIMER6\_CLK Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-2	RESERVED	Rreturns0s	0h	
1-0	CLKSEL	R/W	1h	Selects the Mux select line for TIMER6 clock [warm reset insensitive] 0h (R/W) = Select TCLKIN clock 1h (R/W) = Select CLK_M_OSC clock 2h (R/W) = Select CLK_32KHZ clock 3h (R/W) = Reserved

### 6.13.3.7 PRCM\_CM\_DPLL\_CLKSEL\_TIMER7\_CLK Register (offset = 18h) [reset = 1h]

Register mask: FFFFFFFFh

PRCM\_CM\_DPLL\_CLKSEL\_TIMER7\_CLK is shown in [Figure 6-154](#) and described in [Table 6-170](#).

Selects the Mux select line for TIMER7 clock [warm reset insensitive]

**Figure 6-154. PRCM\_CM\_DPLL\_CLKSEL\_TIMER7\_CLK Register**

**Table 6-170. PRCM\_CM\_DPLL\_CLKSEL\_TIMER7\_CLK Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-2	RESERVED	Rreturns0s	0h	
1-0	CLKSEL	R/W	1h	Selects the Mux select line for TIMER7 clock [warm reset insensitive] 0h (R/W) = Select TCLKIN clock 1h (R/W) = Select CLK_M_OSC clock 2h (R/W) = Select CLK_32KHZ clock 3h (R/W) = Reserved

### 6.13.3.8 PRCM\_CM\_DPLL\_CLKSEL\_TIMER8\_CLK Register (offset = 1Ch) [reset = 1h]

Register mask: FFFFFFFFh

PRCM\_CM\_DPLL\_CLKSEL\_TIMER8\_CLK is shown in [Figure 6-155](#) and described in [Table 6-171](#).

Selects the Mux select line for TIMER8 clock [warm reset insensitive]

**Figure 6-155. PRCM\_CM\_DPLL\_CLKSEL\_TIMER8\_CLK Register**

**Table 6-171. PRCM\_CM\_DPLL\_CLKSEL\_TIMER8\_CLK Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-2	RSVD	Rreturns0s	0h	
1-0	CLKSEL	R/W	1h	Selects the Mux select line for TIMER8 clock [warm reset insensitive] 0h (R/W) = Select TCLKIN clock 1h (R/W) = Select CLK_M_OSC clock 2h (R/W) = Select CLK_32KHZ clock 3h (R/W) = Reserved

### 6.13.3.9 PRCM\_CM\_DPLL\_CLKSEL\_TIMER9\_CLK Register (offset = 20h) [reset = 1h]

Register mask: FFFFFFFFh

PRCM\_CM\_DPLL\_CLKSEL\_TIMER9\_CLK is shown in [Figure 6-156](#) and described in [Table 6-172](#).

Selects the Mux select line for TIMER9 clock [warm reset insensitive]

**Figure 6-156. PRCM\_CM\_DPLL\_CLKSEL\_TIMER9\_CLK Register**

**Table 6-172. PRCM\_CM\_DPLL\_CLKSEL\_TIMER9\_CLK Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-2	RSVD	Rreturns0s	0h	
1-0	CLKSEL	R/W	1h	Selects the Mux select line for TIMER9 clock [warm reset insensitive] 0h (R/W) = Select TCLKIN clock 1h (R/W) = Select CLK_M_OSC clock 2h (R/W) = Select CLK_32KHZ clock 3h (R/W) = Reserved

### 6.13.3.10 PRCM\_CM\_DPLL\_CLKSEL\_TIMER10\_CLK Register (offset = 24h) [reset = 1h]

Register mask: FFFFFFFFh

PRCM\_CM\_DPLL\_CLKSEL\_TIMER10\_CLK is shown in [Figure 6-157](#) and described in [Table 6-173](#).

Selects the Mux select line for TIMER10 clock [warm reset insensitive]

**Figure 6-157. PRCM\_CM\_DPLL\_CLKSEL\_TIMER10\_CLK Register**

**Table 6-173. PRCM\_CM\_DPLL\_CLKSEL\_TIMER10\_CLK Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-2	RSVD	Rreturns0s	0h	
1-0	CLKSEL	R/W	1h	Selects the Mux select line for TIMER10 clock [warm reset insensitive] 0h (R/W) = Select TCLKIN clock 1h (R/W) = Select CLK_M_OSC clock 2h (R/W) = Select CLK_32KHZ clock 3h (R/W) = Reserved

### 6.13.3.11 PRCM\_CM\_DPLL\_CLKSEL\_TIMER11\_CLK Register (offset = 28h) [reset = 1h]

Register mask: FFFFFFFFh

PRCM\_CM\_DPLL\_CLKSEL\_TIMER11\_CLK is shown in [Figure 6-158](#) and described in [Table 6-174](#).

Selects the Mux select line for TIMER11 clock [warm reset insensitive]

**Figure 6-158. PRCM\_CM\_DPLL\_CLKSEL\_TIMER11\_CLK Register**

**Table 6-174. PRCM\_CM\_DPLL\_CLKSEL\_TIMER11\_CLK Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-2	RSVD	Rreturns0s	0h	
1-0	CLKSEL	R/W	1h	Selects the Mux select line for TIMER11 clock [warm reset insensitive] 0h (R/W) = Select TCLKIN clock 1h (R/W) = Select CLK_M_OSC clock 2h (R/W) = Select CLK_32KHZ clock 3h (R/W) = Reserved

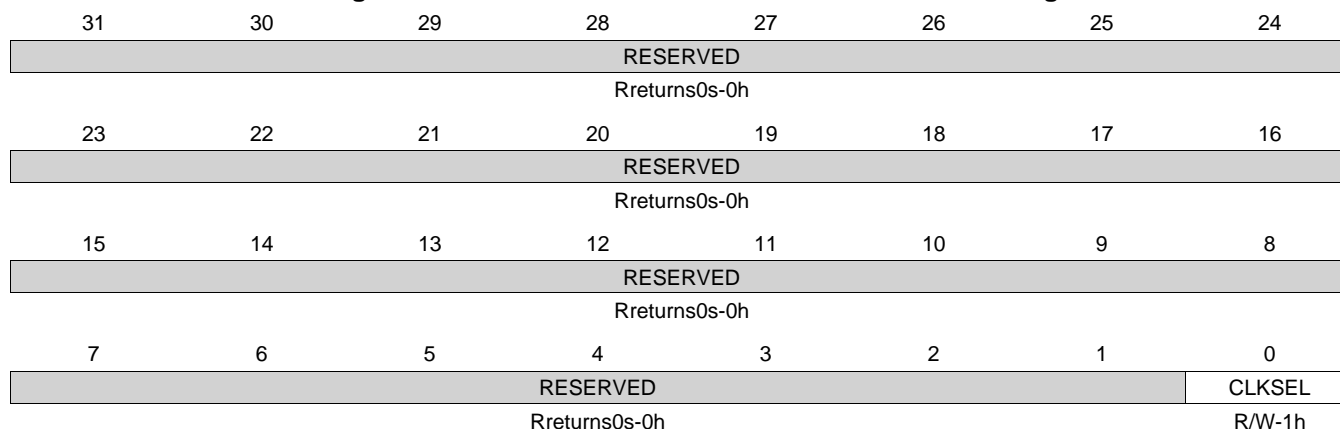

### 6.13.3.12 PRCM\_CM\_DPLL\_CLKSEL\_WDT1\_CLK Register (offset = 2Ch) [reset = 1h]

Register mask: FFFFFFFFh

PRCM\_CM\_DPLL\_CLKSEL\_WDT1\_CLK is shown in [Figure 6-159](#) and described in [Table 6-175](#).

Selects the Mux select line for Watchdog1 clock [warm reset insensitive]

**Figure 6-159. PRCM\_CM\_DPLL\_CLKSEL\_WDT1\_CLK Register**

**Table 6-175. PRCM\_CM\_DPLL\_CLKSEL\_WDT1\_CLK Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	RESERVED	Rreturns0s	0h	
0	CLKSEL	R/W	1h	Selects the Mux select line for WDT1 clock [warm reset insensitive] 0h (R/W) = Select 32KHZ clock from RC Oscillator 1h (R/W) = Select 32KHZ from 32K Clock divider

### 6.13.3.13 PRCM\_CM\_DPLL\_CLKSEL\_SYNCTIMER\_CLK Register (offset = 30h) [reset = 0h]

Register mask: FFFFFFFFh

PRCM\_CM\_DPLL\_CLKSEL\_SYNCTIMER\_CLK is shown in [Figure 6-160](#) and described in [Table 6-176](#).

Selects the Mux select line for SYNCTIMER clock [warm reset insensitive]

**Figure 6-160. PRCM\_CM\_DPLL\_CLKSEL\_SYNCTIMER\_CLK Register**

**Table 6-176. PRCM\_CM\_DPLL\_CLKSEL\_SYNCTIMER\_CLK Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-2	RSVD	Rreturns0s	0h	
1-0	CLKSEL	R/W	0h	Selects the Mux select line for SYNCTIMER clock 0h (R/W) = Select RTC 32K clock 1h (R/W) = Reserved 2h (R/W) = Select PER PLL 32KHz clock 3h (R/W) = Reserved

### 6.13.3.14 PRCM\_CM\_DPLL\_CLKSEL\_MAC\_CLK Register (offset = 34h) [reset = 4h]

Register mask: FFFFFFFFh

PRCM\_CM\_DPLL\_CLKSEL\_MAC\_CLK is shown in [Figure 6-161](#) and described in [Table 6-177](#).

Selects the clock divide ration for MII clock [warm reset insensitive]

**Figure 6-161. PRCM\_CM\_DPLL\_CLKSEL\_MAC\_CLK Register**

31	30	29	28	27	26	25	24

Bit	Field	Type	Reset	Description
31-3	RESERVED	Rreturns0s	0h	
2	MII_CLK_SEL	R/W	1h	MII Clock Divider Selection. This bit is warm reset insensitive when CPSW RESET_ISO is enabled 0h (R/W) = Selects 1/2 divider of SYSCLK2 1h (R/W) = Selects 1/5 divide ratio of SYSCLK2
1-0	RESERVED	Rreturns0s	0h	

### 6.13.3.15 PRCM\_CM\_DPLL\_CLKSEL\_CPTS\_RFT\_CLK Register (offset = 38h) [reset = 0h]

Register mask: FFFFFFFFh

PRCM\_CM\_DPLL\_CLKSEL\_CPTS\_RFT\_CLK is shown in [Figure 6-162](#) and described in [Table 6-178](#).

Selects the Mux select line for CPTS RFT clock [warm reset insensitive]

**Figure 6-162. PRCM\_CM\_DPLL\_CLKSEL\_CPTS\_RFT\_CLK Register**

**Table 6-178. PRCM\_CM\_DPLL\_CLKSEL\_CPTS\_RFT\_CLK Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-2	RESERVED	Rreturns0s	0h	
1-0	CLKSEL	R/W	0h	<p>Selects the Mux select line for cpgmac rft clock [warm reset insensitive]</p> <p>0h (R/W) = Select HSDIVIDER_CORE M4 output</p> <p>1h (R/W) = Select HSDIVIDE_CORE M5 Output</p> <p>2h (R/W) = Selects DISP PLL clock as CPTS RFT Clock</p>

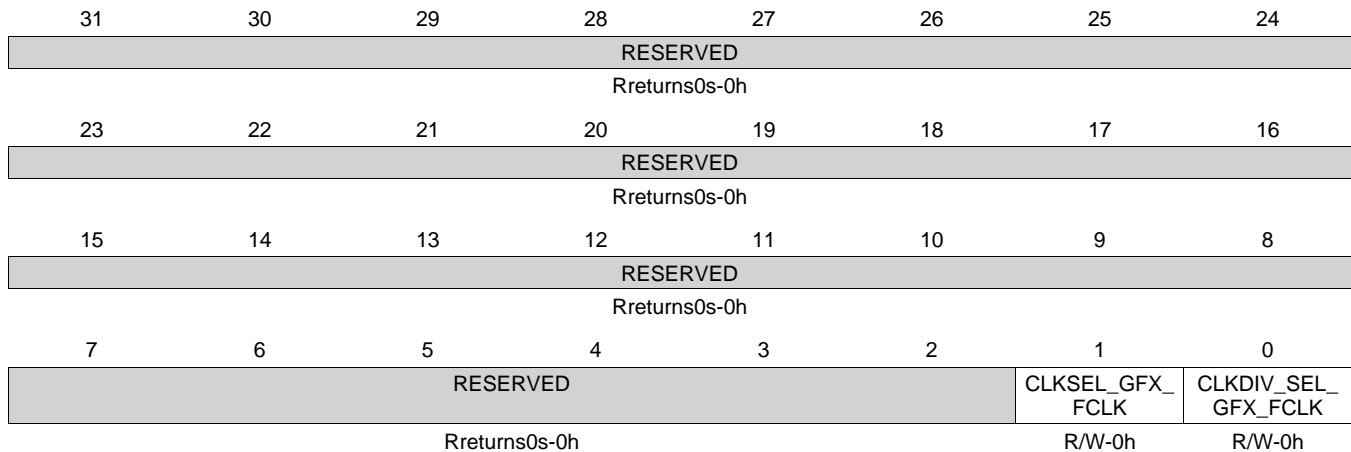

### 6.13.3.16 PRCM\_CM\_DPLL\_CLKSEL\_GFX\_FCLK Register (offset = 3Ch) [reset = 0h]

Register mask: FFFFFFFFh

PRCM\_CM\_DPLL\_CLKSEL\_GFX\_FCLK is shown in [Figure 6-163](#) and described in [Table 6-179](#).

Selects the divider value for GFX clock [warm reset insensitive]

**Figure 6-163. PRCM\_CM\_DPLL\_CLKSEL\_GFX\_FCLK Register**

**Table 6-179. PRCM\_CM\_DPLL\_CLKSEL\_GFX\_FCLK Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-2	RESERVED	Rreturns0s	0h	
1	CLKSEL_GFX_FCLK	R/W	0h	Selects the clock on gfx fclk [warm reset insensitive] 0h (R/W) = SGX FCLK is from CORE PLL (same as L3 clock) 1h (R/W) = SGX FCLK is from PER PLL (192 MHz clock)
0	CLKDIV_SEL_GFX_FCLK	R/W	0h	Selects the divider value on gfx fclk [warm reset insensitive] 0h (R/W) = SGX FCLK is same as L3 Clock or 192MHz Clock 1h (R/W) = SGX FCLK is L3 clock/2 or 192Mhz/2

### 6.13.3.17 PRCM\_CM\_DPLL\_CLKSEL\_GPIO0\_DBCLK Register (offset = 40h) [reset = 0h]

Register mask: FFFFFFFFh

PRCM\_CM\_DPLL\_CLKSEL\_GPIO0\_DBCLK is shown in [Figure 6-164](#) and described in [Table 6-180](#).

Selects the Mux select line for GPIO0 debounce clock [warm reset insensitive]

**Figure 6-164. PRCM\_CM\_DPLL\_CLKSEL\_GPIO0\_DBCLK Register**

**Table 6-180. PRCM\_CM\_DPLL\_CLKSEL\_GPIO0\_DBCLK Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-3	RSVD	Rreturns0s	0h	
2-0	CLKSEL	R/W	0h	Selects the Mux select line for GPIO0 debounce clock [warm reset insensitive] 0h (R/W) = Select 32KHZ clock from RC Oscillator 1h (R/W) = Select 32KHZ from 32K Crystal Oscillator 2h (R/W) = Select 32KHz from PER_PLL (Source: 192MHz) Clock Divider 3h (R/W) = Select 32KHz from SYS_CLK (Source: main XTAL oscillator clock) Clock Divider 4h (R/W) = Reserved

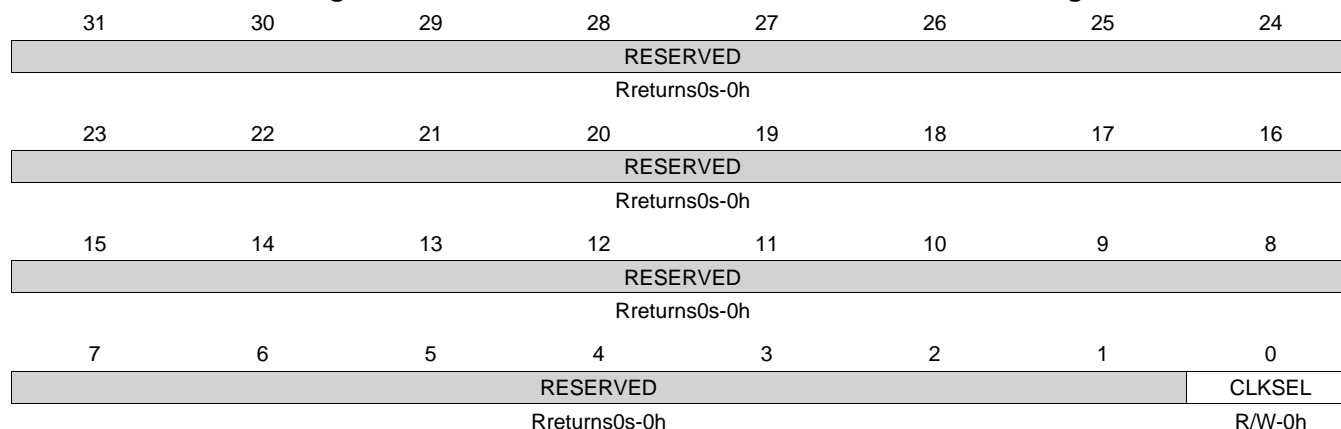

### 6.13.3.18 PRCM\_CM\_CLKSEL\_PRU\_ICSS\_OCP\_CLK Register (offset = 48h) [reset = 0h]

Register mask: FFFFFFFFh

PRCM\_CM\_CLKSEL\_PRU\_ICSS\_OCP\_CLK is shown in [Figure 6-165](#) and described in [Table 6-181](#).

Controls Mux Select of PRU-ICSS OCP clock mux

**Figure 6-165. PRCM\_CM\_CLKSEL\_PRU\_ICSS\_OCP\_CLK Register**

**Table 6-181. PRCM\_CM\_CLKSEL\_PRU\_ICSS\_OCP\_CLK Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	RESERVED	Rreturns0s	0h	
0	CLKSEL	R/W	0h	Controls Mux Select of PRU-ICSS OCP clock mux 0h (R/W) = Select L3F clock as OCP Clock of PRU-ICSS 1h (R/W) = Select DISP DPLL clock as OCP clock of PRU-ICSS

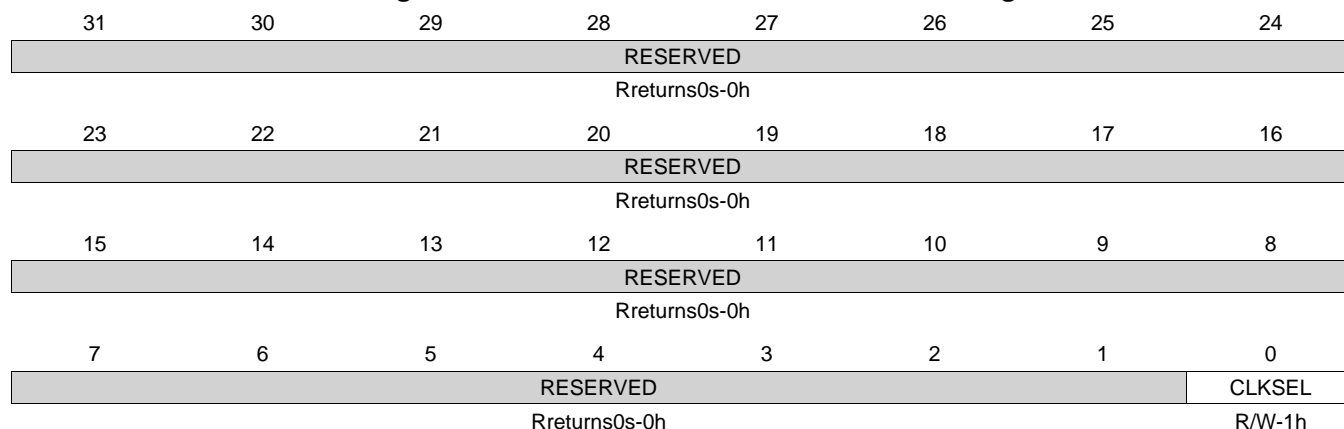

### 6.13.3.19 PRCM\_CM\_CLKSEL\_ADC1\_CLK Register (offset = 4Ch) [reset = 1h]

Register mask: FFFFFFFFh

PRCM\_CM\_CLKSEL\_ADC1\_CLK is shown in [Figure 6-166](#) and described in [Table 6-182](#).

Selects the Mux select line for ADC1 clock [warm reset insensitive]

**Figure 6-166. PRCM\_CM\_CLKSEL\_ADC1\_CLK Register**

**Table 6-182. PRCM\_CM\_CLKSEL\_ADC1\_CLK Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-1	RESERVED	Rreturns0s	0h	
0	CLKSEL	R/W	1h	Selects the Mux select line for ADC1 clock [warm reset insensitive] 0h (R/W) = Select Main Crystal clock as ADC1 clock 1h (R/W) = Select 192MHz PER PLL clock output as ADC1 clock

### 6.13.3.20 PRCM\_CM\_DPLL\_CLKSEL\_DLL\_AGING\_CLK Register (offset = 50h) [reset = 0h]

Register mask: FFFFFFFFh

PRCM\_CM\_DPLL\_CLKSEL\_DLL\_AGING\_CLK is shown in [Figure 6-167](#) and described in [Table 6-183](#).

Selects the clock divider for DLL\_AGING module clock [warm reset insensitive]

**Figure 6-167. PRCM\_CM\_DPLL\_CLKSEL\_DLL\_AGING\_CLK Register**

### 6.13.3.21 PRCM\_CM\_DPLL\_CLKSEL\_USBPHY32KHZ\_GCLK Register (offset = 60h) [reset = 0h]

Register mask: FFFFFFFFh

PRCM\_CM\_DPLL\_CLKSEL\_USBPHY32KHZ\_GCLK is shown in [Figure 6-168](#) and described in [Table 6-184](#).

Selects the Mux select line for USBPHY 32KHZ clock [warm reset insensitive]

### 6.13.4 PRCM\_CM\_GFX Registers

[Table 6-185](#) lists the memory-mapped registers for the PRCM\_CM\_GFX. All register offset addresses not listed in [Table 6-185](#) should be considered as reserved locations and the register contents should not be modified.

**Table 6-185. PRCM\_CM\_GFX REGISTERS**

Offset	Acronym	Register Name	Section
0h	PRCM_CM_GFX_L3_CLKSTCTRL		<a href="#">Section 6.13.4.1</a>
20h	PRCM_CM_GFX_CLKCTRL		<a href="#">Section 6.13.4.2</a>

### 6.13.4.1 PRCM\_CM\_GFX\_L3\_CLKSTCTRL Register (offset = 0h) [reset = 2h]

Register mask: FFFFFFFFh

PRCM\_CM\_GFX\_L3\_CLKSTCTRL is shown in [Figure 6-169](#) and described in [Table 6-186](#).

This register enables the domain power state transition. It controls the SW supervised clock domain state transition between ON-ACTIVE and ON-INACTIVE states. It also hold one status bit per clock input of the domain.

### 6.13.6.1 PRCM\_CM\_PER\_L3\_CLKSTCTRL Register (offset = 0h) [reset = 402h]

Register mask: FFFFFFFFh

PRCM\_CM\_PER\_L3\_CLKSTCTRL is shown in [Figure 6-173](#) and described in [Table 6-192](#).

This register enables the domain power state transition. It controls the SW supervised clock domain state transition between ON-ACTIVE and ON-INACTIVE states. It also hold one status bit per clock input of the domain.

As long as in this configuration, power domain sleep transition cannot happen. 3h (R) = Reserved

### 6.13.6.13 PRCM\_CM\_PER\_L3S\_CLKSTCTRL Register (offset = 200h) [reset = 302h]

Register mask: FFFFFFFFh

PRCM\_CM\_PER\_L3S\_CLKSTCTRL is shown in [Figure 6-185](#) and described in [Table 6-204](#).

This register enables the domain power state transition. It controls the SW supervised clock domain state transition between ON-ACTIVE and ON-INACTIVE states. It also hold one status bit per clock input of the domain.

**Figure 6-185. PRCM\_CM\_PER\_L3S\_CLKSTCTRL Register**

Bit	Field	Type	Reset	Description
31-19	RESERVED	Rreturns0s	0h	
18	STBYST	R	1h	Module standby status. This bit is warm reset insensitive when CPSW RESET_ISO is enabled 0h (R) = Module is functional (not in standby) 1h (R) = Module is in standby
17-16	IDLEST	R	3h	Module idle status. This bit is warm reset insensitive when CPSW RESET_ISO is enabled 0h (R) = Module is fully functional, including OCP 1h (R) = Module is performing transition: wakeup, or sleep, or sleep abortion 2h (R) = Module is in Idle mode (only OCP part). It is functional if using separate functional clock 3h (R) = Module is disabled and cannot be accessed
15-2	RESERVED	Rreturns0s	0h	
1-0	MODULEMODE	R/W	0h	Control the way mandatory clocks are managed. This bit is warm reset insensitive when CPSW RESET_ISO is enabled 0h (R/W) = Module is disable by SW. Any OCP access to module results in an error, except if resulting from a module wakeup (asynchronous wakeup). 1h (R) = Reserved 2h (R/W) = Module is explicitly enabled. Interface clock (if not used for functions) may be gated according to the clock domain state. Functional clocks are guaranteed to stay present. As long as in this configuration, power domain sleep transition cannot happen. 3h (R) = Reserved

### 6.13.6.77 PRCM\_CM\_PER\_OCPWP\_L3\_CLKSTCTRL Register (offset = C00h) [reset = 2h]

Register mask: FFFFFFFFh

PRCM\_CM\_PER\_OCPWP\_L3\_CLKSTCTRL is shown in [Figure 6-249](#) and described in [Table 6-268](#).

This register enables the domain power state transition. It controls the SW supervised clock domain state transition between ON-ACTIVE and ON-INACTIVE states. It also hold one status bit per clock input of the domain.

Interface clock (if not used for functions) may be gated according to the clock domain state. Functional clocks are guarantied to stay present. As long as in this configuration, power domain sleep transition cannot happen. 3h (R) = Reserved

### 6.13.8.3 PRCM\_CM\_L3S\_ADC0\_CLKSTCTRL Register (offset = 100h) [reset = 2h]

Register mask: FFFFFFFFh

PRCM\_CM\_L3S\_ADC0\_CLKSTCTRL is shown in [Figure 6-255](#) and described in [Table 6-276](#).

This register enables the domain power state transition. It controls the SW supervised clock domain state transition between ON-ACTIVE and ON-INACTIVE states. It also hold one status bit per clock input of the domain.

11	DPLL_REGM4XEN	Rreturns0s	0h	Enable the REGM4XEN mode of the DPLL. Please check the DPLL documentation to check when this mode can be enabled. 0h (R) = REGM4XEN mode of the DPLL is disabled
10	DPLL_LPMODE_EN	R/W	0h	Set the DPLL in Low Power mode. Check the DPLL documentation to see when this can be enabled. 0h (R/W) = Low power mode of the DPLL is disabled 1h (R/W) = Low power mode of the DPLL is enabled
9	DPLL_RELOCK_RAMP_E N	R/W	0h	If enabled, the clock ramping feature is used applied during the lock process, as well as the relock process. If disabled, the clock ramping feature is used only during the first lock.

**Table 6-293. PRCM\_CM\_CLKMODE\_DPLL\_CORE Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
8	DPLL_DRIFTGUARD_EN	R/W	0h	This bit allows to enable or disable the automatic recalibration feature of the DPLL. The DPLL will automatically start a recalibration process upon assertion of the DPLL's RECAL flag if this bit is set. 0h (R/W) = DRIFTGUARD feature is disabled 1h (R/W) = DRIFTGUARD feature is enabled
7-5	DPLL_RAMP_RATE	R/W	0h	Selects the time in terms of DPLL REFCLKs spent at each stage of the clock ramping process 0h (R/W) = 2 REFCLKs 1h (R/W) = 4 REFCLKs 2h (R/W) = 8 REFCLKs 3h (R/W) = 16 REFCLKs 4h (R/W) = 32 REFCLKs 5h (R/W) = 64 REFCLKs 6h (R/W) = 128 REFCLKs 7h (R/W) = 512 REFCLKs
4-3	DPLL_RAMP_LEVEL	R/W	0h	The DPLL provides an output clock frequency ramping feature when switching from bypass clock to normal clock during lock and re-lock. The frequency ramping will happen in a maximum of 4 steps in frequency before the DPLL's frequency lock indicator is asserted. This register is used to enable/disable the DPLL ramping feature. If enabled, it is also used to select the algorithm used for clock ramping 0h (R/W) = CLKOUT => No ramping CLKOUTX2 => No ramping 1h (R/W) = CLKOUT => Bypass clk -> Fout/8 -> Fout/4 -> Fout/2 -> Fout CLKOUTX2 => Bypass clk -> Foutx2/8 -> Foutx2/4 -> Foutx2/2 -> Foutx2 2h (R/W) = CLKOUT => Bypass clk -> Fout/4 -> Fout/2 -> Fout/1.5 -> Fout CLKOUTX2 => Bypass clk -> Foutx2/4 -> Foutx2/2 -> Foutx2/1.5 -> Foutx2 3h (R/W) = Reserved
2-0	DPLL_EN	R/W	4h	DPLL control. Upon Warm Reset, the PRCM DPLL control state machine updates this register to reflect MN Bypass mode. 0h (R/W) = Reserved 1h (R/W) = Reserved 2h (R/W) = Reserved 3h (R/W) = Reserved 4h (R/W) = Put the DPLL in MN Bypass mode. The DPLL_MULT register bits are reset to 0 automatically by putting the DPLL in this mode. 5h (R/W) = Put the DPLL in Idle Bypass Low Power mode. 6h (R/W) = Put the DPLL in Idle Bypass Fast Relock mode. 7h (R/W) = Enables the DPLL in Lock mode

### 6.13.8.21 PRCM\_CM\_IDLEST\_DPLL\_CORE Register (offset = 524h) [reset = 0h]

Register mask: FFFFFFFFh

PRCM\_CM\_IDLEST\_DPLL\_CORE is shown in [Figure 6-273](#) and described in [Table 6-294](#).

This register allows monitoring the master clock activity. This register is read only and automatically updated. [warm reset insensitive]

### 6.13.8.27 PRCM\_CM\_SSC\_MODFREQDIV\_DPLL\_CORE Register (offset = 54Ch) [reset = 0h]

Register mask: FFFFFFFFh

PRCM\_CM\_SSC\_MODFREQDIV\_DPLL\_CORE is shown in [Figure 6-279](#) and described in [Table 6-300](#).

Control the Modulation Frequency (Fm) for Spread Spectrum Clocking technique by defining it as a ratio of DPLL\_REFCLK/4

$$F_m = [DPLL\_REFCLK/4]/MODFREQDIV$$

$$MODFREQDIV = MODFREQDIV\_MANTISSA * 2^{MODFREQDIV\_EXPONENT}$$

[warm reset insensitive]

**Table 6-303. PRCM\_CM\_CLKSEL\_DPLL\_MPU Register Field Descriptions**

Bit	Field	Type	Reset	Description
31-24	DCC_COUNT_MAX	R/W	5h	The value "NbCycles" set in this field determines the duration of the clock ramp step during which output frequency is $F_{dpll}/(2^M \cdot M2)$ . The duration is computed as $32 \times \text{NbCycles}$ of WKUP-L4 clock cycles (SYSCLK/~26MHz). Duration should be > 1.5us to allow enough time for DCC to lock. This bit-field is only relevant when DCC_EN=1.
23	DPLL_BYP_CLKSEL	R/W	0h	Selects CLKINP or CLKINPULOW as Bypass Clock 0h (R/W) = Selects CLKINP Clock as BYPASS Clock 1h (R/W) = Selects CLKINPULOW as Bypass Clock
22	DCC_EN	R/W	0h	Enable or disable Duty Cycle Correction. Must be enabled only for frequency > 1GHz. When enabled, the CLKOUTHIF output of the DPLL is used after duty cycle correction instead of CLKOUT. M3 divider is hard-wired to 1 so the lock frequency $F_{dpll}$ is directly provided to MPU. 0h (R/W) = DCC disabled 1h (R/W) = DCC enabled
21-19	RESERVED	Rreturns0s	0h	
18-8	DPLL_MULT	R/W	0h	DPLL multiplier factor (2 to 2047). This register is automatically cleared to 0 when the DPLL_EN field in the *CLKMODE_DPLL* register is set to select MN Bypass mode. (equal to input M of DPLL M=2 to 2047 => DPLL multiplies by M). 0h (R/W) = 0 : Reserved 1h (R/W) = 1 : Reserved
7	RESERVED	Rreturns0s	0h	
6-0	DPLL_DIV	R/W	0h	DPLL divider factor (0 to 127) (equal to input N of DPLL actual division factor is N+1).

### 6.13.8.31 PRCM\_CM\_DIV\_M2\_DPLL\_MPU Register (offset = 570h) [reset = 1h]

Register mask: FFFFFFFFh

PRCM\_CM\_DIV\_M2\_DPLL\_MPU is shown in [Figure 6-283](#) and described in [Table 6-304](#).

This register provides controls over the M2 divider of the DPLL.

10	DPLL_LPMODE_EN	R/W	0h	Set the DPLL in Low Power mode. Check the DPLL documentation to see when this can be enabled. 0h (R/W) = Low power mode of the DPLL is disabled 1h (R/W) = Low power mode of the DPLL is enabled
9	DPLL_RELOCK_RAMP_E N	R/W	0h	If enabled, the clock ramping feature is used applied during the lock process, as well as the relock process. If disabled, the clock ramping feature is used only during the first lock.

**Table 6-322. PRCM\_CM\_CLKMODE\_DPLL\_DISP Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
8	DPLL_DRIFTGUARD_EN	R/W	0h	This bit allows to enable or disable the automatic recalibration feature of the DPLL. The DPLL will automatically start a recalibration process upon assertion of the DPLL's RECAL flag if this bit is set. 0h (R/W) = DRIFTGUARD feature is disabled 1h (R/W) = DRIFTGUARD feature is enabled
7-5	DPLL_RAMP_RATE	R/W	0h	Selects the time in terms of DPLL REFCLKs spent at each stage of the clock ramping process 0h (R/W) = 2 REFCLKs 1h (R/W) = 4 REFCLKs 2h (R/W) = 8 REFCLKs 3h (R/W) = 16 REFCLKs 4h (R/W) = 32 REFCLKs 5h (R/W) = 64 REFCLKs 6h (R/W) = 128 REFCLKs 7h (R/W) = 512 REFCLKs
4-3	DPLL_RAMP_LEVEL	R/W	0h	The DPLL provides an output clock frequency ramping feature when switching from bypass clock to normal clock during lock and re-lock. The frequency ramping will happen in a maximum of 4 steps in frequency before the DPLL's frequency lock indicator is asserted. This register is used to enable/disable the DPLL ramping feature. If enabled, it is also used to select the algorithm used for clock ramping 0h (R/W) = CLKOUT => No ramping CLKOUTX2 => No ramping 1h (R/W) = CLKOUT => Bypass clk -> Fout/8 -> Fout/4 -> Fout/2 -> Fout CLKOUTX2 => Bypass clk -> Foutx2/8 -> Foutx2/4 -> Foutx2/2 -> Foutx2 2h (R/W) = CLKOUT => Bypass clk -> Fout/4 -> Fout/2 -> Fout/1.5 -> Fout CLKOUTX2 => Bypass clk -> Foutx2/4 -> Foutx2/2 -> Foutx2/1.5 -> Foutx2 3h (R/W) = Reserved
2-0	DPLL_EN	R/W	4h	DPLL control. Upon Warm Reset, the PRCM DPLL control state machine updates this register to reflect MN Bypass mode. 0h (R/W) = Reserved 1h (R/W) = Reserved 2h (R/W) = Reserved 3h (R/W) = Reserved 4h (R/W) = Put the DPLL in MN Bypass mode. The DPLL_MULT register bits are reset to 0 automatically by putting the DPLL in this mode. 5h (R/W) = Put the DPLL in Idle Bypass Low Power mode. 6h (R/W) = Put the DPLL in Idle Bypass Fast Relock mode. 7h (R/W) = Enables the DPLL in Lock mode

### 6.13.8.50 PRCM\_CM\_IDLEST\_DPLL\_DISP Register (offset = 624h) [reset = 0h]

Register mask: FFFFFFFFh

PRCM\_CM\_IDLEST\_DPLL\_DISP is shown in [Figure 6-302](#) and described in [Table 6-323](#).

This register allows monitoring the master clock activity. This register is read only and automatically updated. [warm reset insensitive]

### 6.13.8.62 PRCM\_CM\_SHADOW\_FREQ\_CONFIG1 Register (offset = 7A0h) [reset = D0Ch]

Register mask: FFFFFFFFh

PRCM\_CM\_SHADOW\_FREQ\_CONFIG1 is shown in [Figure 6-314](#) and described in [Table 6-335](#).

Shadow register to program new DPLL configuration affecting EMIF and GPMC (L3 clock) functional frequency during DVFS. The PRCM h/w automatically applies the new configuration after EMIF/GPMC have been put in idle state.

**Figure 6-314. PRCM\_CM\_SHADOW\_FREQ\_CONFIG1 Register**

Bit	Field	Type	Reset	Description
31-16	RSVD5	R	0h	
15-11	DPLL_DDR_M2_DIV	R/W	1h	Shadow register for CM_DIV_M2_DPLL_DDR.DPLL_CLKOUT_DIV. The main register is loaded by WKUP-M3 with the shadow register value after EMIF IDLE if the FREQ_UPDATE field is set to '1'. Divide value from 1 to 31. 0h (R/W) = Reserved
10-8	DPLL_DDR_EN	R/W	5h	Shadow register for CM_CLKMODE_DPLL_DDR.DPLL_EN. The main register is loaded by WKUP-M3 with the shadow register value after EMIF IDLE if the FREQ_UPDATE field is set to '1'. 0h (R/W) = Reserved 1h (R/W) = Reserved 2h (R/W) = Reserved 3h (R/W) = Reserved 4h (R/W) = Put the DPLL in MN Bypass mode. The DPLL_MULT register bits are reset to 0 automatically by putting the DPLL in this mode. 5h (R/W) = Put the DPLL in Idle Bypass Low Power mode. 6h (R/W) = Put the DPLL in Idle Bypass Fast Relock mode. 7h (R/W) = Enables the DPLL in Lock mode
7-4	RSVD2	R	0h	
3	DLL_RESET	R/W	1h	Specify if DLL should be reset or not during the frequency change hardware sequence. 0h (R/W) = DLL is not reset during the frequency change hardware sequence 1h (R/W) = DLL is reset automatically during the frequency change hardware sequence

**Table 6-335. PRCM\_CM\_SHADOW\_FREQ\_CONFIG1 Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
2	DLL_OVERRIDE	R/W	1h	Shadow register for CM_DLL_CTRL.DLL_OVERRIDE. The main register is automatically loaded with the shadow register value after EMIF IDLE if the FREQ_UPDATE field is set to '1'. 0h (R/W) = Lock and code outputs are not overridden 1h (R/W) = Lock output is overridden to '1' and code output is overridden with a value coming from control module.
1	RSVD1	R	0h	Reserved
0	FREQ_UPDATE	R/WSpecial	0h	Writing '1' indicates that a new configuration is available. It is automatically cleared by h/w after the configuration has been applied.

### 6.13.8.63 PRCM\_CM\_SHADOW\_FREQ\_CONFIG2 Register (offset = 7A4h) [reset = 410h]

Register mask: FFFFFFFFh

PRCM\_CM\_SHADOW\_FREQ\_CONFIG2 is shown in [Figure 6-315](#) and described in [Table 6-336](#).

Shadow register to program new DPLL configuration affecting GPMC (L3 clock) functional frequency during DVFS. The PRCM h/w automatically applies the new configuration after EMIF/GPMC have been put in idle state.

**Figure 6-315. PRCM\_CM\_SHADOW\_FREQ\_CONFIG2 Register**

31-11	RSVD6	R	0h	
10-8	DPLL_CORE_EN	R/W	4h	Shadow register for CM_CLKMODE_DPLL_CORE.DPLL_EN. 0h (R/W) = Reserved 1h (R/W) = Reserved 2h (R/W) = Reserved 3h (R/W) = Reserved 4h (R/W) = Put the DPLL in MN Bypass mode. The DPLL_MULT register bits are reset to 0 automatically by putting the DPLL in this mode. 5h (R/W) = Put the DPLL in Idle Bypass Low Power mode. 6h (R/W) = Put the DPLL in Idle Bypass Fast Relock mode. 7h (R/W) = Enables the DPLL in Lock mode
7	RSVD5	R	0h	
6-2	DPLL_CORE_M4_DIV	R/W	4h	Shadow register for CM_DIV_M4_DPLL_CORE.DIV. The main register is loaded by WKUP-M3 with the shadow register value after GPMC IDLE if the CM_SHADOW_FREQ_CONFIG1.FREQ_UPDATE field is set to '1' and GPMC_FREQ_UPDATE is set to '1'. Divide value from 1 to 31. 0h (R/W) = Reserved
1	RSVD1	R	0h	Reserved
0	GPMC_FREQ_UPDATE	R/W	0h	Controls whether or not GPMC has to be put automatically into idle during the frequency change operation. 0h (R/W) = GPMC is not put automatically into idle during frequency change operation. 1h (R/W) = GPMC is put automatically into idle during frequency change operation.

## **Control Module**

This chapter describes the control module of the device.

<b>Topic</b>	<b>Page</b>
<b>7.1 Introduction .....</b>	<b>623</b>
<b>7.2 Functional Description .....</b>	<b>623</b>
<b>7.3 Registers .....</b>	<b>634</b>

## 7.1 Introduction

The control module includes status and control logic not addressed within the peripherals or the rest of the device infrastructure. This module provides interface to control the following areas of the device:

- Functional I/O multiplexing
- Emulation controls
- Device control and status
- DDR PHY control and IO control registers
- EDMA event multiplexing control registers

**Note:** For writing to the control module registers, the MPU will need to be in privileged mode of operation and writes will not work from user mode.

## 7.2 Functional Description

### 7.2.1 Pad Control Registers

The Pad Control Registers are 32-bit registers to control the signal muxing and other aspects of each I/O pad. After POR, software must set the pad functional multiplexing and configuration registers to the desired values according to the requested device configuration. The configuration is controlled by pads or by a group of pads. Each configurable pin has its own configuration register for pullup/down control and for the assignment to a given module.

Table 7-1 shows the generic Pad Control Register Description.

**Table 7-1. Pad Control Register Field Descriptions**

Bit	Field	Value	Description
31	Reserved	0	Reserved.
30	WUEVT	0 1	Wakeup event. No event. Event occurred.
29	WUEN	0 1	Wakeup enable. Disable. Enable.
28	DSPULLTYPSELECT	0 1	DS0 mode pullup/down selection. Offmode pulldown selected. Offmode pull-up selected.
27	DSPULLUDENABLE	0 1	DS0 mode pullup/down enable. This is an active low signal. Pullup/down disabled. Pullup/down enabled.
26	DSOUTVALUE	0 1	DS0 mode output value. Set value at 0. Set value at 1.
25	DSOUTENABLE	0 1	DS0 mode output enable. This is an active low signal. Output enabled. Output disabled.
24	DSENABLE	0 1	DS0 mode override control. Note that DSENABLE must be set to 1 only if the PAD values during DS conflict with the system required value. IO state retains previous state when DS0 mode is active. IO state is forced to OFF mode value when DS0 mode is active.
23-20	Reserved	0	Reserved. Read returns 0.
19	SLEWCTRL	0	Select between faster or slower slew rate. Fast

**Table 7-1. Pad Control Register Field Descriptions (continued)**

Bit	Field	Value	Description
		1	Slow <sup>(1)</sup>
18	RXACTIVE	0 1	Input enable value for the pad. Set to 0 for output only. Set to 1 for input or output. Receive disabled. Receiver enabled.
17	PULLTYPESEL	0 1	Pad pullup/down type selection. Pulldown selected. Pullup selected.
16	PULLUDEN	0 1	Pad pullup/down enable. This is an active low signal. Pullup/down enabled. Pullup/down disabled.
15-4	Reserved	0	Reserved. Read returns 0.
3-0	MUXMODE		Pad functional signal mux select.

<sup>(1)</sup> Some peripherals do not support slow slew rate. To determine which interfaces support each slew rate, see the datasheet *AM437x ARM Cortex-A9 Processors* (literature number SPRS851).

### 7.2.1.1 Mode Selection

The MUXMODE field in the pad control registers defines the multiplexing mode applied to the pad. Modes are referred to by their decimal (from 0 to 9) or binary (from 0b0000 to 0b1001) representation. For most pads, the reset value for the MUXMODE field in the registers is 0b111. The exceptions are pads to be used at boot time to transfer data from selected peripherals to the external flash memory.

**Table 7-2. Mode Selection**

MUXMODE	Selected Mode
0000b	Primary Mode = Mode 0
0001b	Mode 1
0010b	Mode 2
0011b	Mode 3
0100b	Mode 4
0101b	Mode 5
0110b	Mode 6
0111b	Mode 7
1000b	Mode 8
1001b	Mode 9

Mode 0 is the primary mode. When mode 0 is set, the function mapped to the pin corresponds to the name of the pin. Mode 1 to mode 9 are possible modes for alternate functions. On each pin, some modes are used effectively for alternate functions, while other modes are unused and correspond to no functional configuration.

**NOTE:** See the device-specific datasheet for a complete list of the signals corresponding to the mux modes for each pin.

### 7.2.1.2 Pull Selection

There is no automatic gating control to ensure that internal weak pull- down/pull up resistors on a pad are disconnected whenever the pad is configured as output. If a pad is always configured in output mode, it is recommended for user software to disable any internal pull resistor tied to it, to avoid unnecessary consumption. The following table summarizes the various possible combinations of PULLTYPESEL and PULLUDEN fields of PAD control register.

**Table 7-3. Pull Selection**

PULL TYPE		Pin Behavior
PULLTYPESEL	PULLUDENABLE	
0b	0b	Pulldown selected and activated
0b	1b	Pulldown selected but not activated
1b	0b	Pullup selected and activated
1b	1b	Pullup selected but not activated

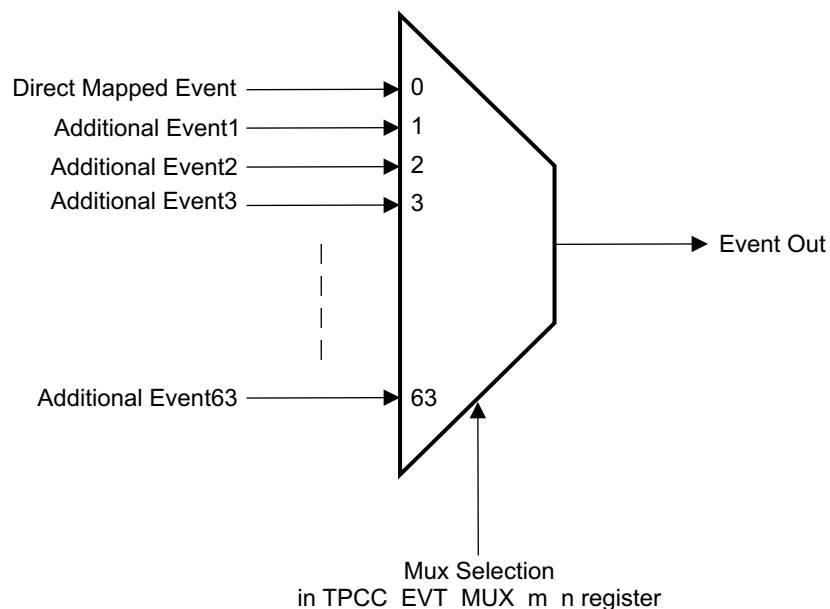

### 7.2.1.3 RX Active

The RXACTIVE bit is used to enable and disable the input buffer. This control can be used to help with power leakage or device isolation through the I/O. The characteristic of the signal is ultimately dictated by the mux mode the pad is put into.

## 7.2.2 EDMA Event Multiplexing

To accommodate the large number of possible DMA events, the device includes an event crossbar which multiplexes a direct mapped event with additional event choices for every EDMA event input. Mux control registers are defined in the Control Module to select the event to be routed to the EDMA3CC (TPCC). The direct mapped event is the default (mux selection set to '0').

**Figure 7-1. Event Crossbar**

For every EDMA event there is a cross bar implemented in the design as shown in the figure. The direct mapped event/interrupt is always connected to Mux input[0]. The additional events are connected to Mux input[1], Mux input[2], and so on, as defined in [Table 10-23, Direct Mapped](#). The Mux selection value is programmed into the corresponding TPCC\_EVT\_MUX\_n register. The EVT\_MUX value can take a value from 1 to 63. Other values are reserved. By default the MUX\_selection value is written to 0, which means the direct mapped event is connected to the Event output.

When one of the additional events is selected through the Cross bar programming, the direct mapped event cannot be used.

For example, when the TINT0 (Timer Interrupt 0) event, which is not directly mapped to the DMA event source, must be connected to EDMA channel 24, which is directly mapped to the SDTXEVT0 event. The user must program the EVT\_MUX\_24 field in TPCC\_EVT\_MUX\_24\_27 register to 22 (the value corresponding to TINT0 interrupt in the crossbar mapping). When this field is set, the TINT0 interrupt event acts as the channel 24 event trigger.

Please note: Once the field is set, the SDTXEVT0 event can no longer be handled by EDMA because it cannot be mapped to any of the other EDMA event inputs. The user must use caution to allocate only unused direct mapped event inputs to the crossbar mapped events to ensure no compromise on the channel allocation for the used event numbers.

## 7.2.3 Device Control and Status

### 7.2.3.1 Control and Boot Status

The device configuration is set during power on or hardware reset (PORz sequence) by the configuration input pins (SYSBOOT[18:0]). The CTRL\_STS register reflects the system boot and the device type configuration values as sampled when the power-on reset (PORz) signal is asserted. The Configuration input pins are sampled continuously during the PORz active period and the final sampled value prior to the last rising edge is latched in the register. The CTRL\_STS register gives the status of the device boot process.

### 7.2.3.2 Interprocessor Communication

The control module has the IPC\_MSG\_REG (14:0) registers which is for sharing messages between the Wakeup Processor and the Cortex-A9 MPU. The Wakeup Processor TX end of event (WAKEPROC\_TXEV\_EOI) register provides the mechanism to clear/enable the TX Event from the Wakeup Processor to Cortex-A9 MPU Subsystem. See the WAKEPROC\_TXEV\_EOI register description for further detail.

For specific information on how the IPC\_MSG\_REG registers are used to communicate with the Wakeup Processor firmware, see [Section 6.4.6](#), *Functional Sequencing for Power Management with Wakeup Processor*.

### 7.2.3.3 Initiator Priority Control

The control module provides the registers to control the bus interconnect priority and the EMIF priority.

#### 7.2.3.3.1 Initiator Priority Control for Interconnect

The INIT\_PRIORITY\_n register controls the infrastructure priority at the bus interconnects. This can be used for dynamic priority escalation. There are bit fields that control the interconnect priority for each bus initiator. By default all the initiators are given equal priority and the allocation is done on a round robin basis.

The priority can take a value from 0 to 3. The following table gives the valid set of priority values.

**Table 7-4. Interconnect Priority Values**

Interconnect Priority Value	Remarks
00	Low priority
01	Medium priority
10	Reserved
11	High priority

#### 7.2.3.3.2 Initiator Priority at EMIF

The MREQPRIO register provides an interface to change the access priorities for the various masters accessing the EMIF(DDR). Software can make use of this register to set the requestor priorities for required EMIF arbitration. The EMIF priority can take a value from 000b to 111b where 000b will be the highest priority and 111b will be lowest priority.

### 7.2.3.4 Peripheral Control and Status

#### 7.2.3.4.1 USB Control and Status

The USB\_CTRLn and USB\_STSn registers reflect the Control and Status of the USB instances. The USB IO lines can be used as UART TX and RX lines the USB Control register bit field GPIOMODE has settings that configures the USB lines as GPIO lines. The other USB PHY control settings for controlling the OTG settings and PHY are part of the USB\_CTRLn register.

The USB\_STSn register gives the status of the USB PHY module. See the USB\_STSn register description for further details.

#### 7.2.3.4.2 USB Charger Detect

Each USB PHY contains circuitry which can automatically detect the presence of a charger attached to the USB port. The charger detection circuitry is compliant to the Battery Charging Specification Revision 1.1 from the USB Implementers Forum, which can be found at [www.usb.org](http://www.usb.org). See this document for more details on USB charger implementation.

##### 7.2.3.4.2.1 Features

The charger detection circuitry of each PHY has the following features:

- Contains a state machine which can automatically detect the presence of a Charging Downstream Port or a Dedicated Charging Port (see the Battery Charging Specification for the definition of these terms)
- Outputs a charger enable signal (3.3 V level active high CMOS driver) when a charger is present.
- Allows you to enable/disable the circuitry to save power
- The detection circuitry requires only a 3.3-V supply to be present to operate.
- The charger detection also has a manual mode which allows the user to implement the battery charging specification in software.

