D	If <i>PIDCode</i> = IN Halt QHD If <i>PIDCode</i> = OUT Retry start-split	This is a degenerate case where the start-split was issued, but all of the complete-splits were skipped and all possible intervening opportunities to detect the missed data failed to fire. If <i>PIDCode</i> is an IN, then the Queue head must be halted. If <i>PIDCode</i> is an OUT, then the transfer state is not advanced and the state exited (for example, start-split is retried). This is a host-induced error and does not effect <i>CERR</i> . In either case, set the <i>Missed Micro-frame</i> bit in the status field to a one. Note: When executing in the context of a <i>Recovery Path</i> mode, the host controller is allowed to process the queue head and take the actions indicated above, or it may wait until the queue head is visited in the

Table 11-46. Interrupt IN/OUT Do Complete Split State Execution Criteria

		normal processing mode. Regardless, the host controller must not execute a start-split in the context of a executing in a <i>Recovery Path</i> mode.
--	--	--

Managing QH.FrameTag Field

The *QH.FrameTag* field in a queue head is completely managed by the host controller. The rules for setting *QH.FrameTag* are simple:

- Rule 1: If transitioning from Do Start Split to Do Complete Split and the current value of *FRINDEX*[2:0] is 6 *QH.FrameTag* is set to *FRINDEX*[7:3] + 1. This accommodates split transactions whose start-split and complete-splits are in different *H-Frames* (case 2a, see [Figure 11-21](#)).
- Rule 2: If the current value of *FRINDEX*[2:0] is 7, *QH.FrameTag* is set to *FRINDEX*[7:3] + 1. This accommodates staying in Do Complete Split for cases 2a, 2b, and 2c ([Figure 11-21](#)).
- Rule 3: If transitioning from Do_Start Split to Do Complete Split and the current value of *FRINDEX*[2:0] is not 6, or currently in Do Complete Split and the current value of (*FRINDEX*[2:0]) is not 7, *FrameTag* is set to *FRINDEX*[7:3]. This accommodates all other cases ([Figure 11-21](#)).

11.1.3.3.12.2.6 Rebalancing the periodic schedule

System software must occasionally adjust a periodic queue head's S-mask and C-mask fields during operation.

This need occurs when adjustments to the periodic schedule create a new bandwidth budget and one or more queue head's are assigned new execution footprints (that is, new S-mask and C-mask values).

It is imperative that System software must not update these masks to new values in the midst of a split transaction. In order to avoid any race conditions with the update, the EHCI host controller provides a simple assist to system software. System software sets the *Inactivate-on-next-Transaction (I)* bit to a one to signal the host controller that it intends to update the S-mask and C-mask on this queue head. System software will then wait for the host controller to observe the *I-bit* is a one and transition the *Active* bit to a zero. The rules for how and when the host controller sets the *Active* bit to zero are enumerated below:

- If the *Active* bit is a zero, no action is taken. The host controller does not attempt to advance the queue when the *I-bit* is a one.
- If the *Active* bit is a one and the *SplitXState* is DoStart (regardless of the value of *S-mask*), the host controller will simply set *Active* bit to a zero. The host controller is

not required to write the transfer state back to the *current* qTD. Note that if the *S-mask* indicates that a start-split is scheduled for the current micro-frame, the host controller must not issue the start-split bus transaction. It must set the *Active* bit to zero.

System software must save transfer state before setting the *I-bit* to a one. This is required so that it can correctly determine what transfer progress (if any) occurred after the *I-bit* was set to a one and the host controller executed its final bus-transaction and set *Active* to a zero.

After system software has updated the *S-mask* and *C-mask*, it must then reactivate the queue head. Because the *Active* bit and the *I-bit* cannot be updated with the same write, system software needs to use the following algorithm to coherently re-activate a queue head that has been stopped via the *I-bit*.

1. Set the *Halted* bit to a one, then
2. Set the *I-bit* to a zero, then
3. Set the *Active* bit to a one and the *Halted* bit to a zero in the same write.

Setting the *Halted* bit to a one inhibits the host controller from attempting to advance the queue between the time the *I-bit* goes to a zero and the *Active* bit goes to a one.

11.1.3.3.12.3 Split Transaction Isochronous

Full-speed isochronous transfers are managed using the split-transaction protocol through a USB 2.0 transaction translator in a USB2.0 Hub. The EHCI controller utilizes siTD data structure to support the special requirements of isochronous split-transactions.