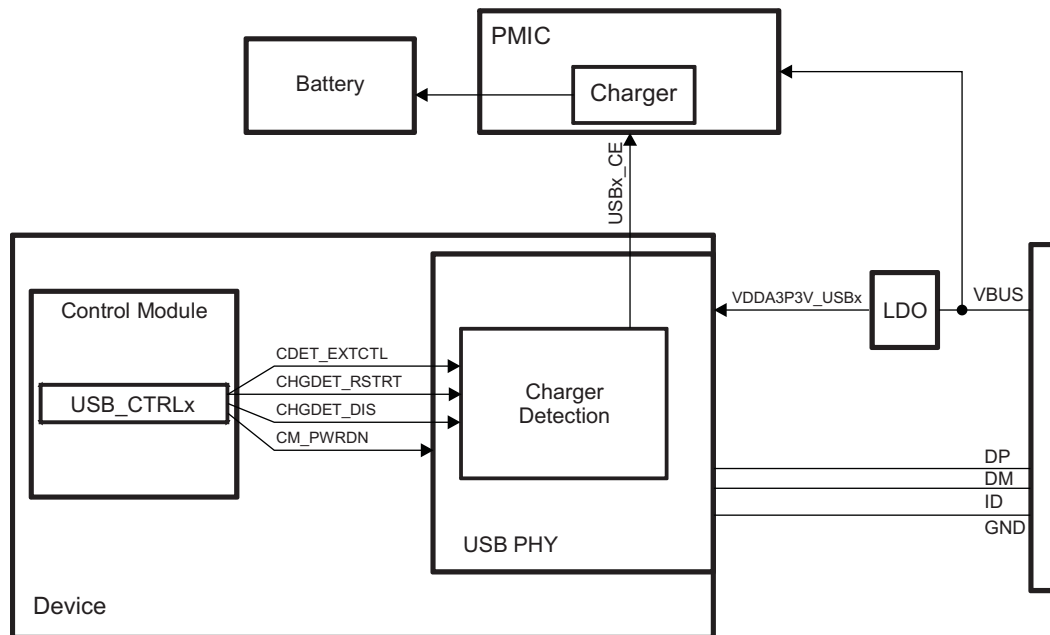

##### 7.2.3.4.2.2 Operation

The control module gives the following interface to control the automatic charger detection circuitry:

- USB\_CTRLx.CDET\_EXTCTL: Turns the automatic detection on/off. Keep this bit 0 to keep the automatic detection on. Changing this to 1 enables the manual mode.
- USB\_CTRLx.CHGDET\_RSTRT: Restarts the charger detection state machine. To initiate the charger detection, change this bit from 1 to 0. If this bit is 1, the charger enable output (CE) is disabled.
- USB\_CTRLx.CHGDET\_DIS: Enables/disables the charger detection circuitry. Keep this bit 0 to keep this charger detection enabled. Setting this bit to 1 will power down the charger detection circuitry.
- USB\_CTRLx.CM\_PWRDN: Powers up/down the PHY which contains the charger detection circuitry. Clear this bit to 0 to enable power to the PHY.

To start the charger detection during normal operation, ensure that the PHY and charger are enabled and the automatic detection is turned on. Then, initiate a charger detection cycle by transitioning CHGDET\_RSTRT from 1 to 0. If a Charging Downstream Port or a Dedicated Charging Port is detected, the charger enable signal (USBx\_CE) will be driven high and remain high until the charger is disabled by either CHGDET\_DIS = 1 or CHGDET\_RSTRT=1. If the port remains unconnected after initiating the charger detect cycle, it will continue the detection until a charger is detected or an error condition occurs. Note that USBx\_CE is not an open drain output.

To disable the charger after successful detection, you must disable the charger detect circuitry with CHGDET\_DIS or CHGDET\_RSTRT, even if the charger is physically disconnected.

**Figure 7-2. USB Charger Detection**

Charger detection can be automatically started with no power to the rest of the device. If VDDA3P3V\_USBx is present, via an LDO powered by VBUS connected to a host, the charger detection state machine will automatically start and perform detection. If a charger is detected, USBx\_CE will be driven high, otherwise it will be driven low.

The charger detection circuitry performs the following steps of the Battery Charging specification v1.1:

1. VBUS Detect
2. Data Contact Detect
3. Primary Detection

Secondary Detection (to distinguish between a Charging Downstream Port and a Dedicated Charging Port) is a newly added feature of the v1.2 spec and is not implemented in the charger detection state machine.

#### 7.2.3.4.3 Ethernet MII Mode Selection

The control module provides a mechanism to select the Mode of operation of Ethernet MII interface. The GMII\_SEL register has register bit fields to select the MII/RMII/RGMII modes, clock sources, and delay mode.

#### 7.2.3.4.4 Ethernet Module Reset Isolation Control

This feature allows the device to undergo a warm reset without disrupting the switch or traffic being routed through the switch during the reset condition. The CPSW Reset Isolation register (RESET\_ISO) has an ISO\_CONTROL field which controls the reset isolation feature.

If the reset isolation is enabled, any warm reset source will be blocked to the EMAC switch. If the EMAC reset isolation is NOT active (default state), then the warm reset sources are allowed to propagate as normal including to the EMAC Switch module (both reset inputs to the IP). All cold or POR resets will always propagate to the EMAC switch module as normal.

When RESET\_ISO is enabled, the following registers will not be disturbed by a warm reset:

- GMII\_SEL
- CONF\_GPMC\_A[11:0]
- CONF\_GPMC\_WAIT0
- CONF\_GPMC\_WPN
- CONF\_GPMC\_BEN1
- CONF\_GPMC\_CSN2
- CONF\_GPMC\_CSN3
- CONF\_MII1\_COL
- CONF\_MII1\_CRS
- CONF\_MII1\_RXERR
- CONF\_MII1\_TXEN
- CONF\_MII1\_RXDV
- CONF\_MII1\_TXD[3:0]
- CONF\_MII1\_TXCLK
- CONF\_MII1\_RXCLK
- CONF\_MII1\_RXD[3:0]
- CONF\_RMII1\_REFCLK
- CONF\_MDIO
- CONF\_MDC

### 7.2.3.4.5 Timer/eCAP Event Capture Control

The capture event input sources for Timer5, 6, 7 and eCAP0, 1, 2 are selected using the TIMER\_EVT\_CAPTURE and ECAP\_EVT\_CAPTURE registers. The following table lists the available sources for those events.

**Table 7-5. Available Sources for Timer[5–7] and eCAP[0–2] Events**

Event No.	Source module	Interrupt Name/Pin
0	For Timer 5 MUX input from IO signal TIMER5	TIMER5 IO pin
	For Timer 6 MUX input from IO signal TIMER6	TIMER6 IO pin
	For Timer 7 MUX input from IO signal TIMER7	TIMER7 IO pin
	For eCAP 0 MUX input from IO signal eCAP0	eCAP0 IO pin
	For eCAP 1 MUX input from IO signal eCAP1	eCAP1 IO pin
	For eCAP 2 MUX input from IO signal eCAP2	eCAP2 IO pin
1	UART0	UART0INT
2	UART1	UART1INT
3	UART2	UART2INT
4	UART3	UART3INT
5	UART4	UART4INT
6	UART5	UART5INT
7	3PGSW	3PGSWRXTHR0
8	3PGSW	3PGSWRXINT0
9	3PGSW	3PGSWTXINT0
10	3PGSW	3PGSWMISC0
11	McASP0	MCATXINT0
12	McASP0	MCARXINT0
13	McASP1	MCATXINT1
14	McASP1	MCARXINT1
15	GPIO4	GPIOINT4A
16	GPIO4	GPIOINT4B
17	GPIO0	GPIOINT0A
18	GPIO0	GPIOINT0B
19	GPIO1	GPIOINT1A
20	GPIO1	GPIOINT1B
21	GPIO2	GPIOINT2A
22	GPIO2	GPIOINT2B
23	GPIO3	GPIOINT3A
24	GPIO3	GPIOINT3B
25	DCAN0	DCAN0_INT0
26	DCAN0	DCAN0_INT1
27	DCAN0	DCAN0_PARITY
28	DCAN1	DCAN1_INT0
29	DCAN1	DCAN1_INT1
30	DCAN1	DCAN1_PARITY

### 7.2.3.4.6 ADC0 Capture Control

The following chip level events can be connected through the software-controlled multiplexer to the ADC0 module.

1. PRU-ICSS1 Host Event 0
2. Timer 4 Event
3. Timer 5 Event
4. Timer 6 Event
5. Timer 7 Event
6. ext\_hw\_trigger

This pin is the external hardware trigger to start the ADC0 channel conversion. The ADC0\_EVT\_CAPT register needs to be programmed to select the proper source for this conversion.

**Figure 7-3. ADC0 External Hardware Events**

Table 7-6 contains the value to be programmed in the selection mux.

**Table 7-6. Selection Mux Values**

ADC0_EVT_CAPT Value	ADC0 External Event Selected
000	PRU-ICSS1 Host Event 0
001	Timer 4 Event
010	Timer 5 Event
011	Timer 6 Event
100	Timer 7 Event
101	ext_hw_trigger
110-111	Reserved

### 7.2.3.4.7 ADC1 Capture Control

The following chip level events can be connected through the software-controlled multiplexer to the ADC1 module.

1. PRU-ICSS1 Host Event 0
2. Timer 4 Event
3. Timer 5 Event
4. Timer 6 Event
5. Timer 7 Event
6. ext\_hw\_trigger

This pin is the external hardware trigger to start the ADC channel conversion. The ADC1\_EVT\_CAPT register needs to be programmed to select the proper source for this conversion.

**Figure 7-4. ADC1 External Hardware Events**

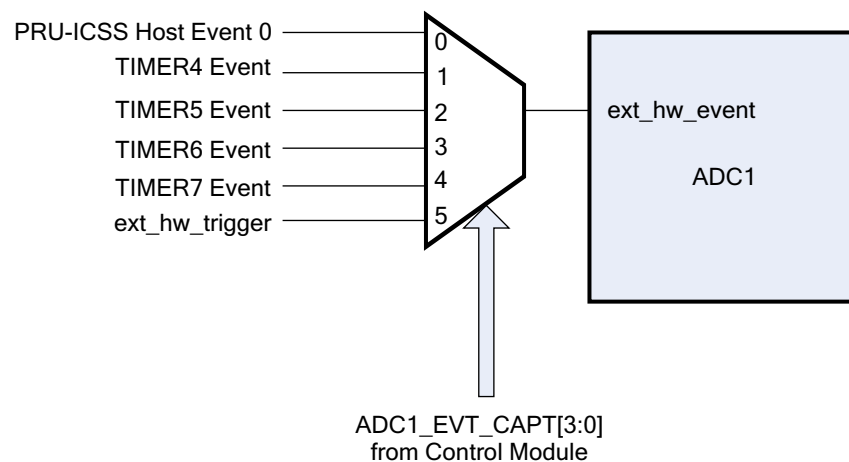

Table 7-7 contains the value to be programmed in the selection mux.

**Table 7-7. Selection Mux Values**

ADC1_EVT_CAPT Value	ADC1 External Event Selected
000	PRU-ICSS1 Host Event 0
001	Timer 4 Event
010	Timer 5 Event
011	Timer 6 Event
100	Timer 7 Event
101	ext_hw_trigger
110-111	Reserved

### 7.2.3.4.8 SRAM LDO Control

The device incorporates two instances of the SRAM LDO (VSLDO) module. One of these LDOs powers the ARM internal SRAM and the other powers the OCMC SRAMs. In the CTRL\_VSLDO register, the VSLDO\_CORE\_AUTO\_RAMP\_EN bit, when set, allows the VSLDO, which powers the OCMC SRAMs, to be put into retention during deepsleep and enable lower power consumption. Since the VSLDO is shared between WKUP\_PROC memories and CORE memories, the VSLDO has to be brought out of retention on any wakeup event. This bit allows this functionality and should be set to allow proper sleep/wakeup operation during Standby and DeepSleep modes. Similar functionality is not necessary for the LDO powering the ARM internal SRAM. It can be put in retention mode using PRM\_LDO\_SRAM\_MPU\_CTRL.

## 7.2.4 DDR IO Control Settings

Table 7-8 describes the slew rate settings available on the DDR IOs.

**Table 7-8. DDR Slew Rate Control Settings<sup>(1)</sup>**

sr1	sr0	Slew Rate Level
0	0	Fastest
1	0	Fast
0	1	Slow
1	1	Slowest

<sup>(1)</sup> These values are programmed in the following registers: [ddr\\_addrctrl\\_ioctrl](#), [ddr\\_data0\\_ioctrl](#), [ddr\\_data1\\_ioctrl](#), [ddr\\_data2\\_ioctrl](#), [ddr\\_data3\\_ioctrl](#).

Table 7-9 describes the impedance control settings available on the DDR IOs.

**Table 7-9. DDR Impedance Control Settings<sup>(1)(2)</sup>**

I2	I1	I0	Output Impedance ( $R_{on}$ )	Drive Strength $ I_{OH} ,  I_{OL} $	Example: $R_{on}$ for $R_{ext} =$ 49.9 ohms	Example: $ I_{OH} ,  I_{OL} $ for $R_{ext} =$ 49.9 ohms
0	0	0	$1.6 \cdot R_{ext}$	$0.625 \cdot I_{out}$	80 ohms	5 mA
0	0	1	$1.33 \cdot R_{ext}$	$0.75 \cdot I_{out}$	67 ohms	6 mA
0	1	0	$1.14 \cdot R_{ext}$	$0.875 \cdot I_{out}$	57 ohms	7 mA
0	1	1	$R_{ext}$	$I_{out}$	50 ohms	8 mA
1	0	0	$0.88 \cdot R_{ext}$	$1.125 \cdot I_{out}$	44 ohms	9 mA
1	0	1	$0.8 \cdot R_{ext}$	$1.250 \cdot I_{out}$	40 ohms	10 mA
1	1	0	$0.73 \cdot R_{ext}$	$1.375 \cdot I_{out}$	36 ohms	11 mA
1	1	1	$0.67 \cdot R_{ext}$	$1.5 \cdot I_{out}$	33 ohms	12 mA

<sup>(1)</sup> These values are programmed in the following registers: [ddr\\_addrctrl\\_ioctrl](#), [ddr\\_data0\\_ioctrl](#), [ddr\\_data1\\_ioctrl](#), [ddr\\_data2\\_ioctrl](#), [ddr\\_data3\\_ioctrl](#).

<sup>(2)</sup>  $R_{ext}$  is the external VTP compensation resistor connected to DDR\_VTP terminal.

### 7.2.4.1 DDR IO Pin Mapping

Table 7-10 describes the address control mapping for LPDDR2/DDR3.

**Table 7-10. Address Control Mapping for LPDDR2/DDR3**

Device	LPDDR2	DDR3
ddr_ck	CK_t	CK
ddr_nck	CK_c	CK#
ddr_rasn	CA0	RAS#

## 7.3 Registers

### 7.3.1 CONTROL\_MODULE Registers

Table 7-11 lists the memory-mapped registers for the CONTROL\_MODULE. All register offset addresses not listed in Table 7-11 should be considered as reserved locations and the register contents should not be modified.

**Table 7-11. CONTROL\_MODULE Registers**

Offset	Acronym	Register Name	Section
0h	CTRL_REVISION		<a href="#">Section 7.3.1.1</a>
4h	CTRL_HWINFO		<a href="#">Section 7.3.1.2</a>
10h	CTRL_SYSCONFIG		<a href="#">Section 7.3.1.3</a>
40h	CTRL_STS		<a href="#">Section 7.3.1.4</a>
1E0h	CTRL_MPU_L2		<a href="#">Section 7.3.1.5</a>
428h	CTRL_CORE_SLDO		<a href="#">Section 7.3.1.6</a>
42Ch	CTRL_MPU_SLDO		<a href="#">Section 7.3.1.7</a>
444h	CTRL_CLK32KDIVRATIO		<a href="#">Section 7.3.1.8</a>

17	NARROW_ONLY	R/W	0h	Should be 1 if EMIF is operated in Narrow mode (16 bit only).
16	EN_ECC	R	0h	ECC not supported - Reserved
15-14	PHY_NUM_OF_SAMPLES	R/W	0h	Controls the number of samples used during read data eye training Should be 0x0 (4 samples) for incremental leveling and 0x3 (128 samples) for full leveling
13	PHY_SEL_LOGIC	R/W	0h	Selects data read eye training algorithm Value 0(algorithm #1) is recommended
12	PHY_ALL_DQ_MPR_RD_RESP	R/W	0h	Controls the number of DQ pins used during read data eye training Value 1 (all DQs used) is recommended if the memory provides a leveling response on all DQs value 0 (only one DQ) recommended if memory only provides a single DQ
11-9	PHY_OUTPUT_STS_SELECT	R/W	0h	Use to select the status to be observed on the spare_out pins through EMIF_SDRAM_STATUS_EXT register 0: phy_reg_rdlvl_start_ratio(7 to 0) 1: phy_reg_rdlvl_start_ratio(15 to 8) 2: phy_reg_rdlvl_end_ratio(7 to 0) 3: phy_reg_rdlvl_end_ratio(15 to 8)
8	DYNAMIC_PWRDN_EN	R/W	0h	Enables dynamic PWRDN control in the IOs to reduce power consumption
7	RESERVED	R/W	0h	
6-5	PHY_RD_LOCAL_ODT	R/W	0h	DDR IOs termination control value during reads. Used to control the termination resistance value. ODT is enabled only during reads when termination is required. Available values are described in the DDR IO spec.
4	RESERVED	R/W	0h	
3	DFI_CLOCK_PHASE_CTRL	R/W	0h	DFI clock division phase control in EMIF4D5SS Recommended 0
2	RESERVED	R/W	0h	
1	EN_SLICE_1	R/W	1h	Enable CMD PHY1

**Table 7-294. CTRL\_EMIF\_SDRAM\_CONFIG\_EXT Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
0	EN_SLICE_0	R/W	1h	Enable CMD PHY0

### 7.3.1.284 CTRL\_EMIF\_SDRAM\_STS\_EXT Register (offset = 1464h) [reset = 0h]

Register mask: FFFFFFFFh

CTRL\_EMIF\_SDRAM\_STS\_EXT is shown in [Figure 7-288](#) and described in [Table 7-295](#).

**Figure 7-288. CTRL\_EMIF\_SDRAM\_STS\_EXT Register**

**Table 7-296. CTRL\_DISPPLL\_CLKCTRL Register Field Descriptions**

Bit	Field	Type	Reset	Description
31	CYCLESIPEN	R/W	0h	FailSafe enable to trigger re-calibration in case CycleSlip occurs between REFCLK & FBCLK.
30	ENSSC	R/W	0h	Controls Clock Spreading 1: Enables clock spreading 0: Disables clock spreading
29	RESERVED	R/W	0h	
28-24	NWEELLTRIM	R/W	0h	Trim values for the PLL
23	IDLE	R/W	1h	Sets PLL to Idle mode. When SYSRESET = 0 and TINITZ = 1 0: PLL will go to Active and Locked 1: PLL will go to Idle Bypass low power
22	BYPASSACKZ	R/W	0h	Bypass status acknowledge signal.
21	STBYRET	R/W	0h	Standby retention control 1: Prepares ADPLLJ for retention by gating all the internal clocks 0: Prepares ADPLLJ for relock when out of retention by removing the gating on all internal clocks
20	CLKOUTEN	R/W	1h	CLKOUT enable or disable 1: Synchronously enables CLKOUT 0: Synchronously disables CLKOUT
19	RESERVED	R/W	0h	
18	ULOWCLKEN	R/W	0h	Select CLKOUT source in bypass 0: When ADPLLJ in bypass mode CLKOUT = CLKINP/(N2+1) 1: When ADPLLJ in bypass mode CLKOUT = CLKINPULOW
17	CLKDCOLDOPWDNZ	R/W	0h	0: Asynchronous power down for CLKDCOLDO o/p.
16	M2PWDNZ	R/W	1h	0: Asynchronous power down for M2 divider 1: M2 divider is functional
15	M3PWDNZ	R/W	0h	0: Asynchronous power down for M3 divider 1: M3 divider is functional
14	STOPMODE	R/W	0h	When in Lossclk/Stbyret 0: Limp mode 1: Stopmode
13	LOWCURRSTDBY	R/W	0h	When in Lossclk/Stbyret/Idle 0: Fast relock 1: Slow relock

**Table 7-296. CTRL\_DISPPLL\_CLKCTRL Register Field Descriptions (continued)**

Bit	Field	Type	Reset	Description
12	LPMODE	R/W	0h	Can be set to '1' in cases with $CLKINP/(N+1) = 1\text{MHz}$ and $CLKINP*M/(N+1) = 100\text{MHz}$
11	DRIFTGUARDEN	R/W	0h	When RECAL status flag is asserted '1' enables recalibration
10	REGM4XEN	R/W	0h	Enable REGM*4 (Active High). Can be set to '1' only for $CLKOUT*M2 > 150\text{MHz}$ when LPMODE = '0' and $CLKOUT*M2 > 60\text{MHz}$ when LPMODE = '1'. This bit should not be changed on the fly in locked condition. INITIALIZATION should follow change of this bit.
9	RESERVED	R/W	0h	
8	RELAXED_LOCK	R/W	0h	0: FREQLOCK asserted when DC frequency error 1% 1: FREQLOCK asserted when DC frequency error 2%
7-1	RESERVED	R/W	0h	
0	TINITZ	R/W	1h	PLL core soft reset

### 7.3.1.286 CTRL\_DISPPLL\_TEN Register (offset = 3004h) [reset = 0h]

9.4 ELM.....	1517

## 9.1 GPMC

### 9.1.1 Introduction

The general-purpose memory controller (GPMC) is an unified memory controller dedicated to interfacing external memory devices:

- Asynchronous SRAM-like memories and application-specific integrated circuit (ASIC) devices
- Asynchronous, synchronous, and page mode (only available in non-multiplexed mode) burst NOR flash devices
- NAND Flash
- Pseudo-SRAM devices

#### 9.1.1.1 GPMC Features

The general features of the GPMC module include:

- Data path to external memory device can be 16- or 8-bit wide
- 32-bit OCPIP 2.0 compliant core, single slave interface. Support non-wrapping and wrapping burst up to 16x32bits.
- Up to 100 MHz external memory clock performance (single device)
- Support for the following memory types:
  - External asynchronous or synchronous 8-bit width memory or device (non burst device)
  - External asynchronous or synchronous 16-bit width memory or device
  - External 16-bit non-multiplexed NOR Flash device
  - External 16-bit address and data multiplexed NOR Flash device
  - External 8-bit and 16-bit NAND flash device
  - External 16-bit pSRAM device
- Up to 16-bit ECC support for NAND flash using BCH code (t=4, 8 or 16) or Hamming code for 8-bit or 16-bit NAND-flash, organized with page size of 512 bytes, 1K bytes, or more.
- Support 512M Bytes maximum addressing capability which can be divided into seven independent chip-select with programmable bank size and base address on 16M Bytes, 32M Bytes, 64M Bytes, or 128M Bytes boundary
- Fully pipelined operation for optimal memory bandwidth usage
- Support external device clock frequency of 1, 2, 3 and 4 divider from L3 clock.
- Support programmable auto-clock gating when there is no access.
- Support Midlreq/SidleAck protocol
- Support the following interface protocols when communicating with external memory or external devices.
  - Asynchronous read/write access
  - Asynchronous read page access (4-8-16 Word16)
  - Synchronous read/write access
  - Synchronous read burst access without wrap capability (4-8-16 Word16)
  - Synchronous read burst access with wrap capability (4-8-16 Word16)
- Address and Data multiplexed access
- Each chip-select as independent and programmable control signal timing parameters for Setup and Hold time. Parameters are set according to the memory device timing parameters, with one L3 clock cycle timing granularity.
- Flexible internal access time control (wait state) and flexible handshake mode using external WAIT pins monitoring (up to two WAIT pins)
- Support bus keeping
- Support bus turn around

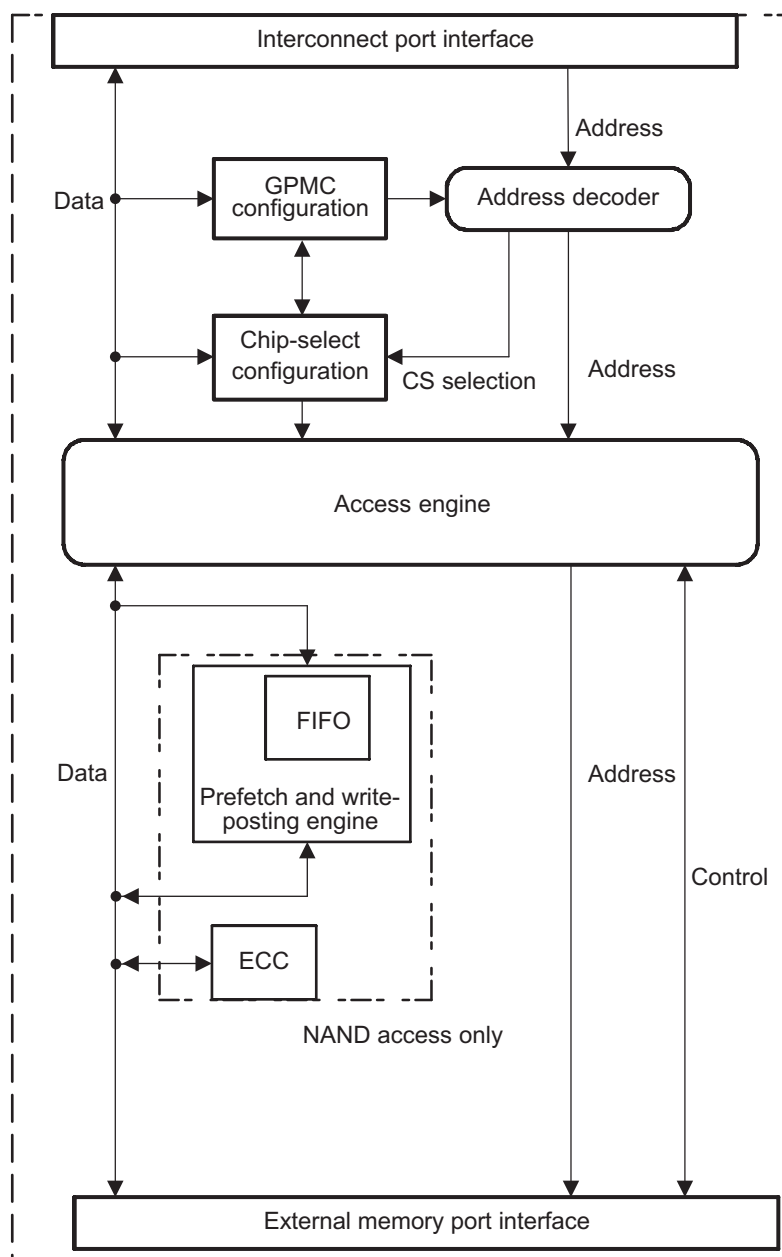

- Pre-fetch and write posting engine associated with system DMA to get full performance from NAND device with minimum impact on NOR/SRAM concurrent access.
- On the fly ECC Hamming Code calculation to improve NAND usage reliability with minimum impact on SW

### 9.1.1.2 Block Diagram

The GPMC can access various external devices through the L3 Slow Interconnect. The flexible programming model allows a wide range of attached device types and access schemes. Based on the programmed configuration bit fields stored in the GPMC registers, the GPMC is able to generate all control signals timing depending on the attached device and access type. Given the chip-select decoding and its associated configuration registers, the GPMC selects the appropriate device type control signals timing.

[Figure 9-1](#) shows the GPMC functional block diagram. The GPMC consists of six blocks:

- Interconnect port interface
- Address decoder, GPMC configuration, and chip-select configuration register file
- Access engine
- Prefetch and write-posting engine
- Error correction code engine (ECC)
- External device/memory port interface

**Figure 9-1. GPMC Block Diagram**

### 9.1.1.3 Unsupported GPMC Features

The following module features are not supported in this device.

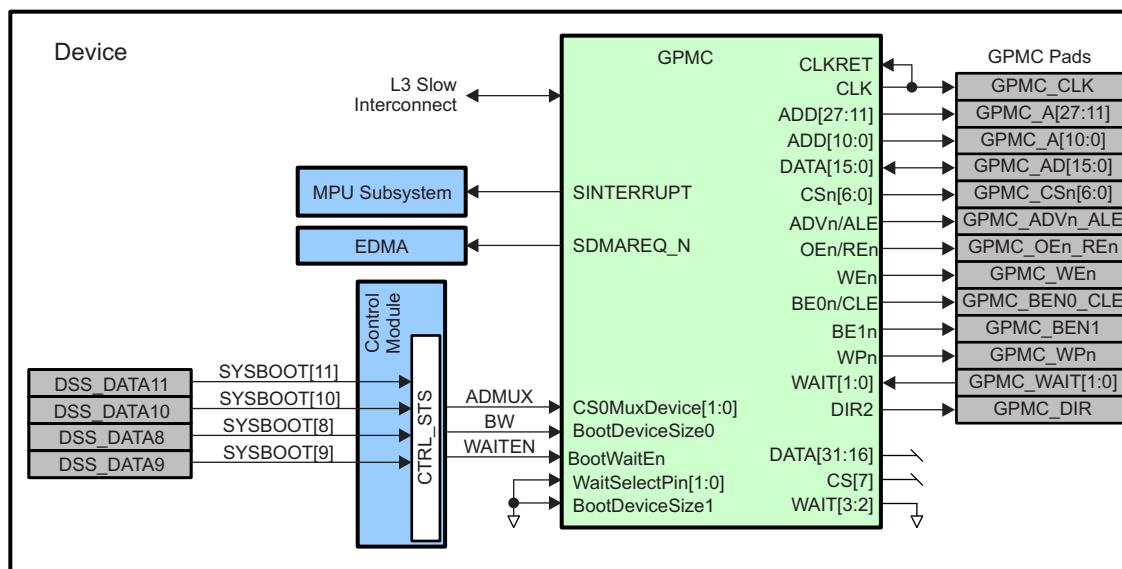

**Table 9-1. Unsupported GPMC Features**

Feature	Reason
Chip Select 7	Not pinned out
32-bit devices	Only 16 data lines pinned out
WAIT[3:2]	Not pinned out. All CS regions must use WAIT0 or WAIT1

## 9.1.2 Integration

An instantiation of GPMC provides this device with access to NAND Flash, NOR Flash, and other asynchronous and synchronous interface peripherals. Figure 9-2 shows the integration of the GPMC module in this device.

Figure 9-2. GPMC Integration

### 9.1.2.1 GPMC Connectivity Attributes

The general connectivity attributes for the GPMC module are shown in Table 9-2.

Table 9-2. GPMC Connectivity Attributes

Attributes	Type
Power Domain	Peripheral Domain
Clock Domain	PD_PER_L3S_GCLK
Reset Signals	PER_DOM_RST_N
Idle/Wakeup Signals	Smart Idle
Interrupt Requests	1 interrupt to MPU Subsystem (GPMCINT)
DMA Requests	1 DMA request to EDMA (GPMCEVT)
Physical Address	L3 Slow Slave Port Memory and control register regions qualified with MAddressSpace bit

### 9.1.2.2 GPMC Clock and Reset Management

The GPMC is a synchronous design and operates from the same clock as the Slow L3. All timings use this clock as a reference.

Table 9-3. GPMC Clock Signals

Clock Signal	Max Freq	Reference / Source	Comments
prcm_gpmc_clk Interface / Functional clock	100 MHz	CORE_CLKOUTM4 / 2	pd_per_l3s_gclk From PRCM

### 9.1.2.3 GPMC Signal List

The GPMC external interface signals are shown in Table 9-4.

**Table 9-4. GPMC Signal List**

Signal	Type	Description
GPMC_A[27:0]	O	Address outputs
GPMC_AD[15:0]	I/O	Data[15:0] in non-muxed mode. A[16:1], D[15:0] in AD-muxed mode. A[27:17], A[16:1], D[15:0] in AAD-muxed mode.
GPMC_CSn[6:0]	O	Chip selects (active low)
GPMC_CLK	O <sup>(1)</sup>	Synchronous mode clock
GPMC_ADVn_ALE	O	Address Valid or Address Latch Enable depending if NOR or NAND protocol memories are selected.
GPMC_OEn_REn	O	Output Enable (active low). Also used as Read Enable (active low) for NAND protocol memories
GPMC_WEn	O	Write Enable (active low)
GPMC_BE0n_CLE	O	Lower Byte Enable (active low). Also used as Command Latch Enable for NAND protocol memories
GPMC_BE1n	O	Upper Byte Enable (active low)
GPMC_WPn	O	Write Protect (active low)
GPMC_WAIT[1:0]	I	External wait signal for NOR and NAND protocol memories.
GPMC_DIR	O	GPMC.D[15:0] signal direction control Low during transmit (for write access: data OUT from GPMC to memory) High during receive (for read access: data IN from memory to GPMC)

<sup>(1)</sup> GPMC\_CLK is also used as a re-timing input. The associated CONF\_<module>\_<pin>\_RXACTIVE bit for the output clock must be set to 1 to enable the clock input back to the module. It is also recommended to place a 33-ohm resistor in series (close to the processor) to avoid signal reflections.

## 9.1.3 Functional Description

### 9.1.3.1 GPMC Signals

Table 9-5 shows the use of address and data GPMC controller pins based on the type of external device.

**Table 9-5. GPMC Pin Multiplexing Options**

GPMC Signal	Non Multiplexed Address Data 16- Bit Device <sup>(1)</sup>	Non Multiplexed Address Data 8-Bit Device	Multiplexed Address Data 16- Bit Device <sup>(1)</sup>	16-Bit NAND Device	8-Bit NAND Device

GPMC_WAIT0	WAIT0	WAIT0	WAIT0	R/B0n (ready/busy)	R/B0n (ready/busy)
GPMC_WAIT1	WAIT1	WAIT1	WAIT1	R/B1n (ready/busy)	R/B1n (ready/busy)
GPMC_WEn	WEn (Write Enable)	WEn (Write Enable)	WEn (Write Enable)	WEn (write enable)	WEn (write enable)
GPMC_WPn	WPn (Write Protect)	WPn (Write Protect)	WPn (Write Protect)	WPn (write protect)	WPn (write protect)

With all device types, the GPMC does not drive unnecessary address lines. They stay at their reset value of 00.

Address mapping supports address/data-multiplexed 16-bit wide devices:

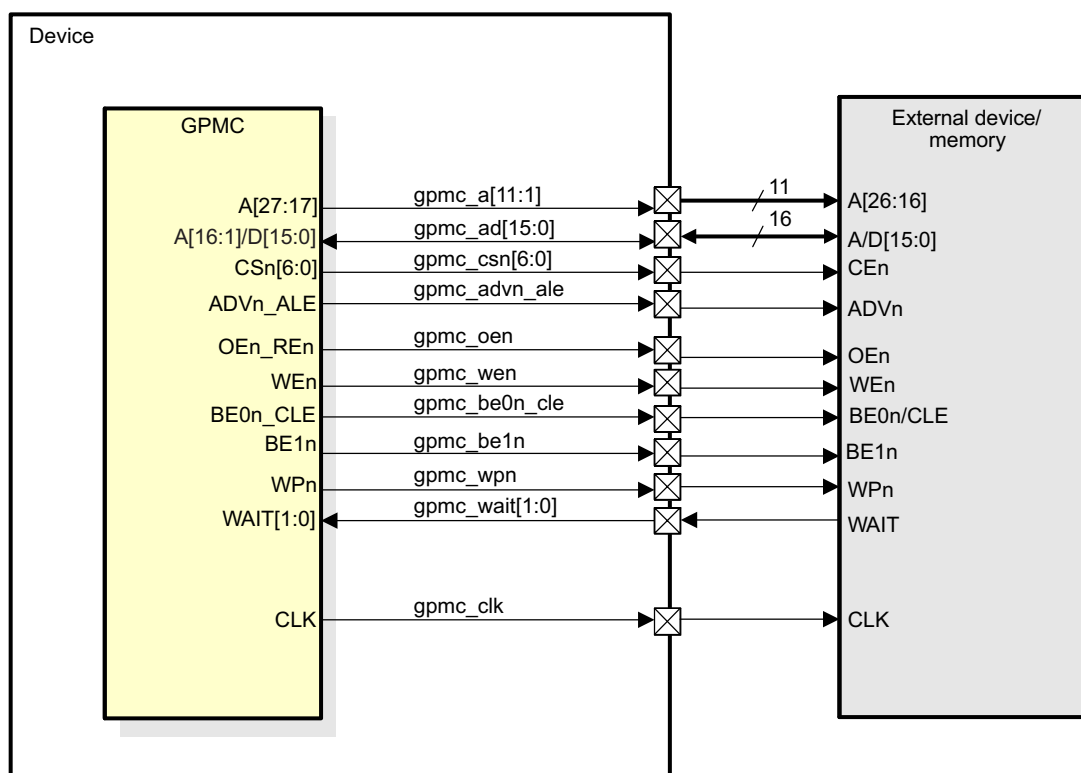

- The NOR flash memory controller still supports non-multiplexed address and data memory devices.
- Multiplexing mode can be selected through the GPMC\_CONFIG1\_i[9-8] MUXADDDATA bit field.
- Asynchronous page mode is not supported for multiplexed address and data devices.

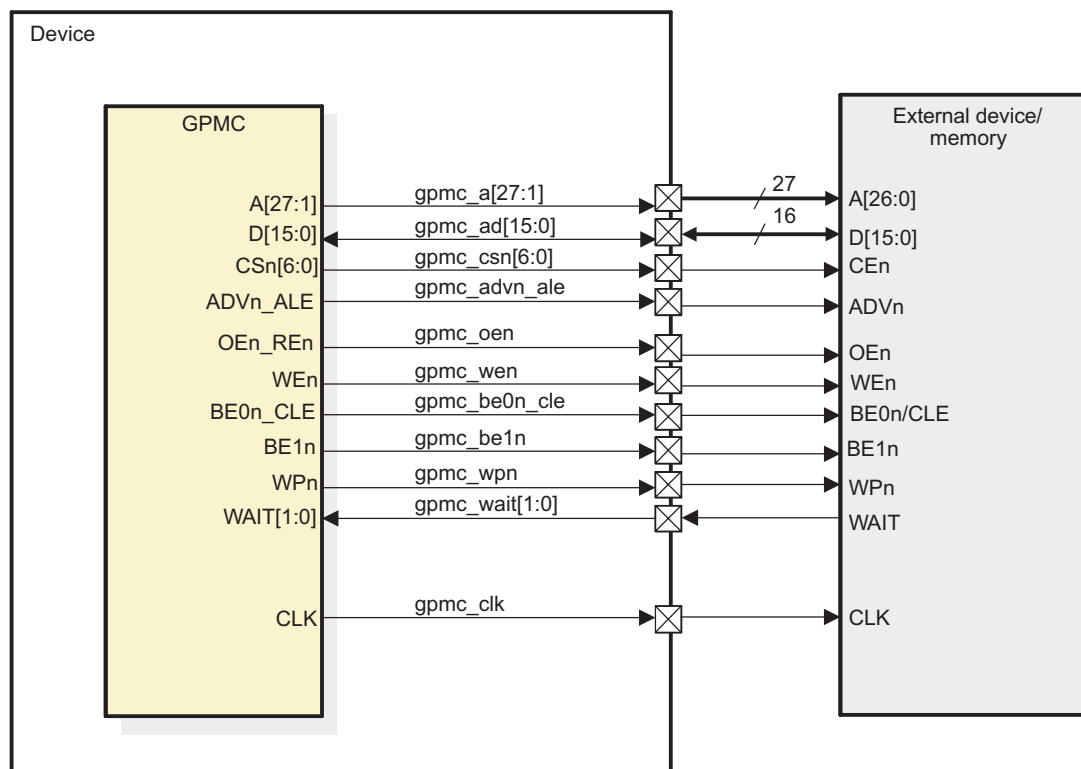

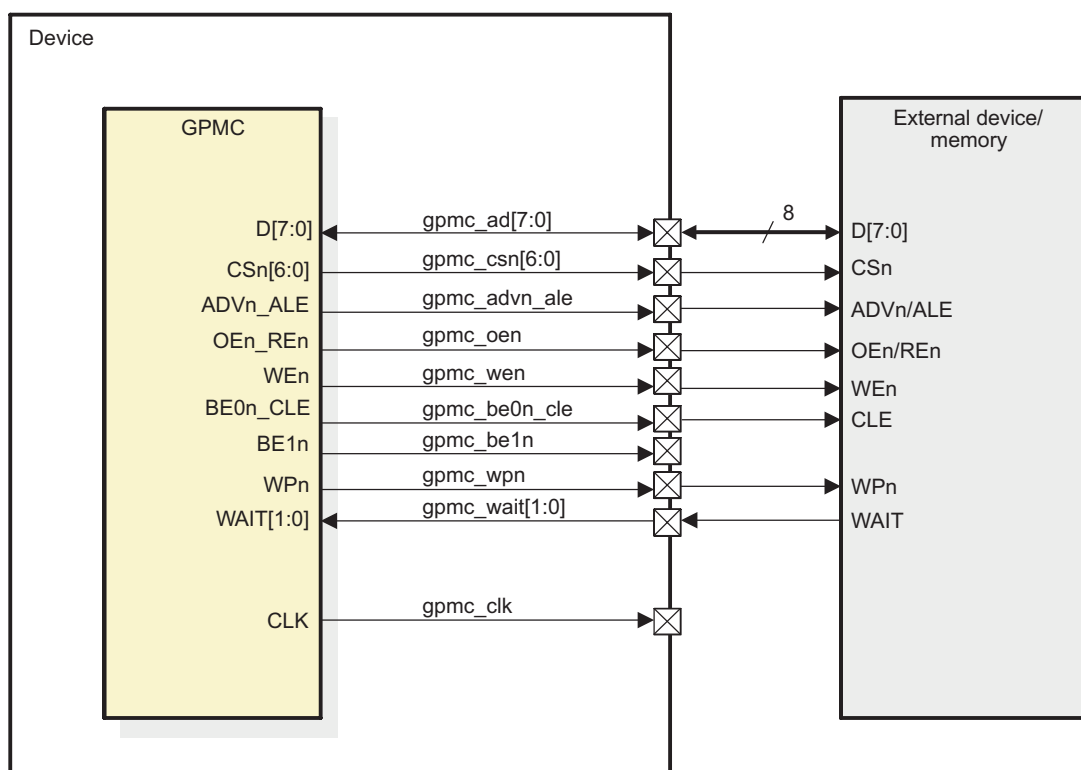

### 9.1.3.2 GPMC Modes

This section shows three GPMC external connections options:

- [Figure 9-3](#) shows a connection between the GPMC and a 16-bit synchronous address/data-multiplexed (or AAD-multiplexed, but this protocol use less address pins) external memory device.
- [Figure 9-4](#) shows a connection between the GPMC and a 16-bit synchronous nonmultiplexed external memory device .
- [Figure 9-5](#) shows a connection between the GPMC and a 8-bit NAND device

**Figure 9-3. GPMC to 16-Bit Address/Data-Multiplexed Memory**

**Figure 9-4. GPMC to 16-Bit Non-multiplexed Memory**

**Figure 9-5. GPMC to 8-Bit NAND Device**

### 9.1.3.3 GPMC Functional Description

The GPMC basic programming model offers maximum flexibility to support various access protocols for each of the configurable chip-selects. Use optimal chip-select settings, based on the characteristics of the external device:

- Different protocols can be selected to support generic asynchronous or synchronous random-access devices (NOR flash, SRAM) or to support specific NAND devices.
- The address and the data bus can be multiplexed on the same external bus.
- Read and write access can be independently defined as asynchronous or synchronous.
- System requests (byte, 16-bit word, burst) are performed through single or multiple accesses. External access profiles (single, multiple with optimized burst length, native- or emulated-wrap) are based on external device characteristics (supported protocol, bus width, data buffer size, native-wrap support).
- System burst read or write requests are synchronous-burst (multiple-read or multiple-write). When neither burst nor page mode is supported by external memory or ASIC devices, system burst read or write requests are translated to successive single synchronous or asynchronous accesses (single reads or single writes). 8-bit wide devices are supported only in single synchronous or single asynchronous read or write mode.
- To simulate a programmable internal-wait state, an external wait pin can be monitored to dynamically control external access at the beginning (initial access time) of and during a burst access.

Each control signal is controlled independently for each chip-select. The internal functional clock of the GPMC (GPMC\_FCLK) is used as a time reference to specify the following:

- Read- and write-access duration
- Most GPMC external interface control-signal assertion and deassertion times
- Data-capture time during read access
- External wait-pin monitoring time
- Duration of idle time between accesses, when required

### 9.1.3.3.1 GPMC Clock Configuration

Table 9-6 describes the GPMC clocks.

**Table 9-6. GPMC Clocks**

Signal	I/O	Description
GPMC_FCLK	I	Functional and interface clock
GPMC_CLK	O	External clock provided to synchronous external memory devices.

The GPMC\_CLK is generated by the GPMC from the internal GPMC\_FCLK clock. The source of the GPMC\_FCLK is described in . The GPMC\_CLK is configured via the GPMC\_CONFIG1\_i[1-0] GPMCFCLKDIVIDER field (for i = 0 to 3) as shown in Table 9-7.

**Table 9-7. GPMC\_CONFIG1\_i Configuration**

Source Clock	GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER	GPMC_CLK Generated Clock Provided to External Memory Device
GPMC_FCLK	00	GPMC_FCLK
	01	GPMC_FCLK/2
	10	GPMC_FCLK/3
	11	GPMC_FCLK/4

### 9.1.3.3.2 GPMC Software Reset

The GPMC can be reset by software through the GPMC\_SYSCONFIG[1] SOFTRESET bit. Setting the bit to 1 enables an active software reset that is functionally equivalent to a hardware reset. Hardware and software resets initialize all GPMC registers and the finite state-machine (FSM) immediately and unconditionally. The GPMC\_SYSSTS[0] RESETDONE bit indicates that the software reset is complete when its value is 1. The software must ensure that the software reset completes before doing GPMC operations.

### 9.1.3.3.3 GPMC Power Management

GPMC power is supplied by the CORE power domain, and GPMC power management complies with system power-management guidelines. Table 9-8 describes power-management features available for the GPMC module.

**Table 9-8. GPMC Local Power Management Features**

Feature	Registers	Description
Clock Auto Gating	GPMC_SYSCONFIG[0] AUTOIDLE] bit	This bit allows a local power optimization inside the module, by gating the GPMC_FCLK clock upon the internal activity.
Slave Idle Modes	GPMC_SYSCONFIG[4-3] SIDLEMODE bit field	Force-idle, No-idle and Smart-idle wakeup modes are available
Clock Activity	N/A	Feature not available
Master Standby Modes	N/A	Feature not available
Global Wake-up Enable	N/A	Feature not available
Wake-up Sources Enable	N/A	Feature not available

### 9.1.3.3.4 GPMC Interrupt Requests

The GPMC generates one interrupt event as shown in [Figure 9-2](#).

- The interrupt request goes from GPMC (GPMC\_IRQ) to the MPU subsystem: A\_IRQ\_100

[Table 9-9](#) lists the event flags, and their mask, that can cause module interrupts.

**Table 9-9. GPMC Interrupt Events**

Event Flag	Event Mask	Sensitivity	Map to	Description
GPMC_IRQSTS[9] WAIT1EDGEDETECTIO NSTS	GPMC_IRQEN[9] WAIT1EDGEDETECTIO NEN	Edge	A_IRQ_100	Wait1 edge detection interrupt: Triggered if a rising or falling edge is detected on the GPMC_WAIT1 signal. The rising or falling edge detection of Wait1 is selected through GPMC_CONFIG[9] WAIT1PINPOLARITY bit.
GPMC_IRQSTS[8] WAIT0EDGEDETECTIO NSTS	GPMC_IRQEN[8] WAIT0EDGEDETECTIO NEN	Edge	A_IRQ_100	Wait0 edge detection interrupt: Triggered if a rising or falling edge is detected on the GPMC_WAIT0 signal. The rising or falling edge detection of Wait0 is selected through GPMC_CONFIG[8] WAIT0PINPOLARITY bit.
GPMC_IRQSTS[1] TERMINALCOUNTSTS	GPMC_IRQEN[1] TERMINALCOUNTENA BLE	Level	A_IRQ_100	Terminal count event: Triggered on prefetch process completion, that is when the number of currently remaining data to be requested reaches 0.
GPMC_IRQSTS[0] FIFOEVTSTS	GPMC_IRQEN[0] FIFOEVTEN	Level	A_IRQ_100	FIFO event interrupt: Indicates FIFO levels availability for in Write-Posting mode and prefetch mode. GPMC_PREFETCH_CONFIG[2] DMAMODE bit shall be cleared to 0.

### 9.1.3.3.5 GPMC DMA Requests

The GPMC generates one DMA event, from GPMC (GPMC\_DMA\_REQ) to the eDMA: e\_DMA\_53

### 9.1.3.3.6 L3 Slow Interconnect Interface

The GPMC L3 Slow interconnect interface is a pipelined interface including an 16 × 32-bit word write buffer. Any system host can issue external access requests through the GPMC. The device system can issue the following requests through this interface:

- One 8-bit / 16-bit / 32-bit interconnect access (read/write)
- Two incrementing 32-bit interconnect accesses (read/write)
- Two wrapped 32-bit interconnect accesses (read/write)
- Four incrementing 32-bit interconnect accesses (read/write)
- Four wrapped 32-bit interconnect accesses (read/write)
- Eight incrementing 32-bit interconnect accesses (read/write)
- Eight wrapped 32-bit interconnect accesses (read/write)

Only linear burst transactions are supported; interleaved burst transactions are not supported. Only power-of-two-length precise bursts 2 × 32, 4 × 32, 8 × 32 or 16 × 32 with the burst base address aligned on the total burst size are supported (this limitation applies to incrementing bursts only).

This interface also provides one interrupt and one DMA request line, for specific event control.

It is recommended to program the GPMC\_CONFIG1\_i ATTACHEDDEVICEPAGELENGTH field ([24-23]) according to the effective attached device page length and to enable the GPMC\_CONFIG1\_i WRAPBURST bit ([31]) if the attached device supports wrapping burst. However, it is possible to emulate wrapping burst on a non-wrapping memory by providing relevant addresses within the page or splitting transactions. Bursts larger than the memory page length are chopped into multiple bursts transactions. Due to the alignment requirements, a page boundary is never crossed.

### 9.1.3.3.7 GPMC Address and Data Bus

The current application supports GPMC connection to NAND devices and to address/data-multiplexed memories or devices. Connection to address/data-nonmultiplexed memories Depending on the GPMC configuration of each chip-select, address and data bus lines that are not required for a particular access protocol are not updated (changed from current value) and are not sampled when input (input data bus).

- For address/data-multiplexed and AAD-multiplexed NOR devices, the address is multiplexed on the data bus.
- 8-bit wide NOR devices do not use GPMC I/O: GPMC\_AD[15-8] for data (they are used for address if needed).
- 16-bit wide NAND devices do not use GPMC I/O: GPMC\_A[27-0].
- 8-bit wide NAND devices do not use GPMC I/O: GPMC\_A[27-0] and GPMC I/O: GPMC\_AD[15-8].

#### 9.1.3.3.7.1 GPMC I/O Configuration Setting

---

**NOTE:** In this section and next sections, the *i* in GPMC\_CONFIGx\_i stands for the GPMC chip-select *i* where *i* = 0 to 6.

---

To select a NAND device, program the following register fields:

- GPMC\_CONFIG1\_i[11-10] DEVICETYPE field = 10b
- GPMC\_CONFIG1\_i[9-8] MUXADDDATA bit = 00

To select an address/data-multiplexed device, program the following register fields:

- GPMC\_CONFIG1\_i[11-10] DEVICETYPE field = 00
- GPMC\_CONFIG1\_i[9-8] MUXADDDATA bit = 10b

To select an address/address/data-multiplexed device, program the following register fields:

- GPMC\_CONFIG1\_i[11-10] DEVICETYPE field = 00
- GPMC\_CONFIG1\_i[9-8] MUXADDDATA bit = 01b

To select an address/data-nonmultiplexed device, program the following register fields:

- GPMC\_CONFIG1\_i[11-10] DEVICETYPE field = 00
- GPMC\_CONFIG1\_i[9-8] MUXADDDATA bit = 00

### 9.1.3.3.8 Address Decoder and Chip-Select Configuration

Addresses are decoded accordingly with the address request of the chip-select and the content of the chip-select base address register file, which includes a set of global GPMC configuration registers and eight sets of chip-select configuration registers.

The GPMC configuration register file is memory-mapped and can be read or written with byte, 16-bit word, or 32-bit word accesses. The register file should be configured as a noncacheable, nonbufferable region to prevent any desynchronization between host execution (write request) and the completion of register configuration (write completed with register updated). [Section 9.1.6](#) provides the GPMC register locations. For the map of GPMC memory locations, see [Table 9-51](#).

After the chip-select is configured, the access engine accesses the external device, drives the external interface control signals, and applies the interface protocol based on user-defined timing parameters and settings.

### 9.1.3.3.8.1 Chip-Select Base Address and Region Size

Any external memory or ASIC device attached to the GPMC external interface can be accessed by any device system host within the GPMC 512-Mbyte contiguous address space. For details, see [Table 9-51](#).

The GPMC 512 Mbyte address space can be divided into a maximum of seven chip-select regions with programmable base address and programmable CS size. The CS size is programmable from 16 to 256MB (must be a power-of-2) and is defined by the mask field. Attached memory smaller than the programmed CS region size is accessed through the entire CS region (aliasing).

Each chip-select has a 6-bit base address encoding and a 4-bit decoding mask, which must be programmed according to the following rules:

- The programmed chip-select region base address must be aligned on the chip-select region size address boundary and is limited to a power-of-2 address value. During access decoding, the register base address value is used for address comparison with the address-bit line mapping as described in [Figure 9-6](#) (with A0 as the device system byte-address line). Base address is programmed through the GPMC\_CONFIG7\_i[5-0] BASEADDRESS bit field.
- The register mask is used to exclude some address lines from the decoding. A register mask bit field cleared to 0 suppresses the associated address line from the address comparison (incoming address bit line is don't care). The register mask value must be limited to the subsequent value, based on the desired chip-select region size. Any other value has an undefined result. When multiple chip-select regions with overlapping addresses are enabled concurrently, access to these chip-select regions is cancelled and a GPMC access error is posted. The mask field is programmed through the GPMC\_CONFIG7\_i[11-8] MASKADDRESS bit field.

**Figure 9-6. Chip-Select Address Mapping and Decoding Mask**

A mask value of 0010 or 1001 must be avoided because it will create holes in the chip-select address space.

Chip-select configuration (base and mask address or any protocol and timing settings) must be performed while the associated chip-select is disabled through the GPMC\_CONFIG7\_i[6] CSVALID bit. In addition, a chip-select configuration can only be disabled if there is no ongoing access to that chip-select. This requires activity monitoring of the prefetch or write-posting engine if the engine is active on the chip-select. Also, the write buffer state must be monitored to wait for any posted write completion to the chip-select.

Any access attempted to a nonvalid GPMC address region (CSVALID disabled or address decoding outside a valid chip-select region) is not propagated to the external interface and a GPMC access error is posted. In case of chip-selects overlapping, an error is generated and no access will occur on either chip-select. Chip-select 0 is the only chip-select region enabled after either a power-up or a GPMC reset.

Although the GPMC interface can drive up to seven chip-selects, the frequency specified for this interface is for a specific load. If this load is exceeded, the maximum frequency cannot be reached. One solution is to implement a board with buffers, to allow the slowest device to maintain the total load on the lines.

### 9.1.3.3.8.2 Access Protocol

#### 9.1.3.3.8.2.1 Supported Devices

The access protocol of each chip-select can be independently specified through the GPMC\_CONFIG1\_i[11-10] DEVICETYPE parameter for:

- Random-access synchronous or asynchronous memory like NOR flash, SRAM
- NAND flash asynchronous devices

For more information about the NAND flash GPMC basic programming model and NAND support, see [Section 9.1.3.3.12](#) and [Section 9.1.3.3.12.1](#).

#### 9.1.3.3.8.2.2 Access Size Adaptation and Device Width

Each chip-select can be independently configured through the GPMC\_CONFIG1\_i[13-12] DEVICESIZE field to interface with a 16-bit wide device or an 8-bit wide device. System requests with data width greater than the external device data bus width are split into successive accesses according to both the external device data-bus width and little-endian data organization.

An 8-bit wide device must be interfaced to the D0-D7 external interface bus lane. GPMC data accesses only use this bus lane when the associated chip-select is attached to an 8-bit wide device.

The 8-bit wide device can be interfaced in asynchronous or synchronous mode in single data phase (no 8-bit wide device burst mode). If the 8-bit wide device is set in the chip-select configuration register, ReadMultiple and WriteMultiple bit fields are considered “don’t care” and only single accesses are performed.

A 16-bit wide device can be interfaced in asynchronous or synchronous mode, with single or multiple data phases for an access, and with native or emulated wrap mode support.

#### 9.1.3.3.8.2.3 Address/Data-Multiplexing Interface

For random synchronous or asynchronous memory interfacing (DEVICETYPE = 0b00), an address- and data-multiplexing protocol can be selected through the GPMC\_CONFIG1\_i[9-8] MUXADDDATA bit field. The ADVn signal must be used as the external device address latch control signal. For the associated chip-select configuration, ADVn assertion and deassertion time and OEn assertion time must be set to the appropriate value to meet the address latch setup/hold time requirements of the external device (see [Section 9.1.2](#)).

This address/data-multiplexing interface is not applicable to NAND device interfacing. NAND devices require a specific address, command, and data multiplexing protocol (see [Section 9.1.3.3.12](#)).

### 9.1.3.3.8.3 External Signals

#### 9.1.3.3.8.3.1 WAIT Pin Monitoring Control

GPMC access time can be dynamically controlled using an external gpmc\_wait pin when the external device access time is not deterministic and cannot be defined and controlled only using the GPMC internal RDACCESSTIME, WRACCESSTIME and PAGEBURSTACCESSTIME wait state generator.

The GPMC features two input wait pin: gpmc\_wait1, and gpmc\_wait0. This pin allow control of external devices with different wait-pin polarity. They also allow the overlap of wait-pin assertion from different devices without affecting access to devices for which the wait pin is not asserted.

- The GPMC\_CONFIG1\_i[17-16] WAITPINSELECT bit field (where i = 0 to 6) selects which input gpmc\_wait pin is used for the device attached to the corresponding chip-select.
- The polarity of the wait pin is defined through the WAITxPINPOLARITY bit of the GPMC\_CONFIG register. A wait pin configured to be active low means that low level on the WAIT signal indicates that the data is not ready and that the data bus is invalid. When WAIT is inactive, data is valid.

The GPMC access engine can be configured per CS to monitor the wait pin of the external memory device or not, based on the access type: read or write.

- The GPMC\_CONFIG1\_i[22] WAITREADMONITORING bit defines whether the wait pin should be monitored during read accesses or not.
- The GPMC\_CONFIG1\_i[21] WAITWRITEMONITORING bit defines whether the wait pin should be monitored during write accesses or not.

The GPMC access engine can be configured to monitor the wait pin of the external memory device asynchronously or synchronously with the GPMC\_CLK clock, depending on the access type: synchronous or asynchronous (the GPMC\_CONFIG1\_i[29] READTYPE and GPMC\_CONFIG1\_i[27] WRITETYPE bits).

#### 9.1.3.3.8.3.2 Wait Monitoring During an Asynchronous Read Access

When wait-pin monitoring is enabled for read accesses (WAITREADMONITORING), the effective access time is a logical AND combination of the RDACCESSTIME timing completion and the wait-deasserted state.

During asynchronous read accesses with wait-pin monitoring enabled, the wait pin must be at a valid level (asserted or deasserted) for at least two GPMC clock cycles before RDACCESSTIME completes, to ensure correct dynamic access-time control through wait-pin monitoring. The advance pipelining of the two GPMC clock cycles is the result of the internal synchronization requirements for the WAIT signal.

In this context, RDACCESSTIME is used as a WAIT invalid timing window and is set to such a value that the wait pin is at a valid state two GPMC clock cycles before RDACCESSTIME completes.

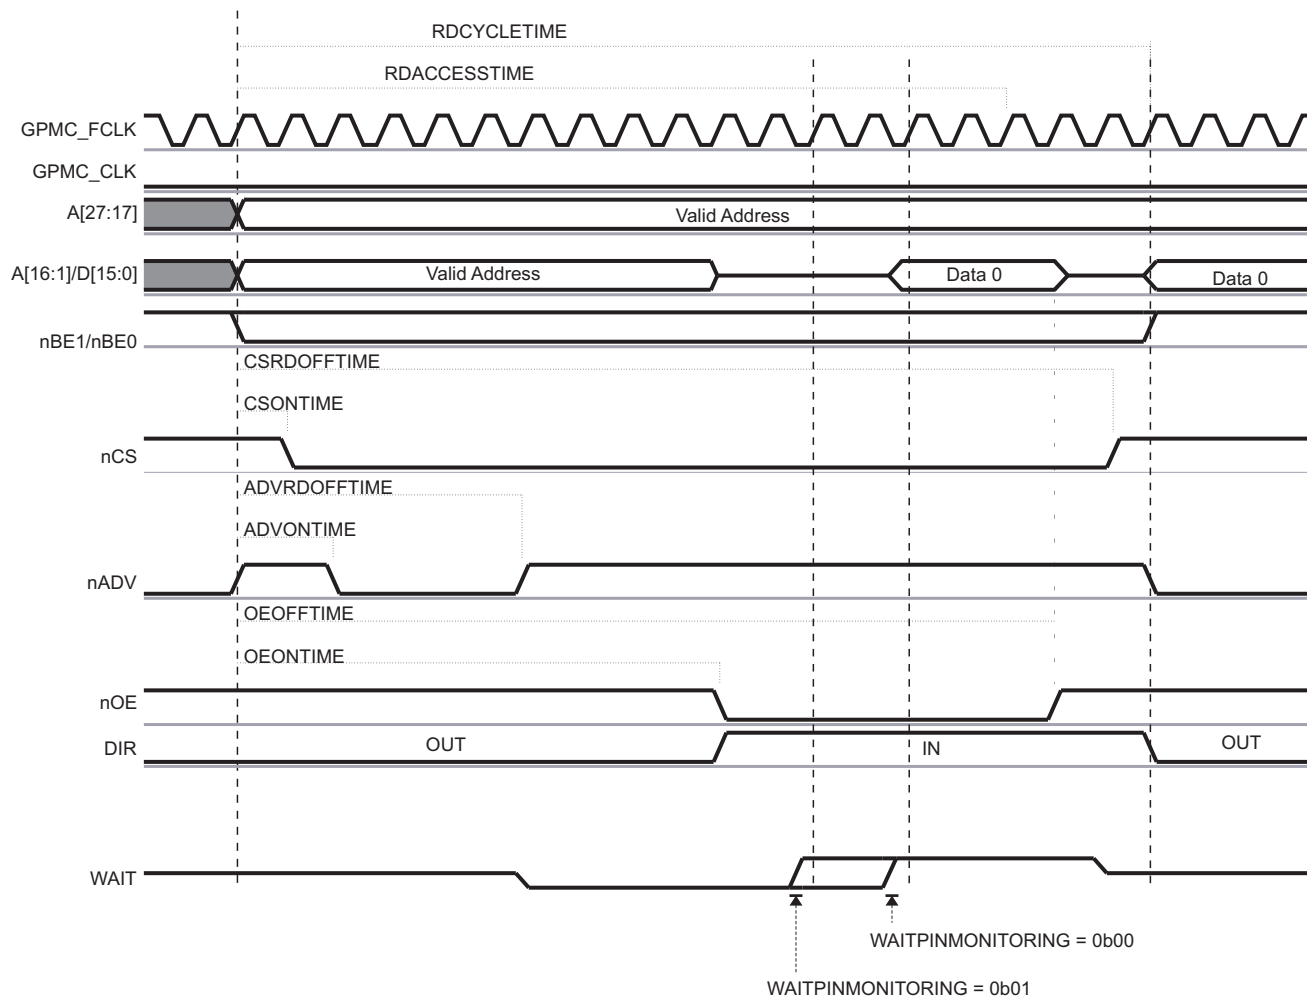

Similarly, during a multiple-access cycle (for example, asynchronous read page mode), the effective access time is a logical AND combination of PAGEBURSTACCESSTIME timing completion and the wait-deasserted state. Wait-monitoring pipelining is also applicable to multiple accesses (access within a page).

- WAIT monitored as active freezes the CYCLETIME counter. For an access within a page, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as asserted extends the current access time in the page. Control signals are kept in their current state. The data bus is considered invalid, and no data are captured during this clock cycle.
- WAIT monitored as inactive unfreezes the CYCLETIME counter. For an access within a page, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as inactive completes the current access time and starts the next access phase in the page. The data bus is considered valid, and data are captured during this clock cycle. In case of a single access or if this was the last access in a multiple-access cycle, all signals are controlled according to their related control timing value and according to the CYCLETIME counter status.

When a delay larger than two GPMC clocks must be observed between wait-pin deactivation time and data valid time (including the required GPMC and the device data setup time), an extra delay can be added between wait-pin deassertion time detection and effective data-capture time and the effective unlock of the CYCLETIME counter. This extra delay can be programmed in the GPMC\_CONFIG1\_i[19-18] WAITMONITORINGTIME field.

- The WAITMONITORINGTIME parameter does not delay the wait-pin active or inactive detection, nor does it modify the two GPMC clocks pipelined detection delay.
- This extra delay is expressed as a number of GPMC\_CLK clock cycles, even though the access is defined as asynchronous, and no GPMC\_CLK clock is provided to the external device. Still, GPMCFCLKDIVIDER is used as a divider for the GPMC clock, so it must be programmed to define the correct WAITMONITORINGTIME delay.

Figure 9-7 shows wait behavior during an asynchronous single read access.

**Figure 9-7. Wait Behavior During an Asynchronous Single Read Access (GPMCFCLKDivider = 1)**

The WAIT signal is active low. GPMC\_CONFIG1\_i[19-18] WAITMONITORINGTIME = 00b or 01b.

#### 9.1.3.3.3.3 Wait Monitoring During an Asynchronous Write Access

When wait-pin monitoring is enabled for write accesses (GPMC\_CONFIG1\_i[21] WAITWRITEMONITORING bit = 1), the WAIT-invalid timing window is defined by the WRACCESSTIME field. WRACCESSTIME must be set so that the wait pin is at a valid state two GPMC clock cycles before WRACCESSTIME completes. The advance pipelining of the two GPMC clock cycles is the result of the internal synchronization requirements for the WAIT signal.

- WAIT monitored as active freezes the CYCLETIME counter. This informs the GPMC that the data bus is not captured by the external device. The control signals are kept in their current state. The data bus still drives the data.
- WAIT monitored as inactive unfreezes the CYCLETIME counter. This informs that the data bus is correctly captured by the external device. All signals, including the data bus, are controlled according to their related control timing value and to the CYCLETIME counter status.

When a delay larger than two GPMC clock cycles must be observed between wait-pin deassertion time and the effective data write into the external device (including the required GPMC data setup time and the device data setup time), an extra delay can be added between wait-pin deassertion time detection and effective data write time into the external device and the effective unfreezing of the CYCLETIME counter. This extra delay can be programmed in the GPMC\_CONFIG1\_i[19-18] WAITMONITORINGTIME fields.

- The WAITMONITORINGTIME parameter does not delay the wait-pin assertion or deassertion detection, nor does it modify the two GPMC clock cycles pipelined detection delay.
- This extra delay is expressed as a number of GPMC\_CLK clock cycles, even though the access is defined as asynchronous, and even though no clock is provided to the external device. Still, GPMC\_CONFIG1\_i[1-0] GPMCFCLKDIVIDER is used as a divider for the GPMC clock and so it must be programmed to define the correct WAITMONITORINGTIME delay.

#### 9.1.3.3.8.3.4 Wait Monitoring During a Synchronous Read Access

During synchronous accesses with wait-pin monitoring enabled, the wait pin is captured synchronously with GPMC\_CLK, using the rising edge of this clock.

The WAIT signal can be programmed to apply to the same clock cycle it is captured in. Alternatively, it can be sampled one or two GPMC\_CLK cycles ahead of the clock cycle it applies to. This pipelining is applicable to the entire burst access, and to all data phase in the burst access. This WAIT pipelining depth is programmed in the GPMC\_CONFIG1\_i[19-18] WAITMONITORINGTIME field, and is expressed as a number of GPMC\_CLK clock cycles.

In synchronous mode, when wait-pin monitoring is enabled (GPMC\_CONFIG1\_i[22] WAITREADMONITORING bit), the effective access time is a logical AND combination of the RDACCESSTIME timing completion and the WAIT deasserted-state detection.

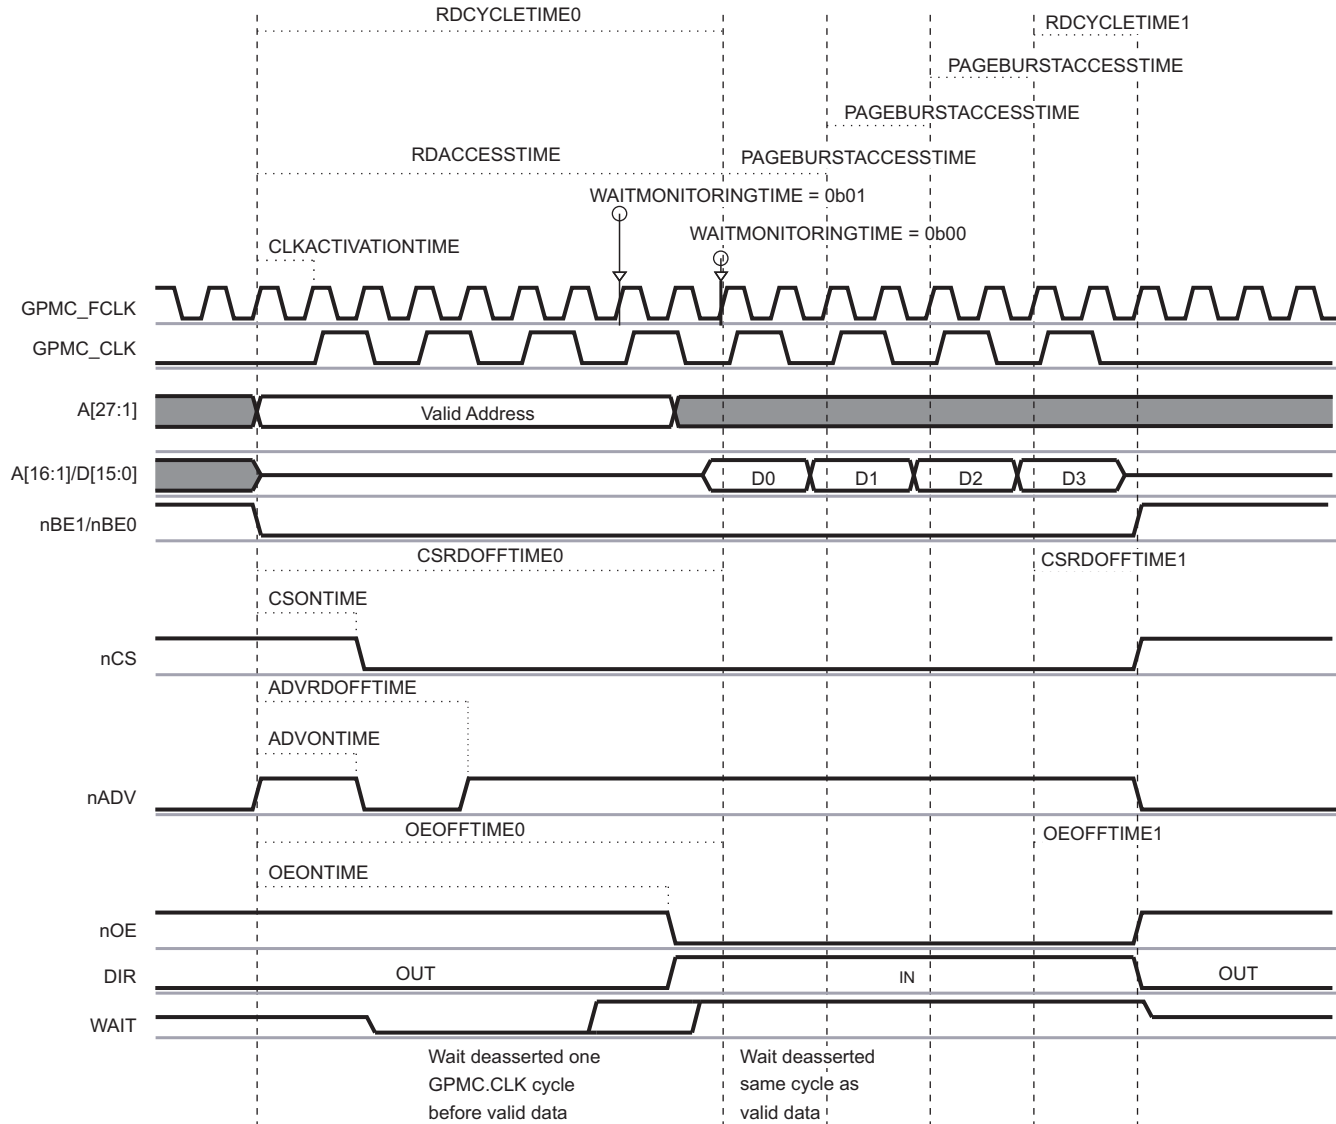

Depending on the programmed WAITMONITORINGTIME value, the wait pin should be at a valid level, either asserted or deasserted:

- In the same clock cycle the data is valid if WAITMONITORINGTIME = 0 ( at RDACCESSTIME completion)
- In the WAITMONITORINGTIME x (GPMCFCLKDIVIDER + 1) GPMC\_FCLK clock cycles before RDACCESSTIME completion if WAITMONITORINGTIME not equal to 0

Similarly, during a multiple-access cycle (burst mode), the effective access time is a logical AND combination of PAGEBURSTACCESSTIME timing completion and the wait-inactive state. The Wait pipelining depth programming applies to the whole burst access.

- WAIT monitored as active freezes the CYCLETIME counter. For an access within a burst (when the CYCLETIME counter is by definition in a lock state), WAIT monitored as active extends the current access time in the burst. Control signals are kept in their current state. The data bus is considered invalid, and no data are captured during this clock cycle.
- WAIT monitored as inactive unfreezes the CYCLETIME counter. For an access within a burst (when the CYCLETIME counter is by definition in lock state), WAIT monitored as inactive completes the current access time and starts the next access phase in the burst. The data bus is considered valid, and data are captured during this clock cycle. In a single access or if this was the last access in a multiple-access cycle, all signals are controlled according to their relative control timing value and the CYCLETIME counter status.

Figure 9-8 shows wait behavior during a synchronous read burst access.

**Figure 9-8. Wait Behavior During a Synchronous Read Burst Access**

The WAIT signal is active low. WAITMONITORINGTIME = 00b or 01b.

#### 9.1.3.3.8.3.5 Wait Monitoring During a Synchronous Write Access

During synchronous accesses with wait-pin monitoring enabled (the WAITWRITEMONITORING bit), the wait pin is captured synchronously with GPMC\_CLK, using the rising edge of this clock.

If enabled, external wait-pin monitoring can be used in combination with WRACCESSTIME to delay the effective memory device GPMC\_CLK capture edge.

Wait-monitoring pipelining depth is similar to synchronous read access:

- At WRACCESSTIME completion if WAITMONITORINGTIME = 0
- In the WAITMONITORINGTIME x (GPMCFCLKDIVIDER + 1) GPMC\_FCLK cycles before WRACCESSTIME completion if WAITMONITORINGTIME not equal to 0.

Wait-monitoring pipelining definition applies to whole burst accesses:

- WAIT monitored as active freezes the CYCLETIME counter. For accesses within a burst, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as active indicates that the data bus is not being captured by the external device. Control signals are kept in their current state. The data bus is kept in its current state.
- WAIT monitored as inactive unfreezes the CYCLETIME counter. For accesses within a burst, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as inactive indicates the effective data capture of the bus by the external device and starts the next access of the burst. In case of a single access or if this was the last access in a multiple access cycle, all signals, including the data bus, are controlled according to their related control timing value and the CYCLETIME counter status.

Wait monitoring is supported for all configurations except for GPMC\_CONFIG1\_i[19-18]  
WAITMONITORINGTIME = 0 for write bursts with a clock divider of 1 or 2 (GPMC\_CONFIG1\_i[1-0]  
GPMCFCLKDIVIDER field equal to 0 or 1, respectively).

#### 9.1.3.3.8.3.6 WAIT With NAND Device

For details about the use of the wait pin for communication with a NAND flash external device, see [Section 9.1.3.3.12.2](#).

#### 9.1.3.3.8.3.7 Idle Cycle Control Between Successive Accesses

##### 9.1.3.3.8.3.7.1 Bus Turnaround (BUSTURNAROUND)

To prevent data-bus contention, an access that follows a read access to a slow memory/device must be delayed (in other words, control the CSn/OEn de-assertion to data bus in high-impedance delay).

The bus turnaround is a time-out counter starting after CSn or OEn de-assertion time, whichever occurs first, and delays the next access start-cycle time. The counter is programmed through the GPMC\_CONFIG6\_i[3-0] BUSTURNAROUND bit field.

After a read access to a chip-select with a non zero BUSTURNAROUND, the next access is delayed until the BUSTURNAROUND delay completes, if the next access is one of the following:

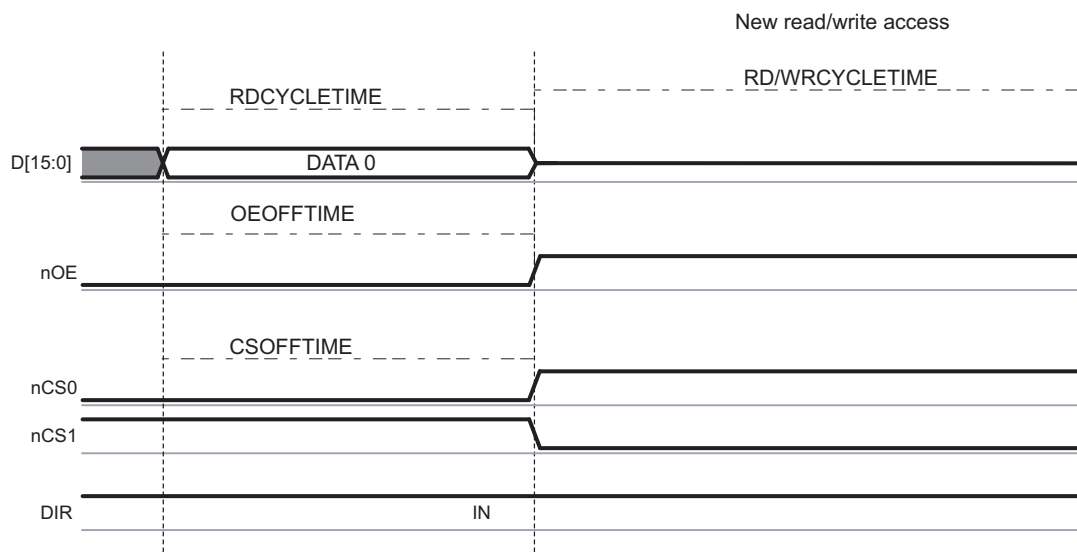

- A write access to any chip-select (same or different from the chip-select data was read from)
- A read access to a different chip-select from the chip-select data was read access from
- A read or write access to a chip-select associated with an address/data-multiplexed device

Bus keeping starts after bus turnaround completion so that DIR changes from IN to OUT after bus turnaround. The bus will not have enough time to go into high-impedance even though it could be driven with the same value before bus turnaround timing.

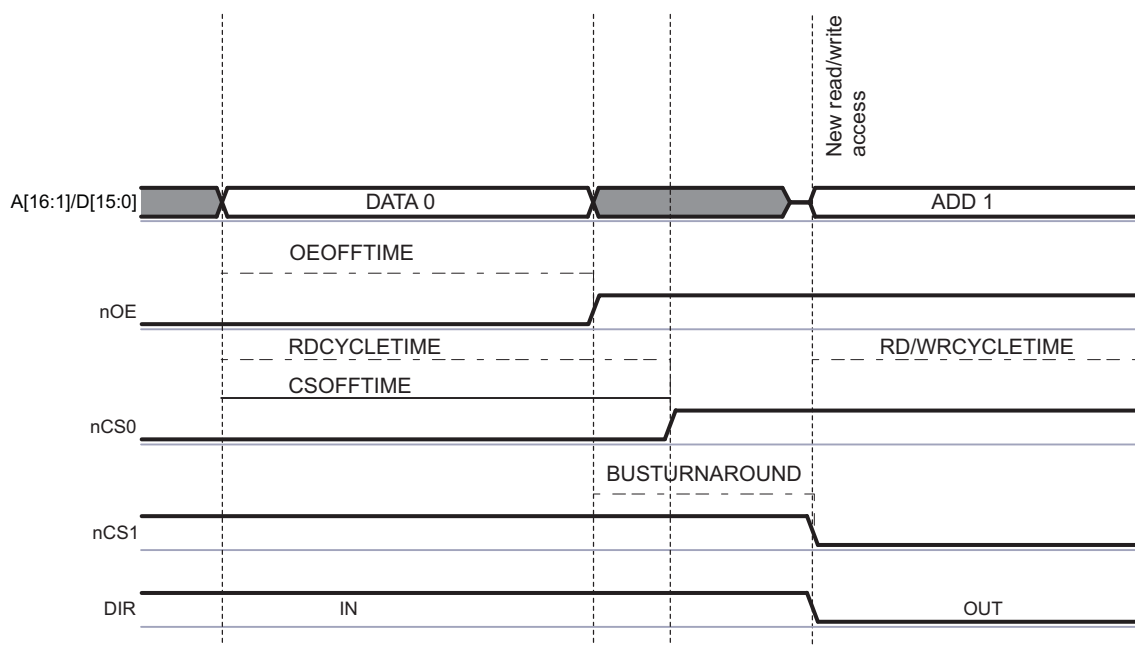

BUSTURNAROUND delay runs in parallel with GPMC\_CONFIG6\_i[3-0] CYCLE2CYCLEDELAY delays. It should be noted that BUSTURNAROUND is a timing parameter for the ending chip-select access while CYCLE2CYCLEDELAY is a timing parameter for the following chip-select access. The effective minimum delay between successive accesses is driven by these delay timing parameters and by the access type of the following access. See [Figure 9-9](#) to [Figure 9-11](#).

Another way to prevent bus contention is to define an earlier CSn or OEn deassertion time for slow devices or to extend the value of RDCYCLETIME. Doing this prevents bus contention, but affects all accesses of this specific chip-select.

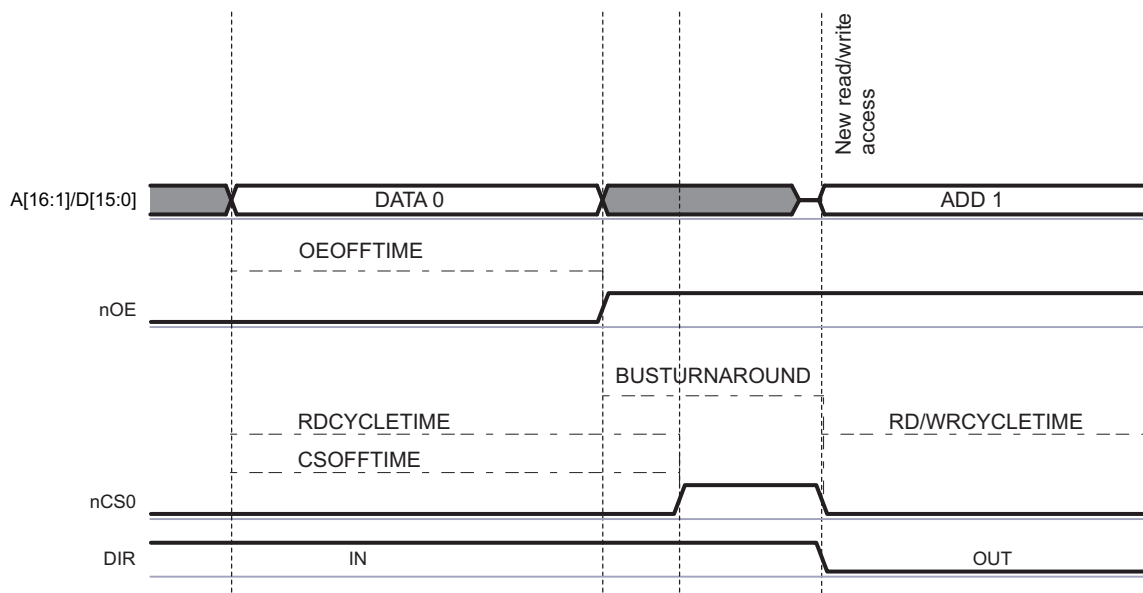

**Figure 9-9. Read to Read for an Address-Data Multiplexed Device, On Different CS, Without Bus Turnaround (CS0n Attached to Fast Device)**

**Figure 9-10. Read to Read / Write for an Address-Data Multiplexed Device, On Different CS, With Bus Turnaround**

**Figure 9-11. Read to Read / Write for a Address-Data or AAD-Multiplexed Device, On Same CS, With Bus Turnaround**

#### 9.1.3.3.8.3.7.2 Idle Cycles Between Accesses to Same Chip-Select (CYCLE2CYCLESAMEECSEN, CYCLE2CYCLEDELAY)

Some devices require a minimum chip-select signal inactive time between accesses. The GPMC\_CONFIG6\_i[7] CYCLE2CYCLESAMEECSEN bit enables insertion of a minimum number of GPMC\_FCLK cycles, defined by the GPMC\_CONFIG6\_i[11-8] CYCLE2CYCLEDELAY field, between successive accesses of any type (read or write) to the same chip-select.

If CYCLE2CYCLESAMEECSEN is enabled, any subsequent access to the same chip-select is delayed until its CYCLE2CYCLEDELAY completes. The CYCLE2CYCLEDELAY counter starts when CSRD OFFTIME/CSWROFFTIME completes.

The same applies to successive accesses occurring during 32-bit word or burst accesses split into successive single accesses when the single-access mode is used (GPMC\_CONFIG1\_i[30] READMULTIPLE = 0 or GPMC\_CONFIG1\_i[28] WRITEMULTIPLE = 0).

All control signals are kept in their default states during these idle GPMC\_FCLK cycles. This prevents back-to-back accesses to the same chip-select without idle cycles between accesses.

#### 9.1.3.3.8.3.7.3 Idle Cycles Between Accesses to Different Chip-Select (CYCLE2CYCLEDIFFECSEN, CYCLE2CYCLEDELAY)

Because of the pipelined behavior of the system, successive accesses to different chip-selects can occur back-to-back with no idle cycles between accesses. Depending on the control signals (CSn, ADV\_ALEn, BE0\_CLEn, OE\_REn, WEn) assertion and de-assertion timing parameters and on the IC timing parameters, some control signals assertion times may overlap between the successive accesses to different CS. Similarly, some control signals (WEn, OE\_REn) may not respect required transition times.

To work around the overlapping and to observe the required control-signal transitions, a minimum of CYCLE2CYCLEDELAY inactive cycles is inserted between the access being initiated to this chip-select and the previous access ending for a different chip-select. This applies to any type of access (read or write).

If GPMC\_CONFIG6\_i[6] CYCLE2CYCLEDIFFCSEN is enabled, the chip-select access is delayed until CYCLE2CYCLEDELAY cycles have expired since the end of a previous access to a different chip-select. CYCLE2CYCLEDELAY count starts at CSRDOFFTIME/CSWROFFTIME completion. All control signals are kept inactive during the idle GPMC\_FCLK cycles.

CYCLE2CYCLESAMECSEN and CYCLE2CYCLEDIFFCSEN should be set in registers to respectively get idle cycles inserted between accesses on this chip-select and after accesses to a different chip-select.

The CYCLE2CYCLEDELAY delay runs in parallel with the BUSTURNAROUND delay. It should be noted that BUSTURNAROUND is a timing parameter defined for the ending chip-select access, whereas CYCLE2CYCLEDELAY is a timing parameter defined for the starting chip-select access. The effective minimum delay between successive accesses is based on the larger delay timing parameter and on access type combination, since bus turnaround does not apply to all access types. See [Section 9.1.3.3.8.3.7.1](#) for more details on bus turnaround.

[Table 9-10](#) describes the configuration required for idle cycle insertion.

**Table 9-10. Idle Cycle Insertion Configuration**

First Access Type	BUSTURN AROUND Timing Parameter	Second Access Type	Chip-Select	Addr/Data Multiplexed	CYCLE2 CYCLE SAMECSEN Parameter	CYCLE2 CYCLE DIFFCSEN Parameter	Idle Cycle Insertion Between the Two Accesses
R/W	0	R/W	Any	Any	0	x	No idle cycles are inserted if the two accesses are well pipelined.
R	>0	R	Same	Nonmuxed	x	0	No idle cycles are inserted if the two accesses are well pipelined.
R	>0	R	Different	Nonmuxed	0	0	BUSTURNAROUND cycles are inserted.
R	>0	R/W	Any	Muxed	0	0	BUSTURNAROUND cycles are inserted.
R	>0	W	Any	Any	0	0	BUSTURNAROUND cycles are inserted.
W	>0	R/W	Any	Any	0	0	No idle cycles are inserted if the two accesses are well pipelined.
R/W	0	R/W	Same	Any	1	x	CYCLE2CYCLEDELAY cycles are inserted.
R/W	0	R/W	Different	Any	x	1	CYCLE2CYCLEDELAY cycles are inserted.
R/W	>0	R/W	Same	Any	1	x	CYCLE2CYCLEDELAY cycles are inserted. If BTA idle cycles already apply on these two back-to-back accesses, the effective delay is max (BUSTURNAROUND, CYCLE2CYCLEDELAY).
R/W	>0	R/W	Different	Any	x	1	CYCLE2CYCLEDELAY cycles are inserted. If BTA idle cycles already apply on these two back-to-back accesses, the effective delay is maximum (BUSTURNAROUND, CYCLE2CYCLEDELAY).

#### 9.1.3.3.8.3.8 Slow Device Support (TIMEPARAGRANULARITY Parameter)

All access-timing parameters can be multiplied by 2 by setting the GPMC\_CONFIG1\_i[4] TIMEPARAGRANULARITY bit. Increasing all access timing parameters allows support of slow devices.

#### 9.1.3.3.8.3.9 GPMC\_DIR Pin

The GPMC\_DIR pin is used to control I/O direction on the GPMC data bus GPMC\_D[15-0]. Depending on top-level pad multiplexing, this signal can be output and used externally to the device, if required. The GPMC\_DIR pin is low during transmit (OUT) and high during receive (IN).

For write accesses, the GPMC\_DIR pin stays OUT from start-cycle time to end-cycle time.

For read accesses, the GPMC\_DIR pin goes from OUT to IN at OEn assertion time and stays IN until:

- BUSTURNAROUND is enabled
  - The GPMC\_DIR pin goes from IN to OUT at end-cycle time plus programmable bus turnaround time.
- BUSTURNAROUND is disabled
  - After an asynchronous read access, the GPMC\_DIR pin goes from IN to OUT at RDACCESSTIME + 1 GPMC\_FCLK cycle or when RDCYCLETIME completes, whichever occurs last.
  - After a synchronous read access, the GPMC\_DIR pin goes from IN to OUT at RDACCESSTIME + 2 GPMC\_FCLK cycles or when RDCYCLETIME completes, whichever occurs last.

Because of the bus-keeping feature of the GPMC, after a read or write access and with no other accesses pending, the default value of the GPMC\_DIR pin is OUT (see [Section 9.1.3.3.9.10](#)). In nonmultiplexed devices, the GPMC\_DIR pin stays IN between two successive read accesses to prevent unnecessary toggling.

#### 9.1.3.3.8.3.10 Reset

No reset signal is sent to the external memory device by the GPMC. For more information about external-device reset, see [Chapter 6, Power, Reset, and Clock Management \(PRCM\)](#).

The PRCM module provides an input pin, global\_rst\_n, to the GPMC:

- The global\_rst\_n pin is activated during device warm reset and cold reset.
- The global\_rst\_n pin initializes the internal state-machine and the internal configuration registers.

#### 9.1.3.3.8.3.11 Write Protect Signal (WPn)

When connected to the attached memory device, the write protect signal can enable or disable the lockdown function of the attached memory. The GPMC\_WPn output pin value is controlled through the GPMC\_CONFIG[4] WRITEPROTECT bit, which is common to all CS.

#### 9.1.3.3.8.3.12 Byte Enable (BE1n/BE0n)

Byte enable signals (BE1n/BE0n) are:

- Valid (asserted or nonasserted according to the incoming system request) from access start to access completion for asynchronous and synchronous single accesses
- Asserted low from access start to access completion for asynchronous and synchronous multiple read accesses
- Valid (asserted or nonasserted, according to the incoming system request) synchronously to each written data for synchronous multiple write accesses

#### 9.1.3.3.8.4 Error Handling

When an error occurs in the GPMC, the error information is stored in the GPMC\_ERR\_TYPE register and the address of the illegal access is stored in the GPMC\_ERR\_ADDR register. The GPMC keeps only the first error abort information until the GPMC\_ERR\_TYPE register is reset. Subsequent accesses that cause errors are not logged until the error is cleared by hardware with the GPMC\_ERR\_TYPE[0]ERRORVALID bit.

- **ERRORNOTSUPPADD** occurs when an incoming system request address decoding does not match any valid chip-select region, or if two chip-select regions are defined as overlapped, or if a register file access is tried outside the valid address range of 1KB.
- **ERRORNOTSUPPMCMD** occurs when an unsupported command request is decoded at the L3 Slow interconnect interface
- **ERRORTIMEOUT**: A time-out mechanism prevents the system from hanging. The start value of the 9-bit time-out counter is defined in the GPMC\_TIMEOUT\_CTRL register and enabled with the GPMC\_TIMEOUT\_CTRL[0] TIMEOUTEN bit. When enabled, the counter starts at start-cycle time until it reaches 0 and data is not responded to from memory, and then a time-out error occurs. When data are sent from memory, this counter is reset to its start value. With multiple accesses (asynchronous page mode or synchronous burst mode), the counter is reset to its start value for each data access within the burst.

The GPMC does not generate interrupts on these errors. True abort to the MPU or interrupt generation is handled at the interconnect level.

#### 9.1.3.3.9 Timing Setting

The GPMC offers the maximum flexibility to support various access protocols. Most of the timing parameters of the protocol access used by the GPMC to communicate with attached memories or devices are programmable on a chip-select basis. Assertion and deassertion times of control signals are defined to match the attached memory or device timing specifications and to get maximum performance during accesses. For more information on GPMC\_CLK and GPMC\_FCLK see [Section 9.1.3.3.9.6](#).

In the following sections, the start access time refer to the time at which the access begins.

##### 9.1.3.3.9.1 Read Cycle Time and Write Cycle Time (RDCYCLETIME / WRCYCLETIME)

The GPMC\_CONFIG5\_i[4-0] RDCYCLETIME and GPMC\_CONFIG5\_i[12-8] WRCYCLETIME fields define the address bus and byte enables valid times for read and write accesses. To ensure a correct duty cycle of GPMC\_CLK between accesses, RDCYCLETIME and WRCYCLETIME are expressed in GPMC\_FCLK cycles and must be multiples of the GPMC\_CLK cycle. RDCYCLETIME and WRCYCLETIME bit fields can be set with a granularity of 1 or 2 through GPMC\_CONFIG1\_i[4] TIMEPARAGRANULARITY.

When either RDCYCLETIME or WRCYCLETIME completes, if they are not already deasserted, all control signals (CSn, ADV\_ALEn, OE\_REn, WEn, and BE0\_CLEn) are deasserted to their reset values, regardless of their deassertion time parameters.

An exception to this forced deassertion occurs when a pipelined request to the same chip-select or to a different chip-select is pending. In such a case, it is not necessary to deassert a control signal with deassertion time parameters equal to the cycle-time parameter. This exception to forced deassertion prevents any unnecessary glitches. This requirement also applies to BE signals, thus avoiding an unnecessary BE glitch transition when pipelining requests.

If no inactive cycles are required between successive accesses to the same or to a different chip-select (GPMC\_CONFIG6\_i[7] CYCLE2CYCLESAMECSSEN = 0 or GPMC\_CONFIG6\_i[6] CYCLE2CYCLEDIFFCSSEN = 0, where i = 0 to 3), and if assertion-time parameters associated with the pipelined access are equal to 0, asserted control signals (CSn, ADV\_ALEn, BE0\_CLEn, WEn, and OE\_REn) are kept asserted. This applies to any read/write to read/write access combination.

If inactive cycles are inserted between successive accesses, that is, CYCLE2CYCLESAMECSSEN = 1 or CYCLE2CYCLEDIFFCSSEN = 1, the control signals are forced to their respective default reset values for the number of GPMC\_FCLK cycles defined in CYCLE2CYCLEDELAY.

##### 9.1.3.3.9.2 CSn: Chip-Select Signal Control Assertion/Deassertion Time (CSONTIME / CSRDOFFTIME / CSWROFFTIME / CSEXTRADELAY)

The GPMC\_CONFIG2\_i[3-0] CSONTIME field defines the CSn signal-assertion time relative to the start access time. It is common for read and write accesses.

The GPMC\_CONFIG2\_i[12-8] CSRDOFFTIME (read access) and GPMC\_CONFIG2\_i[20-16] CSWROFFTIME (write access) bit fields define the CSn signal deassertion time relative to start access time.

CSONTIME, CSRDOFFTIME and CSWROFFTIME parameters are applicable to synchronous and asynchronous modes. CSONTIME can be used to control an address and byte enable setup time before chip-select assertion. CSRDOFFTIME and CSWROFFTIME can be used to control an address and byte enable hold time after chip-select deassertion.

CSn signal transitions as controlled through CSONTIME, CSRDOFFTIME, and CSWROFFTIME can be delayed by half a GPMC\_FCLK period by enabling the GPMC\_CONFIG2\_i[7] CSEXTRADELAY bit. This half of a GPMC\_FCLK period provides more granularity on the CSn assertion and deassertion time to guarantee proper setup and hold time relative to GPMC\_CLK. CSEXTRADELAY is especially useful in configurations where GPMC\_CLK and GPMC\_FCLK have the same frequency, but can be used for all GPMC configurations. If enabled, CSEXTRADELAY applies to all parameters controlling CSn transitions.

The CSEXTRADELAY bit must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the RDCYCLETIME and WRCYCLETIME bit fields to be greater than the CSn signal-deassertion time, including the extra half-GPMC\_FCLK-period delay.

#### **9.1.3.3.9.3 ADVn/ALE: Address Valid/Address Latch Enable Signal Control Assertion/Deassertion Time (ADVONTIME / ADVRDOFFTIME / ADVWROFFTIME / ADVEXTRADELAY/ADVAADMUXONTIME/ADVAADMUXRDOFFTIME/ADVAADMUXWROFFTIME)**

The GPMC\_CONFIG3\_i[3-0] ADVONTIME field defines the ADVn\_ALE signal-assertion time relative to start access time. It is common to read and write accesses.

The GPMC\_CONFIG3\_i[12-8] ADVRDOFFTIME (read access) and GPMC\_CONFIG3\_i[20-16] ADVWROFFTIME (write access) bit fields define the ADVn\_ALE signal-deassertion time relative to start access time.

ADVONTIME can be used to control an address and byte enable valid setup time control before ADVn\_ALE assertion. ADVRDOFFTIME and ADVWROFFTIME can be used to control an address and byte enable valid hold time control after ADVn\_ALE de-assertion. ADVRDOFFTIME and ADVWROFFTIME are applicable to both synchronous and asynchronous modes.

ADVn\_ALE signal transitions as controlled through ADVONTIME, ADVRDOFFTIME, and ADVWROFFTIME can be delayed by half a GPMC\_FCLK period by enabling the GPMC\_CONFIG3\_i[7] ADVEXTRADELAY bit. This half of a GPMC\_FCLK period provides more granularity on ADVn\_ALE assertion and deassertion time to assure proper setup and hold time relative to GPMC\_CLK. The ADVEXTRADELAY configuration parameter is especially useful in configurations where GPMC\_CLK and GPMC\_FCLK have the same frequency, but can be used for all GPMC configurations. If enabled, ADVEXTRADELAY applies to all parameters controlling ADVn\_ALE transitions.

ADVEXTRADELAY must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the RDCYCLETIME and WRCYCLETIME bit fields to be greater than ADVn\_ALE signal-deassertion time, including the extra half-GPMC\_FCLK-period delay.

The GPMC\_CONFIG3\_i[6-4] ADVAADMUXONTIME, GPMC\_CONFIG3\_i[26-24] ADVAADMUXRDOFFTIME, and GPMC\_CONFIG3\_i[30-28] ADVAADMUXWROFFTIME parameters have the same functions as ADVONTIME, ADVRDOFFTIME, and ADVWROFFTIME, but apply to the first address phase in the AAD-multiplexed protocol. It is the user responsibility to make sure ADVAADMUXxxOFFTIME is programmed to a value lower than or equal to ADVxxOFFTIME. Functionality in AAD-mux mode is undefined if the settings do not comply with this requirement. ADVAADMUXxxOFFTIME can be programmed to the same value as ADVONTIME if no high ADVn pulse is needed between the two AAD-mux address phases, which is the typical case in synchronous mode. In this configuration, ADVn is kept low until it reaches the correct ADVxxOFFTIME.

See [Section 9.1.3.3.12](#) for more details on ADVONTIME, ADVRDOFFTIME, ADVWROFFTIME, and ADVAADMUXRDOFFTIME, ADVAADMUXWROFFTIME usage for CLE and ALE (Command / Address Latch Enable) usage for a NAND Flash interface.

#### **9.1.3.3.9.4 OEn/REn: Output Enable / Read Enable Signal Control Assertion / Deassertion Time (OEONTIME / OEOFFTIME / OEEXTRADELAY / OEAADMUXONTIME / OEAADMUXOFFTIME)**

The GPMC\_CONFIG4\_i[3-0] OEONTIME field defines the OEn\_REn signal assertion time relative to start access time. It is applicable only to read accesses.

The GPMC\_CONFIG4\_i[12-8] OEOFFTIME field defines the OEn\_REn signal deassertion time relative to start access time. It is applicable only to read accesses. OEn\_REn is not asserted during a write cycle.

OEONTIME, OEOFFTIME, OEAADMUXONTIME and OEAADMUXOFFTIME parameters are applicable to synchronous and asynchronous modes. OEONTIME can be used to control an address and byte enable valid setup time control before OEn\_REn assertion. OEOFFTIME can be used to control an address and byte enable valid hold time control after OEn\_REn assertion.

OEAADMUXONTIME and OEAADMUXOFFTIME parameters have the same functions as OEONTIME and OEOFFTIME, but apply to the first OE assertion in the AAD-multiplexed protocol for a read phase, or to the only OE assertion for a write phase. It is the user responsibility to make sure OEAADMUXOFFTIME is programmed to a value lower than OEONTIME. Functionality in AAD-mux mode is undefined if the settings do not comply with this requirement. OEAADMUXOFFTIME shall never be equal to OEONTIME because the AAD-mux protocol requires a second address phase with the OEn signal de-asserted before OEn can be asserted again to define a read command.

The OEn\_REn signal transitions as controlled through OEONTIME, OEOFFTIME, OEAADMUXONTIME and OEAADMUXOFFTIME can be delayed by half a GPMC\_FCLK period by enabling the GPMC\_CONFIG4\_i[7] OEEXTRADELAY bit. This half of a GPMC\_FCLK period provides more granularity on OEn\_REn assertion and deassertion time to assure proper setup and hold time relative to GPMC\_CLK. If enabled, OEEXTRADELAY applies to all parameters controlling OEn\_REn transitions.

OEEXTRADELAY must be used carefully, to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program RDCYCLETIME and WRCYCLETIME to be greater than OEn\_REn signal-deassertion time, including the extra half-GPMC\_FCLK-period delay.

When the GPMC generates a read access to an address-/data-multiplexed device, it drives the address bus until OEn assertion time.

#### **9.1.3.3.9.5 WEn: Write Enable Signal Control Assertion / Deassertion Time (WEONTIME / WEOFFTIME / WEEXTRADELAY)**

The GPMC\_CONFIG4\_i[19-16] WEONTIME field (where i = 0 to 3) defines the WEn signal-assertion time relative to start access time. The GPMC\_CONFIG4\_i[28-24] WEOFFTIME field defines the WEn signal-deassertion time relative to start access time. These bit fields only apply to write accesses. WEn is not asserted during a read cycle.

WEONTIME can be used to control an address and byte enable valid setup time control before WEn assertion. WEOFFTIME can be used to control an address and byte enable valid hold time control after WEn assertion.

WEn signal transitions as controlled through WEONTIME, and WEOFFTIME can be delayed by half a GPMC\_FCLK period by enabling the GPMC\_CONFIG4\_i[23] WEEXTRADELAY bit. This half of a GPMC\_FCLK period provides more granularity on WEn assertion and deassertion time to guaranty proper setup and hold time relative to GPMC\_CLK. If enabled, WEEXTRADELAY applies to all parameters controlling WEn transitions.

The WEEXTRADELAY bit must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the WRCYCLETIME bit field to be greater than the WEn signal-deassertion time, including the extra half-GPMC\_FCLK-period delay.

#### 9.1.3.3.9.6 GPMC\_CLK

GPMC\_CLK is the external clock provided to the attached synchronous memory or device.

- The GPMC\_CLK clock frequency is the GPMC\_FCLK functional clock frequency divided by 1, 2, 3, or 4, depending on the GPMC\_CONFIG1\_i[1-0] GPMCFCLKDIVIDER bit field, with a guaranteed 50-percent duty cycle.
- The GPMC\_CLK clock is only activated when the access in progress is defined as synchronous (read or write access).
- The GPMC\_CONFIG1\_i[26-25] CLKACTIVATIONTIME field defines the number of GPMC\_FCLK cycles from start access time to GPMC\_CLK activation.
- The GPMC\_CLK clock is stopped when cycle time completes and is asserted low between accesses.
- The GPMC\_CLK clock is kept low when access is defined as asynchronous.
- When the GPMC is configured for synchronous mode, the GPMC\_CLK signal (which is an output) must also be set as an input in the Pin Mux configuration for the pin. GPMC\_CLK is looped back through the output and input buffers of the corresponding GPMC\_CLK pad at the device boundary. The looped-back clock is used to synchronize the sampling of the memory signals.

When cycle time completes, the GPMC\_CLK may be high because of the GPMCFCLKDIVIDER bit field. To ensure correct stoppage of the GPMC\_CLK clock within the 50-percent required duty cycle, it is the user's responsibility to extend the RDCYCLETIME or WRCYCLETIME value.

To ensure a correct external clock cycle, the following rules must be applied:

- $(RDCYCLETIME - CLKACTIVATIONTIME)$  must be a multiple of  $(GPMCFCLKDIVIDER + 1)$ .
- The PAGEBURSTACCESSTIME value must be a multiple of  $(GPMCFCLKDIVIDER + 1)$ .