This data structure uses the scheduling model of isochronous TDs (iTD, Section [Isochronous \(High-Speed\) Transfer Descriptor \(iTD\)](#)) (see Section [Managing Isochronous Transfers Using iTDs](#) for the operational model of iTDs) with the contiguous data feature provided by queue heads. This simple arrangement allows a single isochronous scheduling model and adds the additional feature that all data received from the endpoint (per split transaction) must land into a contiguous buffer.

11.1.3.3.12.3.1 Split Transaction Scheduling Mechanisms for Isochronous

Full-speed isochronous transactions are managed through a transaction translator's periodic pipeline. As with full- and low-speed interrupt, system software manages each transaction translator's periodic pipeline by budgeting and scheduling exactly during which micro-frames the start-splits and complete-splits for each full-speed isochronous endpoint occur.

The requirements described in Section [Split Transaction Scheduling Mechanisms for Interrupt](#) apply. The following figure illustrates the general scheduling boundary conditions that are supported by the EHCI periodic schedule. The ^SX and ^CX labels indicate micro-frames where software can schedule start- and complete-splits (respectively). The *H-Frame* boundaries are marked with a large, solid bold vertical line. The *B-Frame* boundaries are marked with a large, bold, dashed line. The bottom of the figure illustrates the relationship of an siTD to the *H-Frame*.