#### 9.1.3.3.9.7 GPMC\_CLK and Control Signals Setup and Hold

Control-signal transition (assertion and deassertion) setup and hold values with respect to the GPMC\_CLK edge can be controlled in the following ways:

- For the GPMC\_CLK signal, the GPMC\_CONFIG1\_i[26-25] CLKACTIVATIONTIME field allows setup and hold control of control-signal assertion time.
- The use of a divided GPMC\_CLK allows setup and hold control of control-signal assertion and deassertion times.
- When GPMC\_CLK runs at the GPMC\_FCLK frequency so that GPMC\_CLK edge and control-signal transitions refer to the same GPMC\_FCLK edge, the control-signal transitions can be delayed by half of a GPMC\_FCLK period to provide minimum setup and hold times. This half-GPMC\_FCLK delay is enabled with the CSEXTRADELAY, ADVEXTRADELAY, OEEXTRADELAY, or WEEEXTRADELAY parameter. This delay must be used carefully to prevent control-signal overlap between successive accesses to different chip-selects. This implies that the RDCYCLETIME and WRCYCLETIME are greater than the last control-signal deassertion time, including the extra half-GPMC\_FCLK cycle.

#### 9.1.3.3.9.8 Access Time (RDACCESSTIME / WRACCESSTIME)

The read access time and write access time durations can be programmed independently through GPMC\_CONFIG5\_i[20-16] RDACCESSTIME and GPMC\_CONFIG6\_i[28-24] WRACCESSTIME. This allows OEn and GPMC data capture timing parameters to be independent of WEn and memory device data capture timing parameters. RDACCESSTIME and WRACCESSTIME bit fields can be set with a granularity of 1 or 2 through GPMC\_CONFIG1\_i[4] TIMEPARAGRANULARITY.

##### 9.1.3.3.9.8.1 Access Time on Read Access

In asynchronous read mode, for single and paged accesses, GPMC\_CONFIG5\_i[[20-16] RDACCESSTIME field defines the number of GPMC\_FCLK cycles from start access time to the GPMC\_FCLK rising edge used for the first data capture. RDACCESSTIME must be programmed to the rounded greater value (in GPMC\_FCLK cycles) of the read access time of the attached memory device.

In synchronous read mode, for single or burst accesses, RDACCESSTIME defines the number of GPMC\_FCLK cycles from start access time to the GPMC\_FCLK rising edge corresponding to the GPMC\_CLK rising edge used for the first data capture.

GPMC\_CLK which is sent to the memory device for synchronization with the GPMC controller, is internally retimed to correctly latch the returned data. GPMC\_CONFIG5\_i[4-0] RDCYCLETIME must be greater than RDACCESSTIME in order to let the GPMC latch the last return data using the internally retimed GPMC\_CLK.

The external WAIT signal can be used in conjunction with RDACCESSTIME to control the effective GPMC data-capture GPMC\_FCLK edge on read access in both asynchronous mode and synchronous mode. For details about wait monitoring, see [Section 9.1.3.3.8.1](#).

#### **9.1.3.3.9.8.2 Access Time on Write Access**

In asynchronous write mode, the GPMC\_CONFIG6\_i[[28-24] WRACCESSTIME timing parameter is not used to define the effective write access time. Instead, it is used as a WAIT invalid timing window, and must be set to a correct value so that the gpmc\_wait pin is at a valid state two GPMC\_CLK cycles before WRACCESSTIME completes. For details about wait monitoring, see [Section 9.1.3.3.8.1](#).

In synchronous write mode, for single or burst accesses, WRACCESSTIME defines the number of GPMC\_FCLK cycles from start access time to the GPMC\_CLK rising edge used by the memory device for the first data capture.

The external WAIT signal can be used in conjunction with WRACCESSTIME to control the effective memory device data capture GPMC\_CLK edge for a synchronous write access. For details about wait monitoring, see [Section 9.1.3.3.8.1](#).

#### **9.1.3.3.9.9 Page Burst Access Time (PAGEBURSTACCESSTIME)**

GPMC\_CONFIG5\_i[27-24] PAGEBURSTACCESSTIME bit field can be set with a granularity of 1 or 2 through the GPMC\_CONFIG1\_i[[4] TIMEPARAGRANULARITY.

##### **9.1.3.3.9.9.1 Page Burst Access Time on Read Access**

In asynchronous page read mode, the delay between successive word captures in a page is controlled through the PAGEBURSTACCESSTIME bit field. The PAGEBURSTACCESSTIME parameter must be programmed to the rounded greater value (in GPMC\_FCLK cycles) of the read access time of the attached device.

In synchronous burst read mode, the delay between successive word captures in a burst is controlled through the PAGEBURSTACCESSTIME field.

The external WAIT signal can be used in conjunction with PAGEBURSTACCESSTIME to control the effective GPMC data capture GPMC\_FCLK edge on read access. For details about wait monitoring, see [Section 9.1.3.3.8.1](#).

##### **9.1.3.3.9.9.2 Page Burst Access Time on Write Access**

Asynchronous page write mode is not supported. PAGEBURSTACCESSTIME is irrelevant in this case.

In synchronous burst write mode, PAGEBURSTACCESSTIME controls the delay between successive memory device word captures in a burst.

The external WAIT signal can be used in conjunction with PAGEBURSTACCESSTIME to control the effective memory-device data capture GPMC\_CLK edge in synchronous write mode. For details about wait monitoring, see [Section 9.1.3.3.8.1](#).

#### **9.1.3.3.9.10 Bus Keeping Support**

At the end-cycle time of a read access, if no other access is pending, the GPMC drives the bus with the last data read after RDCYCLETIME completion time to prevent bus floating and reduce power consumption.

After a write access, if no other access is pending, the GPMC keeps driving the data bus after WRCYCLETIME completes with the same data to prevent bus floating and power consumption.

#### 9.1.3.3.10 NOR Access Description

For each chip-select configuration, the read access can be specified as either asynchronous or synchronous access through the GPMC\_CONFIG1\_i[29] READTYPE bit. For each chip-select configuration, the write access can be specified as either synchronous or asynchronous access through the GPMC\_CONFIG1\_i[27] WRITETYPE bit.

Asynchronous and synchronous read and write access time and related control signals are controlled through timing parameters that refer to GPMC\_FCLK. The primary difference of synchronous mode is the availability of a configurable clock interface (GPMC\_CLK) to control the external device. Synchronous mode also affects data-capture and wait-pin monitoring schemes in read access.

For details about asynchronous and synchronous access, see the descriptions of GPMC\_CLK, RdAccessTime, WrAccessTime, and wait-pin monitoring.

For more information about timing-parameter settings, see the sample timing diagrams in this chapter.

The address bus and BE[1:0]n are fixed for the duration of a synchronous burst read access, but they are updated for each beat of an asynchronous page-read access.

#### 9.1.3.3.10.1 Asynchronous Access Description

This section describes:

- Asynchronous single read operation on an address/data multiplexed device
- Asynchronous single write operation on an address/data-multiplexed device
- Asynchronous single read operation on an AAD-multiplexed device
- Asynchronous single write operation on an AAD-multiplexed device
- Asynchronous multiple (page) read operation on a non-multiplexed device

In asynchronous operations GPMC\_CLK is not provided outside the GPMC and is kept low.

### 9.1.3.3.10.1.1 Access on Address/Data Multiplexed Devices

#### 9.1.3.3.10.1.1.1 Asynchronous Single-Read Operation on an Address/Data Multiplexed Device

Figure 9-12 shows an asynchronous single read operation on an address/data-multiplexed device.

**Figure 9-12. Asynchronous Single Read Operation on an Address/Data Multiplexed Device**

#### 9.1.3.3.10.1.1.2 Asynchronous Single Read on an Address/Data-Multiplexed Device

See the device-specific datasheet for formulas to calculate timing parameters.

Table 9-41 lists the timing bit fields to set up in order to configure the GPMC in asynchronous single read mode.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until OEn assertion time. For details, see Section 9.1.3.3.8.2.3.

Address bits (A[16:1] from a GPMC perspective, A[15:0] from an external device perspective) are placed on the address/data bus, and the remaining address bits GPMC\_A[25:16] are placed on the address bus. The address phase ends at OEn assertion, when the DIR signal goes from OUT to IN.

- Chip-select signal CSn
  - CSn assertion time is controlled by the GPMC\_CONFIG2\_i[3-0] CS ONTIME field. It controls the address setup time to CSn assertion.
  - CSn deassertion time is controlled by the GPMC\_CONFIG2\_i[12-8] CS RD OFFTIME field. It controls the address hold time from CSn deassertion
- Address valid signal ADVn
  - ADVn assertion time is controlled by the GPMC\_CONFIG3\_i[3-0] ADV ONTIME field.
  - ADVn deassertion time is controlled by the GPMC\_CONFIG3\_i[[12-8] ADV RD OFFTIME field.

- Output enable signal OEn
  - OEn assertion indicates a read cycle.
  - OEn assertion time is controlled by the GPMC\_CONFIG4\_i[[3-0] OEONTIME field.
  - OEn deassertion time is controlled by the GPMC\_CONFIG4\_i[[12-8] OEOFFTIME field.
- Read data is latched when RDACCESSTIME completes. Access time is defined in the GPMC\_CONFIG5\_i[[20-16] RDACCESSTIME field.
- Direction signal DIR: DIR goes from OUT to IN at the same time that OEn is asserted.
- The end of the access is defined by the GPMC\_CONFIG5\_i[[4-0] RDCYCLETIME parameter.

In the GPMC, when a 16-bit wide device is attached to the controller, a 32-bit word write access is split into two 16-bit word write accesses. For more information about GPMC access size and type adaptation, see [Section 9.1.3.3.10.5](#). Between two successive accesses, if a OEn pulse is needed:

- The GPMC\_CONFIG6\_i[[11-8] CYCLE2CYCLEDELAY field can be programmed with GPMC\_CONFIG6\_i[[7] CYCLE2CYCLESAMECSSEN enabled.
- The CSWROFFTIME and CSONTIME parameters also allow a chip-select pulse, but this affects all other types of access.

Figure 9-13 shows two asynchronous single-read accesses on an address/data-multiplexed devices.

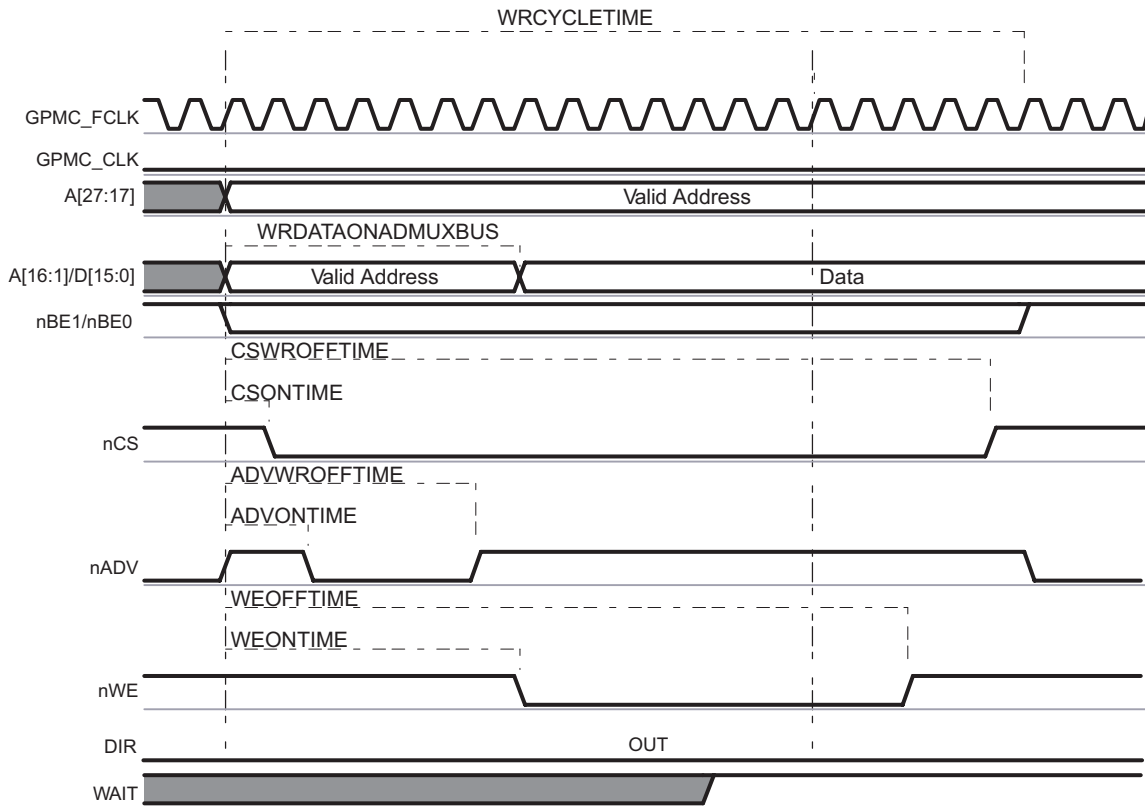

**Figure 9-13. Two Asynchronous Single Read Accesses on an Address/Data Multiplexed Device (32-Bit Read Split Into 2 × 16-Bit Read)**

### 9.1.3.3.10.1.1.3 Asynchronous Single Write Operation on an Address/Data-Multiplexed Device

Figure 9-14 shows an asynchronous single write operation on an address/data-multiplexed device.

**Figure 9-14. Asynchronous Single Write on an Address/Data-Multiplexed Device**

### 9.1.3.3.10.1.1.4 Asynchronous Single Write on an Address/Data-Multiplexed Device

See the device-specific datasheet for formulas to calculate timing parameters.

Table 9-41 lists the timing bit fields to set up in order to configure the GPMC in asynchronous single write mode. When the GPMC generates a write access to an address/data-multiplexed device, it drives the address bus until WEn assertion time. For more information, see Section 9.1.3.3.8.2.3.

The CSn and ADVn signals are controlled in the same way as for asynchronous single read operation on an address/data-multiplexed device.

- Write enable signal WEn
  - WEn assertion indicates a write cycle.
  - WEn assertion time is controlled by the GPMC\_CONFIG4\_i[19-16] WEONTIME field.
  - WEn deassertion time is controlled by the GPMC\_CONFIG4\_i[28-24] WEOFFTIME field.
- Direction signal DIR: DIR signal is OUT during the entire access.
- The end of the access is defined by the GPMC\_CONFIG5\_i[12-8] WRCYCLETIME parameter.

Address bits A[16:1] (GPMC point of view) are placed on the address/data bus at the start of cycle time, and the remaining address bits A[26:17] are placed on the address bus.

Data is driven on the address/data bus at a GPMC\_CONFIG6\_i[19-16] WRDATAONADMUXBUS time.

Write multiple access in asynchronous mode is not supported. If WRITEMULTIPLE is enabled with WRITETYPE as asynchronous, the GPMC processes single asynchronous accesses.

After a write operation, if no other access (read or write) is pending, the data bus keeps its previous value. See [Section 9.1.3.3.9.10](#).

#### 9.1.3.3.10.1.1.5 Asynchronous Multiple (Page) Write Operation on an Address/Data-Multiplexed Device

Write multiple (page) access in asynchronous mode is not supported for address/data-multiplexed devices. If GPMC\_CONFIG1\_i[28] WRITEMULTIPLE is enabled (1) with GPMC\_CONFIG1\_i[27] WRITETYPE as asynchronous (0), the GPMC processes single asynchronous accesses.

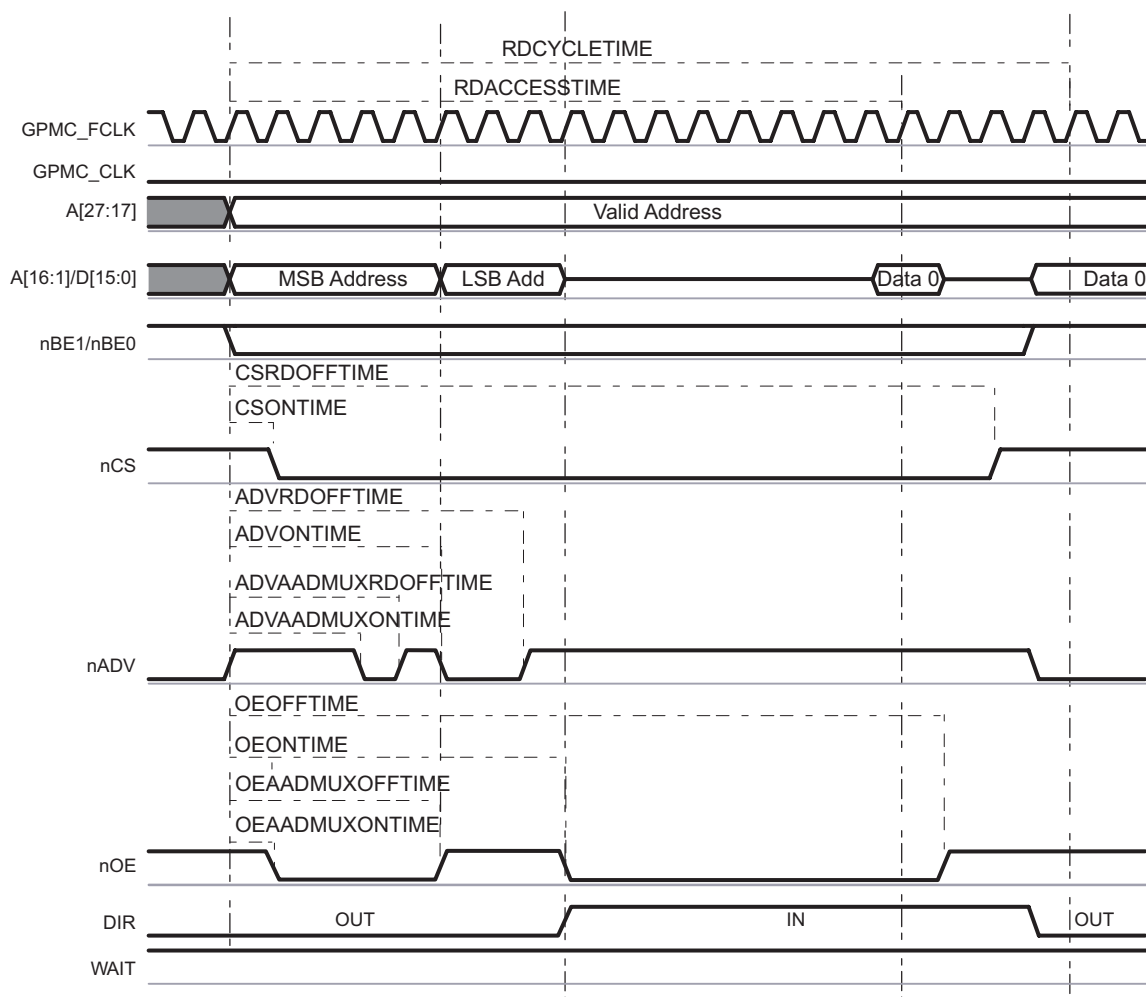

For accesses on non-multiplexed devices, see [Section 9.1.3.3.10.3](#).

#### 9.1.3.3.10.1.2 Access on Address/Address/Data (AAD) Multiplexed Devices

##### 9.1.3.3.10.1.2.1 Asynchronous Single Read Operation on an AAD-Multiplexed Device

[Figure 9-15](#) shows an asynchronous single read operation on an AAD-multiplexed device.

**Figure 9-15. Asynchronous Single-Read on an AAD-Multiplexed Device**

### 9.1.3.3.10.1.2.2 Asynchronous Single Read on an AAD-Multiplexed Device

See the device-specific datasheet for formulas to calculate timing parameters.

[Table 9-41](#) lists the timing bit fields to set up in order to configure the GPMC in asynchronous single write mode.

When the GPMC generates a read access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with OEn driven low. The first address phase ends at the first OEn deassertion time. The second phase for LSB address is qualified with OEn driven high. The second address phase ends at the second OEn assertion time, when the DIR signal goes from OUT to IN.

The CSn and DIR signals are controlled in the same way as for asynchronous single read operation on an address/data-multiplexed device.

- Address valid signal ADVn. ADVn is asserted and deasserted twice during a read transaction:
  - ADVn first assertion time is controlled by the GPMC\_CONFIG3\_i[6-4] ADVAADMUXONTIME field.
  - ADVn first deassertion time is controlled by the GPMC\_CONFIG3\_i[26-24] ADVAADMUXRDOFFTIME field.
  - ADVn second assertion time is controlled by the GPMC\_CONFIG3\_i[3-0] ADVONTIME field.
  - ADVn second deassertion time is controlled by the GPMC\_CONFIG3\_i[12-8] ADVRDOFFTIME field.
- Output Enable signal OEn. OEn is asserted and deasserted twice during a read transaction (OEn second assertion indicates a read cycle):
  - OEn first assertion time is controlled by the GPMC\_CONFIG4\_i[6-4] OEAADMUXONTIME field.
  - OEn first deassertion time is controlled by the GPMC\_CONFIG3\_i[15-13] OEAADMUXOFFTIME field.
  - OEn second assertion time is controlled by the GPMC\_CONFIG4\_i[3-0] OEONTIME field.
  - OEn second deassertion time is controlled by the GPMC\_CONFIG4\_i[12-8] OEOFFTIME field.

### 9.1.3.3.10.1.2.3 Asynchronous Single Write Operation on an AAD-Multiplexed Device

Figure 9-16 shows an asynchronous single write operation on an AAD-multiplexed device.

**Figure 9-16. Asynchronous Single Write on an AAD-Multiplexed Device**

See the device-specific datasheet for formulas to calculate timing parameters.

[Table 9-41](#) lists the timing bit fields to set up to configure the GPMC in asynchronous single write mode.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with OEn driven low. The second phase for LSB address is qualified with OEn driven high. The address phase ends at WEn assertion time.

The CSn, WEn, and DIR signals are controlled in the same way as for asynchronous single write operation on an address/data-multiplexed device.

- Address valid signal ADVn is asserted and deasserted twice during a write transaction
  - ADVn first assertion time is controlled by the GPMC\_CONFIG3\_i[6-4] ADVAADMUXONTIME field.
  - ADVn first deassertion time is controlled by the GPMC\_CONFIG3\_i[30-28] ADVAADMUXWROFFTIME field.
  - ADVn second assertion time is controlled by the GPMC\_CONFIG3\_i[3-0] ADVONTIME field.
  - ADVn second deassertion time is controlled by the GPMC\_CONFIG3\_i[20-16] ADVWROFFTIME field.
- Output Enable signal OEn is asserted during the address phase of a write transaction
  - OEn assertion time is controlled by the GPMC\_CONFIG4\_i[6-4] OEAADMUXONTIME field.
  - OEn deassertion time is controlled by the GPMC\_CONFIG3\_i[15-13] OEAADMUXOFFTIME field.

The address bits for the first address phase are driven onto the data bus until OEn deassertion. Data is driven onto the address/data bus at the clock edge defined by the GPMC\_CONFIG6\_i[19-16] WRDATAONADMUXBUS parameter.

#### **9.1.3.3.10.1.2.4 Asynchronous Multiple (Page) Read Operation on an AAD-Multiplexed Device**

Write multiple (page) access in asynchronous mode is not supported for AAD-multiplexed devices.

If GPMC\_CONFIG1\_i[28] WRITEMULTIPLE is enabled (1) with GPMC\_CONFIG1\_i[27] WRITETYPE as asynchronous (0), the GPMC processes single asynchronous accesses.

For accesses on non-multiplexed devices, see [Section 9.1.3.3.10.3](#).

#### **9.1.3.3.10.2 Synchronous Access Description**

This section details read and write synchronous accesses on address/data multiplexed. All information in this section can be applied to any type of memory - non-multiplexed, address and data multiplexed or AAD-multiplexed - with a difference limited to the address phase. For accesses on non-multiplexed devices, see [Section 9.1.3.3.10.3](#).

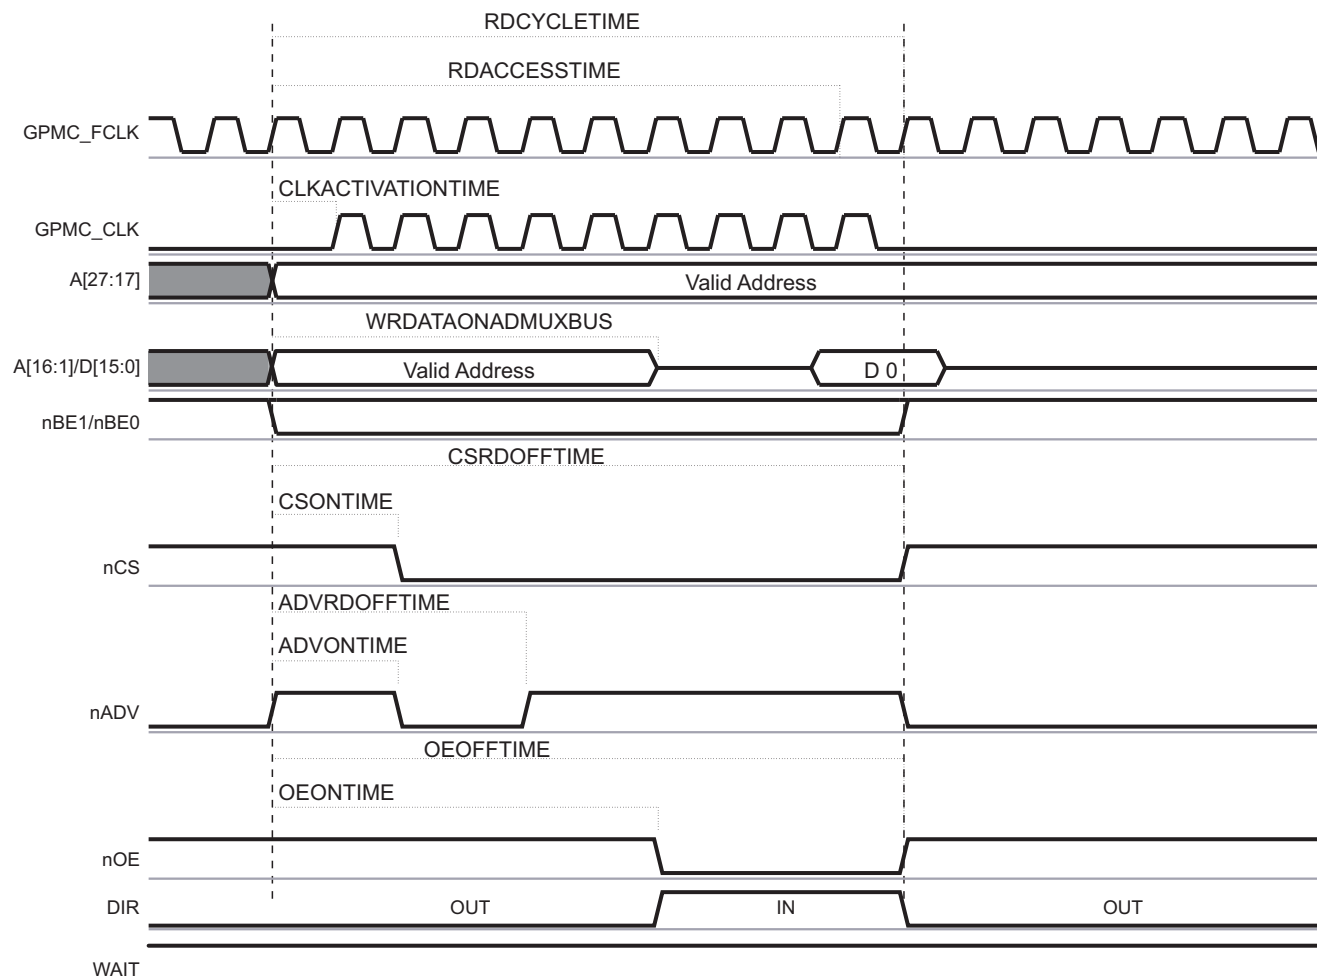

In synchronous operations:

- The GPMC\_CLK clock is provided outside the GPMC when accessing the memory device.
- The GPMC\_CLK clock is derived from the GPMC\_FCLK clock using the GPMC\_CONFIG1\_i[1-0] GPMCFCLKDIVIDER field. In the following section, i stands for the chip-select number, i = 0 to 3.
- The GPMC\_CONFIG1\_i[26-25] CLKACTIVATIONTIME field specifies that the GPMC\_CLK is provided outside the GPMC 0, 1, or 2 GPMC\_FCLK cycles after start access time until RDCYCLETIME or WRCYCLETIME completion.

### 9.1.3.3.10.2.1 Synchronous Single Read

Figure 9-17 and Figure 9-18 show a synchronous single-read operation with GPMCFCLKDIVIDER equal to 0 and 1, respectively.

**Figure 9-17. Synchronous Single Read (GPMCFCLKDIVIDER = 0)**

**Figure 9-18. Synchronous Single Read (GPMCFCLKDIVIDER = 1)**

See the device-specific datasheet for formulas to calculate timing parameters.

[Table 9-41](#) lists the timing bit fields to set up in order to configure the GPMC in asynchronous single read mode.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until OEn assertion time. For details, see [Section 9.1.3.3.8.2.3](#).

- Chip-select signal CSn
  - CSn assertion time is controlled by the GPMC\_CONFIG2\_i[3-0] CSONTIME field and ensures address setup time to CSn assertion.
  - CSn deassertion time is controlled by the GPMC\_CONFIG2\_i[12-8] CSRDOFFTIME field and ensures address hold time to CSn deassertion.
- Address valid signal ADVn
  - ADVn assertion time is controlled by the GPMC\_CONFIG3\_i[3-0] ADVONTIME field.
  - ADVn deassertion time is controlled by the GPMC\_CONFIG3\_i[12-8] ADVRDOFFTIME field.
- Output enable signal OEn
  - OEn assertion indicates a read cycle.
  - OEn assertion time is controlled by the GPMC\_CONFIG4\_i[3-0] OEONTIME field.
  - OEn deassertion time is controlled by the GPMC\_CONFIG4\_i[12-8] OEOFFTIME field.
- Initial latency for the first read data is controlled by GPMC\_CONFIG5\_i[20-16] RDACCESSTIME or by monitoring the WAIT signal.
- Total access time (GPMC\_CONFIG5\_i[4-0] RDCYCLETIME) corresponds to RDACCESSTIME plus the address hold time from CSn deassertion, plus time from RDACCESSTIME to CSRDOFFTIME.

- Direction signal DIR: DIR goes from OUT to IN at the same time as OEn assertion.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with OEn driven low. The second phase for LSB address is qualified with OEn driven high. The address phase ends at WEn assertion time.

The CSn and DIR signals are controlled in the same way as for synchronous single read operation on an address/data-multiplexed device.

- Address valid signal ADVn is asserted and deasserted twice during a read transaction
  - ADVn first assertion time is controlled by the GPMC\_CONFIG3\_i[6-4] ADVAADMUXONTIME field.
  - ADVn first deassertion time is controlled by the GPMC\_CONFIG3\_i[26-24] ADVAADMUXRDOFFTIME field.
  - ADVn second assertion time is controlled by the GPMC\_CONFIG3\_i[3-0] ADVONTIME field.
  - ADVn second deassertion time is controlled by the GPMC\_CONFIG3\_i[12-8] ADVRDOFFTIME field.
- Output Enable signal OEn is asserted and deasserted twice during a read transaction (OEn second assertion indicates a read cycle)
  - OEn first assertion time is controlled by the GPMC\_CONFIG4\_i[6-4] OEAADMUXONTIME field.
  - OEn first deassertion time is controlled by the GPMC\_CONFIG3\_i[15-13] OEAADMUXOFFTIME field.
  - OEn second assertion time is controlled by the GPMC\_CONFIG4\_i[3-0] OEONTIME field.
  - OEn second deassertion time is controlled by the GPMC\_CONFIG4\_i[12-8] OEOFFTIME field.

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See [Section 9.1.3.3.9.10](#).

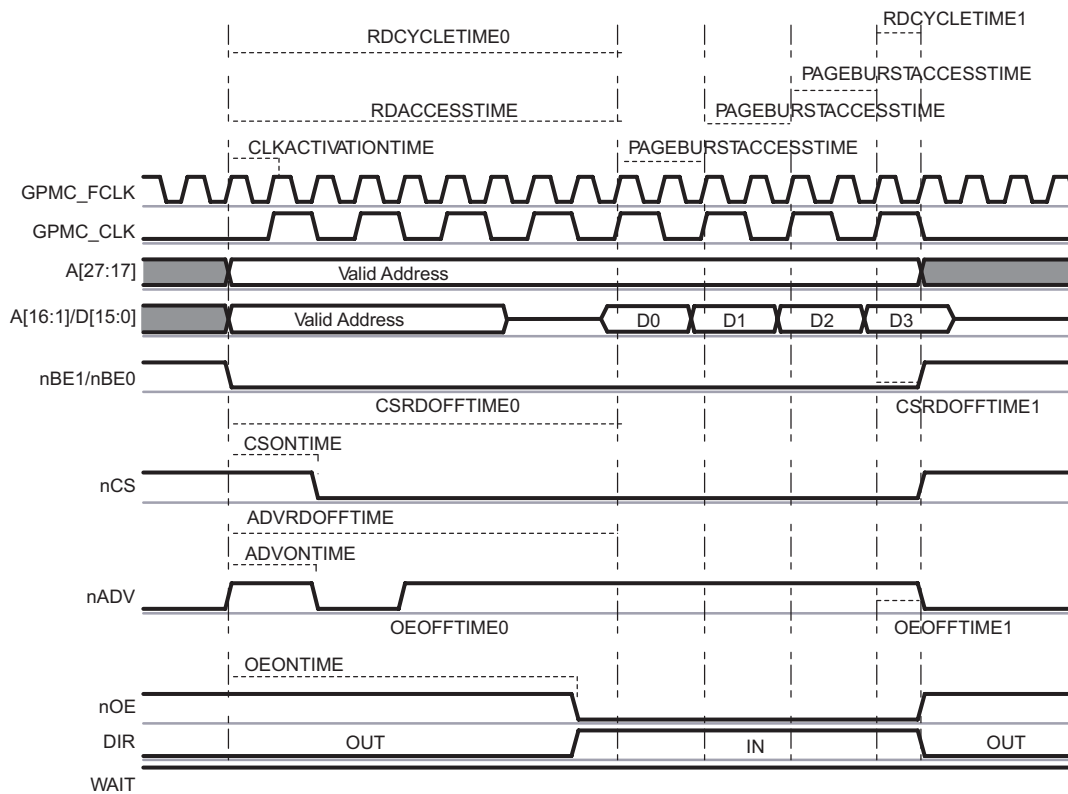

### 9.1.3.3.10.2.2 Synchronous Multiple (Burst) Read (4-, 8-, 16-Word16 Burst With Wraparound Capability)

Figure 9-19 and Figure 9-20 show a synchronous multiple read operation with GPMCFCLKDivider equal to 0 and 1, respectively.

**Figure 9-19. Synchronous Multiple (Burst) Read (GPMCFCLKDIVIDER = 0)**

**Figure 9-20. Synchronous Multiple (Burst) Read (GPMCFCLKDIVIDER = 1)**

When GPMC\_CONFIG5\_i[20-16] RDACCESSTIME completes, control-signal timings are frozen during the multiple data transactions, corresponding to GPMC\_CONFIG5\_i[27-24] PAGEBURSTACCESSTIME multiplied by the number of remaining data transactions.

The CSn, ADVn, OEn and DIR signals are controlled in the same way as for synchronous single read operation. See [Section 9.1.3.3.10.2.1](#).

Initial latency for the first read data is controlled by RDACCESSTIME or by monitoring the WAIT signal. Successive read data are provided by the memory device each one or two GPMC\_CLK cycles. The PAGEBURSTACCESSTIME parameter must be set accordingly with GPMC\_CONFIG1\_i[1-0] GPMCFCLKDIVIDER and the memory-device internal configuration. Depending on the device page length, the GPMC checks device page crossing during a new burst request and purposely insert initial latency (of RDACCESSTIME) when required.

Total access time GPMC\_CONFIG5\_i[4-0] RDCYCLETIME corresponds to RDACCESSTIME plus the address hold time from CSn deassertion. In [Figure 9-19](#), RDCYCLETIME programmed value equals to RDCYCLETIME0 + RDCYCLETIME1.

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See [Section 9.1.3.3.9.10](#).

Burst wraparound is enabled through the GPMC\_CONFIG1\_i[31] WRAPBURST bit and allows a 4-, 8-, or 16-Word16 linear burst access to wrap within its burst-length boundary through GPMC\_CONFIG1\_i[24-23] ATTACHEDDEVICEPAGELENGTH.

### 9.1.3.3.10.2.3 Synchronous Single Write

Burst write mode is used for synchronous single or burst accesses (see [Figure 9-21](#)).

**Figure 9-21. Synchronous Single Write on an Address/Data-Multiplexed Device**

When the GPMC generates a write access to an address/data-multiplexed device, it drives the data bus (with address bits A[16:1]) until [19:16] WRDATAONADMUXBUS time. First data of the burst is driven on the address/data bus at WRDATAONADMUXBUS time.

#### 9.1.3.3.10.2.4 Synchronous Multiple (Burst) Write

Synchronous burst write mode provides synchronous single or consecutive accesses. Figure 9-22 shows a synchronous burst write access when the chip-select is configured in address/data-multiplexed mode.

**Figure 9-22. Synchronous Multiple Write (Burst Write) in Address/Data-Multiplexed Mode**

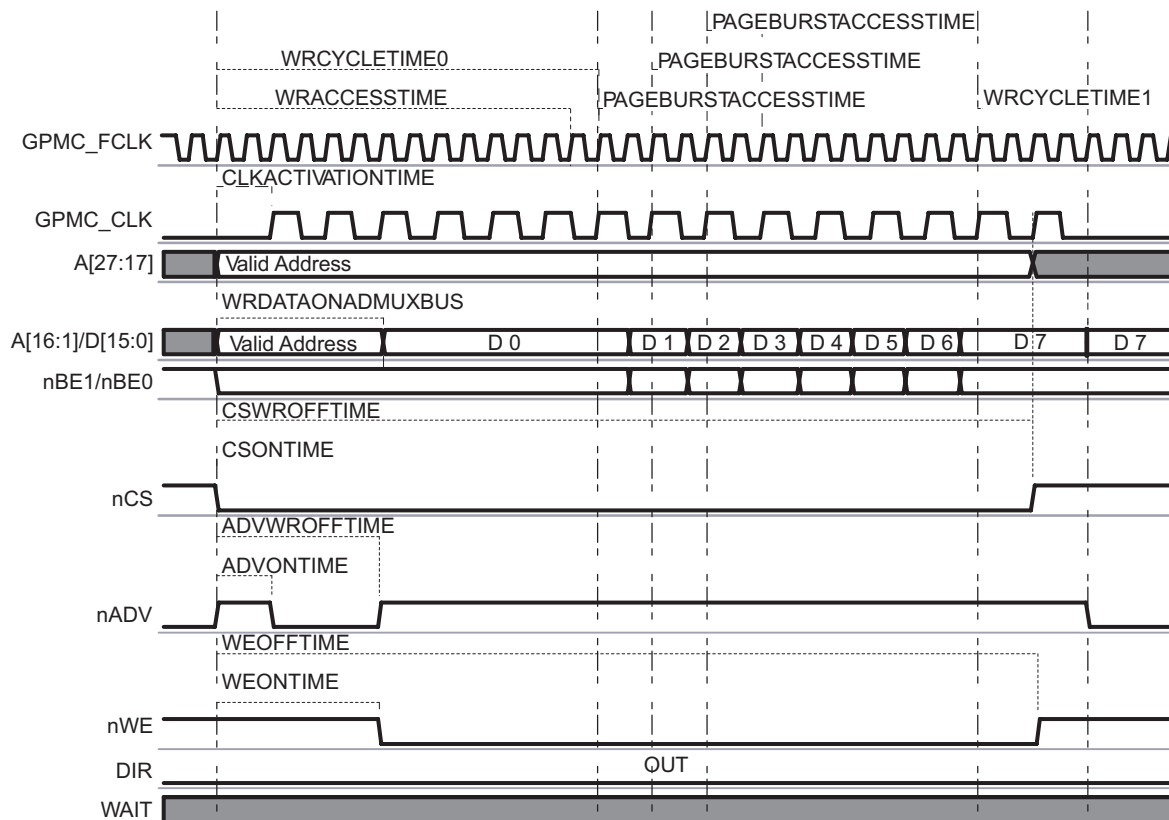

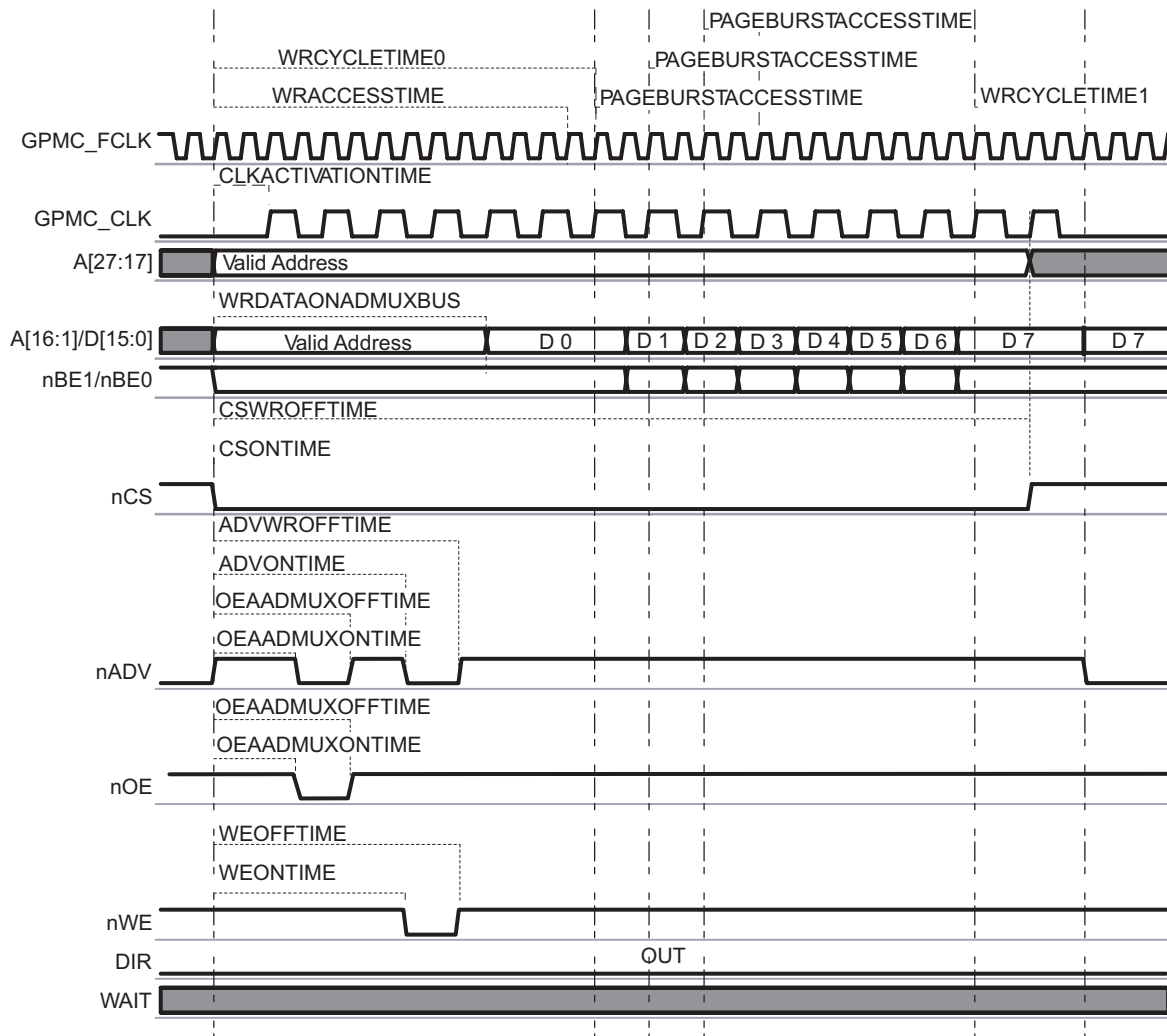

Figure 9-23 shows the same synchronous burst write access when the chip-select is configured in address/address/data-multiplexed (AAD-multiplexed) mode.

**Figure 9-23. Synchronous Multiple Write (Burst Write) in Address/Address/Data-Multiplexed Mode**

The first data of the burst is driven on the A/D bus at GPMC\_CONFIG6\_i[19:16] WRDATAONADMUXBUS.

When WRACCESTIME completes, control-signal timings are frozen during the multiple data transactions, corresponding to the GPMC\_CONFIG5\_i[27:24] PAGEBURSTACCESSTIME multiplied by the number of remaining data transactions.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until OEn assertion time. For details, see [Section 9.1.3.3.8.2.3](#).

- Chip-select signal CSn
  - CSn assertion time is controlled by the GPMC\_CONFIG2\_i[3:0] CSONTIME field and ensures address setup time to CSn assertion.
  - CSn deassertion time controlled by the GPMC\_CONFIG2\_i[20:16] CSWROFFTIME field and ensures address hold time to CSn deassertion.
- Address valid signal ADVn
  - ADVn assertion time is controlled by the GPMC\_CONFIG3\_i[3:0] ADVONTIME field.
  - ADVn deassertion time is controlled by the GPMC\_CONFIG3\_i[20:16] ADVWROFFTIME field.

- Write enable signal WEn
  - WEn assertion indicates a read cycle.
  - WEn assertion time is controlled by the GPMC\_CONFIG4\_i[19-16] WEONTIME field.
  - WEn deassertion time is controlled by the GPMC\_CONFIG4\_i[28-24] WEOFFTIME field.

The WEn falling edge must not be used to control the time when the burst first data is driven in the address/data bus because some new devices require the WEn signal at low during the address phase.

- Direction signal DIR is OUT during the entire access.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with OEn driven low. The second phase for LSB address is qualified with OEn driven high. The address phase ends at WEn assertion time.

The CSn and DIR signals are controlled as detailed above.

- Address valid signal ADVn is asserted and deasserted twice during a read transaction
  - ADVn first assertion time is controlled by the GPMC\_CONFIG3\_i[[6-4] ADVAADMUXONTIME field.
  - ADVn first deassertion time is controlled by the GPMC\_CONFIG3\_i[[26-24] ADVAADMUXRDOFFTIME field.
  - ADVn second assertion time is controlled by the GPMC\_CONFIG3\_i[[3-0] ADVONTIME field.
  - ADVn second deassertion time is controlled by the GPMC\_CONFIG3\_i[[12-8] ADVRDOFFTIME field.
- Output Enable signal OEn is asserted and deasserted twice during a read transaction (OEn second assertion indicates a read cycle)
  - OEn first assertion time is controlled by the GPMC\_CONFIG4\_i[[6-4] OEAADMUXONTIME field.
  - OEn first deassertion time is controlled by the GPMC\_CONFIG4\_i[15-13] OEAADMUXOFFTIME field.
  - OEn second assertion time is controlled by the GPMC\_CONFIG4\_i[3-0] OEONTIME field.
  - OEn second deassertion time is controlled by the GPMC\_CONFIG4\_i[12-8] OEOFFTIME field.

First write data is driven by the GPMC at GPMC\_CONFIG6\_i[19-16] WRDATAONADMUXBUS, when in address/data mux configuration. The next write data of the burst is driven on the bus at WRACCESSTIME + 1 during GPMC\_CONFIG5\_i[27-24] PAGEBURSTACCESSTIME GPMC\_FCLK cycles. The last data of the synchronous burst write is driven until GPMC\_CONFIG5\_i[12-8] WRCYCLETIME completes.

- WRACCESSTIME is defined in the GPMC\_CONFIG6\_i[28-24] register.
- The PAGEBURSTACCESSTIME parameter must be set accordingly with GPMCFCLKDIVIDER and the memory-device internal configuration.

Total access time GPMC\_CONFIG5\_i[12-8] WRCYCLETIME corresponds to WRACCESSTIME plus the address hold time from CSn deassertion. In [Figure 9-23](#) the WRCYCLETIME programmed value equals WRCYCLETIME0 + WRCYCLETIME1. WRCYCLETIME0 and WRCYCLETIME1 delays are not actual parameters and are only a graphical representation of the full WRCYCLETIME value.

After a write operation, if no other access (read or write) is pending, the data bus keeps the previous value. See [Section 9.1.3.3.9.10](#).

### 9.1.3.3.10.3 Asynchronous and Synchronous Accesses in Nonmultiplexed Mode

Page mode is only available in non-multiplexed mode.

- Asynchronous single read operation on a nonmultiplexed device
- Asynchronous single write operation on a nonmultiplexed device
- Asynchronous multiple (page mode) read operation on a nonmultiplexed device
- Synchronous operations on a nonmultiplexed device

### 9.1.3.3.10.3.1 Asynchronous Single Read Operation on a Nonmultiplexed Device

Figure 9-24 shows an asynchronous single read operation on a nonmultiplexed device.

**Figure 9-24. Asynchronous Single Read on an Address/Data-Nonmultiplexed Device**

The 27-bit address is driven onto the address bus A[27:1] and the 16-bit data is driven onto the data bus D[15:0].

Read data is latched at GPMC\_CONFIG1\_5[20-16] RDACCESSTIME completion time. The end of the access is defined by the GPMC\_CONFIG1\_5[4-0] RDCYCLETIME parameter.

CSn, ADVn, OEn and DIR signals are controlled in the same way as address/data multiplexed accesses, see [Section 9.1.3.3.10.1.2](#).

### 9.1.3.3.10.3.2 Asynchronous Single Write Operation on a Nonmultiplexed Device

Figure 9-25 shows an asynchronous single write operation on a nonmultiplexed device.

**Figure 9-25. Asynchronous Single Write on an Address/Data-Nonmultiplexed Device**

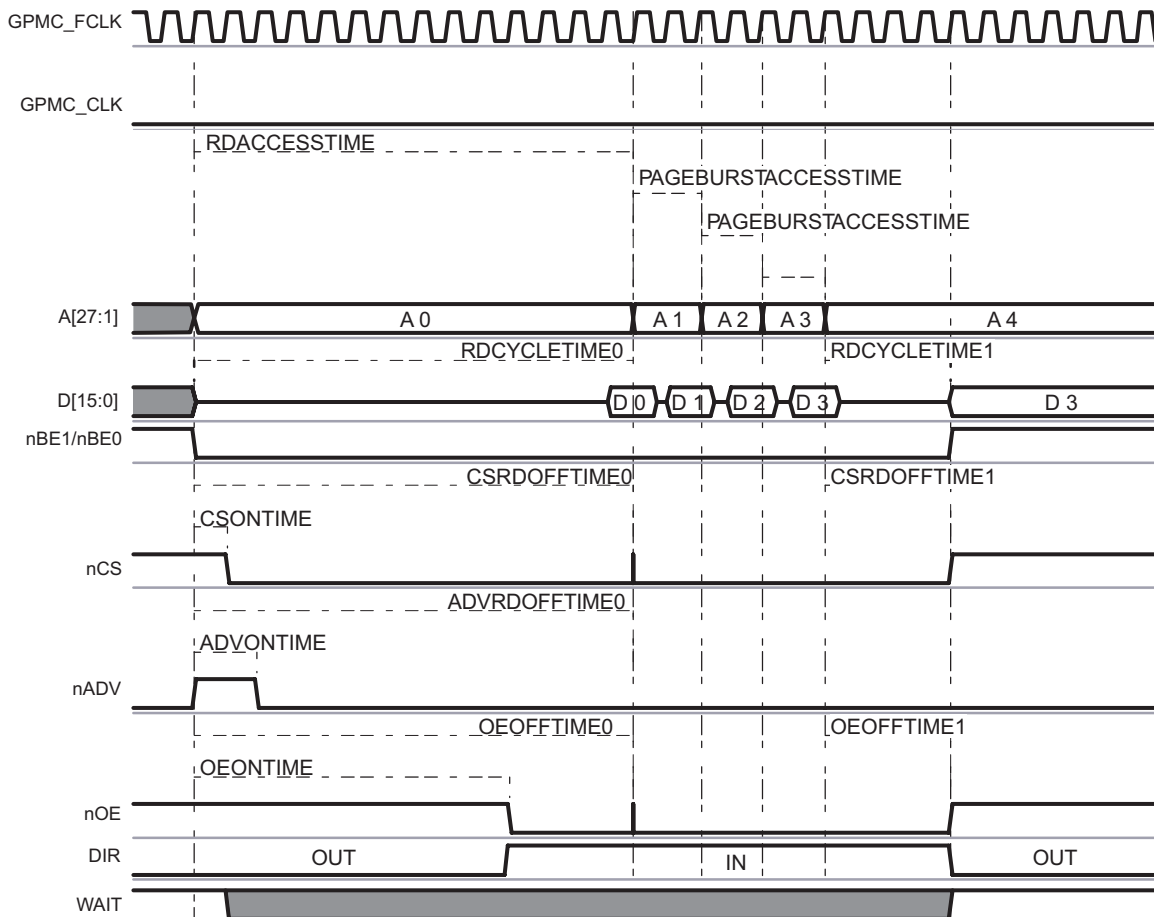

The 27-bit address is driven onto the address bus A[27:1] and the 16-bit data is driven onto the data bus D[15:0].

CSn, ADVn, WEn and DIR signals are controlled in the same way as address/data multiplexed accesses, see [Section 9.1.3.3.10.1.1.3](#).