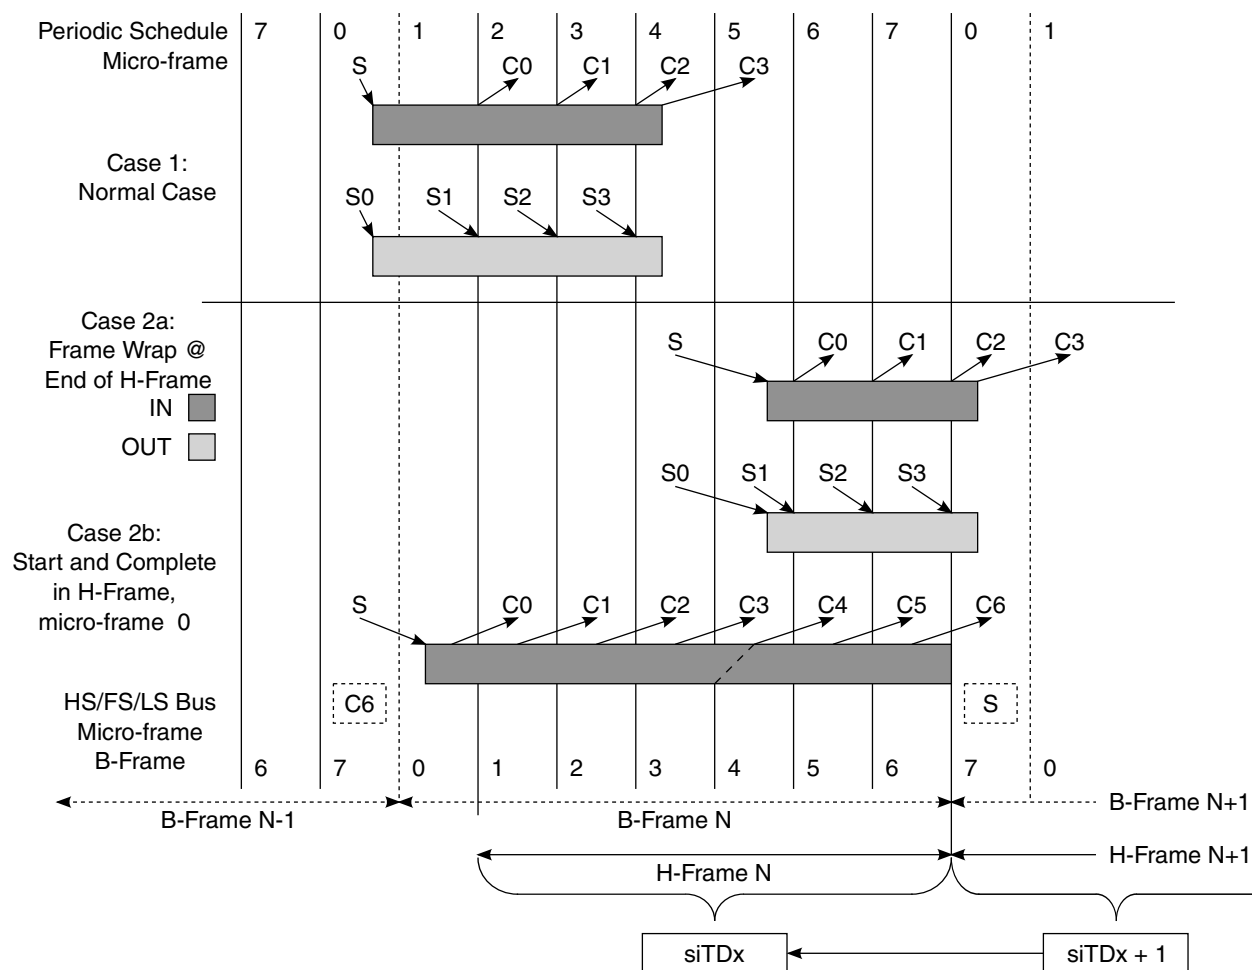

Figure 11-25. Split Transaction, Isochronous Scheduling Boundary Conditions

When the endpoint is an isochronous OUT, there are only start-splits, and no complete-splits. When the endpoint is an isochronous IN, there is at most one start-split and one to *N* complete-splits. The scheduling boundary cases are:

- *Case 1*: The entire split transaction is completely bounded by an *H-Frame*. For example: the start-splits and complete-splits are all scheduled to occur in the same *H-Frame*.

- *Case 2a*: This boundary case is where one or more (at most two) complete-splits of a split transaction IN are scheduled across an *H-Frame* boundary. This can only occur when the split transaction has the possibility of moving data in *B-Frame*, micro-frames 6 or 7 (*H-Frame* micro-frame 7 or 0). When an *H-Frame* boundary wrap condition occurs, the scheduling of the split transaction spans more than one location in the periodic list. (For example, it takes two siTDs in adjacent periodic frame list locations to fully describe the scheduling for the split transaction.)
- Although the scheduling of the split transaction may take two data structures, all of the complete-splits for each full-speed IN isochronous transaction must use only one data pointer. For this reason, siTDs contain a back pointer, the use of which is described below.
- Software must never schedule full-speed isochronous OUTs across an *H-Frame* boundary.
- *Case 2b*: This case can only occur for a very large isochronous IN. It is the only allowed scenario where a start-split and complete-split for the same endpoint can occur in the same micro-frame. Software must enforce this rule by scheduling the large transaction first. Large is defined to be anything larger than 579 byte maximum packet size.

A subset of the same mechanisms employed by full- and low-speed interrupt queue heads are employed in siTDs to schedule and track the portions of isochronous split transactions. The following fields are initialized by system software to instruct the host controller when to execute portions of the split transaction protocol.

- *SplitXState*. This is a single bit residing in the *Status* field of an siTD (see [Figure 11-26](#)). This bit is used to track the current state of the split transaction. The rules for managing this bit are described in [Section Split Transaction Execution State Machine for Interrupt](#).
- *Frame S-mask*. This is a bit-field where-in system software sets a bit corresponding to the micro-frame (within an *H-Frame*) that the host controller should execute a start-split transaction. This is always qualified by the value of the *SplitXState* bit. For example, referring to the IN example in [Figure 11-25](#), case one, the *S-mask* would have a value of 00000001b indicating that if the siTD is traversed by the host controller, and the *SplitXState* indicates Do Start Split, and the current micro-frame as indicated by `USB_n_FRINDEX[2:0]` is 0, then execute a start-split transaction.
- *Frame C-mask*. This is a bit-field where system software sets one or more bits corresponding to the micro-frames (within an *H-Frame*) that the host controller should execute complete-split transactions. The interpretation of this field is always qualified by the value of the *SplitXState* bit. For example, referring to the IN example in [Figure 11-25](#), case one, the *C-mask* would have a value of 00111100b indicating that if the siTD is traversed by the host controller, and the *SplitXState* indicates Do

Complete Split, and the current micro-frame as indicated by *USB_n_FRINDEX*[2:0] is 2, 3, 4, or 5, then execute a complete-split transaction.

- *Back Pointer*. This field in a siTD is used to complete an IN split-transaction using the previous *H-Frame*'s siTD. This is only used when the scheduling of the complete-splits span an *H-Frame* boundary.

There exists a one-to-one relationship between a high-speed isochronous split transaction (including all start- and complete-splits) and one full-speed isochronous transaction. An siTD contains (amongst other things) buffer state and split transaction scheduling information. An siTD's buffer state always maps to one full-speed isochronous data payload. This means that for any full-speed transaction payload, a single siTD's data buffer must be used. This rule applies to both IN and OUTs. An siTD's scheduling information usually also maps to one high-speed isochronous split transaction. The exception to this rule is the *H-Frame* boundary wrap cases mentioned above.

The siTD data structure describes at most, one frame's worth of high-speed transactions and that description is strictly bounded within a frame boundary. The figure below illustrates some examples. On the top are examples of the full-speed transaction footprints for the boundary scheduling cases described above. In the middle are time-frame references for both the *B-Frames* (HS/FS/LS Bus) and the *H-Frames*. On the bottom is illustrated the relationship between the scope of an siTD description and the time references. Each *H-Frame* corresponds to a single location in the periodic frame list. The implication is that each siTD is reachable from a single periodic frame list location at a time.

Figure 11-26. siTD Scheduling Boundary Examples

Each case is described below:

- *Case 1:* One siTD is sufficient to describe and complete the isochronous split transaction because the whole isochronous split transaction is tightly contained within a single *H-Frame*.
- *Case 2a, 2b:* Although both INs and OUTs can have these footprints, OUTs always take only one siTD to schedule. However, INs (for these boundary cases) require two siTDs to complete the scheduling of the isochronous split transaction. siTD_x is used to always issue the start-split and the first *N* complete-splits. The full-speed transaction (for these cases) can deliver data on the full-speed bus segment during micro-frame 7 of *H-Frame*_{Y+1}, or micro-frame 0 of *H-Frame*_{Y+2}. The complete splits are scheduled using siTD_{x+2} (not shown). The complete-splits to extract this data must use the buffer pointer from siTD_{x+1}. The only way for the host controller to reach siTD_{x+1} from *H-Frame*_{Y+2} is to use siTD_{x+2}'s back pointer. The host controller rules for when to use the back pointer are described in Section [Periodic Isochronous - Do Complete Split](#).

Software must apply the following rules when calculating the schedule and linking the schedule data structures into the periodic schedule:

- Software must ensure that an isochronous split-transaction is started so that it will complete before the end of the *B-Frame*.
- Software must ensure that for a single full-speed isochronous endpoint, there is never a start-split and complete-split in *H-Frame, micro-frame 1*. This is mandated as a rule so that case 2a and case 2b can be discriminated. According to the core USB specification, the long isochronous transaction illustrated in Case 2b, could be scheduled so that the start-split was in micro-frame 1 of *H-Frame N* and the last complete-split would need to occur in micro-frame 1 of *H-Frame N+1*. However, it is impossible to discriminate between cases 2a and case 2b, which has significant impact on the complexity of the host controller.

11.1.3.3.12.3.2 Tracking Split Transaction Progress for Isochronous Transfers

To correctly maintain the data stream, the host controller must be able to detect and report errors where device to host data is lost. Isochronous endpoints do not employ the concept of a halt on error, however the host is required to identify and report per-packet errors observed in the data stream. This includes schedule traversal problems (skipped micro-frames), timeouts and corrupted data received.

In similar kind to interrupt split-transactions, the portions of the split transaction protocol must execute in the micro-frames they are scheduled. The queue head data structure used to manage full- and low-speed interrupt has several mechanisms for tracking when portions of a transaction have occurred. Isochronous transfers use siTDs, for their transfers, and the data structures are only reachable via the schedule in the exact micro-frame in which they are required (so all the mechanism employed for tracking in queue heads is not required for siTDs). Software has the option of reusing siTD several times in the complete periodic schedule. However, it must ensure that the results of split transaction *N* are consumed and the siTD reinitialized (activated) before the host controller gets back to the siTD (in a future micro-frame).

Split-transaction isochronous OUTs utilize a low-level protocol to indicate which portions of the split transaction data have arrived. Control over the low-level protocol is exposed in an siTD via the fields *Transaction Position (TP)* and *Transaction Count (T-count)*. If the entire data payload for the OUT split transaction is larger than 188 bytes, there will be more than one start-split transaction, each of which require proper annotation. If host hold-offs occur, then the sequence of annotations received from the host will not be complete, which is detected and handled by the transaction translator. See Section [Periodic Isochronous - Do Start Split](#) for a description on how these fields are used during a sequence of start-split transactions.