### 9.1.3.3.10.3.3 Asynchronous Multiple (Page Mode) Read Operation on a Nonmultiplexed Device

Figure 9-26 shows an asynchronous multiple read operation on a Nonmultiplexed Device, in which two word32 host read accesses to the GPMC are split into one multiple (page mode of 4 word16) read access to the attached device.

**Figure 9-26. Asynchronous Multiple (Page Mode) Read**

The WAIT signal is active low.

CSn, ADVn, OEn and DIR signals are controlled in the same way as address/data multiplexed accesses, see [Section 9.1.3.3.10.1.1.2](#).

When RDACCESSTIME completes, control-signal timings are frozen during the multiple data transactions, corresponding to PAGEBURSTACCESSTIME multiplied by the number of remaining data transactions.

Read data is latched at GPMC\_CONFIG5\_i[20-16] RDACCESSTIME completion time. The end of the access is defined by the GPMC\_CONFIG5\_i[4-0] RDCYCLETIME parameter.

During consecutive accesses, the GPMC increments the address after each data read completes.

Delay between successive read data in the page is controlled by the GPMC\_CONFIG5\_i[27-24] PAGEBURSTACCESSTIME parameter. Depending on the device page length, the GPMC can control device page crossing during a burst request and insert initial RDACCESSTIME latency. Note that page crossing is only possible with a new burst access, meaning a new initial access phase is initiated.

Total access time RDCYCLETIME corresponds to RDACCESSTIME plus the address hold time starting from the CSn deassertion.

- The read cycle time is defined in the GPMC\_CONFIG5\_i[4-0] RDCYCLETIME field.
- In [Figure 9-26](#), the RDCYCLETIME programmed value equals RDCYCLETIME0 (before paged accesses) + RDCYCLETIME1 (after paged accesses).

#### 9.1.3.3.10.3.4 Synchronous Operations on a Nonmultiplexed Device

All information for this section is equivalent to similar operations for address/data- or AAD-multiplexed accesses. The only difference resides in the address phase. See [Section 9.1.4.2](#).

#### 9.1.3.3.10.4 Page and Burst Support

Each chip-select can be configured to process system single or burst requests into successive single accesses or asynchronous page/synchronous burst accesses, with appropriate access size adaptation.

Depending on the external device page or burst capability, read and write accesses can be independently configured through the GPMC. The GPMC\_CONFIG1\_i[30] READMULTIPLE and GPMC\_CONFIG1\_i[28] WRITEMULTIPLE bits are associated with the READTYPE and WRITETYPE parameters.

- Asynchronous write page mode is not supported.
- 8-bit wide device support is limited to nonburstable devices (READMULTIPLE and WRITEMULTIPLE are ignored).
- Not applicable to NAND device interfacing.

#### 9.1.3.3.10.5 System Burst Versus External Device Burst Support

The device system can issue the following requests to the GPMC:

- Byte, 16-bit word, 32-bit word requests (byte enable controlled). This is always a single request from the interconnect point of view.
- Incrementing fixed-length bursts of two words, four words, and eight words
- Wrapped (critical word access first) fixed-length burst of two, four, or eight words

To process a system request with the optimal protocol, the READMULTIPLE (and READTYPE) and WRITEMULTIPLE (and WRITETYPE) parameters must be set according to the burstable capability (synchronous or asynchronous) of the attached device.

The GPMC access engine issues only fixed-length burst. The maximum length that can be issued is defined per CS by the GPMC\_CONFIG1\_i[24-23] ATTACHEDDEVICEPAGELENGTH field. When the ATTACHEDDEVICEPAGELENGTH value is less than the system burst request length (including the appropriate access size adaptation according to the device width), the GPMC splits the system burst request into multiple bursts. Within the specified 4-, 8-, or 16-word value, the ATTACHEDDEVICEPAGELENGTH field value must correspond to the maximum-length burst supported by the memory device configured in fixed-length burst mode (as opposed to continuous burst mode).

To get optimal performance from memory devices that natively support 16 Word16-length-wrapping burst capability (critical word access first), the ATTACHEDDEVICEPAGELENGTH parameter must be set to 16 words and the GPMC\_CONFIG1\_i[31] WRAPBURST bit must be set to 1. Similarly DEVICESPAGELENGTH is set to 4 and 8 for memories supporting respectively 4 and 8 Word16-length-wrapping burst.

When the memory device does not offer (or is not configured to offer) native 16 Word16-length-wrapping burst, the WRAPBURST parameter must be cleared, and the GPMC access engine emulates the wrapping burst by issuing the appropriate burst sequences according to the ATTACHEDDEVICEPAGELENGTH value.

When the memory device does not support native-wrapping burst, there is usually no difference in behavior between a fixed burst length mode and a continuous burst mode configuration (except for a potential power increase from a memory-speculative data prefetch in a continuous burst read). However, even though continuous burst mode is compatible with GPMC behavior, because the GPMC access engine issues only fixed-length burst and does not benefit from continuous burst mode, it is best to configure the memory device in fixed-length burst mode.

The memory device maximum-length burst (configured in fixed-length burst wrap or nonwrap mode) usually corresponds to the memory device data buffer size. Memory devices with a minimum of 16 half-word buffers are the most appropriate (especially with wrap support), but memory devices with smaller buffer size (4 or 8) are also supported, assuming that the GPMC\_CONFIG1\_i[24-23] ATTACHEDDEVICEPAGELENGTH field is set accordingly to 4 or 8 words.

The device system issues only requests with addresses or starting addresses for nonwrapping burst requests; that is, the request size boundary is aligned. In case of an eight-word-wrapping burst, the wrapping address always occurs on the eight-words boundary. As a consequence, all words requested must be available from the memory data buffer when the buffer size is equal to or greater than the ATTACHEDDEVICEPAGELENGTH value. This usually means that data can be read from or written to the buffer at a constant rate (number of cycles between data) without wait states between data accesses. If the memory does not behave this way (nonzero wait state burstable memory), wait-pin monitoring must be enabled to dynamically control data-access completion within the burst.

When the system burst request length is less than the ATTACHEDDEVICEPAGELENGTH value, the GPMC proceeds with the required accesses.

#### 9.1.3.3.11 pSRAM Access Specificities

pSRAM devices are SRAM-pin-compatible low-power memories that contain a self-refreshed DRAM memory array. The GPMC\_CONFIG1\_i[[11-10] DEVICETYPE field shall be cleared to 0b00.

The pSRAM devices uses the NOR protocol. It support the following operations:

- Asynchronous single read
- Asynchronous page read
- Asynchronous single write
- Synchronous single read and write
- Synchronous burst read
- Synchronous burst write (not supported by NOR Flash memory)

pSRAM devices must be powered up and initialized in a predefined manner according to the specifications of the attached device.

pSRAM devices can be programmed to use either mode: fixed or variable latency. pSRAM devices can either automatically schedule autorefresh operations, which force the GPMC to use its WAIT signal capability when read or write operations occur during an internal self-refresh operation, or pSRAM devices automatically include the autorefresh operation in the access time. These devices do not require additional WAIT signal capability or a minimum CSn high pulse width between consecutive accesses to ensure that the correct internal refresh operation is scheduled.

#### 9.1.3.3.12 NAND Access Description

NAND (8-bit and 16-bit) memory devices using a standard NAND asynchronous address/data-multiplexing scheme can be supported on any chip-select with the appropriate asynchronous configuration settings

As for any other type of memory compatible with the GPMC interface, accesses to a chip-select allocated to a NAND device can be interleaved with accesses to chip-selects allocated to other external devices.

This interleaved capability limits the system to *chip enable don't care* NAND devices, because the chip-select allocated to the NAND device must be de-asserted if accesses to other chip-selects are requested.

##### 9.1.3.3.12.1 NAND Memory Device in Byte or 16-Bit Word Stream Mode

NAND devices require correct command and address programming before data array read or write accesses. The GPMC does not include specific hardware to translate a random address system request into a NAND-specific multiphase access. In that sense, GPMC NAND support, as opposed to random memory-map device support, is data-stream-oriented (byte or 16-bit word).

The GPMC NAND programming model relies on a software driver for address and command formatting with the correct data address pointer value according to the block and page structure. Because of NAND structure and protocol interface diversity, the GPMC does not support automatic command and address phase programming, and software drivers must access the NAND device ID to ensure that correct command and address formatting are used for the identified device.

NAND device data read and write accesses are achieved through an asynchronous read or write access. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Any chip-select region can be qualified as a NAND region to constrain the ADV<sub>n</sub>\_ALE signal as Address Latch Enable (ALE active high, default state value at low) during address program access, and the BE<sub>0n</sub>\_CLE signal as Command Latch Enable (CLE active high, default state value at low) during command program access. GPMC address lines are not used (the previous value is not changed) during NAND access.

#### 9.1.3.3.12.1.1 Chip-Select Configuration for NAND Interfacing in Byte or Word Stream Mode

The GPMC\_CONFIG7<sub>i</sub> register associated with a NAND device region interfaced in byte or word stream mode can be initialized with a minimum size of 16 Mbytes, because any address location in the chip-select memory region can be used to access a NAND data array. The NAND Flash protocol specifies an address sequence where address bits are passed through the data bus in a series of write accesses with the ALE pin asserted. After this address phase, all operations are streamed and the system requests address is irrelevant.

To allow correct command, address, and data-access controls, the GPMC\_CONFIG1<sub>i</sub> register associated with a NAND device region must be initialized in asynchronous read and write modes with the parameters shown in [Table 9-11](#). Failure to comply with these settings corrupts the NAND interface protocol.

The GPMC\_CONFIG1<sub>i</sub> to GPMC\_CONFIG4<sub>i</sub> register associated with a NAND device region must be initialized with the correct control-signal timing value according to the NAND device timing parameters.

**Table 9-11. Chip-Select Configuration for NAND Interfacing**

Bit Field	Register	Value	Comments
WRAPBURST	GPMC_CONFIG1 <sub>i</sub>	0	No wrap
READMULTIPLE	GPMC_CONFIG1 <sub>i</sub>	0	Single access
READTYPE	GPMC_CONFIG1 <sub>i</sub>	0	Asynchronous mode
WRITEMULTIPLE	GPMC_CONFIG1 <sub>i</sub>	0	Single access
WRITETYPE	GPMC_CONFIG1 <sub>i</sub>	0	Asynchronous mode
CLKACTIVATIONTIME	GPMC_CONFIG1 <sub>i</sub>	0b00	
ATTACHEDDEVICEPAGELENGTH	GPMC_CONFIG1 <sub>i</sub>	Don't care	Single-access mode
WAITREADMONITORING	GPMC_CONFIG1 <sub>i</sub>	0	Wait not monitored by GPMC access engine
WAITWRITEMONITORING	GPMC_CONFIG1 <sub>i</sub>	0	Wait not monitored by GPMC access engine
WAITMONITORINGTIME	GPMC_CONFIG1 <sub>i</sub>	Don't care	Wait not monitored by GPMC access engine
WAITPINSELECT	GPMC_CONFIG1 <sub>i</sub>		Select which wait is monitored by edge detectors
DEVICESIZE	GPMC_CONFIG1 <sub>i</sub>	0b00 or 0b01	8- or 16-bit interface
DEVICETYPE	GPMC_CONFIG1 <sub>i</sub>	0b10	NAND device in stream mode
MUXADDDATA	GPMC_CONFIG1 <sub>i</sub>	0b00	Nonmultiplexed mode
TIMEPARAGRANULARITY	GPMC_CONFIG1 <sub>i</sub>	0	Timing achieved with best GPMC clock granularity
GPMCFCLKDIVIDER	GPMC_CONFIG1 <sub>i</sub>	Don't care	Asynchronous mode

#### 9.1.3.3.12.1.2 NAND Device Command and Address Phase Control

NAND devices require multiple address programming phases. The MPU software driver is responsible for issuing the correct number of command and address program accesses, according to the device command set and the device address-mapping scheme.

NAND device-command and address-phase programming is achieved through write requests to the GPMC\_NAND\_COMMAND<sub>i</sub> and GPMC\_NAND\_ADDR<sub>i</sub> register locations with the correct command and address values. These locations are mapped in the associated chip-select register region. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Command and address values are not latched during the access and cannot be read back at the register location.

- Only write accesses must be issued to these locations, but the GPMC does not discard any read access. Accessing a NAND device with OEn and CLE or ALE asserted (read access) can produce undefined results.
- Write accesses to the GPMC\_NAND\_COMMAND\_i register location and to the GPMC\_NAND\_ADDR\_i register location must be posted for faster operations. The GPMC\_CONFIG[0] NANDFORCEPOSTEDWRITE bit enables write accesses to these locations as posted, even if they are defined as nonposted.

A write buffer is used to store write transaction information before the external device is accessed:

- Up to eight consecutive posted write accesses can be accepted and stored in the write buffer.
- For nonposted write, the pipeline is one deep.
- A GPMC\_STS[0] EMPTYWRITEBUFFERSTS bit stores the empty status of the write buffer.

The GPMC\_NAND\_COMMAND\_i and GPMC\_NAND\_ADDR\_i registers are 32-bit word locations, which means any 32-bit word or 16-bit word access is split into 4- or 2-byte accesses if an 8-bit wide NAND device is attached. For multiple-command phase or multiple-address phase, the software driver can use 32-bit word or 16-bit word access to these registers, but it must account for the splitting and little-endian ordering scheme. When only one byte command or address phase is required, only byte write access to a GPMC\_NAND\_COMMAND\_i and GPMC\_NAND\_ADDR\_i can be used, and any of the four byte locations of the registers are valid.

The same applies to GPMC\_NAND\_COMMAND\_i and GPMC\_NAND\_ADDR\_i 32-bit word write access to a 16-bit wide NAND device (split into two 16-bit word accesses). In the case of a 16-bit word write access, the MSByte of the 16-bit word value must be set according to the NAND device requirement (usually 0). Either 16-bit word location or any one of the four byte locations of the registers is valid

### 9.1.3.3.12.1.3 Command Latch Cycle

Writing data at the GPMC\_NAND\_COMMAND\_i location places the data as the NAND command value on the bus, using a regular asynchronous write access.

- CSn[i] is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- CLE is controlled by the ADVONTIME and ADVWROFFTIME timing parameters.
- WE is controlled by the WEONTIME and WEOFFTIME timing parameters.
- ALE and REn (OEn) are maintained inactive.

Figure 9-27 shows the NAND command latch cycle.

CLE is shared with the BE0n output signal and has an inverted polarity from BE0n. The NAND qualifier deals with this. During the asynchronous NAND data access cycle, BE0n (also BE1n) must not toggle, because it is shared with CLE.

NAND Flash memories do not use byte enable signals at all.

**Figure 9-27. NAND Command Latch Cycle**

### 9.1.3.3.12.1.4 Address Latch Cycle

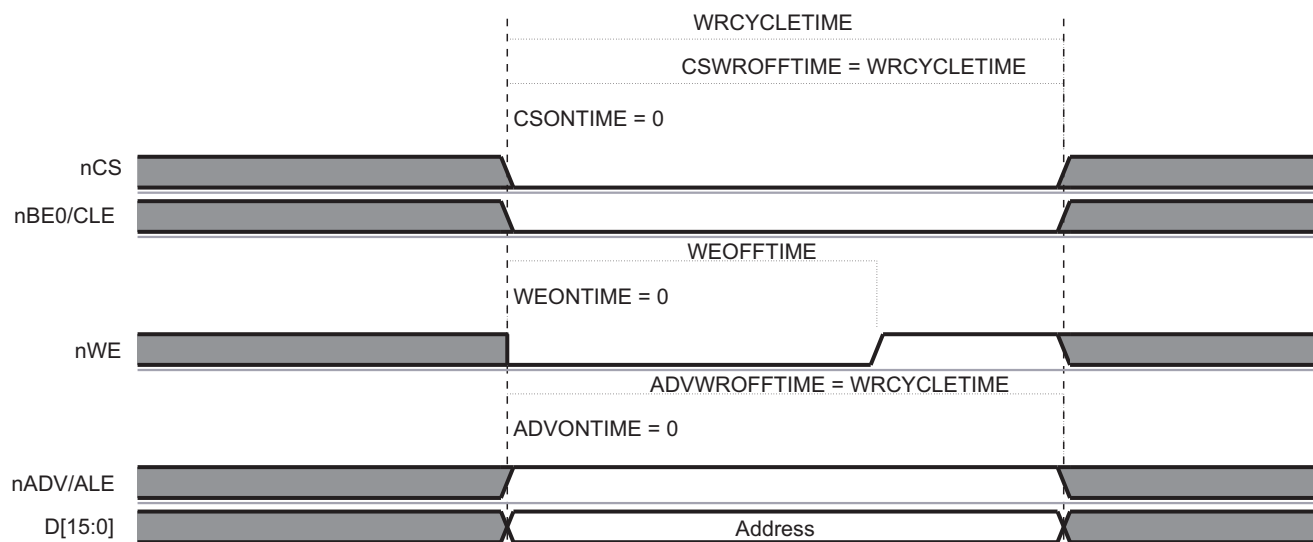

Writing data at the GPMC\_NAND\_ADDR\_i location places the data as the NAND partial address value on the bus, using a regular asynchronous write access.

- CSn is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- ALE is controlled by the ADVONTIME and ADVWROFFTIME timing parameters.
- WEn is controlled by the WEONTIME and WEOFFTIME timing parameters.
- CLE and REn (OEn) are maintained inactive.

Figure 9-28 shows the NAND address latch cycle.

ALE is shared with the ADVn output signal and has an inverted polarity from ADVn. The NAND qualifier deals with this. During the asynchronous NAND data access cycle, ALE is kept stable.

**Figure 9-28. NAND Address Latch Cycle**

### 9.1.3.3.12.1.5 NAND Device Data Read and Write Phase Control in Stream Mode

NAND device data read and write accesses are achieved through a read or write request to the chip-select-associated memory region at any address location in the region or through a read or write request to the GPMC\_NAND\_DATA\_i location mapped in the chip-select-associated control register region. GPMC\_NAND\_DATA\_i is not a true register, but an address location to enable REn or WEn signal control. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Reading data from the GPMC\_NAND\_DATA\_i location or from any location in the associated chip-select memory region activates an asynchronous read access.

- CSn is controlled by the CSONTIME and CSRDOFFTIME timing parameters.
- REn is controlled by the OEONTIME and OEOFFTIME timing parameters.
- To take advantage of REn high-to-data invalid minimum timing value, the RDACCESSTIME can be set so that data are effectively captured after REn deassertion. This allows optimization of NAND read access cycle time completion. For optimal timing parameter settings, see the NAND device and the device IC timing parameters.

ALE, CLE, and WEn are maintained inactive.

Figure 9-29 shows the NAND data read cycle.

**Figure 9-29. NAND Data Read Cycle**

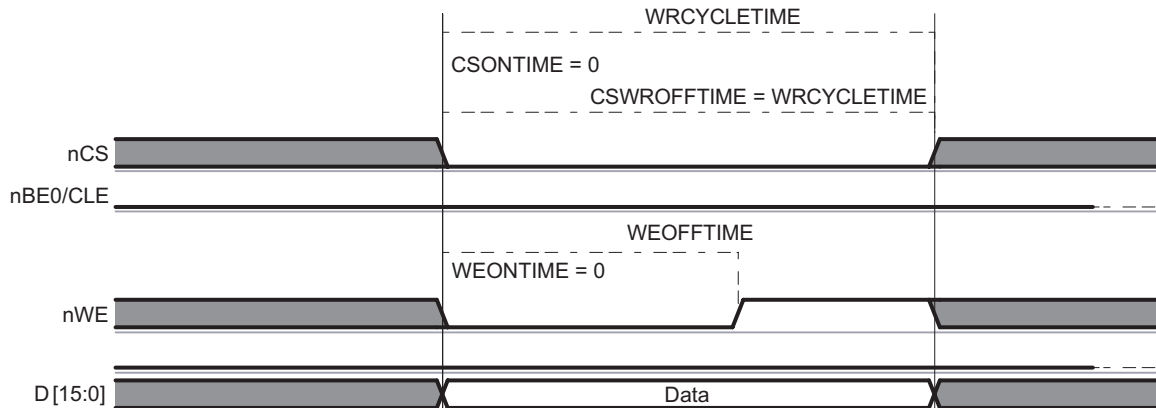

Writing data to the GPMC\_NAND\_DATA\_i location or to any location in the associated chip-select memory region activates an asynchronous write access.

- CSn is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- WEn is controlled by the WEONTIME and WEOFFTIME timing parameters.
- ALE, CLE, and REn (OEn) are maintained inactive.

Figure 9-30 shows the NAND data write cycle.

**Figure 9-30. NAND Data Write Cycle**

#### 9.1.3.3.12.1.6 NAND Device General Chip-Select Timing Control Requirement

For most NAND devices, read data access time is dominated by CSn-to-data-valid timing and has faster REn-to-data-valid timing. Successive accesses with CSn deassertions between accesses are affected by this timing constraint. Because accesses to a NAND device can be interleaved with other chip-select accesses, there is no certainty that CSn always stays low between two accesses to the same chip-select. Moreover, an CSn deassertion time between the same chip-select NAND accesses is likely to be required as follows: the CSn deassertion requires programming CYCLETIME and RDACCESSTIME according to the CSn-to-data-valid critical timing.

To get full performance from NAND read and write accesses, the prefetch engine can dynamically reduce RDCYCLETIME, WRCYCLETIME, RDACCESSTIME, WRACCESSTIME, CSRDOFFTIME, CSWROFFTIME, ADVROFFTIME, ADVWROFFTIME, OEOFFTIME, and WEOFFTIME on back-to-back NAND accesses (to the same memory) and suppress the minimum CSn high pulse width between accesses. For more information about optimal prefetch engine access, see [Section 9.1.3.3.12.4](#).

Some NAND devices require minimum write-to-read idle time, especially for device-status read accesses following status-read command programming (write access). If such write-to-read transactions are used, a minimum CSn high pulse width must be set. For this, CYCLE2CYCLESAMECSN and CYCLE2CYCLEDELAY must be set according to the appropriate timing requirement to prevent any timing violation.

NAND devices usually have an important REn high to data bus in tristate mode. This requires a bus turnaround setting (BUSTURNAROUND = 1), so that the next access to a different chip-select is delayed until the BUSTURNAROUND delay completes. Back-to-back NAND read accesses to the same NAND Flash are not affected by the programmed bus turnaround delay.

#### 9.1.3.3.12.1.7 Read and Write Access Size Adaptation

##### 9.1.3.3.12.1.7.1 8-Bit Wide NAND Device

Host 16-bit word and 32-bit word read and write access requests to a chip-select associated with an 8-bit wide NAND device are split into successive read and write byte accesses to the NAND memory device. Byte access is ordered according to little-endian organization. A NAND 8-bit wide device must be interfaced on the D0D7 interface bus lane. GPMC data accesses are justified on this bus lane when the chip-select is associated with an 8-bit wide NAND device.

##### 9.1.3.3.12.1.7.2 16-Bit Wide NAND Device

Host 32-bit word read and write access requests to a chip-select associated with a 16-bit wide NAND device are split into successive read and write 16-bit word accesses to the NAND memory device. 16-bit word access is ordered according to little-endian organization.

Host byte read and write access requests to a 16-bit wide NAND device are completed as 16-bit accesses on the device itself, because there is no byte-addressing capability on 16-bit wide NAND devices. This means that the NAND device address pointer is incremented on a 16-bit word basis and not on a byte basis. For a read access, only the requested byte is given back to the host, but the remaining byte is not stored or saved by the GPMC, and the next byte or 16-bit word read access gets the next 16-bit word NAND location. For a write access, the invalid byte part of the 16-bit word is driven to FF, and the next byte or 16-bit word write access programs the next 16-bit word NAND location.

Generally, byte access to a 16-bit wide NAND device should be avoided, especially when ECC calculation is enabled. 8-bit or 16-bit ECC-based computations are corrupted by a byte read to a 16-bit wide NAND device, because the nonrequested byte is considered invalid on a read access (not captured on the external data bus; FF is fed to the ECC engine) and is set to FF on a write access.

Host requests (read/write) issued in the chip-select memory region are translated in successive single or split accesses (read/write) to the attached device. Therefore, incrementing 32-bit burst requests are translated in multiple 32-bit sequential accesses following the access adaptation of the 32-bit to 8- or 16-bit device.

#### **9.1.3.3.12.2 NAND Device-Ready Pin**

The NAND memory device provides a ready pin to indicate data availability after a block/page opening and to indicate that data programming is complete. The ready pin can be connected to one of the WAIT GPMC input pins; data read accesses must not be tried when the ready pin is sampled inactive (device is not ready) even if the associated chip-select WAITREADMONITORING bit field is set. The duration of the NAND device busy state after the block/page opening is so long (up to 50  $\mu$ s) that accesses occurring when the ready pin is sampled inactive can stall GPMC access and eventually cause a system time-out.

If a read access to a NAND flash is done using the wait monitoring mode, the device is blocked during a page opening, and so is the GPMC. If the correct settings are used, other chip-selects can be used while the memory processes the page opening command.

To avoid a time-out caused by a block/page opening delay in NAND flash, disable the wait pin monitoring for read and write accesses (that is, set the GPMC\_CONFIG1\_i[[21] WAITWRITEMONITORING and GPMC\_CONFIG1\_i[[22] WAITREADMONITORING bits to 0 and use one of the following methods instead:

- Use software to poll the WAITnSTS bit ( $n = 0$  to 1) of the GPMC\_STS register.
- Configure an interrupt that is generated on the WAIT signal change (through the GPMC\_IRQEN [11-8]bits).

Even if the READWAITMONITORING bit is not set, the external memory nR/B pin status is captured in the programmed WAIT bit in the GPMC\_STS register.

The READWAITMONITORING bit method must be used for other memories than NAND flash, if they require the use of a WAIT signal.

##### **9.1.3.3.12.2.1 Ready Pin Monitored by Software Polling**

The ready signal state can be monitored through the GPMC\_STS WAITxSTS bit ( $x = 0$  or 1). The software must monitor the ready pin only when the signal is declared valid. Refer to the NAND device timing parameters to set the correct software temporization to monitor ready only after the invalid window is complete from the last read command written to the NAND device.

##### **9.1.3.3.12.2.2 Ready Pin Monitored by Hardware Interrupt**

Each gpmc\_wait input pin can generate an interrupt when a wait-to-no-wait transition is detected. Depending on whether the GPMC\_CONFIG WAITxPINPOLARITY bits ( $x = 0$  or 1) is active low or active high, the wait-to-no-wait transition is a low-to-high external WAIT signal transition or a high-to-low external WAIT signal transition, respectively.

The wait transition pin detector must be cleared before any transition detection. This is done by writing 1 to the WAITxEDGEDETECTIONSTS bit ( $x = 0$  or  $1$ ) of the GPMC\_IRQSTS register according to the gpmc\_wait pin used for the NAND device-ready signal monitoring. To detect a wait-to-no-wait transition, the transition detector requires a wait active time detection of a minimum of two GPMC\_FCLK cycles. Software must incorporate precautions to clear the wait transition pin detector before wait (busy) time completes.

A wait-to-no-wait transition detection can issue a GPMC interrupt if the WAITxEDGEDETECTIONENABLE bit in the GPMC\_IRQEN register is set and if the WAITxEDGEDETECTIONSTS bit field in the GPMC\_IRQSTS register is set.

The WAITMONITORINGTIME field does not affect wait-to-no-wait transition time detection.

It is also possible to poll the WAITxEDGEDETECTIONSTS bit field in the GPMC\_IRQSTS register according to the gpmc\_wait pin used for the NAND device ready signal monitoring.

#### 9.1.3.3.12.3 ECC Calculator

The General Purpose Memory Controller includes an Error Code Correction (ECC) calculator circuitry that enables on the fly ECC calculation during data read or data program (that is, write) operations. The page size supported by the ECC calculator in one calculation/context is 512 bytes.

The user can choose from two different algorithms with different error correction capabilities through the GPMC\_ECC\_CONFIG[16] ECCALGORITHM bit:

- Hamming code for 1-bit error code correction on 8- or 16-bit NAND Flash organized with page size greater than 512 bytes
- BCH (Bose-Chaudhuri-Hocquenghem) code for 4- to 16-bit error correction

The GPMC does not directly handle the error code correction itself. During writes, the GPMC computes parity bits. During reads, the GPMC provides enough information for the processor to correct errors without reading the data buffer all over again.

The Hamming code ECC is based on a 2-dimensional (row and column) bit parity accumulation. This parity accumulation is either accomplished on the programmed number of bytes or 16-bit words read from the memory device, or written to the memory device in stream mode.

Because the ECC engine includes only one accumulation context, it can be allocated to only one chip-select at a time through the GPMC\_ECC\_CONFIG[3-1] ECCCS bit field. Even if two CS use different ECC algorithms, one the Hamming code and the other a BCH code, they must define separate ECC contexts because some of the ECC registers are common to all types of algorithms.

##### 9.1.3.3.12.3.1 Hamming Code

All references to Error Code Correction (ECC) in this subsection refer to the 1-bit error correction Hamming code.

The ECC is based on a two-dimensional (row and column) bit parity accumulation known as Hamming Code. The parity accumulation is done for a programmed number of bytes or 16-bit word read from the memory device or written to the memory device in stream mode.

There is no automatic error detection or correction, and it is the software NAND driver responsibility to read the multiple ECC calculation results, compare them to the expected code value, and take the appropriate corrective actions according to the error handling strategy (ECC storage in spare byte, error correction on read, block invalidation).

The ECC engine includes a single accumulation context. It can be allocated to a single designated chip-select at a time and parallel computations on different chip-selects are not possible. Since it is allocated to a single chip-select, the ECC computation is not affected by interleaved GPMC accesses to other chip-selects and devices. The ECC accumulation is sequentially processed in the order of data read from or written to the memory on the designated chip-select. The ECC engine does not differentiate read accesses from write accesses and does not differentiate data from command or status information. It is the software responsibility to make sure only relevant data are passed to the NAND flash memory while the ECC computation engine is active.

The starting NAND page location must be programmed first, followed by an ECC accumulation context reset with an ECC enabling, if required. The NAND device accesses discussed in the following sections must be limited to data read or write until the specified number of ECC calculations is completed.

#### 9.1.3.3.12.3.1.1 ECC Result Register and ECC Computation Accumulation Size

The GPMC includes up to nine ECC result registers (GPMC\_ECCj\_RESULT, j = 1 to 9) to store ECC computation results when the specified number of bytes or 16-bit words has been computed.

The ECC result registers are used sequentially; one ECC result is stored in one ECC result register on the list, the next ECC result is stored in the next ECC result register on the list, and so forth, until the last ECC computation. The value of the GPMC\_ECCj\_RESULT register value is valid only when the programmed number of bytes or 16-bit words has been accumulated, which means that the same number of bytes or 16-bit words has been read from or written to the NAND device in sequence.

The GPMC\_ECC\_CTRL[3-0] ECCPOINTER field must be set to the correct value to select the ECC result register to be used first in the list for the incoming ECC computation process. The ECCPointer can be read to determine which ECC register is used in the next ECC result storage for the ongoing ECC computation. The value of the GPMC\_ECCj\_RESULT register (j = 1 to 9) can be considered valid when ECCPOINTER equals j + 1. When the GPMC\_ECCj\_RESULT (where j = 9) is updated, ECCPOINTER is frozen at 10, and ECC computing is stopped (ECCENABLE = 0).

The ECC accumulator must be reset before any ECC computation accumulation process. The GPMC\_ECC\_CTRL[8] ECCCLR bit must be set to 1 (nonpersistent bit) to clear the accumulator and all ECC result registers.

For each ECC result (each register, j = 1 to 9), the number of bytes or 16-bit words used for ECC computing accumulation can be selected from between two programmable values.

The ECCjRESULTSIZES bits (j = 1 to 9) in the GPMC\_ECC\_SIZE\_CONFIG register select which programmable size value (ECCSIZE0 or ECCSIZE1) must be used for this ECC result (stored in GPMC\_ECCj\_RESULT register).

The ECCSIZE0 and ECCSIZE1 fields allow selection of the number of bytes or 16-bit words used for ECC computation accumulation. Any even values from 2 to 512 are allowed.

Flexibility in the number of ECCs computed and the number of bytes or 16-bit words used in the successive ECC computations enables different NAND page error-correction strategies. Usually based on 256 or 512 bytes and on 128 or 256 16-bit word, the number of ECC results required is a function of the NAND device page size. Specific ECC accumulation size can be used when computing the ECC on the NAND spare byte.

For example, with a 2 Kbyte data page 8-bit wide NAND device, eight ECCs accumulated on 256 bytes can be computed and added to one extra ECC computed on the 24 spare bytes area where the eight ECC results used for comparison and correction with the computed data page ECC are stored. The GPMC then provides nine GPMC\_ECCj\_RESULT registers (j= 1 to 9) to store the results. In this case, ECCSIZE0 is set to 256, and ECCSIZE1 is set to 24; the ECC[1-8]RESULTSIZES bits are cleared to 0, and the ECC9RESULTSIZES bit is set to 1.

#### 9.1.3.3.12.3.1.2 ECC Enabling

The GPMC\_ECC\_CONFIG[3-1] ECCCS field selects the allocated chip-select. The GPMC\_ECC\_CONFIG[0] ECCENABLE bit enables ECC computation on the next detected read or write access to the selected chip-select.

The ECCPOINTER, ECCCLR, ECCSIZE, ECCjRESULTSIZES (where j = 1 to 9), ECC16B, and ECCCS fields must not be changed or cleared while an ECC computation is in progress.

The ECC accumulator and ECC result register must not be changed or cleared while an ECC computation is in progress.

[Table 9-12](#) describes the ECC enable settings.

**Table 9-12. ECC Enable Settings**

Bit Field	Register	Value	Comments
ECCCS	GPMC_ECC_CONFIG	0-3h	Selects the chip-select where ECC is computed
ECC16B	GPMC_ECC_CONFIG	0/1	Selects column number for ECC calculation
ECCCLR	GPMC_ECC_CTRL	0-7h	Clears all ECC result registers
ECCPOINTER	GPMC_ECC_CTRL	0-7h	A write to this bit field selects the ECC result register where the first ECC computation is stored. Set to 1 by default.
ECCSIZE1	GPMC_ECC_SIZE_CONFIG	0-FFh	Defines ECCSIZE1
ECCSIZE0	GPMC_ECC_SIZE_CONFIG	0-FFh	Defines ECCSIZE0
ECCjRESULTSIZ (j from 1 to 9)	GPMC_ECC_SIZE_CONFIG	0/1	Selects the size of ECCn result register
ECCENABLE	GPMC_ECC_CONFIG	1	Enables the ECC computation

### 9.1.3.3.12.3.1.3 ECC Computation

The ECC algorithm is a multiple parity bit accumulation computed on the odd and even bit streams extracted from the byte or Word 16 streams. The parity accumulation is split into row and column accumulations, as shown in Figure 9-31 and Figure 9-32. The intermediate row and column parities are used to compute the upper level row and column parities. Only the final computation of each parity bit is used for ECC comparison and correction.

P1o = bit7 XOR bit5 XOR bit3 XOR bit1 on each byte of the data stream

P1e = bit6 XOR bit4 XOR bit2 XOR bit0 on each byte of the data stream

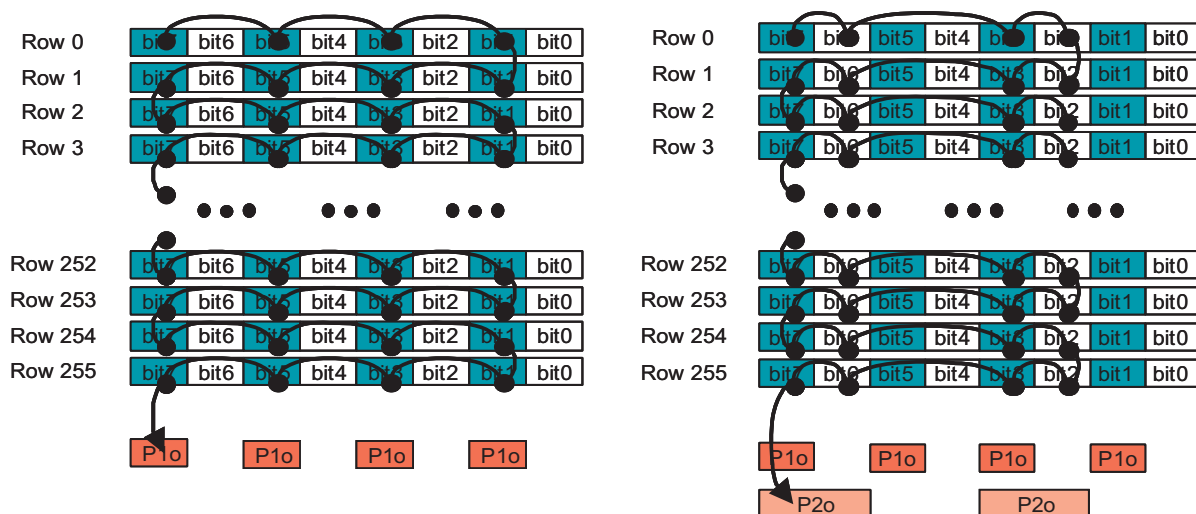

P2o = bit7 XOR bit6 XOR bit3 XOR bit2 on each byte of the data stream

P2e = bit5 XOR bit4 XOR bit1 XOR bit0 on each byte of the data stream

P4o = bit7 XOR bit6 XOR bit5 XOR bit4 on each byte of the data stream

P4e = bit3 XOR bit2 XOR bit1 XOR bit0 on each byte of the data stream

Each column parity bit is XORed with the previous accumulated value.

**Figure 9-31. Hamming Code Accumulation Algorithm (1 of 2)**

For line parities, the bits of each new data are XORed together, and line parity bits are computed as:

$P8e = \text{row0 XOR row2 XOR row4 XOR ... XOR row254}$

$P8o = \text{row1 XOR row3 XOR row5 XOR ... XOR row255}$

$P16e = \text{row0 XOR row1 XOR row4 XOR row5 XOR ... XOR row252 XOR row 253}$

$P16o = \text{row2 XOR row3 XOR row6 XOR row7 XOR ... XOR row254 XOR row 255}$

Unused parity bits in the result registers are cleared to 0.

**Figure 9-32. Hamming Code Accumulation Algorithm (2 of 2)**

Figure 9-33 shows ECC computation for a 256-byte data stream (read or write). The result includes six column parity bits (P1o-P2o-P4o for odd parities, and P1e-P2e-P4e for even parities) and sixteen row parity bits (P8o-P16o-P32o--P1024o for odd parities, and P8e-P16e-P32e--P1024e for even parities).

**Figure 9-33. ECC Computation for a 256-Byte Data Stream (Read or Write)**

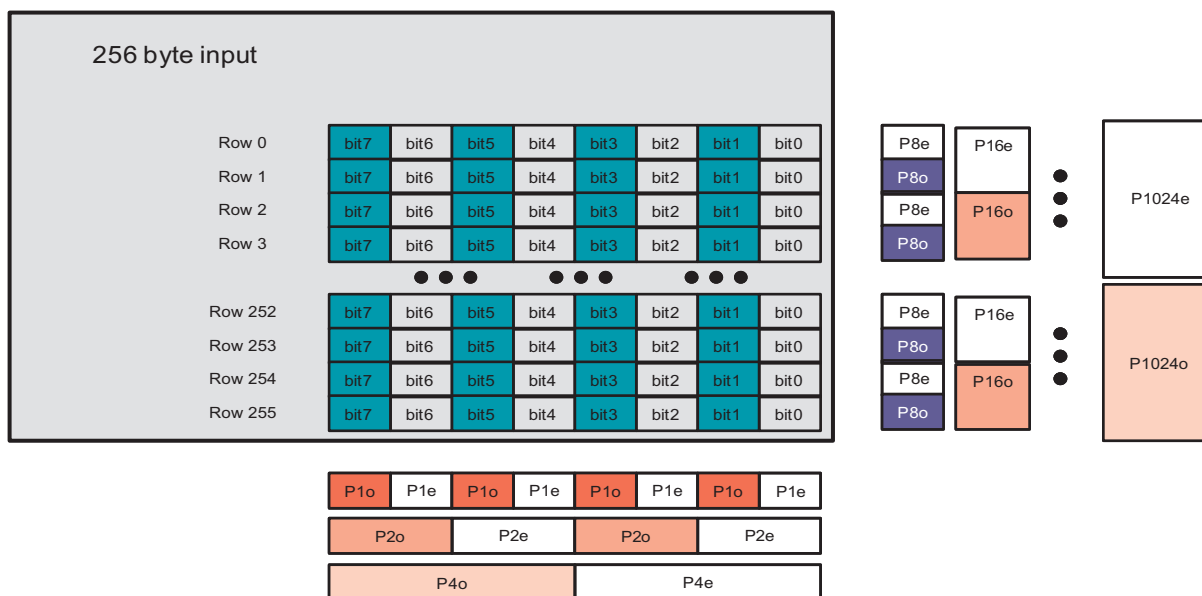

Figure 9-34 shows ECC computation for a 512-byte data stream (read or write). The result includes six column parity bits (P1o-P2o-P4o for odd parities, and P1e-P2e-P4e for even parities) and eighteen row parity bits (P8o-P16o-P32o--P1024o- - P2048o for odd parities, and P8e-P16e-P32e--P1024e- P2048e for even parities).

For a 2 Kbytes page, four 512 bytes ECC calculations plus one for the spare area are required. Results are stored in the GPMC\_ECCj\_RESULT registers (j = 1 to 9).

**Figure 9-34. ECC Computation for a 512-Byte Data Stream (Read or Write)**

#### 9.1.3.3.12.3.1.4 ECC Comparison and Correction

To detect an error, the computed ECC result must be XORed with the parity value stored in the spare area of the accessed page.

- If the result of this logical XOR is all 0s, no error is detected and the read data is correct.
- If every second bit in the parity result is a 1, one bit is corrupted and is located at bit address (P2048o, P1024o, P512o, P256o, P128o, P64o, P32o, P16o, P8o, P4o, P2o, P1o). The software must correct the corresponding bit.
- If only one bit in the parity result is 1, it is an ECC error and the read data is correct.

#### 9.1.3.3.12.3.1.5 ECC Calculation Based on 8-Bit Word

The 8-bit based ECC computation is used for 8-bit wide NAND device interfacing.

The 8-bit based ECC computation can be used for 16-bit wide NAND device interfacing to get backward compatibility on the error-handling strategy used with 8-bit wide NAND devices. In this case, the 16-bit wide data read from or written to the NAND device is fragmented into 2 bytes. According to little-endian access, the least significant bit (LSB) of the 16-bit wide data is ordered first in the byte stream used for 8-bit based ECC computation.

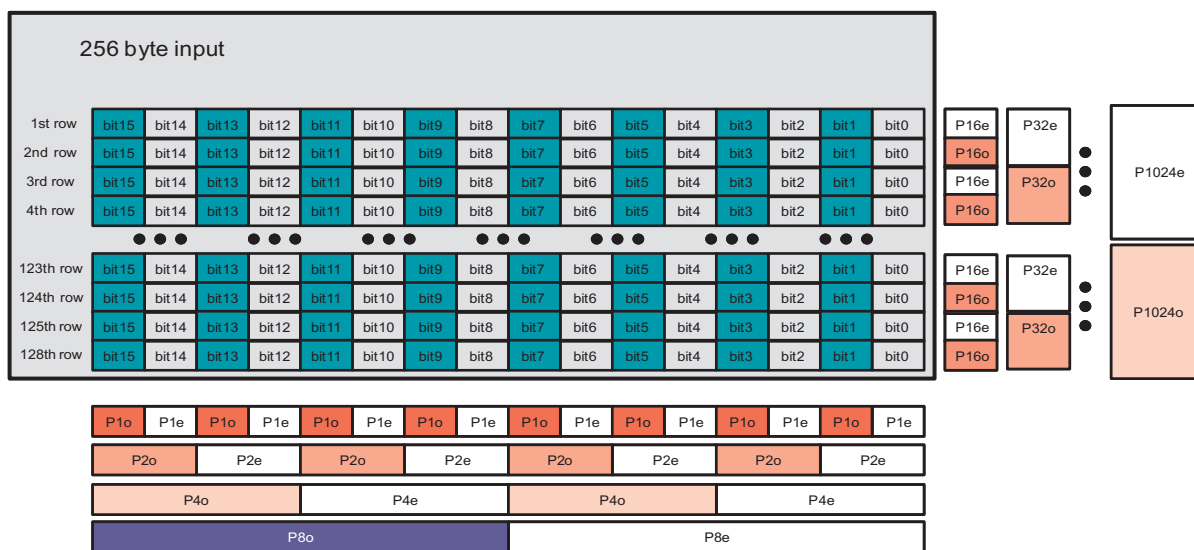

### 9.1.3.3.12.3.16 ECC Calculation Based on 16-Bit Word

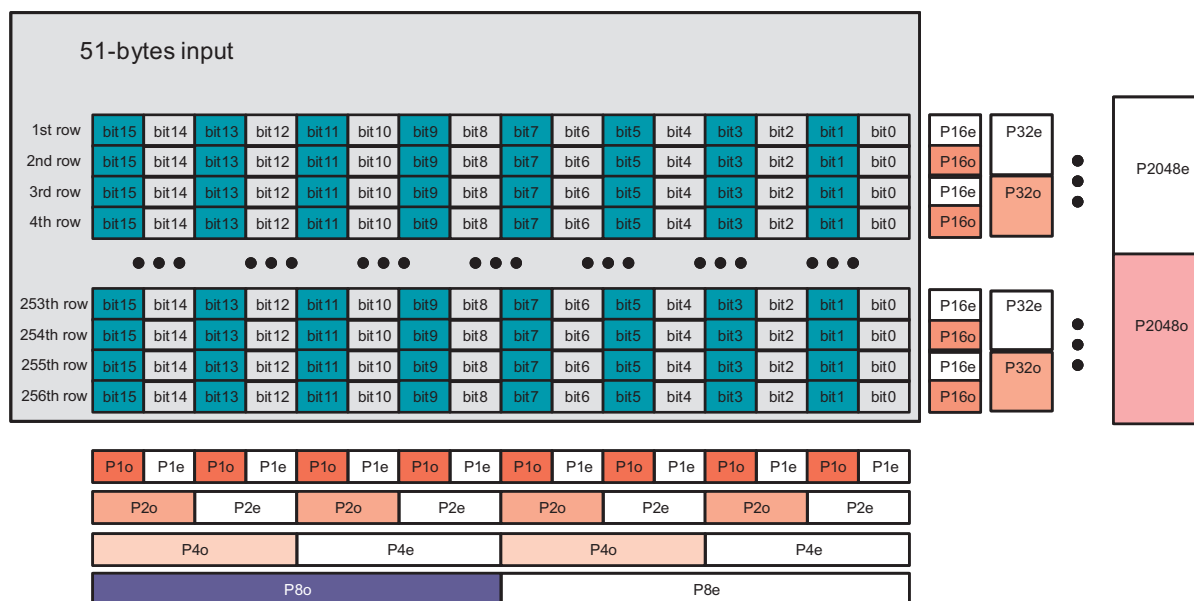

ECC computation based on a 16-bit word is used for 16-bit wide NAND device interfacing. This ECC computation is not supported when interfacing an 8-bit wide NAND device, and the GPMC\_ECC\_CONFIG[7] ECC16B bit must be cleared to 0 when interfacing an 8-bit wide NAND device.

The parity computation based on 16-bit words affects the row and column parity mapping. The main difference is that the odd and even parity bits P8o and P8e are computed on rows for an 8-bit based ECC while there are computed on columns for a 16-bit based ECC. Figure 9-35 and Figure 9-36.

**Figure 9-35. 128 Word16 ECC Computation**

**Figure 9-36. 256 Word16 ECC Computation**

### 9.1.3.3.12.3.2 BCH Code (Bose-Chaudhuri-Hocquenghem)

All references to Error Code Correction (ECC) in this subsection refer to the 4- to 16-bit error correction BCH code.

#### 9.1.3.3.12.3.2.1 Requirements

Read and write accesses to a NAND flash take place by whole pages, in a predetermined sequence: first the data byte page itself, then some spare bytes, including the BCH ECC (and other information). The NAND IC can cache a full page, including spares, for read and write accesses.

Typical page write sequence:

- Sequential write to NAND cache of main data + spare data, for a page. ECC is calculated on the fly. Calculated ECC may be inserted on the fly in the spares, or replaced by dummy accesses.
- When the calculated ECC is replaced by dummy accesses, it must be written to the cache in a second, separate phase. The ECC module is disabled during that time.
- NAND writes its cache line (page) to the array

Typical page read sequence:

- Sequential read of a page. ECC is calculated on the fly.
- ECC module buffers status determines the presence of errors.
- Accesses to several memories may be interleaved by the GPMC, but only one of those memories can be a NAND using the BCH engine at a time; in other words, only one BCH calculation (for example, for a single page) can be on-going at any time. Note also that the sequential nature of NAND accesses guarantees that the data is always written / read out in the same order. BCH-relevant accesses are selected by the GPMCs chip-select.
- Each page may hold up to 4 Kbytes of data, spare bytes not included. This means up to 8 x 512-byte BCH messages. Since all the data is written / read out first, followed by the BCH ECC, this means that the BCH engine must be able to hold 8 104-bit remainders or syndromes (or smaller, 52-bit ones) at the same time.

The BCH module has the capacity to store all remainders internally. After the page start, an internal counter is used to detect the 512-byte sector boundaries. On those boundaries, the current remainder is stored and the divider reset for the next calculation. At the end of the page, the BCH module contains all remainders.

- NAND access cycles hold 8 or 16 bits of data each (1 or 2 bytes); Each NAND cycle takes at least 4 cycles of the GPMCs internal clock. This means the NAND flash timing parameters must define a RDCYCLETIME and a WRCYCLETIME of at least 4 clock cycles after optimization when using the BCH calculator.
- The spare area is assumed to be large enough to hold the BCH ECC, that is, to have at least a message of 13 bytes available per 512-byte sector of data. The zone of unused spare area by the ECC may or may not be protected by the same ECC scheme, by extending the BCH message beyond 512 bytes (maximum codeword is 1023-byte long, ECC included, which leaves a lot of space to cover some spares bytes).

### 9.1.3.3.12.3.2.2 Memory-Mapping of the BCH Codeword

BCH encoding considers a block of data to protect as a polynomial message  $M(x)$ . In our standard case, 512 bytes of data (that is, 2 bits = 4096 bits) are seen as a polynomial of degree  $2^{13} - 1 = 4095$ , with parameters ranging from  $M_0$  to  $M_{4095}$ . For 512 bytes of data, 52 bits are required for 4-bit error correction, and 104 bits are required for 8-bit error correction and 207 bits are required for 16-bit error correction. The ECC is a remainder polynomial  $R(x)$  of degree 103 (or 51, depending on the selected mode). The complete codeword  $C(x)$  is the concatenation of  $M(x)$  and  $R(x)$  as shown in [Table 9-13](#).

**Table 9-13. Flattened BCH Codeword Mapping (512 Bytes + 104 Bits)**

	Message $M(x)$	ECC $R(x)$			
Bit number	$M_{4095}$	...	$M_0$	$R_{103}$	...
					$R_0$

If the message is extended by the addition of spare bytes to be protected by the same ECC, the principle is still valid. For example, a 3-byte extension of the message gives a polynomial message  $M(x)$  of degree  $((512 + 3) \times 8) - 1 = 4119$ , for a total of  $3 + 13 = 16$  spare bytes of spare, all protected as part of the same codeword.

The message and the ECC bits are manipulated and mapped in the GPMC byte-oriented system. The ECC bits are stored in:

- GPMC\_BCH\_RESULT0\_i
- GPMC\_BCH\_RESULT1\_i
- GPMC\_BCH\_RESULT2\_i
- GPMC\_BCH\_RESULT3\_i

### 9.1.3.3.12.3.2.3 Memory Mapping of the Data Message

The data message mapping shall follow the following rules:

- Bit endianness within a byte is little-endian, that is, the bytes LS bit is also the lowest-degree polynomial parameter: a byte  $b_7$ - $b_0$  (with  $b_0$  the LS bit) represents a segment of polynomial  $b_7 * x + b_6 * x + \dots + b_0 * x$
- The message is mapped in the NAND starting with the highest-order parameters, that is, in the lowest addresses of a NAND page.
- Byte endianness within the NANDs 16-bit words is big endian. This means that the same message mapped in 8- and 16-bit memories has the same content at the same byte address.

The BCH module has no visibility over actual addresses. The most important point is the sequence of data word the BCH sees. However, the NAND page is always scanned incrementally in read and write accesses, and this produces the mapping patterns described in the following.

[Table 9-14](#) and [Table 9-15](#) show the mapping of the same 512-byte vector (typically a BCH message) in the NAND memory space. Note that the byte 'address' is only an offset modulo 512 (200h), since the same page may contain several contiguous 512-byte sectors (BCH blocks). The LSB and MSB are respectively the bits  $M_0$  and  $M_{(2^{12}-1)}$  of the codeword mapping given above. In both cases the data vectors are aligned, that is, their boundaries coincide with the RAMs data word boundaries.