The fields *siTD.T-Count* and *siTD.TP* are used by the host controller to drive and sequence the transaction position annotations. It is the responsibility of system software to properly initialize these fields in each siTD. Once the budget for a split-transaction

isochronous endpoint is established, *S-mask*, *T-Count*, and *TP* initialization values for all the siTD associated with the endpoint are constant. They remain constant until the budget for the endpoint is recalculated by software and the periodic schedule adjusted.

For IN-endpoints, the transaction translator simply annotates the response data packets with enough information to allow the host controller to identify the last data. As with split transaction Interrupt, it is the host controller's responsibility to detect when it has missed an opportunity to execute a complete-split. The following field in the siTD is used to track and detect errors in the execution of a split transaction for an IN isochronous endpoint.

- *C-prog-mask*. This is an eight-bit bit-vector where the host controller keeps track of which complete-splits have been executed. Due to the nature of the Transaction Translator periodic pipeline, the complete-splits need to be executed in-order. The host controller needs to detect when the complete-splits have not been executed in order. This can only occur due to system hold-offs where the host controller cannot get to the memory-based schedule. *C-prog-mask* is a simple bit-vector that the host controller sets a bit for each complete-split executed. The bit position is determined by the micro-frame (USB_n_FRINDEX[2:0]) number in which the complete-split was executed. The host controller always checks *C-prog-mask* before executing a complete-split transaction. If the previous complete-splits have not been executed, then it means one (or more) have been skipped and data has potentially been lost. System software is required to initialize this field to zero before setting an siTD's *Active* bit to a one.

If a transaction translator returns with the final data before all of the complete-splits have been executed, the state of the transfer is advanced so that the remaining complete-splits are not executed. Refer to Section [Asynchronous - Do Complete Split](#) for a description on how the state of the transfer is advanced. It is important to note that an IN siTD is retired based solely on the responses from the Transaction Translator to the complete-split transactions. This means, for example, that it is possible for a transaction translator to respond to a complete-split with an MDATA PID. The number of bytes in the MDATA's data payload could cause the siTD field *Total Bytes to Transfer* to decrement to zero. This response can occur, before all of the scheduled complete-splits have been executed. In other interface, data structures (for example, high-speed data streams through queue heads), the transition of *Total Bytes to Transfer* to zero signals the end of the transfer and results in setting of the *Active* bit to zero. However, in this case, the result has not been delivered by the Transaction Translator and the host must continue with the next complete-split transaction to extract the residual transaction state. This scenario occurs because of the pipeline rules for a Transaction Translator (see Chapter 11 of the Universal Serial Bus Revision 2.0). In summary the periodic pipeline rules require that on a micro-frame boundary, the Transaction Translator will hold the final two bytes received (if it has not seen an End Of Packet (EOP)) in the full-speed bus pipe stage and give the

remaining bytes to the high-speed pipeline stage. At the micro-frame boundary, the Transaction Translator could have received the entire packet (including both CRC bytes) but not received the packet EOP. In the next micro-frame, the Transaction Translator will respond with an MDATA and send all of the data bytes (with the two CRC bytes being held in the full-speed pipeline stage). This could cause the siTD to decrement its *Total Bytes to Transfer* field to zero, indicating it has received all expected data. The host must still execute one more (scheduled) complete-split transaction in order to extract the results of the full-speed transaction from the Transaction Translator (for example, the Transaction Translator may have detected a CRC failure, and this result must be forwarded to the host).

If the host experiences hold-offs that cause the host controller to skip one or more (but not all) scheduled split transactions for an isochronous OUT, then the protocol to the transaction translator will not be consistent and the transaction translator will detect and react to the problem. Likewise, for host hold-offs that cause the host controller to skip one or more (but not all) scheduled split transactions for an isochronous IN, the *C-prog-mask* is used by the host controller to detect errors. However, if the host experiences a hold-off that causes it to skip all of an siTD, or an siTD expires during a host hold off (for example, a hold-off occurs and the siTD is no longer reachable by the host controller in order for it to report the hold-off event), then system software must detect that the siTDs have not been processed by the host controller (that is, state not advanced) and report the appropriate error to the client driver.

11.1.3.3.12.3.3 Split Transaction Execution State Machine for Isochronous

In the following presentation, all references to micro-frame are in the context of a micro-frame within an *H-Frame*.

If the *Active* bit in the *Status* byte is a zero, the host controller will ignore the siTD and continue traversing the periodic schedule. Otherwise the host controller will process the siTD as specified below. A split transaction state machine is used to manage the split-transaction protocol sequence. The host controller uses the fields defined in Section [Tracking Split Transaction Progress for Interrupt Transfers](#), plus the variable *cMicroFrameBit* defined in Section [Split Transaction Execution State Machine for Interrupt](#) to track the progress of an isochronous split transaction. The figure below illustrates the state machine for managing an siTD through an isochronous split transaction. Bold, dotted circles denote the state of the *Active* bit in the *Status* field of a siTD. The Bold, dotted arcs denote the transitions between these states. Solid circles denote the states of the split transaction state machine and the solid arcs denote the transitions between these states. Dotted arcs and boxes reference actions that take place either as a result of a transition or from being in a state.

Figure 11-27. Split Transaction State Machine for Isochronous

11.1.3.3.12.3.4 Periodic Isochronous - Do Start Split

Isochronous split transaction OUTs use only this state.

An siTD for a split-transaction isochronous IN is either initialized to this state, or the siTD transitions to this state from Do Complete Split when a case 2a (IN) or 2b scheduling boundary isochronous split-transaction completes.

Each time the host controller reaches an active siTD in this state, it checks the *siTD.S-mask* against *cMicroFrameBit*. If there is a one in the appropriate position, the siTD will execute a start-split transaction. By definition, the host controller cannot *reach* an siTD at the wrong time. If the *I/O* field indicates an IN, then the start-split transaction includes only the extended token plus the full-speed token. Software must initialize the *siTD.Total Bytes To Transfer* field to the number of bytes expected. This is usually the maximum packet size for the full-speed endpoint. The host controller exits this state when the start-split transaction is complete.

The remainder of this section is specific to an isochronous OUT endpoint (that is, the *I/O* field indicates an OUT). When the host controller executes a start-split transaction for an isochronous OUT it includes a data payload in the start-split transaction. The memory

buffer address for the data payload is constructed by concatenating *siTD.Current Offset* with the page pointer indicated by the page selector field (*siTD.P*). A zero in this field selects Page 0 and a 1 selects Page 1. During the start-split for an OUT, if the data transfer crosses a page boundary during the transaction, the host controller must detect the page cross, update the *siTD.P*-bit from a zero to a one, and begin using the *siTD.Page 1* with *siTD.Current Offset* as the memory address pointer. The field *siTD.TP* is used to annotate each start-split transaction with the indication of which part of the split-transaction data the current payload represents (ALL, BEGIN, MID, END). In all cases the host controller simply uses the value in *siTD.TP* to mark the start-split with the correct transaction position code.

T-Count is always initialized to the number of start-splits for the current frame. *TP* is always initialized to the first required transaction position identifier. The scheduling boundary case (see [Figure 11-26](#)) is used to determine the initial value of *TP*. The initial cases are summarized in the following table.

Table 11-47. Initial Conditions for OUT siTD's TP and T-count Fields

Case	T-count	TP	Description
1, 2a	=1	ALL	When the OUT data payload is less than (or equal to) 188 bytes, only one start-split is required to move the data. The one start-split must be marked with an ALL.
1, 2a	!=1	BEGIN	When the OUT data payload is greater than 188 bytes more than one start-split must be used to move the data. The initial start-split must be marked with a BEGIN.

After each start-split transaction is complete, the host controller updates *T-Count* and *TP* appropriately so that the next start-split is correctly annotated.

The table below illustrates all of the *TP* and *T-count* transitions, which must be accomplished by the host controller.

Table 11-48. Transaction Position (TP)/Transaction Count (T-Count) Transition Table

TP	T-count next	TP next	Description
ALL	0	N/A	Transition from ALL, to done.
BEGIN	1	END	Transition from BEGIN to END. Occurs when <i>T-count</i> starts at 2.
BEGIN	!=1	MID	Transition from BEGIN to MID. Occurs when <i>T-count</i> starts at greater than 2.
MID	!=1	MID	<i>TP</i> stays at MID while <i>T-count</i> is not equal to 1 (that is, greater than 1). This case can occur for any of the scheduling boundary cases where the <i>T-count</i> starts greater than 3.
MID	1	END	Transition from MID to END. This case can occur for any of the scheduling boundary cases where the <i>T-count</i> starts greater than 2.

The start-split transactions do not receive a handshake from the transaction translator, so the host controller always advances the transfer state in the siTD after the bus transaction is complete. To advance the transfer state the following operations take place:

- The *siTD.Total Bytes To Transfer* and the *siTD.Current Offset* fields are adjusted to reflect the number of bytes transferred.
- The *siTD.P* (page selector) bit is updated appropriately.
- The *siTD.TP* and *siTD.T-count* fields are updated appropriately as defined in [Table 11-48](#).