**Table 9-14. Aligned Message Byte Mapping in 8-bit NAND**

Byte Offset	8-Bit Word
0	(msb) Byte 511 (1FFh)
1h	Byte 510 (1FEh)
⋮	⋮
1FFh	Byte 0 (0) (LSB)

**Table 9-15. Aligned Message Byte Mapping in 16-bit NAND**

Byte Offset	16-Bit Words MSB	16-Bit Words LSB
0	Byte 510 (1FEh)	(msb) Byte 511 (1FFh)
2h	Byte 508 (1FCh)	Byte 509 (1FDh)
⋮	⋮	⋮
1FEh	Byte 0 (0)	(lsb) Byte 1 (1)

Table 9-16 and Table 9-17 show the mapping in memory of arbitrarily-sized messages, starting on access (byte or 16-bit word) boundaries for more clarity. Note that message may actually start and stop on arbitrary nibbles. A nibble is a 4-bit entity. The unused nibbles are not discarded, and they can still be used by the BCH module, but as part of the next message section (for example, on another sectors ECC).

**Table 9-16. Aligned Nibble Mapping of Message in 8-bit NAND**

Byte Offset	8-Bit Word	
	4-Bit Most Significant Nibble	4-Bit Less Significant Nibble
1	(MSB) Nibble S-1	Nibble S-2
2	Nibble S-3	Nibble S-4
⋮	⋮	⋮
S/2 - 2	Nibble 3	Nibble 2
S/2 - 1	Nibble 1	Nibble 0 (LSB)

**Table 9-17. Misaligned Nibble Mapping of Message in 8-bit NAND**

Byte Offset	8-Bit Word	
	4-Bit Most Significant Nibble	4-Bit Less Significant Nibble
1	(MSB) Nibble S-1	Nibble S-2
2	Nibble S-3	Nibble S-4
⋮	⋮	⋮
(S+1)/2 - 2	Nibble 2	Nibble 1
(S+1)/2 - 1	Nibble 0 (LSB)	

**Table 9-18. Aligned Nibble Mapping of Message in 16-bit NAND**

Byte Offset	16-Bit Word			
	4-Bit Most Significant Nibble		4-Bit Less Significant Nibble	
0	Nibble S-3	Nibble S-4	(MSB) Nibble S-1	Nibble S-2
2	Nibble S-7	Nibble S-8	Nibble S-5	Nibble S-6
⋮	⋮	⋮	⋮	⋮
S/2 - 4	Nibble 5	Nibble 4	Nibble 7	Nibble 6
S/2 - 2	Nibble 1	Nibble 0 (LSB)	Nibble 3	Nibble 2

**Table 9-19. Misaligned Nibble Mapping of Message in 16-bit NAND (1 Unused Nibble)**

Byte Offset	16-Bit Word			
	4-Bit Most Significant Nibble		4-Bit Less Significant Nibble	
0	Nibble S-3	Nibble S-4	(MSB) Nibble S-1	Nibble S-2
2	Nibble S-7	Nibble S-8	Nibble S-5	Nibble S-6
⋮	⋮	⋮	⋮	⋮
(S+1)/2 - 4	Nibble 4	Nibble 3	Nibble 6	Nibble 5
(S+1)/2 - 2	Nibble 0 (LSB)		Nibble 2	Nibble 1

**Table 9-20. Misaligned Nibble Mapping of Message in 16-bit NAND (2 Unused Nibble)**

Byte Offset	16-Bit Word			
	4-Bit Most Significant Nibble		4-Bit Less Significant Nibble	
0	Nibble S-3	Nibble S-4	(MSB) Nibble S-1	Nibble S-2
2	Nibble S-7	Nibble S-8	Nibble S-5	Nibble S-6
⋮	⋮	⋮	⋮	⋮
(S+2)/2 - 4	Nibble 3	Nibble 2	Nibble 5	Nibble 4
(S+2)/2 - 2			Nibble 1	Nibble 0 (LSB)

**Table 9-21. Misaligned Nibble Mapping of Message in 16-bit NAND (3 Unused Nibble)**

Byte Offset	16-Bit Word			
	4-Bit Most Significant Nibble		4-Bit Less Significant Nibble	
0	Nibble S-3	Nibble S-4	(MSB) Nibble S-1	Nibble S-2
2	Nibble S-7	Nibble S-8	Nibble S-5	Nibble S-6
⋮	⋮	⋮	⋮	⋮
(S+3)/2 - 4	Nibble 2	Nibble 1	Nibble 4	Nibble 3
(S+3)/2 - 2			Nibble 0 (LSB)	

Note that many other cases exist than the ones represented above, for example, where the message does not start on a word boundary.

#### 9.1.3.3.12.3.2.4 Memory Mapping of the ECC

The ECC (or remainder) is presented by the BCH module as a single 104-bit (or 52-bit), little-endian vector. It is up to the software to fetch those 13 bytes (or 6 bytes) from the modules interface, then store them to the NANDs spare area (page write) or to an intermediate buffer for comparison with the stored ECC (page read). There are no constraints on the ECC mapping inside the spare area: it is a softwarecontrolled operation.

However, it is advised to maintain a coherence in the respective formats of the message or the ECC remainder once they have been read out of the NAND. The error correction algorithm works from the complete codeword (concatenated message and remainder) once an error as been detected. The creation of this codeword should be made as straightforward as possible.

There are cases where the same NAND access contains both data and the ECC protecting that data. This is the case when the data/ECC boundary (which can be on any nibble) does not coincide with an access boundary. The ECC is calculated on-the-fly following the write. In that case, the write must also contain part of the ECC because it is impossible to insert the ECC on-the-fly. Instead:

- During the initial page write (BCH encoding), the ECC is replaced by dummy bits. The BCH encoder is by definition turned OFF during the ECC section, so the BCH result is unmodified.
- During a second phase, the ECC is written to the correct location, next to the actual data.
- The completed line buffer is then written to the NAND array.

#### 9.1.3.3.12.3.2.5 Wrapping Modes

For a given wrapping mode, the module automatically goes through a specific number of sections, as data is being fed into the module. For each section, the BCH core can be enabled (in which case the data is fed to the BCH divider) or not (in which case the BCH simply counts to the end of the section). When enabled, the data is added to the ongoing calculation for a given sector number (for example, number 0).

Wrapping modes are described below. To get a better understanding and see the real-life read and write sequences implemented with each mode, see [Section 9.1.3.3.12.3.3](#).

For each mode:

- A sequence describes the mode in pseudo-language, with for each section the size and the buffer used for ECC processing (if ON). The programmable lengths are size, size0 and size1.
- A checksum condition is given. If the checksum condition is not respected for a given mode, the modules behavior is unpredictable. S is the number of sectors in the page; size0 and size1 are the section sizes programmed for the mode, in nibbles.

Note that wrapping modes 8, 9, 10, and 11 insert a 1-nibble padding where the BCH processing is OFF. This is intended for  $t = 4$  ECC, where ECC is 6 bytes long and the ECC area is expected to include (at least) 1 unused nibble to remain byte-aligned.

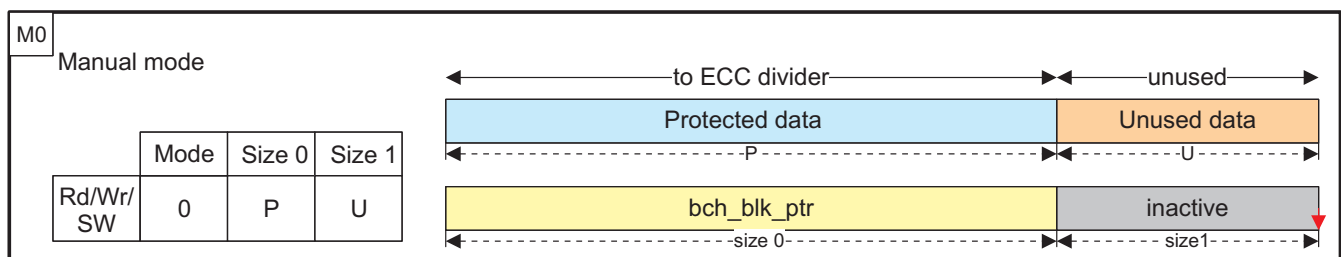

#### 9.1.3.3.12.3.2.6 Manual Mode (0x0)

This mode is intended for short sequences, added manually to a given buffer through the software data port input. A complete page may be built out of several such sequences.

To process an arbitrary sequence of 4-bit nibbles, accesses to the software data port shall be made, containing the appropriate data. If the sequence end does not coincide with an access boundary (for example, to process 5 nibbles = 20 bits in 16-bit access mode) and those nibbles need to be skipped, a number of unused nibbles shall be programmed in size1 (in the same example: 5 nibbles to process + 3 to discard = 8 nibbles = exactly 2 x 16-bit accesses: we must program size0 = 5, size1 = 3).

[Figure 9-37](#) shows the manual mode sequence and mapping. In this figure, size and size0 are the same parameter.

**Figure 9-37. Manual Mode Sequence and Mapping**

Section processing sequence:

- One time with buffer
  - size0 nibbles of data, processing ON
  - size1 nibbles of unused data, processing OFF

Checksum: size0 + size1 nibbles must fit in a whole number of accesses.

In the following sections, S is the number of sectors in the page.

#### **9.1.3.3.12.3.2.7 Mode 0x1**

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S - (size0 + size1)

#### **9.1.3.3.12.3.2.8 Mode 0xA (10)**

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
  - 1 nibble pad spare, processing OFF
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S - (size0 + 1 + size1)

#### **9.1.3.3.12.3.2.9 Mode 0x2**

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing OFF
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S - (size0 + size1)

#### **9.1.3.3.12.3.2.10 Mode 0x3**

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time with buffer 0
  - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S - size1)

#### 9.1.3.3.12.3.2.11 Mode 0x7

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time with buffer 0
  - size0 nibbles spare, processing ON
- Repeat S times (no buffer used)
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = size0 + (S - size1)

#### 9.1.3.3.12.3.2.12 Mode 0x8

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time with buffer 0
  - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
  - 1 nibble padding spare, processing OFF
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S - (1+size1))

#### 9.1.3.3.12.3.2.13 Mode 0x4

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time (no buffer used)
  - size0 nibbles spare, processing OFF
- Repeat with buffer 0 to S-1
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S - size1)

#### 9.1.3.3.12.3.2.14 Mode 0x9

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- One time (no buffer used)
  - size0 nibbles spare, processing OFF
- Repeat with buffer 0 to S-1
  - 1 nibble padding spare, processing OFF
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S - (1+size1))

#### 9.1.3.3.12.3.2.15 Mode 0x5

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S - (size0 + size1)

#### 9.1.3.3.12.3.2.16 Mode 0xB (11)

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
  - 1 nibble padding spare, processing OFF
  - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S - (size0 + 1 + size1)

#### 9.1.3.3.12.3.2.17 Mode 0x6

Page processing sequence:

- Repeat with buffer 0 to S-1
  - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
  - size0 nibbles spare, processing ON
- Repeat S times (no buffer used)
  - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S - (size0 + size1)

### 9.1.3.3.12.3.3 Supported NAND Page Mappings and ECC Schemes

The following rules apply throughout the entire mapping description:

- Main data area (sectors) size is hardcoded to 512 bytes.
- Spare area size is programmable.
- All page sections (of main area data bytes, protected spare bytes, unprotected spare bytes, and ECC) are defined as explained in [Section 9.1.3.3.12.3.2.3](#).

Each one of the following sections shows a NAND page mapping example (per-sector spare mappings, pooled spare mapping, per-sector spare mapping, with ECC separated at the end of the page).

In the mapping diagrams, sections that belong to the same BCH codeword have the same color (blue or green); unprotected sections are not covered (orange) by the BCH scheme.

Below each mapping diagram, a write (encoding) and read (decoding: syndrome generation) sequence is given, with the number of the active buffers at each point in time (yellow). In the inactive zones (grey), no computing is taking place but the data counter is still active.

In [Figure 9-38](#) to [Figure 9-40](#), tables on the left summarize the mode, size0, size1 parameters to program for respectively write and read processing of a page, with the given mapping, where:

- P is the size of spare byte section Protected by the ECC (in nibbles)
- U is the size of spare byte section Unprotected by the ECC (in nibbles)
- E is the size of the ECC itself (in nibbles)
- S is the number of Sectors per page (2 in the current diagrams)

Each time the processing of a BCH block is complete (ECC calculation for write/encoding, syndrome generation for read/decoding, indicated by red arrows), the update pointer is pulsed. Note that the processing for block 0 can be the first or the last to complete, depending on the NAND page mapping and operation (read or write). All examples show a page size of 1kByte + spares, that is,  $S = 2$  sectors of 512 bytes. The same principles can be extended to larger pages by adding more sectors.

The actual BCH codeword size is used during the error location work to restrict the search range: by definition, errors can only happen in the codeword that was actually written to the NAND, and not in the mathematical codeword of  $n = 2 - 1 = 8191$  bits. That codeword (higher-order bits) is all-zero and implicit during computations.

The actual BCH codeword size depends on the mode, on the programmed sizes and on the sector number (all sizes in nibbles):

- Spares mapped and protected per sector ([Figure 9-38](#): see M1-M2-M3-M9-M10):
  - all sectors:  $(512) + P + E$
- Spares pooled and protected by sector 0 ([Figure 9-38](#): see M5-M6):
  - sector 0 codeword:  $(512) + P + E$
  - other sectors:  $(512) + E$
- Unprotected spares ([Figure 9-38](#): see M4-M7-M8-M11-M12):
  - all codewords  $(512) + E$

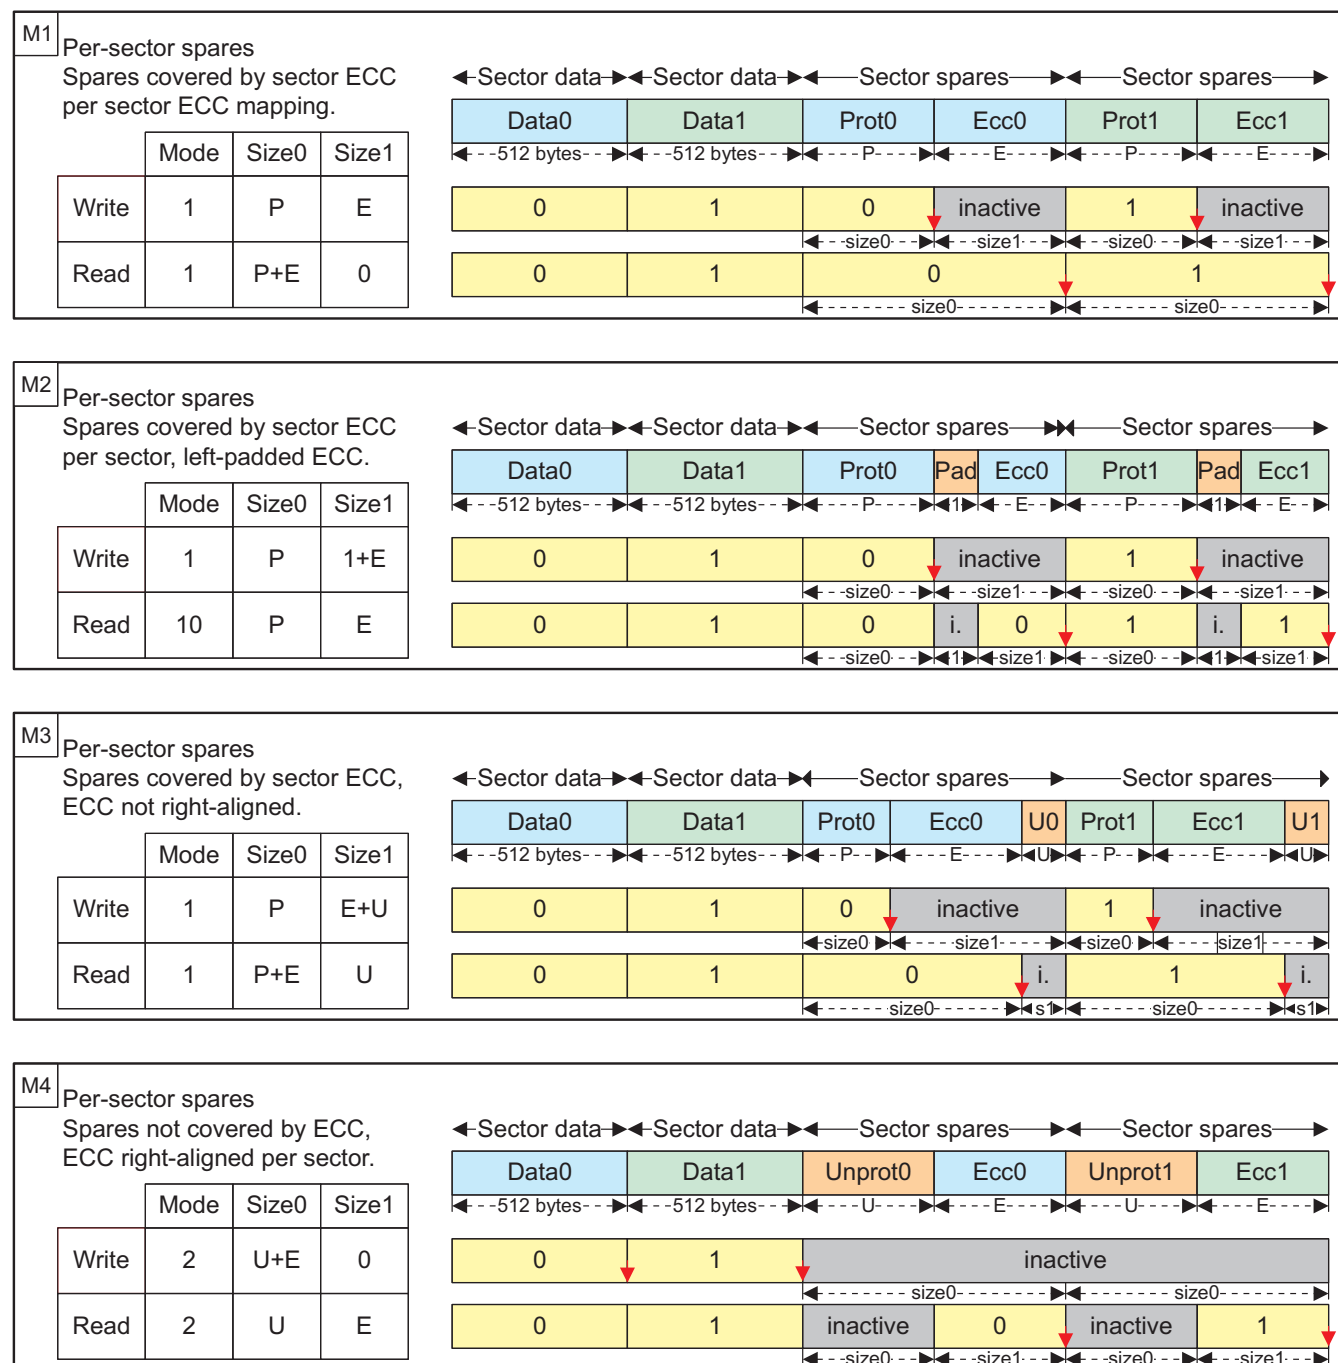

### 9.1.3.3.12.3.3.1 Per-Sector Spare Mappings

In these schemes (Figure 9-38), each 512-byte sector of the main area has its own dedicated section of the spare area. The spare area of each sector is composed of:

- ECC, which must be located after the data it protects
- other data, which may or may not be protected by the sectors ECC

Figure 9-38. NAND Page Mapping and ECC: Per-Sector Schemes

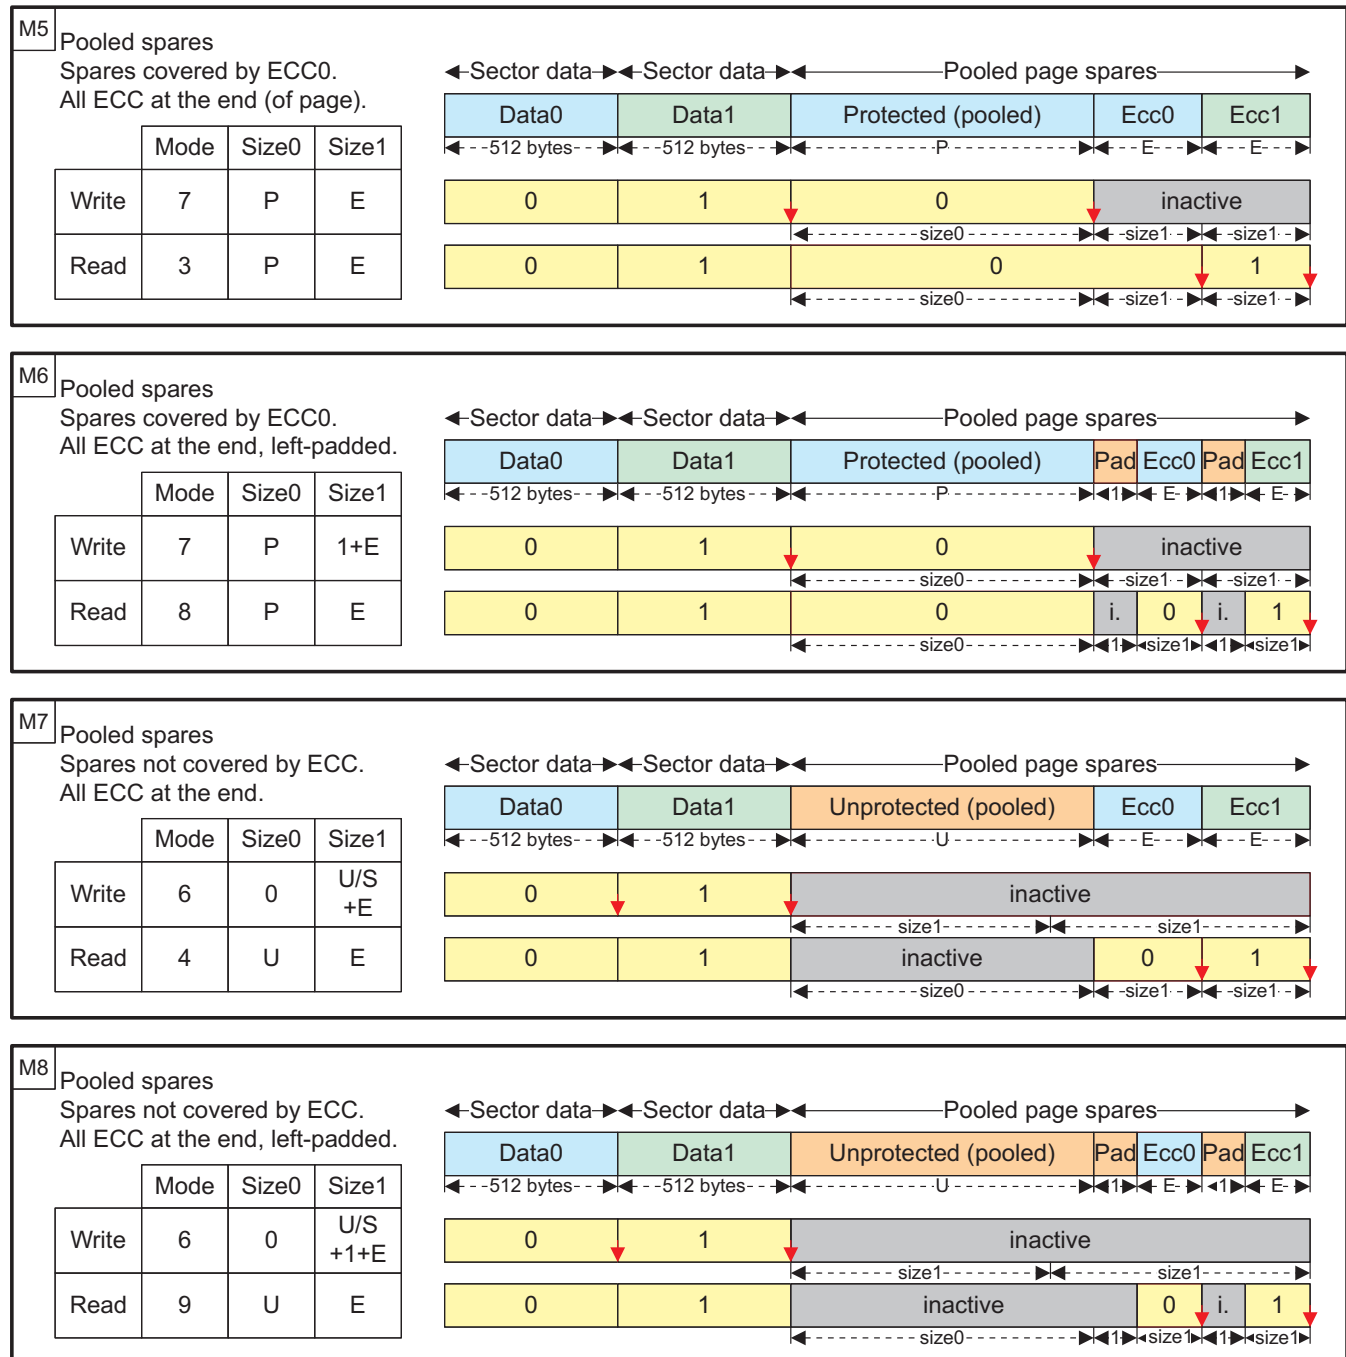

### 9.1.3.3.12.3.3.2 Pooled Spare Mapping

In these schemes (Figure 9-39), the spare area is pooled for the page.

- The ECC of each sector is aligned at the end of the spare area.
- The non-ECC spare data may or may not be covered by the ECC of sector 0

**Figure 9-39. NAND Page Mapping and ECC: Pooled Spare Schemes**

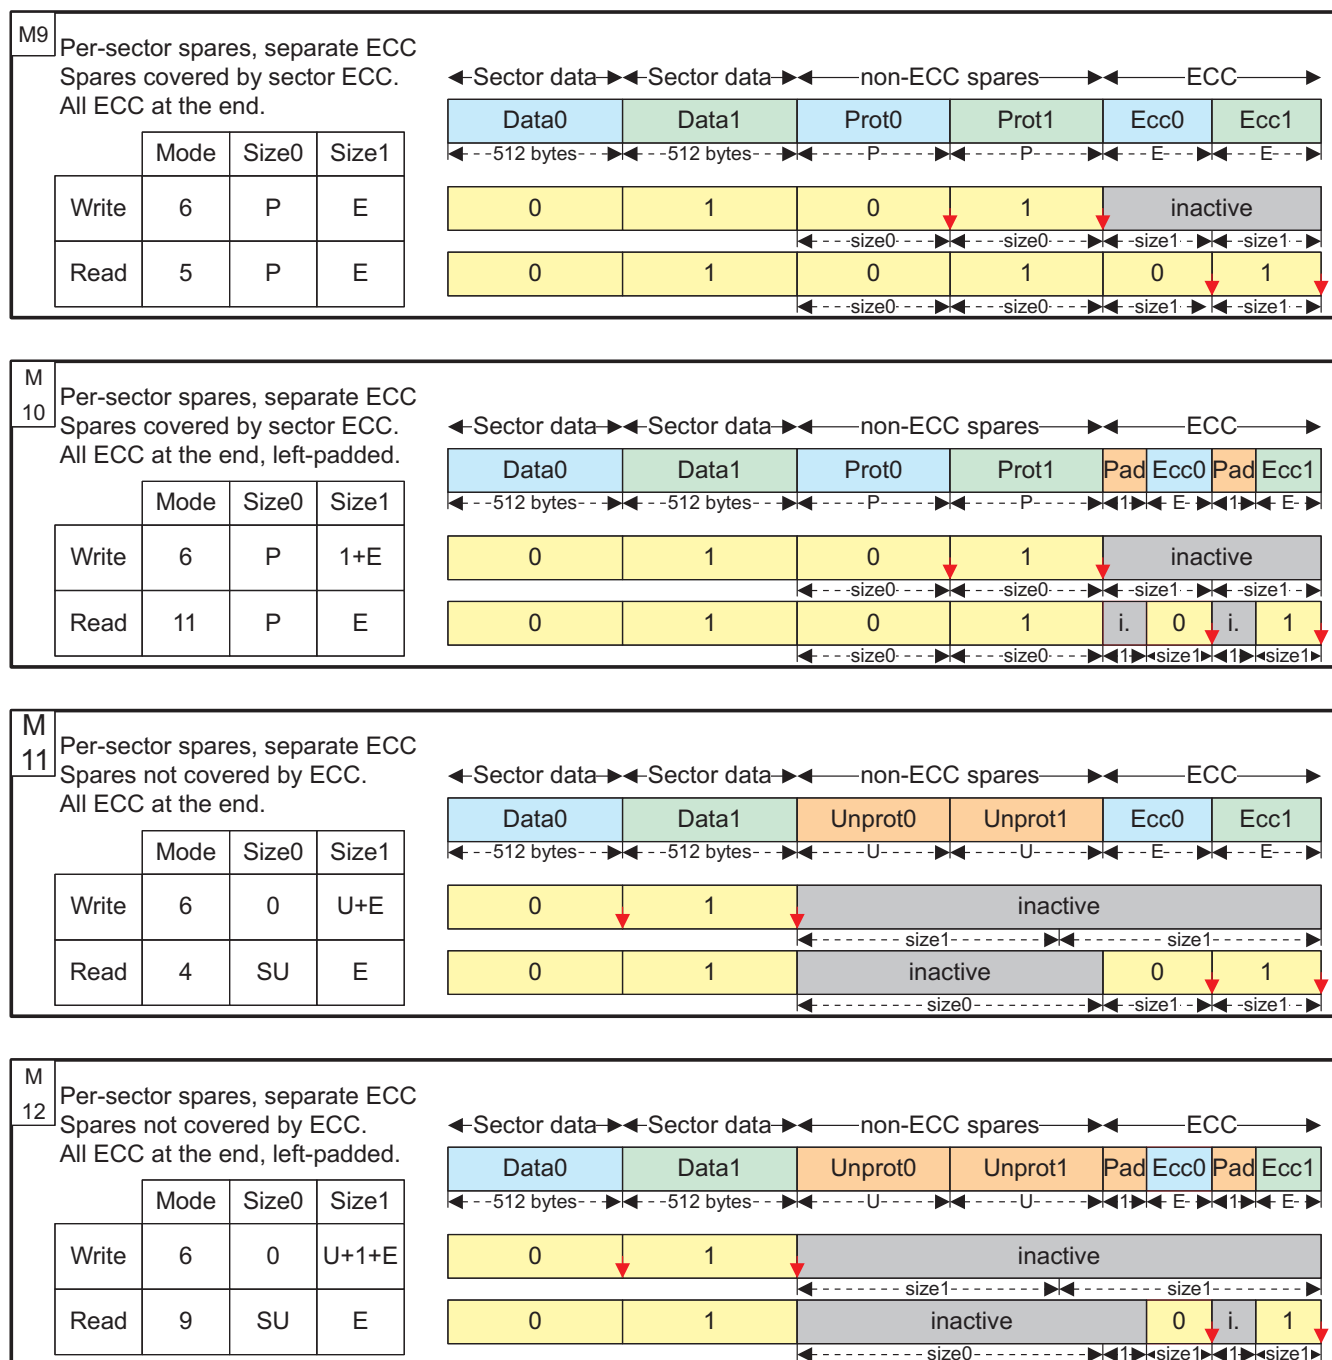

### 9.1.3.3.12.3.3.3 Per-Sector Spare Mapping, With ECC Separated at the End of the Page

In these schemes (Figure 9-40), each 512-byte sector of the main area is associated with two sections of the spare area.

- ECC section, all aligned at the end of the page
- other data section, aligned before the ECCs, each of which may or may not be protected by its sectors ECC

Figure 9-40. NAND Page Mapping and ECC: Per-Sector Schemes, with Separate ECC

#### 9.1.3.3.12.4 Prefetch and Write-Posting Engine

NAND device data access cycles are usually much slower than the MPU system frequency; such NAND read or write accesses issued by the processor will impact the overall system performance, especially considering long read or write sequences required for NAND page loading or programming. To minimize this effect on system performance, the GPMC includes a prefetch and write-posting engine, which can be used to read from or write to any chip-select location in a buffered manner.

The prefetch and write-posting engine is a simplified embedded-access requester that presents requests to the access engine on a user-defined chip-select target. The access engine interleaves these requests with any request coming from the L3 interface; as a default the prefetch and write-posting engine has the lowest priority.

The prefetch and write-posting engine is dedicated to data-stream access (as opposed to random data access); thus, it is primarily dedicated to NAND support. The engine does not include an address generator; the request is limited to chip-select target identification. It includes a 64-byte FIFO associated with a DMA request synchronization line, for optimal DMA-based use.

The prefetch and write-posting engine uses an embedded 64 bytes (32 16-bit word) FIFO to prefetch data from the NAND device in read mode (prefetch mode) or to store host data to be programmed into the NAND device in write mode (write-posting mode). The FIFO draining and filling (read and write) can be controlled either by the MPU through interrupt synchronization (an interrupt is triggered whenever a programmable threshold is reached) or the sDMA through DMA request synchronization, with a programmable request byte size in both prefetch or posting mode.

The prefetch and write-posting engine includes a single memory pool. Therefore, only one mode, read or write, can be used at any given time. In other words, the prefetch and write-posting engine is a single-context engine that can be allocated to only one chip-select at a time for a read prefetch or a write-posting process.

The engine does not support atomic command and address phase programming and is limited to linear memory read or write access. In consequence, it is limited to NAND data-stream access. The engine relies on the MPU NAND software driver to control block and page opening with the correct data address pointer initialization, before the engine can read from or write to the NAND memory device.

Once started, the engine data reads and writes sequencing is solely based on FIFO location availability and until the total programmed number of bytes is read or written.

Any host-concurrent accesses to a different chip-select are correctly interleaved with ongoing engine accesses. The engine has the lowest priority access so that host accesses to a different chip-select do not suffer a large latency.

A round-robin arbitration scheme can be enabled to ensure minimum bandwidth to the prefetch and write-posting engine in the case of back-to-back direct memory requests to a different chip-select. If the GPMC\_PREFETCH\_CONFIG1[23] PFPWENROUNDROBIN bit is enabled, the arbitration grants the prefetch and write posting engine access to the GPMC bus for a number of requests programmed in the GPMC\_PREFETCH\_CONFIG1[19-16] PFPWWEIGHTEDPRIO field.

The prefetch/write-posting engine read or write request is routed to the access engine with the chip-select destination ID. After the required arbitration phase, the access engine processes the request as a single access with the data access size equal to the device size specified in the corresponding chip-select configuration.

The destination chip-select configuration must be set to the NAND protocol-compatible configuration for which address lines are not used (the address bus is not changed from its current value). Selecting a different chip-select configuration can produce undefined behavior.

#### 9.1.3.3.12.4.1 General Facts About the Engine Configuration

The engine can be configured only if the GPMC\_PREFETCH\_CTRL[0] STARTENGINE bit is de-asserted.

The engine must be correctly configured in prefetch or write-posting mode and must be linked to a NAND chip-select before it can be started. The chip-select is linked using the GPMC\_PREFETCH\_CONFIG1[26-24] ENGINECSSELECTOR field.

In both prefetch and write-posting modes, the engine respectively uses byte or 16-bit word access requests for an 8- or 16-bit wide NAND device attached to the linked chip-select. The FIFOTHRESHOLD and TRANSFERCOUNT fields must be programmed accordingly as a number of bytes or a number of 16-bit word.

When the GPMC\_PREFETCH\_CONFIG1[7] ENABLEENGINE bit is set, the FIFO entry on the L3 interconnect port side is accessible at any address in the associated chip-select memory region. When the ENABLEENGINE bit is set, any host access to this chip-select is rerouted to the FIFO input. Directly accessing the NAND device linked to this chip-select from the host is still possible through these registers:

- GPMC\_NAND\_COMMAND\_i
- GPMC\_NAND\_ADDR\_i
- GPMC\_NAND\_DATA\_i

The FIFO entry on the L3 interconnect port can be accessed with Byte, 16-bit word, or 32-bit word access size, according to little-endian format, even though the FIFO input is 32-bit wide.

The FIFO control is made easier through the use of interrupts or DMA requests associated with the FIFOTHRESHOLD bit field. The GPMC\_PREFETCH\_STS[30-24] FIFOPINTER field monitors the number of available bytes to be read in prefetch mode or the number of free empty slots which can be written in write-posting mode. The GPMC\_PREFETCH\_STS[13-0] COUNTVALUE field monitors the number of remaining bytes to be read or written by the engine according to the TRANSFERCOUNT value. The FIFOPINTER and COUNTVALUE bit fields are always expressed as a number of bytes even if a 16-bit wide NAND device is attached to the linked chip-select.

In prefetch mode, when the FIFOPINTER equals 0, that is, the FIFO is empty, a host read access receives the byte last read from the FIFO as its response. In case of 32-bit word or 16-bit word read accesses, the last byte read from the FIFO is copied the required number of times to fit the requested word size. In write-posting mode, when the FIFOPINTER equals 0, that is, the FIFO is full, a host write overwrites the last FIFO byte location. There is no underflow or overflow error reporting in the GPMC.

#### 9.1.3.3.12.4.2 Prefetch Mode

The prefetch mode is selected when the GPMC\_PREFETCH\_CONFIG1[0] ACCESSMODE bit is cleared.

The MPU NAND software driver must issue the block and page opening (READ) command with the correct data address pointer initialization before the engine can be started to read from the NAND memory device. The engine is started by asserting the GPMC\_PREFETCH\_CTRL[0] STARTENGINE bit. The STARTENGINE bit automatically clears when the prefetch process completes.

If required, the ECC calculator engine must be initialized (i.e., reset, configured, and enabled) before the prefetch engine is started, so that the ECC is correctly computed on all data read by the prefetch engine.

When the GPMC\_PREFETCH\_CONFIG1[3] SYNCHROMODE bit is cleared, the prefetch engine starts requesting data as soon as the STARTENGINE bit is set. If using this configuration, the host must monitor the NAND device-ready pin so that it only sets the STARTENGINE bit when the NAND device is in a ready state, meaning data is valid for prefetching.

When the SYNCHROMODE bit is set, the prefetch engine starts requesting data when an active to inactive wait signal transition is detected. The transition detector must be cleared before any transition detection; see [Section 9.1.3.3.12.2.2](#). The GPMC\_PREFETCH\_CONFIG1[5-4] WAITPINSELECTOR field selects which gpmc\_wait pin edge detector triggers the prefetch engine in this synchronized mode.

If the STARTENGINE bit is set after the NAND address phase (page opening command), the engine is effectively started only after the actual NAND address phase completion. To prevent GPMC stall during this NAND address phase, set the STARTENGINE bit field before NAND address phase completion when in synchronized mode. The prefetch engine will start when an active to inactive wait signal transition is detected. The STARTENGINE bit is automatically cleared on prefetch process completion.

The prefetch engine issues a read request to fill the FIFO with the amount of data specified by GPMC\_PREFETCH\_CONFIG2[13-0] TRANSFERCOUNT field.

[Table 9-22](#) describes the prefetch mode configuration.

**Table 9-22. Prefetch Mode Configuration**

Bit Field	Register	Value	Comments
STARTENGINE	GPMC_PREFETCH_CTRL	0	Prefetch engine can be configured only if STARTENGINE is cleared to 0.
ENGINECSSELECTOR	GPMC_PREFETCH_CONFIG1	0 to 3h	Selects the chip-select associated with a NAND device where the prefetch engine is active.
ACCESSMODE	GPMC_PREFETCH_CONFIG1	0	Selects prefetch mode
FIFOTHRESHOLD	GPMC_PREFETCH_CONFIG1		Selects the maximum number of bytes read or written by the host on DMA or interrupt request
TRANSFERCOUNT	GPMC_PREFETCH_CONFIG1		Selects the number of bytes to be read or written by the engine to the selected chip-select
SYNCHROMODE	GPMC_PREFETCH_CONFIG1	0/1	Selects when the engine starts the access to the chip-select
WAITPINSELECT	GPMC_PREFETCH_CONFIG1	0 to 1	Selects wait pin edge detector (if GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE = 1)
ENABLEOPTIMIZEDACCESS	GPMC_PREFETCH_CONFIG1	0/1	See <a href="#">Section 9.1.3.3.12.4.6</a>
CYCLEOPTIMIZATION	GPMC_PREFETCH_CONFIG1		Number of clock cycle removed to timing parameters
ENABLEENGINE	GPMC_PREFETCH_CONFIG1	1	Engine enabled
STARTENGINE	GPMC_PREFETCH_CONFIG1	1	Starts the prefetch engine

### 9.1.3.3.12.4.3 FIFO Control in Prefetch Mode

The FIFO can be drained directly by the MPU or by an eDMA channel.

In MPU draining mode, the FIFO status can be monitored through the GPMC\_PREFETCH\_STS[30-24] FIFOPINTER field or through the GPMC\_PREFETCH\_STS[16] FIFOTHRSTS bit. The FIFOPINTER indicates the current number of available data to be read; FIFOTHRSTS set to 1 indicates that at least FIFOTHRESHOLD bytes are available from the FIFO.

An interrupt can be triggered by the GPMC if the GPMC\_IRQEN[0] FIFOEVTEN bit is set. The FIFO interrupt event is logged, and the GPMC\_IRQSTS[0] FIFOEVTSTS bit is set. To clear the interrupt, the MPU must read all the available bytes, or at least enough bytes to get below the programmed FIFO threshold, and the FIFOEVTSTS bit must be cleared to enable further interrupt events. The FIFOEVTSTS bit must always be reset prior to asserting the FIFOEVTEN bit to clear any out-of-date logged interrupt event. This interrupt generation must be enabled after enabling the STARTENGINE bit.

Prefetch completion can be monitored through the GPMC\_PREFETCH\_STS[13-0] COUNTVALUE field. COUNTVALUE indicates the number of currently remaining data to be requested according to the TRANSFERCOUNT value. An interrupt can be triggered by the GPMC when the prefetch process is complete (that is, COUNTVALUE equals 0) if the GPMC\_IRQEN[1] TERMINALCOUNTEVTEN bit is set. At prefetch completion, the TERMINALCOUNT interrupt event is also logged, and the GPMC\_IRQSTS[1] TERMINALCOUNTSTS bit is set. To clear the interrupt, the MPU must clear the TERMINALCOUNTSTS bit. The TERMINALCOUNTSTS bit must always be cleared prior to asserting the TERMINALCOUNTEVTEN bit to clear any out-of-date logged interrupt event.

---

**NOTE:** The COUNTVALUE value is only valid when the prefetch engine is active (started), and an interrupt is only triggered when COUNTVALUE reaches 0, that is, when the prefetch engine automatically goes from an active to an inactive state.

---

The number of bytes to be prefetched (programmed in TRANSFERCOUNT) must be a multiple of the programmed FIFOTHRESHOLD to trigger the correct number of interrupts allowing a deterministic and transparent FIFO control. If this guideline is respected, the number of ISR accesses is always required and the FIFO is always empty after the last interrupt is triggered. In other cases, the TERMINALCOUNT interrupt must be used to read the remaining bytes in the FIFO (the number of remaining bytes being lower than the FIFOTHRESHOLD value).

In DMA draining mode, the GPMC\_PREFETCH\_CONFIG1[2] DMAMODE bit must be set so that the GPMC issues a DMA hardware request when at least FIFOTHRESHOLD bytes are ready to be read from the FIFO. The DMA channel owning this DMA request must be programmed so that the number of bytes programmed in FIFOTHRESHOLD is read from the FIFO during the DMA request process. The DMA request is kept active until this number of bytes has effectively been read from the FIFO, and no other DMA request can be issued until the ongoing active request is complete.

In prefetch mode, the TERMINALCOUNT event is also a source of DMA requests if the number of bytes to be prefetched is not a multiple of FIFOTHRESHOLD, the remaining bytes in the FIFO can be read by the DMA channel using the last DMA request. This assumes that the number of remaining bytes to be read is known and controlled through the DMA channel programming model.

Any potentially active DMA request is cleared when the prefetch engine goes from inactive to active prefetch (the STARTENGINE bit is set to 1). The associated DMA channel must always be enabled by the MPU after setting the STARTENGINE bit so that the out-of-date active DMA request does not trigger spurious DMA transfers.

#### 9.1.3.3.12.4.4 Write-Posting Mode

The write-posting mode is selected when the GPMC\_PREFETCH\_CONFIG1[0] ACCESSMODE bit is set.

The MPU NAND software driver must issue the correct address pointer initialization command (page program) before the engine can start writing data into the NAND memory device. The engine starts when the GPMC\_PREFETCH\_CTRL[0] STARTENGINE bit is set to 1. The STARTENGINE bit clears automatically when posting completes. When all data have been written to the NAND memory device, the MPU NAND software driver must issue the second cycle program command and monitor the status for programming process completion (adding ECC handling, if required).

If used, the ECC calculator engine must be started (configured, reset, and enabled) before the posting engine is started so that the ECC parities are properly calculated on all data written by the prefetch engine to the associated chip-select.

In write-posting mode, the GPMC\_PREFETCH\_CONFIG1[3] SYNCHROMODE bit must be cleared so that posting starts as soon as the STARTENGINE bit is set and the FIFO is not empty.

If the STARTENGINE bit is set after the NAND address phase (page program command), the STARTENGINE setting is effective only after the actual NAND command completion. To prevent GPMC stall during this NAND command phase, set the STARTENGINE bit field before the NAND address completion and ensure that the associated DMA channel is enabled after the NAND address phase.

The posting engine issues a write request when valid data are available from the FIFO and until the programmed GPMC\_PREFETCH\_CONFIG2[13-0] TRANSFERCOUNT accesses have been completed.

The STARTENGINE bit clears automatically when posting completes. When all data have been written to the NAND memory device, the MPU NAND software driver must issue the second cycle program command and monitor the status for programming process completion. The closing program command phase must only be issued when the full NAND page has been written into the NAND flash write buffer, including the spare area data and the ECC parities, if used.

**Table 9-23. Write-Posting Mode Configuration**

Bit Field	Register	Value	Comments
STARTENGINE	GPMC_PREFETCH_CTRL	0	Write-posting engine can be configured only if STARTENGINE is cleared to 0.
ENGINECSSELECTOR	GPMC_PREFETCH_CONFIG1	0 to 3h	Selects the chip-select associated with a NAND device where the prefetch engine is active
ACCESSMODE	GPMC_PREFETCH_CONFIG1	1	Selects write-posting mode
FIFOTHRESHOLD	GPMC_PREFETCH_CONFIG1		Selects the maximum number of bytes read or written by the host on DMA or interrupt request
TRANSFERCOUNT	GPMC_PREFETCH_CONFIG2		Selects the number of bytes to be read or written by the engine from/to the selected chip-select
SYNCHROMODE	GPMC_PREFETCH_CONFIG1	0	Engine starts the access to chip-select as soon as STARTENGINE is set.
ENABLEOPTIMIZEDACCESS	GPMC_PREFETCH_CONFIG1	0/1	See <a href="#">Section 9.1.3.3.12.4.6</a>
CYCLEOPTIMIZATION	GPMC_PREFETCH_CONFIG		
ENABLEENGINE	GPMC_PREFETCH_CONFIG1	1	Engine enabled
STARTENGINE	GPMC_PREFETCH_CTRL	1	Starts the prefetch engine

### 9.1.3.3.12.4.5 FIFO Control in Write-Posting Mode

The FIFO can be filled directly by the MPU or by an sDMA channel.

In MPU filling mode, the FIFO status can be monitored through the FIFOPINTER or through the GPMC\_PREFETCH\_STS[16] FIFOTHRSTS bit. FIFOPINTER indicates the current number of available free byte places in the FIFO, and the FIFOTHRSTS bit, when set, indicates that at least FIFOTHRESHOLD free byte places are available in the FIFO.

An interrupt can be issued by the GPMC if the GPMC\_IRQEN[0] FIFOEVTEN bit is set. When the interrupt is fired, the GPMC\_IRQSTS[0] FIFOEVTSTS bit is set. To clear the interrupt, the MPU must write enough bytes to fill the FIFO, or enough bytes to get below the programmed threshold, and the FIFOEVTSTS bit must be cleared to get further interrupt events. The FIFOEVTSTS bit must always be cleared prior to asserting the FIFOEVTEN bit to clear any out-of-date logged interrupt event. This interrupt must be enabled after enabling the STARTENGINE bit

The posting completion can be monitored through the GPMC\_PREFETCH\_STS[13-0] COUNTVALUE field. COUNTVALUE indicates the current number of remaining data to be written based on the TRANSFERCOUNT value. An interrupt is issued by the GPMC when the write-posting process completes (that is, COUNTVALUE equal to 0) if the GPMC\_IRQEN[1] TERMINALCOUNTEVTEN bit is set. When the interrupt is fired, the GPMC\_IRQSTS[1] TERMINALCOUNTSTS bit is set. To clear the interrupt, the MPU must clear the TERMINALCOUNTSTS bit. The TERMINALCOUNTSTS bit must always be cleared prior to asserting the TERMINALCOUNTEVTEN bit to clear any out-of-date logged interrupt event.

---

**NOTE:** The COUNTVALUE value is only valid if the write-posting engine is active and started, and an interrupt is only issued when COUNTVALUE reaches 0, that is, when the posting engine automatically goes from active to inactive.

---

In DMA filling mode, the DMAMode bit field in the GPMC\_PREFETCH\_CONFIG1[2] DMAMODE bit must be set so that the GPMC issues a DMA hardware request when at least FIFOTHRESHOLD bytes-free places are available in the FIFO. The DMA channel owning this DMA request must be programmed so that a number of bytes equal to the value programmed in the FIFOTHRESHOLD bit field are written into the FIFO during the DMA access. The DMA request remains active until the associated number of bytes has effectively been written into the FIFO, and no other DMA request can be issued until the ongoing active request has been completed.

Any potentially active DMA request is cleared when the prefetch engine goes from inactive to active prefetch (STARTENGINE set to 1). The associated DMA channel must always be enabled by the MPU after setting the STARTENGINE bit so that an out-of-date active DMA request does not trigger spurious DMA transfers.

In write-posting mode, the DMA or the MPU fill the FIFO with no consideration to the associated byte enables. Any byte stored in the FIFO is written into the memory device.

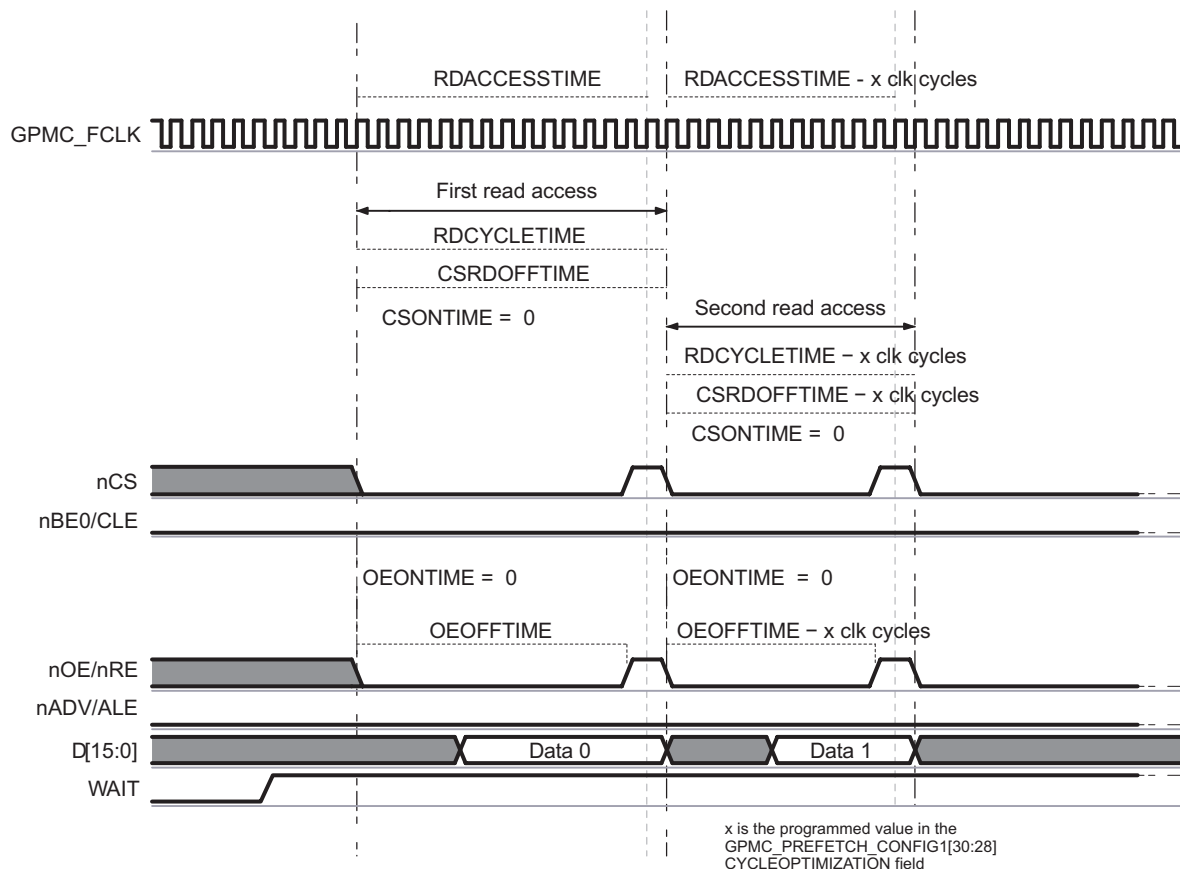

#### 9.1.3.3.12.4.6 Optimizing NAND Access Using the Prefetch and Write-Posting Engine

Access time to a NAND memory device can be optimized for back-to-back accesses if the associated CSn signal is not deasserted between accesses. The GPMC access engine can track prefetch engine accesses to optimize the access timing parameter programmed for the allocated chip-select, if no accesses to other chip-selects (that is, interleaved accesses) occur. Similarly, the access engine also eliminates the CYCLE2CYCLEDELAY even if CYCLE2CYCLESAMECSN is set. This capability is limited to the prefetch and write-posting engine accesses, and MPU accesses to a NAND memory device (through the defined chip-select memory region or through the GPMC\_NAND\_DATA\_i are never optimized.