These fields are then written back to the memory based siTD. The *S-mask* is fixed for the life of the current budget. As mentioned above, *TP* and *T-count* are set specifically in each siTD to reflect the data to be sent from this siTD. Therefore, regardless of the value of *S-mask*, the actual number of start-split transactions depends on *T-count* (or equivalently, *Total Bytes to Transfer*). The host controller must set the *Active* bit to a zero when it detects that all of the schedule data has been sent to the bus. The preferred method is to detect when *T-Count* decrements to zero as a result of a start-split bus transaction. Equivalently, the host controller can detect when *Total Bytes to Transfer* decrements to zero. Either implementation must ensure that if the initial condition is *Total Bytes to Transfer* equal to zero and *T-count* is equal to a one, then the host controller will issue a single start-split, with a zero-length data payload. Software must ensure that *TP*, *T-count* and *Total Bytes to Transfer* are set to deliver the appropriate number of bus transactions from each siTD. An inconsistent combination will yield undefined behavior.

If the host experiences hold-offs that cause the host controller to skip start-split transactions for an OUT transfer, the state of the transfer will not progress appropriately. The transaction translator will observe protocol violations in the arrival of the start-splits for the OUT endpoint (that is, the transaction position annotation will be incorrect as received by the transaction translator).

Example scenarios are described in [Section Split Transaction for Isochronous - Processing Examples](#).

A host controller implementation can optionally track the progress of an OUT split transaction by setting appropriate bits in the *siTD.C-prog-mask* as it executes each scheduled start-split. The *checkPreviousBit()* algorithm defined in [Periodic Isochronous - Do Complete Split](#) can be used prior to executing each start-split to determine whether start-splits were skipped. The host controller can use this mechanism to detect missed micro-frames. It can then set the siTD's *Active* bit to zero and stop execution of this siTD. This saves on both memory and high-speed bus bandwidth.

11.1.3.3.12.3.5 Periodic Isochronous - Do Complete Split

This state is only used by a split-transaction isochronous IN endpoint.

This state is entered unconditionally from the Do Start State after a start-split transaction is executed for an IN endpoint. Each time the host controller visits an siTD in this state, it conducts a number of tests to determine whether it should execute a complete-split transaction. The individual tests are listed below. The sequence they are applied depends on which micro-frame the host controller is currently executing which means that the tests might not be applied until after the siTD referenced from the back pointer has been fetched.

- Test A. *cMicroFrameBit* is bit-wise anded with *siTD.C-mask* field. A non-zero result indicates that software scheduled a complete-split for this endpoint, during this micro-frame. This test is always applied to a newly fetched siTD that is in this state.
- Test B. The *siTD.C-prog-mask* bit vector is checked to determine whether the previous complete splits have been executed. An example algorithm is below (this is slightly different than the algorithm used in Section [Periodic Isochronous - Do Complete Split](#)). The sequence in which this test is applied depends on the current value of *USB_n_FRINDEX[2:0]*. If *USB_n_FRINDEX[2:0]* is 0 or 1, it is not applied until the back pointer has been used. Otherwise it is applied immediately.

Algorithm Boolean CheckPreviousBit(*siTD.C-prog-mask*, *siTD.C-mask*, *cMicroFrameBit*)

Begin

```

Boolean rvalue = TRUE;
previousBit = cMicroFrameBit rotate-right(1)
-- Bit-wise anding previousBit with C-mask indicates whether there was an intent
-- to send a complete split in the previous micro-frame. So, if the
-- 'previous bit' is set in C-mask, check C-prog-mask to make sure it
-- happened.
if previousBit bitAND siTD.C-mask then
    if not (previousBit bitAND siTD.C-prog-mask) then
        rvalue = FALSE
    End if
End if
Return rvalue

```

End Algorithm

If Test A is true and *USB_n_FRINDEX[2:0]* is zero or one, then this is a case 2a or 2b scheduling boundary (see [Figure 11-25](#)). See Section [Periodic Isochronous - Do Complete Split](#) for details in handling this condition.