The GPMC\_PREFETCH\_CONFIG1[27] ENABLEOPTIMIZEDACCESS bit must be set to enable optimized accesses. To optimize access time, the GPMC\_PREFETCH\_CONFIG1[30-28] CYCLEOPTIMIZATION field defines the number of GPMC\_FCLK cycles to be suppressed from the RDCYCLETIME, WRCYCLETIME, RDACCESSTIME, WRACCESSTIME, CSOFFTIME, ADVOFFTIME, OEOFFTIME, and WEOFFTIME timing parameters.

Figure 9-41, in the case of back-to-back accesses to the NAND flash through the prefetch engine, CYCLE2CYCLESAMECSN is forced to 0 when using optimized accesses. The first access uses the regular timing settings for this chip-select. All accesses after this one use settings reduced by x clock cycles, x being defined by the GPMC\_PREFETCH\_CONFIG1[30-28] CYCLEOPTIMIZATION field.

**Figure 9-41. NAND Read Cycle Optimization Timing Description**

#### 9.1.3.3.12.4.7 Interleaved Accesses Between Prefetch and Write-Posting Engine and Other Chip-Selects

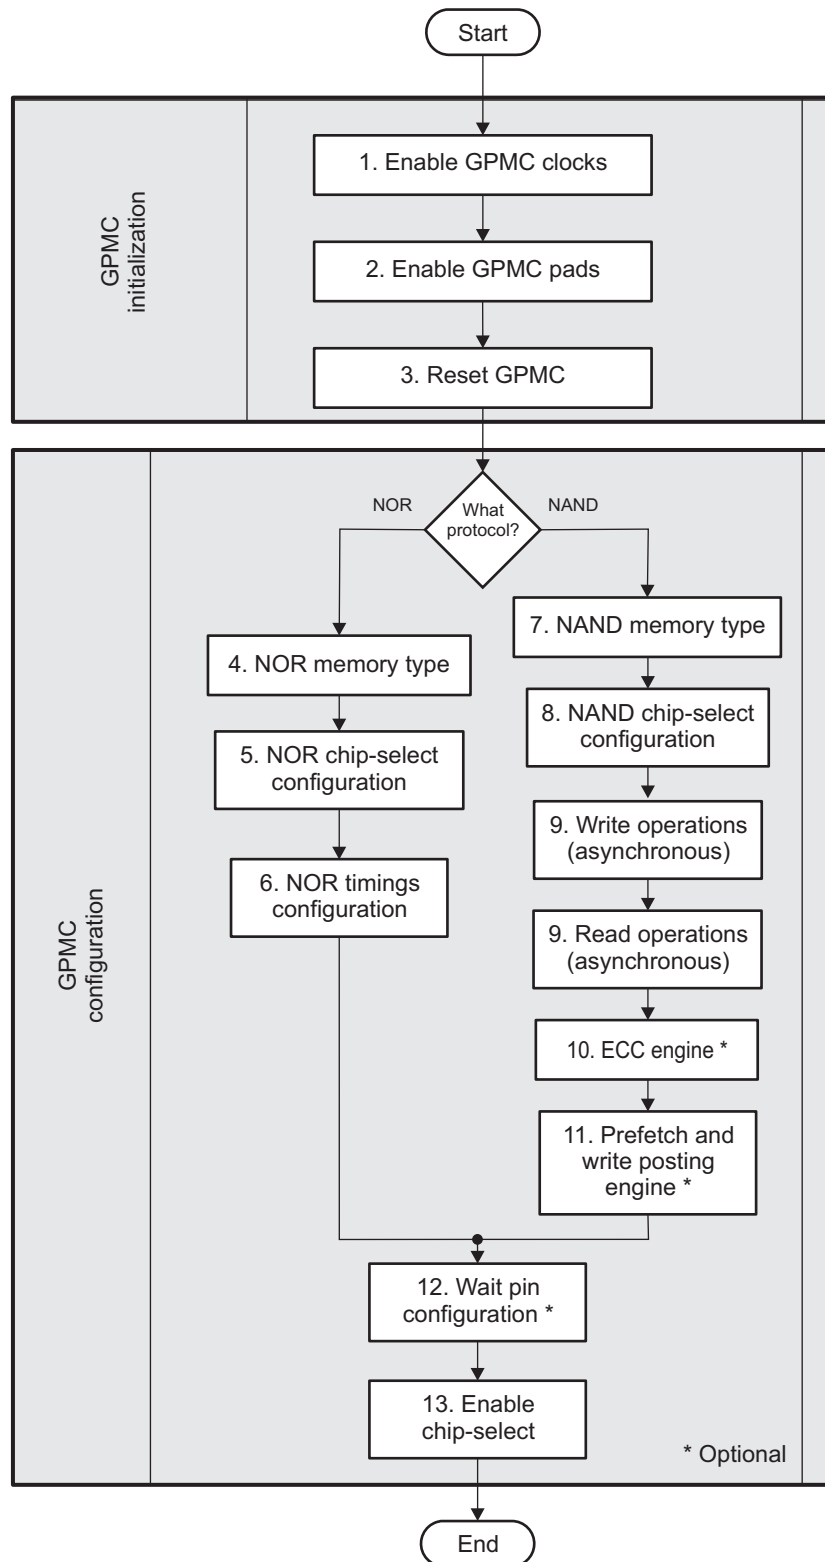

Any on-going read or write access from the prefetch and write-posting engine is completed before an access to any other chip-select can be initiated. As a default, the arbiter uses a fixed-priority algorithm, and the prefetch and write-posting engine has the lowest priority. The maximum latency added to access starting time in this case equals the RDCYCLETIME or WRCYCLETIME (optimized or not) plus the requested BUSTURNAROUND delay for bus turnaround completion programmed for the chip-select to which the NAND device is connected to.

Alternatively, a round-robin arbitration can be used to prioritize accesses to the external bus. This arbitration scheme is enabled by setting the GPMC\_PREFETCH\_CONFIG1[23] PFPWENROUNDROBIN bit. When a request to another chip-select is received while the prefetch and write-posting engine is active, priority is given to the new request. The request processed thereafter is the prefetch and write-posting engine request, even if another interconnect request is passed in the mean time. The engine keeps control of the bus for an additional number of requests programmed in the GPMC\_PREFETCH\_CONFIG1[19-16] PFPWWEIGHTEDPRIO bit field. Control is then passed to the direct interconnect request.

As an example, the round-robin arbitration scheme is selected with PFPWWEIGHTEDPRIO set to 2h. Considering the prefetch and write-posting engine and the interconnect interface are always requesting access to the external interface, the GPMC grants priority to the direct interconnect access for one request. The GPMC then grants priority to the engine for three requests, and finally back to the direct interconnect access, until the arbiter is reset when one of the two initiators stops initiating requests.

#### 9.1.4 GPMC High-Level Programming Model Overview

The high-level programming model introduces a top-down approach for users that need to configure the GPMC module. [Figure 9-42](#) shows a programming model top-level diagram for the GPMC. Each block of the diagram is described in one of the following subsections through a set of registers to configure. [Table 9-24](#) and [Table 9-25](#) list each step in the model.

**Figure 9-42. Programming Model Top-Level Diagram**

**Table 9-24. GPMC Configuration in NOR Mode**

Step	Description
NOR Memory Type	See <a href="#">Table 9-27</a>
NOR Chip-Select Configuration	See <a href="#">Table 9-28</a>
NOR Timings Configuration	See <a href="#">Table 9-29</a>
Wait Pin Configuration	See <a href="#">Table 9-30</a>
Enable Chip-Select	See <a href="#">Table 9-31</a>

**Table 9-25. GPMC Configuration in NAND Mode**

Step	Description
NAND Memory Type	See <a href="#">Table 9-32</a>
NAND Chip-Select Configuration	See <a href="#">Table 9-33</a>
Write Operations (Asynchronous)	See <a href="#">Table 9-34</a>
Read Operations (Asynchronous)	See <a href="#">Table 9-34</a>
ECC Engine	See <a href="#">Table 9-35</a>
Prefetch and Write-Posting Engine	See <a href="#">Table 9-36</a>
Wait Pin Configuration	See <a href="#">Table 9-37</a>
Enable Chip-Select	See <a href="#">Table 9-38</a>

#### 9.1.4.1 GPMC Initialization

[Table 9-26](#) describes the settings required to reset the GPMC.

**Table 9-26. Reset GPMC**

Sub-process Name	Register / Bitfield	Value
Start a software reset	GPMC_SYSCONFIG[1] SOFTRESET	1
Wait until	GPMC_SYSSTS[0] RESETDONE	1

### 9.1.4.2 GPMC Configuration in NOR Mode

This section gives a generic configuration for parameters related to the NOR memory connected to the GPMC. [Table 9-27](#) through [Table 9-31](#) list the steps to configure the GPMC in NOR mode.

**NOTE:** In the tables of this section, 'x' in Value column stands for 'depends on configuration'.

**Table 9-27. NOR Memory Type**

Sub-process Name	Register / Bitfield	Value
Set the NOR protocol	GPMC_CONFIG1_i[11-10] DEVICETYPE	0
Set a device size	GPMC_CONFIG1_i[13-12] DEVICESIZE	x
Select an address and data multiplexing protocol	GPMC_CONFIG1_i[9] MUXADDDATA	x
Set the attached device page length	GPMC_CONFIG1_i[24-23] ATTACHEDDEVICEPAGELENGTH	x
Set the wrapping burst capabilities	GPMC_CONFIG1_i[31] WRAPBURST	x
Select a timing signals latencies factor	GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY	x
Select an output clock frequency	GPMC_CONFIG1_i[1-0] GPMCFCLKDIVIDER	x
Choose an output clock activation time	GPMC_CONFIG1_i[26-25] CLKACTIVATIONTIME	x
Set a single or multiple access for read operations	GPMC_CONFIG1_i[30] READMULTIPLE	x
Set a synchronous or asynchronous mode for read operations	GPMC_CONFIG1_i[29] READTYPE	x
Set a single or multiple access for write operations	GPMC_CONFIG1_i[28] WRITEMULTIPLE	x
Set a synchronous or asynchronous mode for write operations	GPMC_CONFIG1_i[27] WRITETYPE	x

**Table 9-28. NOR Chip-Select Configuration**

Sub-process Name	Register / Bitfield	Value
Select the chip-select base address	GPMC_CONFIG7_i[5-0] BASEADDRESS	x
Select the chip-select mask address	GPMC_CONFIG7_i[11-8] MASKADDRESS	x

**Table 9-29. NOR Timings Configuration**

Sub-process Name	Register / Bitfield	Value
Configure adequate timing parameters in various memory modes	See <a href="#">Section 9.1.4.5</a>	

**Table 9-30. WAIT Pin Configuration**

Sub-process Name	Register / Bitfield	Value
Enable or disable wait pin monitoring for read operations	GPMC_CONFIG1_i[22] WAITREADMONITORING	x
Enable or disable wait pin monitoring for write operations	GPMC_CONFIG1_i[21] WAITWRITEMONITORING	x
Select a wait pin monitoring time	GPMC_CONFIG1_i[19-18] WAITMONITORINGTIME	x
Choose the input wait pin for the chip-select	GPMC_CONFIG1_i[17-16] WAITPINSELECT	x

**Table 9-31. Enable Chip-Select**

Sub-process Name	Register / Bitfield	Value
When all parameters are configured, enable the chip-select	GPMC_CONFIG7_i[6] CSVALID	x

### 9.1.4.3 GPMC Configuration in NAND Mode

This section gives a generic configuration for parameters related to NAND memory connected to the GPMC.

**Table 9-32. NAND Memory Type**

Sub-process Name	Register / Bitfield	Value
Set the NAND protocol	GPMC_CONFIG1_i[11-10] DEVICETYPE	2h
Set a device size	GPMC_CONFIG1_i[13-12] DEVICESIZE	x
Set the address and data multiplexing protocol to non-multiplexed attached device	GPMC_CONFIG1_i[9] MUXADDDATA	0
Select a timing signals latencies factor	GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY	x
Set a synchronous or asynchronous mode and a single or multiple access for read and write operations	See <a href="#">Section 9.1.4.4</a>	x

**Table 9-33. NAND Chip-Select Configuration**

Sub-process Name	Register / Bitfield	Value
Select the chip-select base address	GPMC_CONFIG7_i[5-0] BASEADDRESS	x
Select the chip-select minimum granularity (16M bytes)	GPMC_CONFIG7_i[11-8] MASKADDRESS	x

**Table 9-34. Asynchronous Read and Write Operations**

Sub-process Name	Register / Bitfield	Value
Configure adequate timing parameters in asynchronous modes	See <a href="#">Section 9.1.4.5</a>	

**Table 9-35. ECC Engine**

Sub-process Name	Register / Bitfield	Value
Select the ECC result register where the first ECC computation is stored (Only applies to Hamming)	GPMC_ECC_CONTROL[3-0] ECCPOINTER	x
Clear all ECC result registers	GPMC_ECC_CONTROL[8] ECCCLEAR	Write 1 to clear
Define ECCSIZE0 and ECCSIZE1	GPMC_ECC_SIZE_CONFIG[19-12] ECCSIZE0 and GPMC_ECC_SIZE_CONFIG[29-22] ECCSIZE1	x
Select the size of each of the 9 result registers (size specified by ECCSIZE0 or ECCSIZE1)	GPMC_ECC_SIZE_CONFIG[j-1] ECCjRESULTSIZ where j = 1 to 9	x
Select the chip-select where ECC is computed	GPMC_ECC_SIZE_CONFIG[3-1] ECCCS	x
Select the Hamming code or BCH code ECC algorithm in use	GPMC_ECC_SIZE_CONFIG[16] ECCALGORITHM	x
Select word size for ECC calculation	GPMC_ECC_SIZE_CONFIG[7] ECC16B	x
If the BCH code is used, Set an error correction capability and Select a number of sectors to process	GPMC_ECC_SIZE_CONFIG[13-12] ECCBCHTSEL and GPMC_ECC_SIZE_CONFIG[6-4] ECCTOPSECTOR	x
Enable the ECC computation	GPMC_ECC_SIZE_CONFIG[0] ECCENABLE	1

**Table 9-36. Prefetch and Write-Posting Engine**

Sub-process Name	Register / Bitfield	Value
Disable the engine before configuration	GPMC_PREFETCH_CONTROL[0] STARTENGINE	0
Select the chip-select associated with a NAND device where the prefetch engine is active	GPMC_PREFETCH_CONFIG1[26-24] ENGINECSSELECTOR	x
Select access direction through prefetch engine, read or write.	GPMC_PREFETCH_CONFIG1[0] ACCESSMODE	x
Select the threshold used to issue a DMA request	GPMC_PREFETCH_CONFIG1[14-8] FIFOTHRESHOLD	x
Select either DMA synchronized mode or SW manual mode.	GPMC_PREFETCH_CONFIG1[2] DMAMODE	x
Select if the engine immediately starts accessing the memory upon STARTENGINE assertion or if hardware synchronization based on a WAIT signal is used.	GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE	x
Select which wait pin edge detector should start the engine in synchronized mode	GPMC_PREFETCH_CONFIG1[5-4] WAITPINSELECTOR	x
Enter a number of clock cycles removed to timing parameters (For all back-to-back accesses to the NAND flash but not the first one)	GPMC_PREFETCH_CONFIG1[30-28] CYCLOPTIMIZATION	x
Enable the prefetch postwrite engine	GPMC_PREFETCH_CONFIG1[7] ENABLEENGINE	1
Select the number of bytes to be read or written by the engine to the selected chip-select	GPMC_PREFETCH_CONFIG2[13-0] TRANSFERCOUNT	x
Start the prefetch engine	GPMC_PREFETCH_CONTROL[0] STARTENGINE	1

**Table 9-37. WAIT Pin Configuration**

Sub-process Name	Register / Bitfield	Value
Selects when the engine starts the access to CS	GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE	x
Select which wait pin edge detector should start the engine in synchronized mode	GPMC_PREFETCH_CONFIG1[5-4] WAITPINSELECTOR	x

**Table 9-38. Enable Chip-Select**

Sub-process Name	Register / Bitfield	Value
When all parameters are configured, enable the chip-select	GPMC_CONFIG7_i[6] CSVALID	x

#### 9.1.4.4 Set Memory Access

This section details the bit field to configure to set the GPMC in various memory modes.

**Table 9-39. Mode Parameters Check List Table**

Register	Bit	Bit Field Name	Asynchronous				Synchronous			
			Single Read Access	Single Write Access	Multiple Read (Page) Access	Multiple Write (Page) Access	Single Read Access	Single Write Access	Multiple Read (Burst) Access	Multiple Write (Burst) Access
GPMC_CONFIG1_i	30	READMULTIPLE	0	-	1	N/S	0	-	1	-
GPMC_CONFIG1_i	29	READTYPE	0	-	0	N/S	1	-	1	-
GPMC_CONFIG1_i	28	WRITEMULTIPLE	-	0		N/S	-	0	-	1
GPMC_CONFIG1_i	27	WRITETYPE	-	0		N/S	-	1	-	1

**Table 9-40. Access Type Parameters Check List Table**

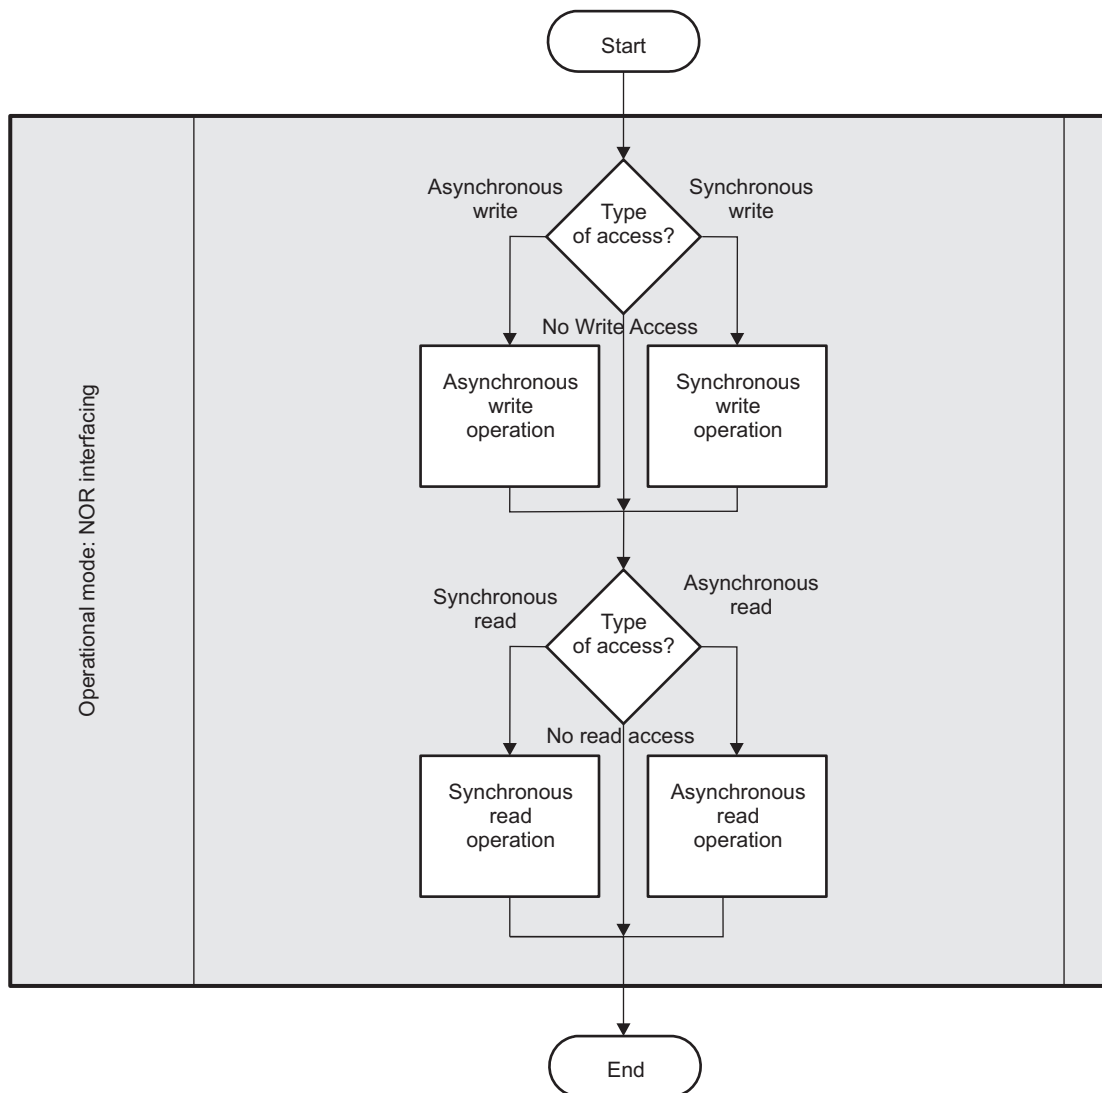

Register	Bit	Bit Field Name	Access Type		
			Non-Mux	Address/Data Mux	AAD Mux
GPMC_CONFIG1_i	9-8	MUXADDDATA	0	2h	1

### 9.1.4.5 GPMC Timing Parameters

Figure 9-43 shows a programming model diagram for the NOR interfacing timing parameters.

Table 9-41 lists bit fields to configure adequate timing parameter in various memory modes.

**Figure 9-43. NOR Interfacing Timing Parameters Diagram**

**Table 9-41. Timing Parameters**

Register	Bit	Bit Field Name	Asynchronous			Synchronous				Access Type		
			Single Read Access	Single Write Access	Multiple Read (Page) access	Single Read Access	Single Write Access	Multiple Read (Burst) Access	Multiple Write (Burst) Access	Non-multiplexed	Address/Data-multiplexed	AAD-multiplexed
GPMC_CONFIG1_i	9-8	MUXADDDATA	y	y	y	y	y	y	y	y	y	y
GPMC_CONFIG1_i	29	READTYPE	y		y	y		y		y	y	y
GPMC_CONFIG1_i	30	READMULTIPLE	y		y	y		y		y	y	y
GPMC_CONFIG1_i	27	WRITETYPE		y			y		y	y	y	y
GPMC_CONFIG1_i	28	WRITEMULTIPLE		y			y		y	y	y	y
GPMC_CONFIG1_i	31	WRAPBURST						y	y	y	y	y
GPMC_CONFIG1_i	26-25	CLKACTIVATIONTIME				y	y	y	y	y	y	y
GPMC_CONFIG1_i	19-18	WAITMONITORINGTIME	y	y	y	y	y	y	y	y	y	y
GPMC_CONFIG1_i	4	TIMEPARAGRANULARITY	y	y	y	y	y	y	y	y	y	y
GPMC_CONFIG2_i	20-16	CSWROFFTIME		y			y		y	y	y	y
GPMC_CONFIG2_i	12-8	CSRDOffTIME	y		y	y		y		y	y	y
GPMC_CONFIG2_i	7	CSEXTRADELAY	y	y	y	y	y	y	y	y	y	y
GPMC_CONFIG2_i	3-0	CSONTIME	y	y	y	y	y	y	y	y	y	y
GPMC_CONFIG3_i	30-28	ADVAADMUXWROFFTIME		y			y		y			y
GPMC_CONFIG3_i	26-24	ADVAADMUXRDOffTIME	y		y	y		y				y
GPMC_CONFIG3_i	6-4	ADVAADMUXONTIME	y	y	y	y	y	y	y			y
GPMC_CONFIG3_i	20-16	ADVWROFFTIME		y			y		y	y	y	y
GPMC_CONFIG3_i	12-8	ADVRDOffTIME	y		y	y		y		y	y	y
GPMC_CONFIG3_i	7	ADVEXTRADELAY	y	y	y	y	y	y	y	y	y	y
GPMC_CONFIG3_i	3-0	ADVONTIME	y	y	y	y	y	y	y	y	y	y

## 9.1.5 Use Cases

### 9.1.5.1 How to Set GPMC Timing Parameters for Typical Accesses

#### 9.1.5.1.1 External Memory Attached to the GPMC Module

As discussed in the introduction to this chapter, the GPMC module supports the following external memory types:

- Asynchronous or synchronous, 8-bit or 16-bit-width memory or device
- 16-bit address/data-multiplexed or not multiplexed NOR flash device
- 8- or 16-bit NAND flash device

The following examples show how to calculate GPMC timing parameters by showing a typical parameter setup for the access to be performed.

The example is based on a 512-Mb multiplexed NOR flash memory with the following characteristics:

- Type: NOR flash (address/data-multiplexed mode)
- Size: 512M bits
- Data Bus: 16 bits wide
- Speed: 104 MHz clock frequency
- Read access time: 80 ns

#### 9.1.5.1.2 Typical GPMC Setup

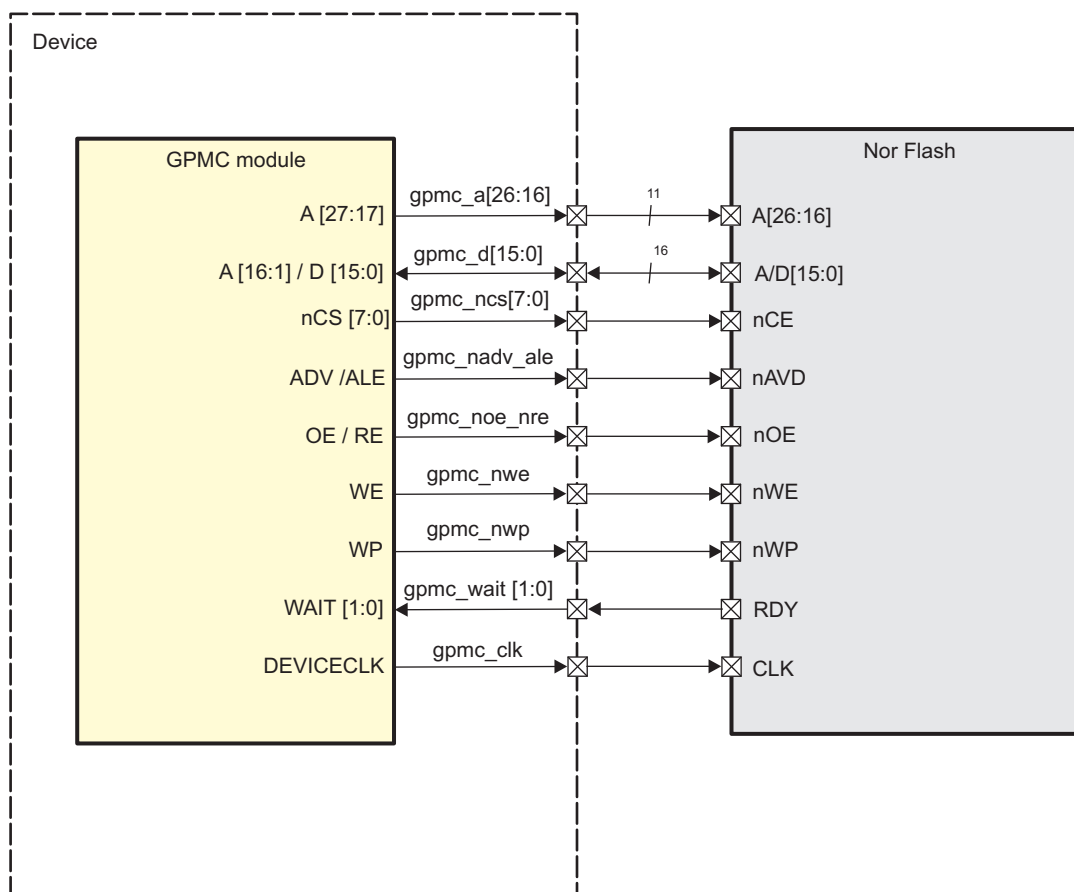

[Table 9-42](#) lists some of the I/Os of the GPMC module.

**Table 9-42. GPMC Signals**

Signal Name	I/O	Description
GPMC_FCLK	Internal	Functional and interface clock. Acts as the time reference.
GPMC_CLK	O	External clock provided to the external device for synchronous operations
GPMC_A[27:17]	O	Address
GPMC_AD[15: 0]	I/O	Data-multiplexed with addresses A[16:1] on memory side
GPMC_CSx <sub>n</sub>	O	Chip-select (where x = 0, or 1)
GPMC_ADV <sub>n</sub> _ALE	O	Address valid enable
GPMC_OE_RE <sub>n</sub>	O	Output enable (read access only)
GPMC_WE <sub>n</sub>	O	Write enable (write access only)
GPMC_WAIT[1:0]	I	Ready signal from memory device. Indicates when valid burst data is ready to be read

Figure 9-44 shows the typical connection between the GPMC module and an attached NOR Flash memory.

**Figure 9-44. GPMC Connection to an External NOR Flash Memory**

The following sections demonstrate how to calculate GPMC parameters for three access types:

- Synchronous burst read
- Asynchronous read
- Asynchronous single write

### 9.1.5.1.3 GPMC Configuration for Synchronous Burst Read Access

The clock runs at 104 MHz (  $f = 104 \text{ MHz}$ ;  $T = 9,615 \text{ ns}$ ).

[Table 9-43](#) shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

[Table 9-44](#) shows how to calculate timings for the GPMC using the memory parameters.

[Figure 9-45](#) shows the synchronous burst read access.

**Table 9-43. Useful Timing Parameters on the Memory Side**

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tCES	CSn setup time to clock	0
tACS	Address setup time to clock	3
tIACC	Synchronous access time	80
tBACC	Burst access time valid clock to output delay	5,2
tCEZ	Chip-select to High-Impedance	7
tOEZ	Output enable to High-Impedance	7
tAVC	ADVn setup time	6
tAVD	AVDn pulse	6
tACH	Address hold time from clock	3

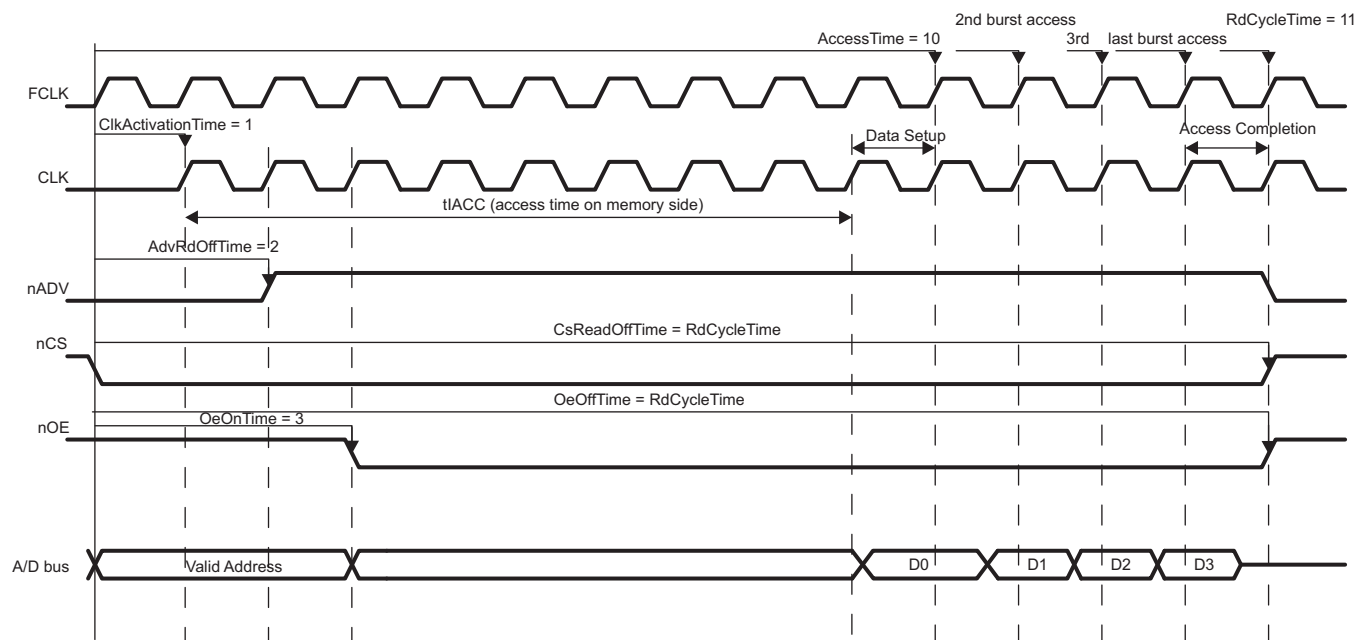

The following terms, which describe the timing interface between the controller and its attached device, are used to calculate the timing parameters on the GPMC side:

- Read Access time (GPMC side): Time required to activate the clock + read access time requested on the memory side + data setup time required for optimal capture of a burst of data
- Data setup time (GPMC side): Ensures a good capture of a burst of data (as opposed to taking a burst of data out). One word of data is processed in one clock cycle ( $T = 9,615 \text{ ns}$ ). The read access time between 2 bursts of data is  $tBACC = 5,2 \text{ ns}$ . Therefore, data setup time is a clock period -  $tBACC = 4,415 \text{ ns}$  of data setup.
- Access completion (GPMC side): (Different from page burst access time) Time required between the last burst access and access completion: CSn/OEn hold time (CSn and OEn must be released at the end of an access. These signals are held to allow the access to complete).
- Read cycle time (GPMC side): Read Access time + access completion
- Write cycle time for burst access: Not supported for NOR flash memory

**Table 9-44. Calculating GPMC Timing Parameters**

Parameter Name on GPMC Side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Register Configurations
GPMC FCLK Divider	-	-	-	GPMCFCLKDIVIDER = 0
ClkActivationTime	$\min(t_{CES}, t_{ACS})$	3	1	CLKACTIVATIONTIME = 1
RdAccessTime	$\text{roundmax}(\text{ClkActivationTime} + t_{IACC} + \text{DataSetupTime})$	94, 03: (9,615 + 80 + 4,415)	10 : $\text{roundmax}(94, 03 / 9,615)$	ACCESSTIME = Ah
PageBurstAccessTime	$\text{roundmax}(t_{BACC})$	$\text{roundmax}(5, 2)$	1	PAGEBURSTACCESSTIME = 1
RdCycleTime	$\text{AccessTime} + \max(t_{CEZ}, t_{OEZ})$	101, 03: (94, 03 + 7)	11	RDCYCLETIME = Bh
CsOnTime	$t_{CES}$	0	0	CSONTIME = 0
CsReadOffTime	RdCycleTime	-	11	CSRDOFFTIME = Bh
AdvOnTime	$t_{AVC}$	0	0	ADVONTIME = 0
AdvRdOffTime	$t_{AVD} + t_{AVC}$	12	2	ADVRDOFFTIME = 2h
OeOnTime	$(\text{ClkActivationTime} + t_{ACH}) < \text{OeOnTime} < (\text{ClkActivationTime} + t_{IACC})$	-	3, for instance	OEONTIME = 3h
OeOffTime	RdCycleTime	-	11	OEOFFTIME = Bh

**Figure 9-45. Synchronous Burst Read Access (Timing Parameters in Clock Cycles)**

#### 9.1.5.1.4 GPMC Configuration for Asynchronous Read Access

The clock runs at 104 MHz (  $f = 104 \text{ MHz}$ ;  $T = 9,615 \text{ ns}$ ).

[Table 9-45](#) shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

[Table 9-46](#) shows how to calculate timings for the GPMC using the memory parameters.

[Figure 9-46](#) shows the asynchronous read access.

**Table 9-45. AC Characteristics for Asynchronous Read Access**

AC Read Characteristics on the Memory Side	Description	Duration (ns)
tCE	Read Access time from CSn low	80
tAAVDS	Address setup time to rising edge of ADVn	3
tAVDP	ADVn low time	6
tCAS	CSn setup time to ADVn	0
tOE	Output enable to output valid	6
tOEZ	Output enable to High-Impedance	7

Use the following formula to calculate the RdCycleTime parameter for this typical access:

$$\text{RdCycleTime} = \text{RdAccessTime} + \text{AccessCompletion} = \text{RdAccessTime} + 1 \text{ clock cycle} + \text{tOEZ}$$

- First, on the memory side, the external memory makes the data available to the output bus. This is the memory-side read access time defined in [Table 9-46](#): the number of clock cycles between the address capture (ADVn rising edge) and the data valid on the output bus.

The GPMC requires some hold time to allow the data to be captured correctly and the access to be finished.

- To read the data correctly, the GPMC must be configured to meet the data setup time requirement of the memory; the GPMC module captures the data on the next rising edge. This is access time on the GPMC side.
- There must also be a data hold time for correctly reading the data (checking that there is no OEn/CSn deassertion while reading the data). This data hold time is 1 clock cycle (that is, AccessTime + 1).
- To complete the access, OEn/CSn signals are driven to high-impedance. AccessTime + 1 + tOEZ is the read cycle time.
- Addresses can now be relatched and a new read cycle begun.

**Table 9-46. GPMC Timing Parameters for Asynchronous Read Access**

Parameter Name on GPMC side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Register Configurations
ClkActivationTime	n/a (asynchronous mode)			
AccessTime	round max (tCE)	80	9	ACCESSTIME = 9h
PageBurstAccessTime	n/a (single access)			
RdCycleTime	AccessTime + 1cycle + tOEZ	96, 615	11	RDCYCLETIME = Bh
CsOnTime	tCAS	0	0	CSONTIME = 0
CsReadOffTime	AccessTime + 1 cycle	89, 615	10	CSRDOFFTIME = Ah
AdvOnTime	tAAVDS	3	1	ADVONTIME = 1
AdvRdOffTime	tAAVDS + tAVDP	9	1	ADVRDOFFTIME = 1
OeOnTime	OeOnTime ≥ AdvRdOffTime (multiplexed mode)	-	3, for instance	OEONTIME = 3h
OeOffTime	AccessTime + 1cycle	89, 615	10	OEOFFTIME = Ah

**Figure 9-46. Asynchronous Single Read Access (Timing Parameters in Clock Cycles)**

### 9.1.5.1.5 GPMC Configuration for Asynchronous Single Write Access

The clock runs at 104 MHz: ( $f = 104 \text{ MHz}$ ;  $T = 9,615 \text{ ns}$ ).

[Table 9-47](#) shows how to calculate timings for the GPMC using the memory parameters.

[Table 9-48](#) shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

[Figure 9-47](#) shows the synchronous burst write access.

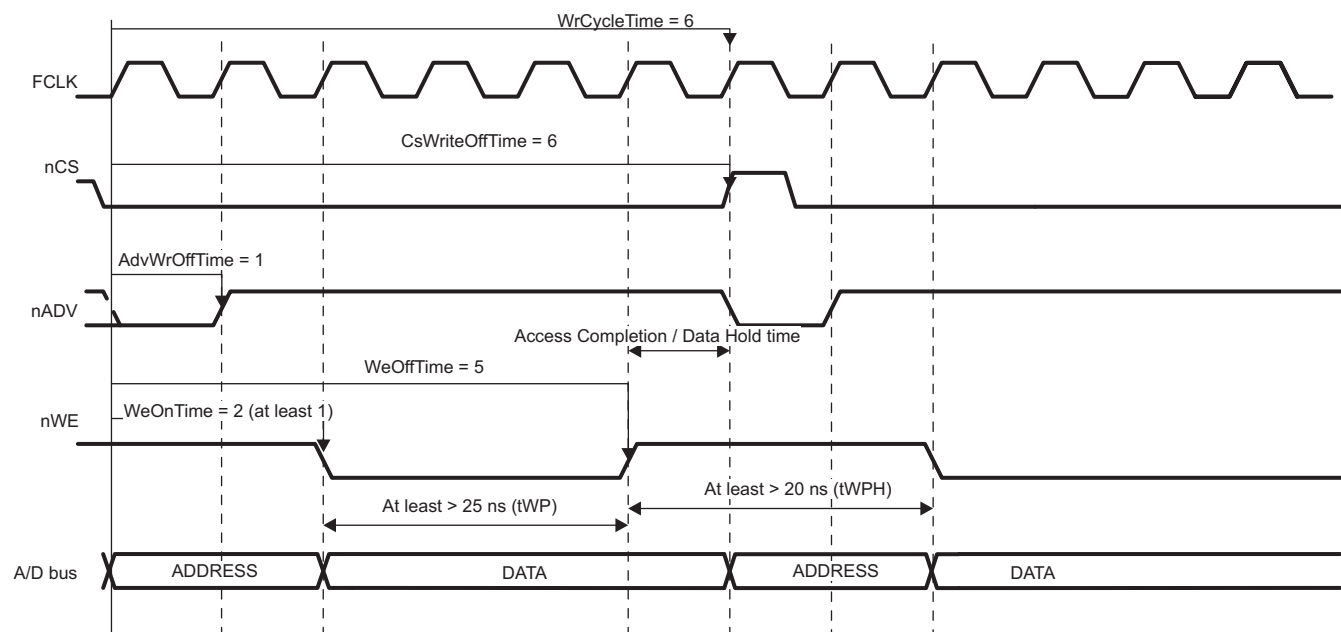

**Table 9-47. AC Characteristics for Asynchronous Single Write (Memory Side)**

AC Characteristics on the Memory Side	Description	Duration (ns)
tWC	Write cycle time	60
tAVDP	ADVn low time	6
tWP	Write pulse width	25
tWPH	Write pulse width high	20
tCS	CSn setup time to WEn	3
tCAS	CSn setup time to ADVn	0
tAVSC	ADVn setup time	3

For asynchronous single write access, write cycle time is  $WtCycleTime = WeOffTime + AccessCompletion = WeOffTime + 1$ . For the AccessCompletion, the GPMC requires 1 cycle of data hold time (CSn de-assertion).

**Table 9-48. GPMC Timing Parameters for Asynchronous Single Write**

Parameter Name on GPMC side	Formula	Duration (ns)	Number of Clock Cycles (F = 104 MHz)	GPMC Register Configurations
ClkActivationTime	n/a (asynchronous mode)			
AccessTime	Applicable only to WAITMONITORING (the value is the same as for read access)			
PageBurstAccessTime	n/a (single access)			
WrCycleTime	WeOffTime + AccessCompletion	57, 615	6	WRCYCLETIME = 6h
CsOnTime	tCAS	0	0	CSONTIME = 0
CsWrOffTime	WeOffTime + 1	57, 615	6	CSWROFFTIME = 6h
AdvOnTime	tAVSC	3	1	ADVONTIME = 1
AdvWrOffTime	tAVSC + tAVDP	9	1	ADVWROFFTIME = 1
WeOnTime	tCS	3	1	WEONTIME = 1
WeOffTime	tCS + tWP + tWPH	48	5	WEOFFTIME = 5h

**Figure 9-47. Asynchronous Single Write Access (Timing Parameters in Clock Cycles)**

### 9.1.5.2 How to Choose a Suitable Memory to Use With the GPMC

This section is intended to help the user select a suitable memory device to interface with the GPMC controller.

#### 9.1.5.2.1 Supported Memories or Devices

NAND flash and NOR flash architectures are the two flash technologies. The GPMC supports various types of external memory or device, basically any one that supports NAND or NOR protocols:

- 8- and 16-bit width asynchronous or synchronous memory or device (8-bit: non burst device only)
- 16-bit address and data multiplexed NOR flash devices (pSRAM)
- 8- and 16-bit NAND flash device

#### 9.1.5.2.2 NAND Interface Protocol

NAND flash architecture, introduced in 1989, is a flash technology. NAND is a page-oriented memory device, that is, read and write accesses are done by pages. NAND achieves great density by sharing common areas of the storage transistor, which creates strings of serially connected transistors (in NOR devices, each transistor stands alone). Thanks to its high density NAND is best suited to devices requiring high capacity data storage, such as pictures, music, or data files. NAND non-volatility, makes of it a good storage solution for many applications where mobility, low power, and speed are key factors. Low pin count and simple interface are other advantages of NAND.

Table 9-49 summarizes the NAND interface signals level applied to external device or memories.

**Table 9-49. NAND Interface Bus Operations Summary**

Bus Operation	CLE	ALE	CEn	WEn	REn	WPn
Read (cmd input)	H	L	L	RE	H	x
Read (add input)	L	H	L	RE	H	x
Write (cmd input)	H	L	L	RE	H	H
Write (add input)	L	H	L	RE	H	H
Data input	L	L	L	RE	H	H
Data output	L	L	L	H	FE	x
Busy (during read)	x	x	H	H	H	x
Busy (during program)	x	x	x	x	x	H
Busy (during erase)	x	x	x	x	x	H
Write protect	x	x	x	x	x	L
Stand-by	x	x	H	x	x	H/L

#### 9.1.5.2.3 NOR Interface Protocol

NOR flash architecture, introduced in 1988, is a flash technology. Unlike NAND, which is a sequential access device, NOR is directly addressable; i.e., it is designed to be a random access device. NOR is best suited to devices used to store and run code or firmware, usually in small capacities. While NOR has fast read capabilities it has slow write and erase functions compared to NAND architecture.

Table 9-50 summarizes the NOR interface signals level applied to external device or memories.

**Table 9-50. NOR Interface Bus Operations Summary**

Bus Operation	CLK	ADVn	CSn	OEn	WEn	WAIT	DQ[15:0]
Read (asynchronous)	x	L	L	L	H	Asserted	Output
Read (synchronous)	Running	L	L	L	H	Driven	Output
Read (burst suspend)	Halted	x	L	H	H	Active	Output
Write	x	L	L	H	L	Asserted	Input

**Table 9-50. NOR Interface Bus Operations Summary (continued)**

Bus Operation	CLK	ADVn	CSn	OEn	WEn	WAIT	DQ[15:0]
Output disable	x	x	L	H	H	Asserted	High-Z
Standby	x	x	H	x	x	High-Z	High-Z

#### **9.1.5.2.4 Other Technologies**

Other supported device type interact with the GPMC through the NOR interface protocol.

OneNAND Flash is a high-density and low-power memory device. It is based on single- or multi-level-cell NAND core with SRAM and logic, and interfaces as a synchronous NOR Flash, plus has synchronous write capability. It reads faster than conventional NAND and writes faster than conventional NOR flash. Hence, it is appropriate for both mass storage and code storage.

pSRAM stands for pseudo-static random access memory. pSRAM is a low-power memory device for mobile applications. pSRAM is based on the DRAM cell with internal refresh and address control features, and interfaces as a synchronous NOR Flash, plus has synchronous write capability.

#### **9.1.5.2.5 Supported Protocols**

The GPMC supports the following interface protocols when communicating with external memory or external devices:

- Asynchronous read/write access
- Asynchronous read page access (4-8-16 Word16)
- Synchronous read/write access
- Synchronous read burst access without wrap capability (4-8-16 Word16)
- Synchronous read burst access with wrap capability (4-8-16 Word16)

#### **9.1.5.2.6 GPMC Features and Settings**

This section lists GPMC features and settings:

- Supported device type: up to four NAND or NOR protocol external memories or devices
- Operating Voltage: 3.3V
- Maximum GPMC addressing capability: 512 MBytes divided into eight chip-selects
- Maximum supported memory size: 256 MBytes (must be a power-of-2)
- Minimum supported memory size: 16 MBytes (must be a power-of-2). Aliasing occurs when addressing smaller memories.
- Data path to external memory or device: 8- and 16-bit wide
- Burst and page access: burst of 4-8-16 Word16
- Supports bus keeping
- Supports bus turn around

## 9.1.6 GPMC Registers

Table 9-51 lists the memory-mapped registers for the GPMC. All register offset addresses not listed in Table 9-51 should be considered as reserved locations and the register contents should not be modified.

**Table 9-51. GPMC Registers**

Offset	Acronym	Register Name	Section

Bit	Field	Type	Reset	Description
31-8	RESERVED	R	0h	
7-0	REV	R	0h	IP revision. Major revision is [7:4]. Minor revision is [3:0]. Examples: 10h for revision 1.0, 21h for revision 2.1.

### 9.1.6.2 GPMC\_SYSCONFIG Register (offset = 10h) [reset = 0h]

GPMC\_SYSCONFIG is shown in [Figure 9-49](#) and described in [Table 9-53](#).

The GPMC\_SYSCONFIG register controls the various parameters of the OCP interface.

**Figure 9-49. GPMC\_SYSCONFIG Register**

4-3	SIDLEMODE	R/W	0h	Idle mode 0h (R/W) = Force-idle. An idle request is acknowledged unconditionally 1h (R/W) = No-idle. An idle request is never acknowledged 2h (R/W) = Smart-idle. Acknowledgment to an idle request is given based on the internal activity of the module 3h (R/W) = Reserved
2	RESERVED	R	0h	
1	SOFTRESET	R/W	0h	Software reset (Set 1 to this bit triggers a module reset. This bit is automatically reset by hardware. During reads, it always returns 0). 0h (R/W) = Normal mode 1h (R/W) = The module is reset
0	AUTOIDLE	R/W	0h	Internal OCP clock gating strategy. 0h (R/W) = Interface clock is free-running 1h (R/W) = Automatic interface clock gating strategy is applied based on the Interconnect activity.

### 9.1.6.3 GPMC\_SYSSTATUS Register (offset = 14h) [reset = 0h]

GPMC\_SYSSTATUS is shown in [Figure 9-50](#) and described in [Table 9-54](#).

The GPMC\_SYSSTATUS register provides status information about the module, excluding the interrupt status information.

**Figure 9-50. GPMC\_SYSSTATUS Register**

#### 9.1.6.4 GPMC\_IRQSTATUS Register (offset = 18h) [reset = 0h]

GPMC\_IRQSTATUS is shown in [Figure 9-51](#) and described in [Table 9-55](#).

The GPMC\_IRQSTATUS interrupt status register regroups all the status of the module internal events that can generate an interrupt.

**Figure 9-51. GPMC\_IRQSTATUS Register**

### 9.1.6.5 GPMC\_IRQENABLE Register (offset = 1Ch) [reset = 0h]

GPMC\_IRQENABLE is shown in [Figure 9-52](#) and described in [Table 9-56](#).

The GPMC\_IRQENABLE interrupt enable register allows to mask/unmask the module internal sources of interrupt, on a event-by-event basis.

**Figure 9-52. GPMC\_IRQENABLE Register**

0	FIFOEVENTENABLE	R/W	0h	Enables the FIFOEvent interrupt 0h (R/W) = FIFOEvent interrupt is masked 1h (R/W) = FIFOEvent interrupt is not masked

### 9.1.6.6 GPMC\_TIMEOUT\_CONTROL Register (offset = 40h) [reset = 0h]

GPMC\_TIMEOUT\_CONTROL is shown in [Figure 9-53](#) and described in [Table 9-57](#).

The GPMC\_TIMEOUT\_CONTROL register allows the user to set the start value of the timeout counter

**Figure 9-53. GPMC\_TIMEOUT\_CONTROL Register**

3-1	RESERVED	R	0h	
0	TIMEOUTENABLE	R/W	0h	Enable bit of the TimeOut feature 0h (R/W) = TimeOut feature is disabled 1h (R/W) = TimeOut feature is enabled

### 9.1.6.7 GPMC\_ERR\_ADDRESS Register (offset = 44h) [reset = 0h]

GPMC\_ERR\_ADDRESS is shown in [Figure 9-54](#) and described in [Table 9-58](#).

The GPMC\_ERR\_ADDRESS register stores the address of the illegal access when an error occurs.

**Figure 9-54. GPMC\_ERR\_ADDRESS Register**

## 9.2 OCMC-RAM

### 9.2.1 Introduction

#### OCMC-RAM Features

The on-chip memory controller consists of two separate modules that are OCP to memory wrappers. The first wrapper is for a ROM; the second is for a RAM. Each wrapper has its own dedicated interface to the L3 interconnect.

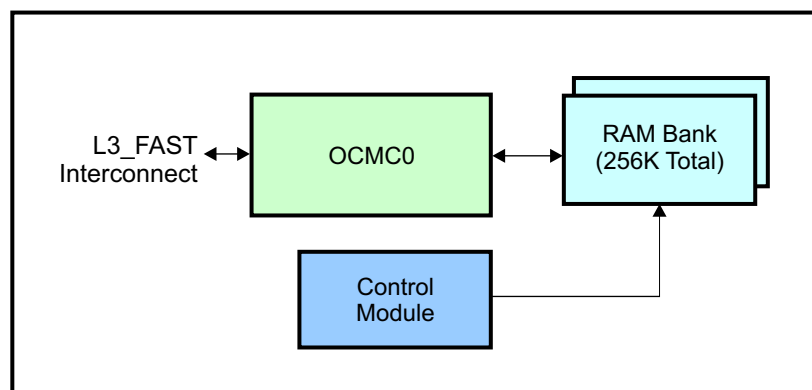

- 32- or 64-bit width
- Initial latency max 2 cycles (due to OCP to memory core wrapper).
- Multiple memory bank control based on address MSBs
- Full OCP IP 2.0 Burst support. No wait state.

#### Unsupported OCMC-RAM Features

For this device, the OCMC-RAM implementation does not support parity.

## 9.2.2 Integration

This device includes a single instantiation of the on-chip memory controller interfacing to a single 64K bank of RAM.

**OCMC RAM Integration**

## OCMC RAM Connectivity Attributes

The general connectivity attributes for the OCMC RAM modules are summarized in [OCMC RAM Connectivity Attributes](#).

### OCMC RAM Connectivity Attributes

Attributes	Type
Power Domain	Peripheral Domain
Clock Domain	PD_PER_L3_GCLK
Reset Signals	PER_DOM_RST_N
Idle/Wakeup Signals	Smart Idle
Interrupt Requests	None
DMA Requests	None
Physical Address	L3 Fast slave port

## OCMC RAM Clock and Reset Management

The OCMC module uses a single clock for the module and its OCP interface.

### OCMC RAM Clock Signals

Clock Signal	Max Freq	Reference / Source	Comments
prcm_ocmc_clock Interface / Functional clock	200 MHz	CORE_CLKOUTM4	pd_per_l3_gclk From PRCM

## OCMC RAM Pin List

The OCMC RAM module does not include any external interface pins.

## 9.3 EMIF

This section describes the external memory interface (EMIF) for the device.

### 9.3.1 Introduction

#### 9.3.1.1 Features

The general features of the EMIF module are as follows:

- 16-bit and 32-bit data path to external SDRAM memory
- One 128-bit OCPIP 2.2 interface
- Support for the following memory types:
  - LPDDR2
  - DDR3

#### External memory features supported:

- Memory device capacity
  - Up to 2GB addressability
- Flexible bank/row/column/chip-select address multiplexing schemes
- CAS latencies:
  - DDR3 => 5, 6, 7, 8, 9, 10, and 11
  - LPDDR2 => 3, 4, 5, 6, 7, and 8
- The following number of internal banks:
  - DDR3 => 1, 2, 4, and 8
  - LPDDR2 => 1, 2, 4, and 8
- Supports 256-, 512-, 1024-, and 2048-word page sizes
- Supports burst length of 8 (sequential burst)
  - DDR3 burst interrupt of BL8 not supported
  - LPDDR2 burst read is interruptible by another read
  - LPDDR2 burst write is interruptible by another write
- Write/read leveling/calibration and data eye training in conjunction with DID for DDR3
- Self-refresh and power-down modes for low power:
  - Flexible OCP to DDR address mapping to support Partial Array Self Refresh in LPDDR2 and DDR3.
  - Temperature-controlled self-refresh for LPDDR2
  - On-chip temperature sensor for DDR3
- Periodic ZQ calibration for LPDDR2 and DDR3
- ODT on DDR3
- Prioritized refresh scheduling
- Programmable SDRAM refresh rate and backlog counter
- Programmable SDRAM timing parameters
- Big and little endian modes

## 9.3.2 Integration

### 9.3.2.1 EMIF Connectivity Attributes

The general connectivity attributes for the EMIF are shown in [Table 9-145](#).

**Table 9-145. EMIF Connectivity Attributes**

Attributes	Type
Power Domain	Peripheral Domain
Clock Domain	PD_PER_EMIF_L3_GCLK (OCP) PD_PER_EMIF_GCLK (Func)
Reset Signals	CORE_PWRON_RET_RST_N EMIF_DDR_PHY_PWRON_RST_N DLL_RST_N
Idle/Wakeup Signals	Smart Idle
Interrupt Requests	1 interrupt to MPU Subsystem (DDRERR0)
DMA Requests	None
Physical Address	L3 Fast Slave Port

### 9.3.2.2 EMIF Clock Management

The EMIF4 OCP interface (ocp\_clk) is clocked by the L3 Fast clock sourced from the Core PLL. The DDR Command and Data macros are clocked by the DDR PLL. The PRCM divides this clock by two to create the EMIF functional clock (m\_clk).

The OCP and functional clocks may be asynchronous because synchronization is managed in the EMIF4 internal FIFO (EMIF4 is set in asynchronous mode).

**Table 9-146. EMIF Clock Signals**

Clock Signal	Maximum Frequency	Reference Source	Comments
sys2e_clk (Interface clock)	200 MHz	CORE_CLKOUTM4	pd_per_emif_l3_gclk From PRCM
m_clk (EMIF functional clock)	100 MHz	DDR PLL CLKOUT / 2	pd_per_emif_gclk From PRCM
cmd0_dfi_clk cmd1_dfi_clk cmd2_dfi_clk data0_dfi_clk data1_dfi_clk data2_dfi_clk data3_dfi_clk (Macro clocks)	400 MHz	DDR PLL CLKOUT	clkout_po From DDR PLL
dll_clk	350 MHz	DDR PLL CLKOUTM4	ddr_dll_gclk From PRCM
dll_aging_clk	25 MHz (typ)	CLK_M_OSC	pd_per_dll_aging_gclk From PRCM

### 9.3.2.3 EMIF Pin List

[Table 9-147](#) shows the EMIF/DDR external interface signals for each of the supported memory types. Note that LPDDR2 uses a multiplexed command/address interface that is different from the other memory types.

**Table 9-147. EMIF Pin List**

Pin	Type	DDR3	LPDDR2	Description
DDR_CK DDR_NCK	O	CK CKn	CK CKn	Differential clock pair
DDR_CKE0	O	CKE0	CKE0	Clock enable 0

DDR_A15	O	A15	not used	Row/column address[15]
DDR_DQS[3:0]	I/O	DQS[3:0]	DQS[3:0]	Data strobes
DDR_DQSn[3:0]	I/O	DQSn[3:0]	DQSn[3:0]	Complimentary data strobes
DDR_DQM[3:0]	O	DQM[3:0]	DM[3:0]	Data masks
DDR_D[31:0]	I/O	DQ[31:0]	DQ[31:0]	Data bus
DDR_ODT[1:0]	O	ODT[1:0]	not used	On-die termination
DDR_RESETh	O	not used	not used	DDR device reset
DDR_VREF <sup>(1)</sup>	I	VREF	VREF	I/O Voltage reference

<sup>(1)</sup> VREF is an analog input used to set the reference switching threshold of the DDR inputs and must be connected to the proper voltage source. It is not directly connected to the memory devices.

### 9.3.3 EMIF Functional Description

#### 9.3.3.1 Block Diagram

The EMIF module provides an interface to DDR3 and LPDDR2 SDRAM memories.

Figure 9-141 shows the interconnection between the EMIF module and the other modules.

Digital locked loops (DLLs) are used to delay the input DQS signals during reads so that these strobe signals can be used to latch incoming data on the DQ pins, as required by the DDR standard.

Physical layers (PHYs) convert single-data rate (SDR) signals to DDR signals.

**Figure 9-141. EMIF Block Diagram**

#### FIFO Description

The EMIF module contains the following FIFOs:

- Command FIFO
- Write data FIFO
- Return command FIFO
- Two read data FIFOs

Figure 9-142 shows the overall architecture of the EMIF FIFOs.

Figure 9-142. FIFO Block Diagram

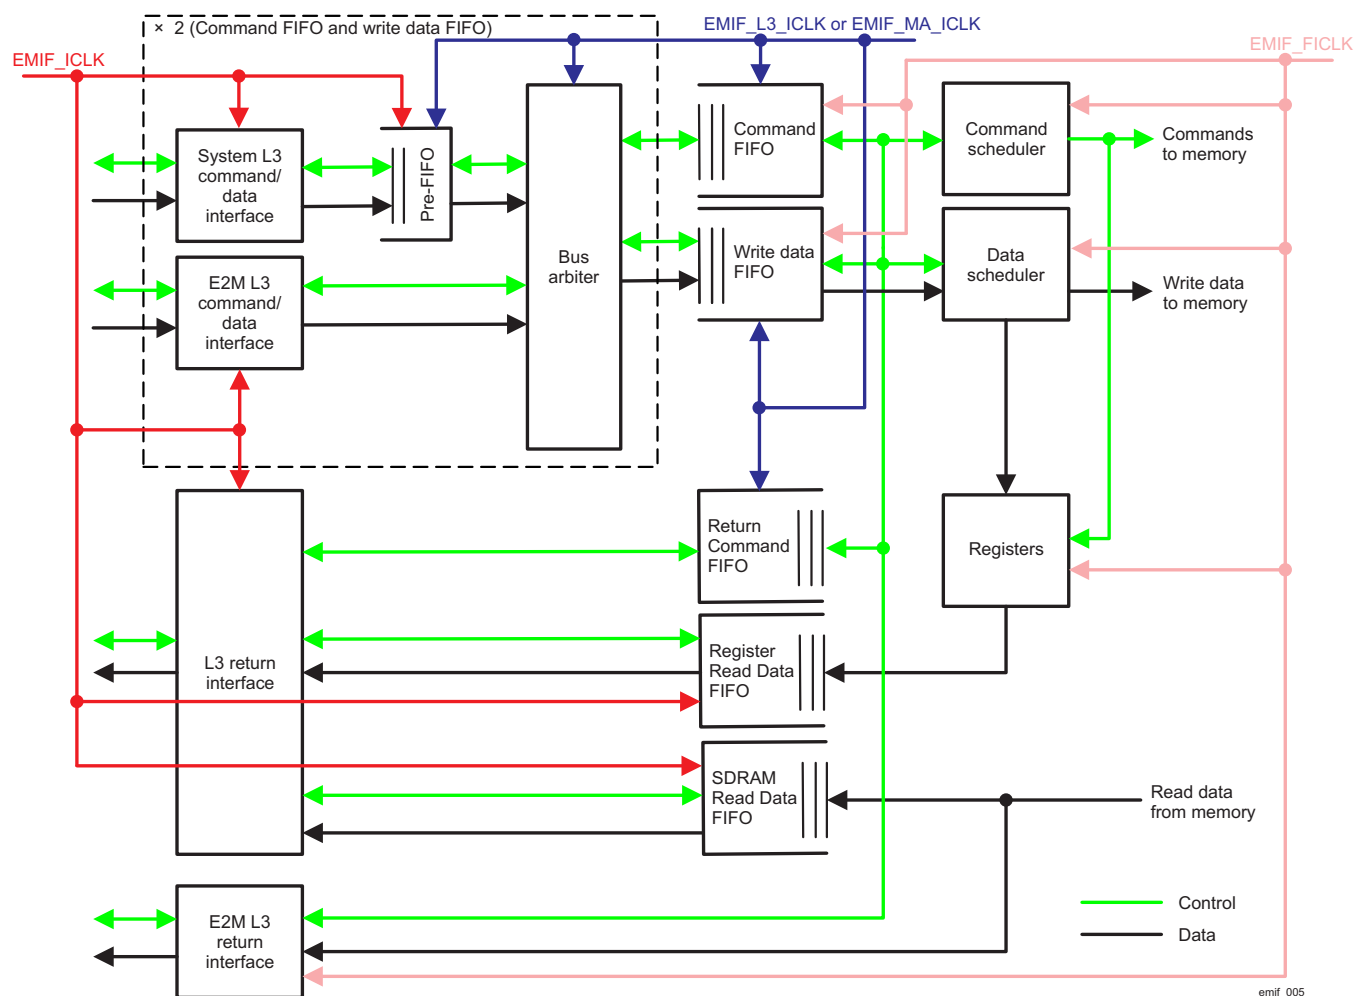

Table 9-148 lists the allocation of the entries.

Table 9-148. FIFO Allocation

Parameter	System Local Interface Entries	MPU Local Interface Entries
Pre Command FIFO	6	4
Command FIFO	Programmable <sup>(1)</sup>	Programmable <sup>(1)</sup>
Pre Write FIFO	6	8
Write Data FIFO (256-bit)	Up to (19 × 256 bits) + 6	Up to 19 + 8
Return Command FIFO	22	24
SDRAM Read Data FIFO	22	24
Register Read Data FIFO	2	0

<sup>(1)</sup> The total number of entries in the command FIFO is 10.

The EMIF has one shared command FIFO, one shared write FIFO and a separate return data FIFO for each of the three interface ports. Because the command FIFO allocation must be controlled in one clock domain, the SYS and LL OCP command and write interfaces are synchronized to the MPU clock domain in the pre-command and pre-write FIFOs. The allocation of each FIFO is shown in Table 9-148.

## MPU Port Restrictions

The EMIF MPU port is defined only to process memory requests. All register accesses are processed through the system port of the EMIF. The EMIF MPU port does not support 2D or register requests required or provided by the system interface. When Class of Service is used, the MPU port has a fixed Connection ID equal to 0x0.

MFLAG is not supported, therefore the EMIF4D\_READ\_WRITE\_EXECUTION\_THR[31] MFLAG\_OVERRIDE bit must always be set to 0x1. When this bit is set to 0x1 Class of Service is used.

To maintain coherency, the following rules must be followed:

- Any command arriving on MPU or system interface that matches an address in the command FIFO is executed after the command in the command FIFO
- The matching address is any address within a 2,000-address boundary
- On a 2D transfer, the starting address is the compared address. The computed addresses of the 2D transfer are not considered in address overlapping.
- Any command arriving within a 10-cycle window of another, from the different interfaces that do not match any address in the command FIFO, but may match command addresses arriving on a different interface, can be executed in any order.

## Arbitration of Commands in the Command FIFO

The EMIF looks at all the commands stored in the command FIFO to schedule commands to the external memory. All commands with the same MConnID on a particular local interface complete in order. The EMIF does not ensure ordering between commands with different MConnIDs or between commands from two local interfaces. For more information about L3\_MAIN interconnect terms (MConnID, MCMD, MADDR, etc.) see [Section 4.1.2, L3 Interconnect](#).

However, the EMIF does maintain data coherency. Therefore, the EMIF blocks a command, regardless of priority or the local interface, if that command is to the same block address (2048 bytes) as an older command that is not complete. Thus, the EMIF may have one pending read or write for each MConnID. Among all pending reads, the EMIF selects all reads that have their corresponding SDRAM banks already open. Similarly, among all pending writes, the EMIF selects all writes that have their corresponding SDRAM banks already open. Accesses to memory mapped registers are treated as accesses that have open banks.

As a result of this reordering, the EMIF may now have several pending reads and writes that have their corresponding banks open. The EMIF then selects the highest priority read from pending reads, and the highest priority write from pending writes. If two or more commands have the highest priority, the EMIF selects the oldest command. As a result, the EMIF may now have the next read and a write command. If the return command FIFO and the read data FIFO have space and the external bus conflict is resolved, the EMIF performs the final read command before the final write command. If the return command FIFO has space but the read data FIFO is full, the EMIF performs the final write command before the final read command. Resolution of external bus conflict means all the SDRAM command-to-command counters are satisfied and the read-to-write or write-to-read turnaround time is met.

The EMIF does not support tag interleaving. In other words, for an local interface, the EMIF completes executing an local command before it switches to another command. The EMIF can, however, interleave execution between commands from two local interfaces.

The data coherency inside the EMIF is ensured only in a single level of local infrastructure. For example, if a write from a secondary local bus segment is blocked by a bridge element, the read from a tertiary bus can still beat the write to the EMIF. In such a case, to confirm that a write from master A has landed before a read from master B is performed, master A must wait for the write status from the EMIF before indicating to master B that the data is ready to be read. If master A does not use the local wait status, it must do the following:

1. Perform the required write.
2. Perform a dummy write to the EMIF4D\_MOD\_ID\_REV register.
3. Perform a dummy read to the EMIF4D\_MOD\_ID\_REV register.
4. Indicate to master B that the data is ready to be read after completion of read in Step 3. The completion of read in Step 3 ensures that the previous writes were done.

Apart from reads and writes, the EMIF must also open and close SDRAM banks and maintain the refresh counts for an SDRAM. The priority of SDRAM commands with respect to refresh levels are:

1. SDRAM refresh request when refresh-must level is reached (highest priority)
2. ZQ calibration
3. Leveling
4. local request for a read or write
5. local request for a write
6. SDRAM activate commands
7. SDRAM deactivate commands
8. SDRAM power-down request
9. SDRAM deep power-down request
10. SDRAM refresh request when refresh-may or release level is reached
11. SDRAM self-refresh request (lowest priority)

To avoid continuous blocking effect which can be caused by a continuous stream of high-priority commands which thus block the lower priority commands, the EMIF momentarily raises the priority of the oldest command over all other commands when the time for the oldest command configured through the EMIF4D\_COS\_CONFIG[7:0] PR\_OLD\_COUNT bit field expires.

It should be taken into account that while performing the scheduling algorithm described, the EMIF may also encounter a condition in which continuous stream of SDRAM commands to a row in an open bank can block commands to another row in the same bank.

In addition to this scheduling, the highest priority condition is a reset command. If this condition occurs, the EMIF abandons what it is currently doing and begins its start-up sequence. In this case, commands and data stored in the FIFOs are lost. The EMIF also starts its start-up sequence whenever the EMIF4D\_SDRAM\_CONFIG register is written and the EMIF4D\_SDRAM\_REFRESH\_CTRL[31] INITREF\_DIS bit is set to 0. In this case, commands and data stored in the FIFOs are not lost. The EMIF ensures that in-flight read or write transactions to the SDRAM are complete before starting the initialization sequence.

All the accesses to an SDRAM are pipelined to maximize use of the external bus. All of these are done while fulfilling the access timing requirements of an SDRAM.

## Clock Management

The EMIF can gate EMIF\_FICLK. There is an internal mechanism that can stop EMIF\_FICLK automatically. EMIF\_FICLK is stopped only after the SDRAM is put into self-refresh mode and the power-idle protocol on the local bus completes. The EMIF\_FICLK frequency can be changed only after putting the external SDRAM in self-refresh mode.

The EMIF waits for the DLL lock before performing any memory access.

EMIF\_FICLK frequency is equal to half of the EMIF\_PHY\_FCLK frequency.

## Reset

The EMIF does not support a software reset.

The EMIF supports a global warm reset mode, during which the EMIF keeps the SDRAM content. Upon a request from the PRCM module indicating a need to enter global warm reset mode, the EMIF does the following:

1. During leveling operation, EMIF will immediately exit this mode and automatically perform a write to the MR1 register of DDR3 memory to disable the leveling at the memory side too.
2. EMIF completes the ongoing access, and then puts the SDRAM in self-refresh mode. If the EMIF4D\_SDRAM\_REFRESH\_CTRL[31] INITREF\_DIS field is set to 1, the EMIF does not put SDRAM in self-refresh mode. If EMIF is in LPDDR2 mode and if the reg\_refresh\_en field in the LPDDR2 Mode Reg Config register is set to 0, the EMIF does not put LPDDR2 in self-refresh.
3. EMIF clears all its FIFO contents.
4. EMIF does not wait for all interrupts to be serviced.

To exit the global warm reset:

1. If the EMIF was in Self Refresh state, it will exit Self Refresh state.
2. If leveling was enabled at the time of a global warm reset, a PHY reset must occur to bring the PHY back into a known state, as it may have been left in a leveling state upon warm reset assertion. To guarantee that the SDRAM memory clocks are off when issuing PHY reset, software can use the EMIF4D\_POWER\_MANAGEMENT\_CTRL register to enter self refresh before asserting the PHY reset.

### 9.3.3.2 System Power Management

#### Self-Refresh Mode

The EMIF supports SDRAM self-refresh mode for low power. The EMIF automatically puts the SDRAM into self-refresh mode after the EMIF is idle for EMIF4D\_POWER\_MANAGEMENT\_CTRL[7:4] SR\_TIMING number of DDR clock cycles and the EMIF4D\_POWER\_MANAGEMENT\_CTRL[10:8] LP\_MODE bit field is set to 0x2. The EMIF will complete all pending refreshes before it puts the SDRAM into self-refresh. Therefore, after the expiration of SR\_TIMING, the EMIF will start issuing refreshes to complete the refresh backlog down to the refresh release level (given that the LPDDR2 requirement of tREFBW is met) and then issues a SELF-REFRESH command to the SDRAM.

In self-refresh mode, the EMIF automatically stops the SDRAM clock. The EMIF drives CKE pin low to maintain self-refresh mode.

When the SDRAM is in self-refresh mode, the EMIF services register accesses normally.

If the reg\_lp\_mode field is a value other than 2, or an SDRAM access is requested while it is in self-refresh, and reg\_t\_cke + 1 cycles have elapsed since the SELF-REFRESH command was issued, the EMIF will bring the SDRAM out of self-refresh. The value of reg\_t\_cke is taken from SDRAM Timing 2 register. For DDR3, EMIF will also exit self-refresh to perform incremental leveling

For LPDDR2, the EMIF:

- Drives phy\_sdramclkstop low to enable clocks.
- Drives pad\_cke\_o high.
- Waits for reg\_t\_xsnr + 1 cycles. The value of reg\_t\_xsnr is taken from SDRAM Timing 2 register.
- Starts an auto-refresh cycle in the next cycle. It also services all refreshes down to the refresh\_release level.
- Enters its idle state and can issue any commands.

For DDR3, the EMIF:

- Drives phy\_sdramclkstop low to enable clocks.
- Drives pad\_cke\_o high.
- Waits for reg\_t\_xsnr + 1 cycles. The value of reg\_t\_xsnr is taken from SDRAM Timing 2 register.
- If the reg\_ddr\_disable\_dll bit in the SDRAM Config register is 1, the EMIF issues a LOAD MODE REGISTER command to the extended mode register 1 (pad\_ba\_o[2:0] = 0x1) with the pad\_a\_o bits

set as follows:

Bits	Value	Description
pad_a_o[15:13]	0x0	Reserved
pad_a_o[12]	0x0	Output buffer enabled
pad_a_o[11]	0x0	TDQS disable
pad_a_o[10]	0x0	Reserved
pad_a_o[9]	reg_ddr_term[2]	DDR3 termination resistor value from SDRAM Config register
pad_a_o[8]	0x0	Reserved
pad_a_o[7]	0x0	Write leveling disabled
pad_a_o[6]	reg_ddr_term[1]	DDR3 termination resistor value from SDRAM Config register
pad_a_o[5]	reg_sdram_drive[1]	SDRAM drive strength from SDRAM Config register
pad_a_o[4:3]	0x0	Additive latency = 0
pad_a_o[2]	reg_ddr_term[0]	DDR3 termination resistor value from SDRAM Config register
pad_a_o[1]	reg_sdram_drive[0]	SDRAM drive strength from SDRAM Config register
pad_a_o[0]	0x0	Disable DLL

- Starts an auto-refresh cycle in the next cycle. It also services all refreshes down to the refresh\_release level.
- Enters its idle state and can issue any other commands except a write or a read. A write or a read will only be issued after reg\_t\_xsrd + 1 clock cycles have elapsed since pad\_cke\_o is driven high. The value of reg\_t\_xsrd is taken from SDRAM Timing 2 register.

To use partial array self-refresh, the EMIF4D\_SDRAM\_REFRESH\_CTRL[26:24] PASR bits must be appropriately programmed. The EMIF performs bank interleaving when EMIFRD\_SDRAM\_CONFIG[28:27] IBANK\_POS = 0x0. Because the SDRAM is partially refreshed during partial array self-refresh, for software ease, it is recommended that the IBANK\_POS bit field to be set to 0x1, 0x2, or 0x3 depending on the scheme used. If IBANK\_POS is set to 0x0, software must move critical data into the banks that are going to be refreshed during partial array self-refresh.

### Power-Down Mode

The EMIF supports SDRAM power-down mode for low power. The EMIF automatically puts the SDRAM into power-down mode after it is idle for EMIF4D\_POWER\_MANAGEMENT\_CTRL[15:12] PD\_TIM number of DDR clock cycles and the EMIF4D\_POWER\_MANAGEMENT\_CTRL[10:8] LP\_MODE bit field is set to 0x4.

If refresh-must level is not reached before power-down entering, EMIF will not precharge all SDRAM banks before it issues the power-down command. As a result of this EMIF puts the SDRAM in active power-down mode. If refresh-must level is reached before power-down entering, EMIF will precharge all SDRAM banks and before it issues the power-down command, EMIF issues refreshes until refresh-release level is reached. As a result of this EMIF puts the SDRAM in precharge power-down mode.

In power-down mode, the EMIF does not stop the clocks to the SDRAM. The EMIF maintains the CKE pin low to maintain the power-down mode.

When the SDRAM is in power-down mode, the EMIF services register accesses normally.

The EMIF brings SDRAM out of power-down mode if the SDRAM is in power-down mode and one of the following occurs:

- EMIF4D\_POWER\_MANAGEMENT\_CTRL[10:8] LP\_MODE bit field is set to a value other than 0x4.
- An SDRAM access is requested.
- The refresh-must level is reached while the SDRAM/NVM is in power-down mode.

For DDR3, the EMIF also exits power-down mode to perform incremental leveling. If the refresh\_must level brings the SDRAM out of power-down mode, EMIF will re-enter power-down mode when the refreshes are complete if there is no SDRAM request.

To exit power-down, the EMIF:

1. Drives CKE high after t\_cke + 1 cycles have elapsed since the power-down command was issued. The

value of `t_cke` is taken from `EMIF4D_SDRAM_TIMING_2[2:0]` `T_CKE` bit field.

2. Waits for `EMIF4D_SDRAM_TIMING_2[30:28]` `T_XP` + 1 cycles
3. Enters its idle state and can issue any commands

#### 9.3.3.2.1 Deep Power-Down Mode

To save the most power, the EMIF supports deep power-down mode for LPDDR2.

The SDRAM can be forced into deep power-down through software by setting to 1 the `DPD_EN` field in the `EMIF4D_POWER_MANAGEMENT_CTRL` register. In this case, the EMIF will continue normal operation until all SDRAM memory access requests have been serviced. At this point the EMIF will issue a DEEP POWER-DOWN command. The EMIF then maintains `pad_cke_o` low to maintain the deep power-down state.

Setting the `EMIF4D_POWER_MANAGEMENT_CTRL[11]` `DPD_EN` field to 1 overrides the setting of `EMIF4D_POWER_MANAGEMENT_CTRL[10:8]` `LP_MODE` field. Therefore, if the SDRAM is in self-refresh or power-down mode, and `EMIF4D_POWER_MANAGEMENT_CTRL[11]` `DPD_EN` field is set to 1, the EMIF will exit those modes and enter deep power-down mode.

When the SDRAM is in deep power-down, the EMIF services register accesses as normal. If the `EMIF4D_POWER_MANAGEMENT_CTRL[11]` `DPD_EN` field is set to 0, or an SDRAM access is requested, the EMIF will bring the SDRAM out of deep power-down by:

- Performing SDRAM initialization, as specified in the LPDDR2 initialization section ([Section 9.3.3.3](#)).
- Entering its idle state where it can issue any command.
- Using software to perform initialization, as specified in the LPDDR2 Initialization section ([Section 9.3.3.3](#)).

Because the EMIF performs initialization upon exiting deep power-down mode, the `REFRESH_RATE` field in the `EMIF4D_SDRAM_REFRESH_CTRL` register must be set appropriately to meet the 200us wait requirement for LPDDR2 during initialization.

#### 9.3.3.2.2 Save and Restore Mode

The LPDDR2/DDR3 memory controller supports a save and restore mechanism to completely switch off power to the LPDDR2/DDR3 memory controller. The following sequence of operations is followed to put the LPDDR2/DDR3 memory controller in off mode:

1. An external master reads the following memory mapped registers and saves their value external to the LPDDR2/DDR3 memory controller.
  - SDRAM Config register (SDRCR)
  - SDRAM Config 2 register
  - SDRAM Refresh Control register (SDRRCR)
  - SDRAM Refresh Control Shadow register (SDRRCRCSR)
  - SDRAM Timing 1 register (SDRTIM1)
  - SDRAM Timing 1 Shadow register (SDRTIM1SR)
  - SDRAM Timing 2 register (SDRTIM2)
  - SDRAM Timing 2 Shadow register (SDRTIM2SR)
  - SDRAM Timing 3 register (SDRTIM3)
  - SDRAM Timing 3 Shadow register (SDRTIM3SR)
  - Power Management Control register (PMCR)
  - Power Management Control Shadow register (PMCSR)
  - Interface Configuration register (INT\_CONFIG)
  - System OCP Interrupt Enable Set Register (SOIESR)
  - DDR PHY Control 1 register (DDRPHYCR)
  - DDR PHY Control 1 Shadow register (DDRPHYCSR)
2. Memory controller completes all pending transactions and drains all its FIFOs.

3. Memory controller puts the SDRAM in self-refresh.
4. Memory controller copies all shadow memory mapped registers to its main registers. It is assumed that the shadow register always has the same value as its corresponding main register.
5. Memory controller waits for all interrupts to be serviced.
6. Memory controller acknowledges assertion of internal power down request.

## Interrupt Support

The EMIF only supports Idle, Write, Read, and WriteNonPost command types (as indicated by MCmd). Also, the EMIF only supports incrementing, wrapping, and two-dimensional block addressing modes (as indicated by MBurstSeq). If an access request for an unsupported command type or addressing mode is received, the EMIF will set the ERR\_SYS or ERR\_LL bit (depending on which interface sent the error command) in the Interrupt Raw Status register. The EMIF will also set these bits if an access request to an unsupported MAddrSpace is received.

The EMIF will also set the reg\_ta\_sys or reg\_ta\_ll bit in Interrupt Raw Status register if a change in SDRAM temperature is detected. For more details, see [Section 9.3.3.5, Temperature Monitoring](#).

The EMIF will only output the interrupts on the interrupt lines if they are enabled by writing a 1 to the corresponding bits in the Interrupt Enable Set register. The interrupts can be disabled by writing a 1 to the corresponding bits in the Interrupt Enable Clear register.

When enabled, the corresponding bits in the Interrupt Status register will also be set if the above error condition occurs. The interrupts can be cleared once serviced by writing a 1 to the corresponding bits either in the Interrupt Raw Status or Interrupt Status register. The software must also write to the End of Interrupt register to indicate that the interrupt was serviced.

## SDRAM Refresh Scheduling

The EMIF uses two counters to schedule the Refresh (REF) commands: a 13-bit decrementing refresh interval counter and a 4-bit refresh backlog counter. The interval counter is used to define the rate at which connected SDRAM devices are refreshed. It is loaded with the value of the EMIF4D\_SDRAM\_REFRESH\_CTRL[15:0] REFRESH\_RATE bit field at reset (only the 13 LSBs are taken). The interval counter decrements by 1 each cycle until it reaches 0x0, at which point it reloads from the EMIF4D\_SDRAM\_REFRESH\_CTRL[15:0] REFRESH\_RATE bit field and restarts decrementing. The counter also reloads and restarts decrementing whenever the EMIF4D\_SDRAM\_REFRESH\_CTRL[15:0] REFRESH\_RATE bit field is updated.

The refresh backlog counter records the number of the outstanding REF commands which the EMIF controller currently has. The backlog counter increments by 1 each time the interval counter reloads (unless it has reached its maximum value of 8). The backlog counter decrements by 1 each time the EMIF issues a REF command (unless it is already 0). For the range of values that the backlog counter can take, there are three levels of urgency with which the EMIF must perform refresh cycle in which it issues REF commands:

1. Refresh-may level is reached when the backlog count is greater than 0x0, which indicates that there is a refresh backlog and if the EMIF is not busy and there are no open SDRAM banks, the EMIF must perform refresh cycle.
2. Refresh-release level is reached when the backlog count is greater than 0x4, which indicates that the refresh backlog is getting bigger and if the EMIF is not busy it must perform refresh cycle even if there is an open SDRAM bank.
3. Refresh-must level is reached when the backlog count is greater than 0x7, which indicates that the refresh backlog is becoming excessive and the EMIF must perform refresh cycle before any new memory access request being serviced. The EMIF starts servicing new memory accesses after the refresh-release level is cleared.

The refresh counters do not operate when the SDRAM is in self-refresh mode. The refresh counters also start tracking the missed refreshes only after initialization is complete for all DDR types except LPDDR2. For LPDDR2, the refresh counters starts tracking missed refreshes after the RESET command is issued. In addition for LPDDR2, the EMIF will ensure that no more than 8 AUTO REFRESH commands are issued in any rolling tREFBW (=4\*8\*tRFC) window.

The time between two REF commands is set through the EMIF4D\_SDRAM\_TIMING\_3[12:4] T\_RFC bit field.

## SDRAM Initialization

### DDR3 SDRAM Initialization

**NOTE:** The EMIF does not perform any transactions until the DDR3 initialization sequence is complete.

On coming out of reset, the EMIF performs a DDR3 SDRAM initialization sequence as follows if EMIF4D\_SDRAM\_CONFIG[31:29] SDRAM\_TYPE is equal to 0x3 and EMIF4D\_SDRAM\_REFRESH\_CTRL[31] INITREF\_DIS bit is set to 0x0:

1. Drives the CKE pin low
2. After 16 SDRAM refresh rate intervals, issues a NOP command with CKE pin held high. The SDRAM refresh rate is as defined in the EMIF4D\_SDRAM\_REFRESH\_CTRL[15:0] REFRESH\_RATE bit field.
3. After one SDRAM refresh rate interval, issues MRS command to the DDR3 MR2 register (bits BA[2:0] = 0x2) with bits A[15:0] set as in [Load Value For The MR2 Register During DDR3 SDRAM Initialization](#)

#### Load Value For The MR2 Register During DDR3 SDRAM Initialization

Bits	Value	Description
A[15:11]	0x0	Reserved
A[10:9]	EMIF4D_SDRAM_CONFIG[22:21] DYN_ODT	Dynamic ODT value
A[8]	0x0	Reserved
A[7]	EMIF4D_SDRAM_REFRESH_CTRL [29] SRT	Self-refresh temperature range
A[6]	EMIF4D_SDRAM_REFRESH_CTRL [28] ASR	Auto self-refresh enable
A[5]	0x0	Reserved
A[4:3]	EMIF4D_SDRAM_CONFIG[17:16] CWL	CAS write latency
A[2:0]	EMIF4D_SDRAM_REFRESH_CTRL [26:24] PASR	Partial array self-refresh

4. Issues MRS command to the DDR3 MR3 register (bits BA[2:0] = 0x3) with A[15:0] = 0x0
5. Issues MRS command to the DDR3 MR1 register (BA[2:0] = 0x1) with A[15:0] set as in [Load Value For The MR1 Register During DDR3 SDRAM Initialization](#)

#### Load Value For The MR1 Register During DDR3 SDRAM Initialization

Bits	Value	Description
A[15:13]	0x0	Reserved
A[12]	0x0	Output buffer enabled
A[11]	0x0	TDQS disable
A[10]	0x0	Reserved
A[9], A[6], A[2]	EMIF4D_SDRAM_CONFIG[26:24] DDR_TERM	DDR3 termination resistor value
A[8]	0x0	Reserved
A[7]	0x0	Write leveling disabled
A[5], A[1]	EMIF4D_SDRAM_CONFIG[19:18] SDRAM_DRIVE	SDRAM drive strength
A[4:3]	0x0	Additive latency = 0
A[0]	EMIF4D_SDRAM_CONFIG[20] DDR_DISABLE_DLL = 0x0	Enable SDRAM DLL

6. Issues MRS command to the DDR3 MR0 register (BA[2:0] = 0x0) with A[15:0] set as in [Load Value For The MR0 Register During DDR3 SDRAM Initialization](#)

#### Load Value For The MR0 Register During DDR3 SDRAM Initialization

Bits	Value	Description
A[15:13]	0x0	Reserved
A[12]	0x1	The DDR3 SDRAM DLL is "ON" after precharge power-down entering
A[11:9]	EMIF4D_SDRAM_TIMING_1[20:17] T_WR	Write recovery for autoprecharge
A[8]	0x1	DLL reset
A[7]	0x0	Normal mode
A[6:4], A[2]	EMIF4D_SDRAM_CONFIG[13:10] CL	Value for CAS latency
A[3]	0x0	Nibble sequential read burst type
A[1:0]	0x0	Burst length of 8

7. Issues a ZQCL command to start long ZQ calibration
8. Waits for  $t_{DLLK}$  and  $t_{ZQinit}$  to complete
9. Issues REF command
10. The EMIF enters its IDLE state.

The EMIF also performs the initialization sequence whenever the EMIF4D\_SDRAM\_CONFIG register is written. But in this case, the EMIF starts from Step 3.

When the EMIF comes out of reset, the delay time in Step 2 resulting from the 16 refresh rate intervals + 8 cycles is approximately  $16 \times \text{REFRESH\_RATE} / \text{input frequency}$ .

### 9.3.3.3 LPDDR2 Initialization

**NOTE:** The EMIF does not perform any transactions until the LPDDR2 initialization sequence is complete.

On coming out of reset, the EMIF performs an LPDDR2 initialization sequence as follows if the `reg_sdram_type` field in the SDRAM Config register is equal to 4:

1. Drives CKE pin high and starts to continuously issues NOP commands.
2. After 16 SDRAM refresh rate intervals, issues a PRECHARGE-ALL command. The SDRAM refresh rate is as defined in the `reg_refresh_rate` field description (see description of SDRAM Refresh Control register).
3. Issues a RESET command.
4. The EMIF enters its IDLE state.
5. The software then performs the LPDDR2 initialization using the EMIF's LPDDR2 Mode Reg Config and LPDDR2 Mode Reg Data registers. The software must enable refreshes by writing a 1 to the `reg_refresh_en` field in the LPDDR2 Mode Reg Config register during the last MRW command.

The EMIF also performs the initialization sequence whenever the SDRAM Config register is written to and the LPDDR2 initialization was not previously performed because `reg_initref_dis` was set to 0. Once the EMIF performs initialization, re-writing the SDRAM Config register will not cause re-initialization.

The `reg_refresh_rate` value at reset is the `config_refresh_def_val` port value. When the EMIF comes out of reset, the delay time in step 2 resulting from the 16 refresh rate intervals and 8 cycles is approximately  $16 * \text{reg\_refresh\_rate} / \text{input frequency}$ . It is up to the user to tie off the `config_refresh_def_val` port with a correct value to meet the typical LPDDR2 device-specified delay time of 200us between power-up and the application of RESET command.

### DDR3 Read-Write Leveling

The EMIF supports read-write leveling in conjunction with the DDR PHY for DDR3. The EMIF supports two types of write/read leveling:

- Full leveling

The EMIF does not perform full leveling after initialization upon reset deassertion. Full leveling must be triggered by software after the EMIF MMR's are properly configured. The EMIF also supports triggering of full leveling through software through the use of the `reg_rdwrlvfull_en` field in the Read-Write Leveling Control register. Full leveling will be interrupted by auto refresh, if a refresh must state is reached. Upon completion of the auto refresh, full leveling will be re-entered at the point it exited and continue till completion.

- Incremental leveling

The EMIF supports incremental leveling to better track voltage and temperature changes during normal operation. The incremental leveling can be enabled by writing a non-zero value to the `reg_wrlvlinc_int`, `reg_rdlvlgateinc_int`, and `reg_rdlvlinc_int` fields in the Read-Write Leveling Control register. The EMIF periodically triggers incremental write leveling every time `reg_wrlvlinc_int` expires. In other words, the `reg_wrlvlinc_int` defines the interval between successive incremental write leveling. Similarly, the EMIF periodically triggers incremental read DQS gate training every time `reg_rdlvlgateinc_int` expires, and triggers incremental read data eye training every time `reg_rdlvlinc_int` expires. To minimize impact on bandwidth, the software can program these intervals such that these three intervals do not expire at same time. The value of interval programmed depends on the slope of voltage and temperature changes.

The EMIF supports increasing the rate of incremental leveling automatically for a defined period of time. This can be achieved by a) programming the Read-Write Leveling Ramp Window register and the Read-Write Leveling Ramp Control register and b) using the `inclvl_rate_chng` port. Whenever a pulse is received on the `inclvl_rate_chng` port, the EMIF uses the intervals programmed in the Read-Write Leveling Ramp Control register until the `reg_rdwrlvlinc_rmp_win` in the Read-Write Leveling Ramp Window register expires. After `reg_rdwrlvlinc_rmp_win` expires, the EMIF switches back to use the intervals programmed in the Read-Write Leveling Control register. To ensure none of the incremental leveling events are missed, the `reg_rdwrlvlinc_rmp_win` must be programmed greater than the intervals in the Read-Write Leveling Ramp Control register.

If the EMIF is in the self-refresh or power-down modes when any of the incremental leveling intervals expire, the EMIF will exit the self-refresh or power-down mode, perform the required leveling, and then re-enter the self-refresh or power-down mode.

Each leveling type has three parts:

- Write leveling
- Read data eye training
- Read DQS gate training

## EMIF Access Cycles

By default, the EMIF keeps SDRAM chip selects signal high. To direct a command to only one of the SDRAMs, EMIF asserts the chip select to the SDRAM for the duration of the command. If the reg\_ebank field in the SDRAM Config register is set to 0, chip select 1 will always be driven high except during initialization and for refresh, power-down, self-refresh, and deep power-down commands.

The EMIF always performs burst accesses to the SDRAM. Multiple SDRAM bursts may need to service a single OCP burst request. Table 9-149 through Table 9-153 show a few examples how EMIF performs SDRAM accesses for a linear incrementing transaction type. T0, T1, and others are clock cycles. R0 is read starting at column 0, R8 is read starting at column 8, and R16 is read starting at column 16. D0-1 is the data from column 0 and 1, D2-3 is the data from column 2 and 3, and so on.

**Table 9-149. 64-Byte Linear Read Starting at Address 0x0 (All DDR)**

T0	T1	T2	T3	T4	T5	T6	T7	T8	T9	T10	T11
R0				R8							
				D0-1	D2-3	D4-5	D6-7	D8-9	D10-11	D12-13	D14-15

**Table 9-150. 64-Byte Linear Read Starting at Address 0x8 (LPDDR2-S2)**

T0	T1	T2	T3	T4	T5	T6	T7	T8	T9	T10	T11	T12	T13	T14
R2			R8				R16							
				D2-3	D4-5	D6-7	D8-9	D10-11	D12-13	D14-15	D16-17	Unuse d	Unuse d	Unuse d

**Table 9-151. 64-Byte Linear Read Starting at Address 0x8 (LPDDR2-S4)**

T0	T1	T2	T3	T4	T5	T6	T7	T8	T9	T10	T11	T12	T13	T14	T15
R2				R8				R16							
				D2-3	D4-5	D6-7	Unuse d	D8-9	D10-11	D12-13	D14-15	D16-17	Unuse d	Unuse d	Unuse d

**Table 9-152. 64-Byte Linear Read Starting at Address 0x10 (All DDR)**

T0	T1	T2	T3	T4	T5	T6	T7	T8	T9	T10	T11	T12	T13
R4		R8				R16							
				D4-5	D6-7	D8-9	D10-11	D12-13	D14-15	D16-17	D18-19	Unused	Unused

**Table 9-153. 64-Byte Linear Read Starting at Address 0x18 (All DDR)**

T0	T1	T2	T3	T4	T5	T6	T7	T8	T9	T10	T11	T12	T13
R6		R8				R16							
				D6-7	Unused	D8-9	D10-11	D12-13	D14-15	D16-17	D18-19	D20-21	Unused

The EMIF uses the unused data phases in the preceding figures by issuing successive read commands if there are reads to open banks pending in the command FIFO.

The write data conversion from single data rate to double data rate must be done outside the EMIF. The SDRAM\_DQS signal generation (with right timing) from the phy\_dqs\_en signal must also be done outside the EMIF.

## Turnaround Time

[Table 9-154](#) lists the turnaround time that EMIF introduces on the data bus for various back-to-back accesses. The EMIF takes advantage of the CAS latencies and packs the commands as close as possible on the control bus to introduce the following turnaround time on the data bus.

**Table 9-154. Turnaround Time**

Current Access	Next Access	Turnaround Time (Number of DDR Clock Cycles)
SDRAM write	SDRAM read	EMIF4D_SDRAM_TIMING_1[2:0] T_WTR + 1 + CL
SDRAM read	SDRAM write	EMIF4D_SDRAM_TIMING_1[31:29] T_RTW + 1

## SDRAM Address Mapping

The LPDDR2/DDR3 memory controller views external LPDDR2/DDR3 SDRAM as one continuous block of memory. This statement is true regardless of the number of memory devices located on the chip select space. The LPDDR2/DDR3 memory controller receives LPDDR2/DDR3 memory access requests along with a 32-bit logical address from the rest of the system. In turn, LPDDR2/DDR3 memory controller uses the logical address to generate a row/page, column, and bank address for the LPDDR2/DDR3 SDRAM. The number of column, row and bank address bits used is determined by the IBANK, RSIZE and PAGESIZE fields (see [Table 9-155](#)). The LPDDR2/DDR3 memory controller uses up to 16 bits for the row/page address.

**Table 9-155. IBANK, RSIZE and PAGESIZE Fields Information**

Bit Field	Bit Value	Bit Description
RSIZE		Defines the number of address lines to be connected to LPDDR2/DDR3 memory device
	0	9 row bits
	1h	10 row bits
	2h	11 row bits
	3h	12 row bits
	4h	13 row bits
	5h	14 row bits
	6h	15 row bits
	7h	16 row bits
PAGESIZE		Defines the page size of each page of the external LPDDR2/DDR3 memory device
	0	256 words (requires 8 column address bits)
	1h	512 words (requires 9 column address bits)
	2h	1024 words (requires 10 column address bits)
	3h	2048 words (requires 11 column address bits)
IBANK		Defines the number of internal banks on the external LPDDR2/DDR3 memory device
	0	1 bank
	1h	2 banks
	2h	4 banks
	3h	8 banks

**Table 9-155. IBANK, RSIZE and PAGESIZE Fields Information (continued)**

Bit Field	Bit Value	Bit Description
EBANK		Defines the number of LPDDR2/DDR3 memory controller chip selects
	0	CS0 only
	1h	Reserved

When addressing SDRAM, if the REG\_IBANK\_POS field in the SDRAM Config register is set to 0, and the REG\_EBANK\_POS field in the SDRAM Config 2 register is also set to 0, the LPDDR2/DDR3 memory controller uses the three fields, IBANK, EBANK and PAGESIZE in the SDRAM Config register to determine the mapping from source address to SDRAM row, column, bank, and chip select. If the REG\_IBANK\_POS field in the SDRAM Config register is set to 1, 2, or 3, or the REG\_EBANK\_POS field in the SDRAM Config 2 register is set to 1, the LPDDR2/DDR3 memory controller uses the 4 fields - IBANK, EBANK, PAGESIZE, and ROWSIZE in the SDRAM Config register to determine the mapping from source address to SDRAM row, column, bank, and chip select. In all cases the LPDDR2/DDR3 memory controller considers its SDRAM address space to be a single logical block regardless of the number of physical devices or whether the devices are mapped across 1 or 2 LPDDR2/DDR3 memory controller chip selects.

#### 9.3.3.3.1 Address Mapping when REG\_IBANK\_POS=0 and REG\_EBANK\_POS=0

For REG\_IBANK\_POS=0 and REG\_EBANK\_POS=0, the effect of address mapping scheme is that as the source address increments across LPDDR2/DDR3 memory device page boundaries, the LPDDR2/DDR3 controller moves onto the same page in the next bank in the current device DDR\_CS<sub>n</sub>[0]. This movement along the banks of the current proceeds to the same page in the next device (if EBANK=1, DDR\_CS<sub>n</sub>[1]) and proceeds through the same page in all its banks before moving over to the next page in the first device(DDR\_CS<sub>n</sub>[0]). The LPDDR2/DDR3 controller exploits this traversal across internal banks and chip selects while remaining on the same page to maximize the number of open LPDDR2/DDR3 memory device banks within the overall LPDDR2/DDR3 memory device space.

Thus, the LPDDR2/DDR3 controller can keep a maximum of 16 banks (8 internal banks across 2 chip selects) open at a time, and can interleave among all of them.

**Table 9-156. OCP Address to LPDDR2/DDR3 Address Mapping for REG\_IBANK\_POS=0 and REG\_EBANK\_POS=0**

Logical Address			
Row Address	Chip Select	Bank Address	Column Address
LPDDR2 = 15 bits DDR3 = 16 bits	# of bits defined by EBANK of SDRCR	# of bits defined by IBANK of SDRCR	# of bits defined by PAGESIZE of SDRCR
	EBANK=0 => 0 bits	IBANK=0 => 0 bits	PAGESIZE=0 => 8 bits
	EBANK=1 => 1 bit	IBANK=1 => 1 bit	PAGESIZE=1 => 9 bits
		IBANK=2 => 2 bits	PAGESIZE=2 => 10 bits
		IBANK=3 => 3 bits	PAGESIZE=3 => 11 bits

#### 9.3.3.3.2 Address Mapping when REG\_IBANK\_POS = 1 and REG\_EBANK\_POS = 0

For REG\_IBANK\_POS = 1 and REG\_EBANK\_POS = 0, the interleaving of banks within a device (per chip select) is limited to 4 banks. However, it can still interleave banks between the two chip selects. Thus, the LPDDR2/DDR3 controller can keep a maximum of 16 banks (8 internal banks across 2 chip selects) open at a time, but can only interleave among eight of them.

**Table 9-157. OCP Address to LPDDR2/DDR3 Address Mapping for REG\_IBANK\_POS=1 and REG\_EBANK\_POS=0**

Logical Address				
Bank Address[2]	Row Address	Chip Select	Bank Address[1:0]	Column Address
# of bits defined by IBANK of SDRCR	# of bits defined by RSIZE of SDRCR	# of bits defined by EBANK of SDRCR	# of bits defined by IBANK of SDRCR	# of bits defined by PAGESIZE of SDRCR
IBANK=0 => 0 bits	RSIZE=0 => 9 bits	EBANK=0 => 0 bits	IBANK=0 => 0 bits	PAGESIZE=0 => 8 bits
IBANK=1 => 0 bits	RSIZE=1 => 10 bits	EBANK=1 => 1 bit	IBANK=1 => 1 bit	PAGESIZE=1 => 9 bits
IBANK=2 => 0 bits	RSIZE=2 => 11 bits		IBANK=2 => 2 bits	PAGESIZE=2 => 10 bits
IBANK=3 => 1 bit	RSIZE=3 => 12 bits		IBANK=3 => 3 bits	PAGESIZE=3 => 11 bits
	RSIZE=4 => 13 bits			
	RSIZE=5 => 14 bits			
	RSIZE=6 => 15 bits			
	RSIZE=7 => 16 bits			

#### 9.3.3.3.3 Address Mapping when REG\_IBANK\_POS=2 and REG\_EBANK\_POS = 0

For REG\_IBANK\_POS=2 and REG\_EBANK\_POS = 0, the interleaving of banks within a device (per chip select) is limited to 2 banks. However, it can still interleave banks between the two chip selects. Thus, the LPDDR2/DDR3 controller can keep a maximum of 16 banks (eight internal banks across 2 chip selects) open at a time, but can only interleave among four of them.

**Table 9-158. OCP Address to LPDDR2/DDR3 Address Mapping for REG\_IBANK\_POS=2 and REG\_EBANK\_POS=0**

Logical Address				
Bank Address[2:1]	Row Address	Chip Select	Bank Address[0]	Column Address
# of bits defined by IBANK of SDRCR	# of bits defined by RSIZE of SDRCR	# of bits defined by EBANK of SDRCR	# of bits defined by IBANK of SDRCR	# of bits defined by PAGESIZE of SDRCR
IBANK=0 => 0 bits	RSIZE=0 => 9 bits	EBANK=0 => 0 bits	IBANK=0 => 0 bits	PAGESIZE=0 => 8 bits
IBANK=1 => 0 bits	RSIZE=1 => 10 bits	EBANK=1 => 1 bit	IBANK=1 => 1 bit	PAGESIZE=1 => 9 bits
IBANK=2 => 1 bit	RSIZE=2 => 11 bits		IBANK=2 => 1 bit	PAGESIZE=2 => 10 bits
IBANK=3 => 2 bits	RSIZE=3 => 12 bits		IBANK=3 => 1 bit	PAGESIZE=3 => 11 bits
	RSIZE=4 => 13 bits			
	RSIZE=5 => 14 bits			
	RSIZE=6 => 15 bits			
	RSIZE=7 => 16 bits			

#### 9.3.3.3.4 Address Mapping when REG\_IBANK\_POS= 3 and REG\_EBANK\_POS = 0

For REG\_IBANK\_POS= 3 and REG\_EBANK\_POS = 0, the LPDDR2/DDR3 controller cannot interleave banks within a device (per chip select). However, it can still interleave banks between the two chip selects. Thus, the LPDDR2/DDR3 controller can keep a maximum of 16 banks (8 internal banks across 2 chip selects) open at a time, but can only interleave among two of them.

**Table 9-159. OCP Address to LPDDR2/DDR3 Address Mapping for REG\_IBANK\_POS=3 and REG\_EBANK\_POS=0**

Logical Address			
Bank Address	Row Address	Chip Select	Column Address
# of bits defined by IBANK of SDRCR	# of bits defined by RSIZE of SDRCR	# of bits defined by EBANK of SDRCR	# of bits defined by PAGESIZE of SDRCR
IBANK=0 => 0 bits	RSIZE=0 => 9 bits	EBANK=0 => 0 bits	PAGESIZE=0 => 8 bits
IBANK=1 => 1 bit	RSIZE=1 => 10 bits	EBANK=1 => 1 bit	PAGESIZE=1 => 9 bits

**Table 9-159. OCP Address to LPDDR2/DDR3 Address Mapping for REG\_IBANK\_POS=3 and REG\_EBANK\_POS=0 (continued)**

Logical Address			
Bank Address	Row Address	Chip Select	Column Address
IBANK=2 => 2 bits	RSIZE=2 => 11 bits		PAGESIZE=2 => 10 bits
IBANK=3 => 3 bits	RSIZE=3 => 12 bits		PAGESIZE=3 => 11 bits
	RSIZE=4 => 13 bits		
	RSIZE=5 => 14 bits		
	RSIZE=6 => 15 bits		
	RSIZE=7 => 16 bits		

### 9.3.3.3.5 Address Mapping when REG\_IBANK\_POS = 0 and REG\_EBANK\_POS = 1

For REG\_IBANK\_POS = 0 and REG\_EBANK\_POS = 1, the LPDDR2/DDR3 memory controller interleaves among all the banks within a device (per chip select). However, the LPDDR2/DDR3 memory controller cannot interleave banks between the two chip selects. Thus, the LPDDR2/DDR3 memory controller can keep a maximum of 16 banks (8 internal banks across 2 chip selects) open at a time, but can only interleave among 8 of them.