If Test A and Test B evaluate to true, then the host controller will execute a complete-split transaction using the transfer state of the current siTD. When the host controller commits to executing the complete-split transaction, it updates *QH.C-prog-mask* by bit-ORing with *cMicroFrameBit*. The transfer state is advanced based on the completion status of the complete-split transaction. To advance the transfer state of an IN siTD, the host controller must:

- Decrement the number of bytes received from *siTD.Total Bytes To Transfer*,
- Adjust *siTD.Current Offset* by the number of bytes received,

- Adjust *siTD.P* (page selector) field if the transfer caused the host controller to use the next page pointer, and
- Set any appropriate bits in the *siTD.Status* field, depending on the results of the transaction.

Note that if the host controller encounters a condition where *siTD.Total Bytes To Transfer* is zero, and it receives more data, the host controller must not write the additional data to memory. The *siTD.Status.Active* bit must be set to zero and the *siTD.Status.Babble Detected* bit must be set to a one. The fields *siTD.Total Bytes To Transfer*, *siTD.Current Offset*, and *siTD.P* (page selector) are not required to be updated as a result of this transaction attempt.

The host controller must accept (assuming good data packet CRC and sufficient room in the buffer as indicated by the value of *siTD.Total Bytes To Transfer*) MDATA and DATA0/1 data payloads up to and including 192 bytes. A host controller implementation may optionally set *siTD.Status Active* to a zero and *siTD.Status.Babble Detected* to a one when it receives MDATA or DATA0/1 with a data payload of more than 192 bytes. The following responses have the noted effects:

- ERR. The full-speed transaction completed with a time-out or bad CRC and this is a reflection of that error to the host. The host controller sets the *ERR* bit in the *siTD.Status* field and sets the *Active* bit to a zero.
- Transaction Error (XactErr). The complete-split transaction encounters a Timeout, CRC16 failure, etc. The *siTD.Status* field *XactErr* field is set to a one and the complete-split transaction must be retried immediately. The host controller must use an internal error counter to count the number of retries as a counter field is not provided in the siTD data structure. The host controller will not retry more than two times. If the host controller exhausts the retries or the end of the micro-frame occurs, the *Active* bit is set to zero.
- DATAx (0 or 1). This response signals that the final data for the split transaction has arrived. The transfer state of the siTD is advanced and the *Active* bit is set to a zero. If the *Bytes To Transfer* field has not decremented to zero (including the reception of the data payload in the DATAx response), then less data than was expected, or allowed for was actually received. This *short packet* event does not set the USBINT status bit in the USBSTS register to a one. The host controller will not detect this condition.
- NYET (and Last). On each NYET response, the host controller also checks to determine whether this is the last complete-split for this split transaction. Last was defined in Section [Periodic Isochronous - Do Complete Split](#) . If it is the last complete-split (with a NYET response), then the transfer state of the siTD is not advanced (never received any data) and the *Active* bit is set to a zero. No bits are set in the *Status* field because this is essentially a skipped transaction. The transaction translator must have responded to all the scheduled complete-splits with NYETs,

meaning that the start-split issued by the host controller was not received. This result should be interpreted by system software as if the transaction was completely skipped. The test for whether this is the last complete split can be performed by XORing C-mask with C-prog-mask. A zero result indicates that all complete-splits have been executed.

- **MDATA (and Last).** See above description for testing for Last. This can only occur when there is an error condition. Either there has been a babble condition on the full-speed link, which delayed the completion of the full-speed transaction, or software set up the *S-mask* and/or *C-masks* incorrectly. The host controller must set *XactErr* bit to a one and the *Active* bit is set to a zero.
- **NYET (and not Last).** See above description for testing for Last. The complete-split transaction received a NYET response from the transaction translator. Do not update any transfer state (except for *C-prog-mask*) and stay in this state.
- **MDATA (and not Last).** The transaction translator responds with an MDATA when it has partial data for the split transaction. For example, the full-speed transaction data payload spans from micro-frame X to X+1 and during micro-frame X, the transaction translator will respond with an MDATA and the data accumulated up to the end of micro-frame X. The host controller advances the transfer state to reflect the number of bytes received.

If Test A succeeds, but Test B fails, it means that one or more of the complete-splits have been skipped. The host controller sets the *Missed Micro-Frame* status bit and sets the *Active* bit to a zero.

11.1.3.3.12.3.6 Complete-Split for Scheduling Boundary Cases 2a, 2b

Boundary cases 2a and 2b (INs only) (see [Figure 11-25](#)) require that the host controller use the transaction state context of the previous siTD to finish the split transaction. The table below enumerates the transaction state fields.

Table 11-49. Summary siTD Split Transaction State

Buffer State	Status	Execution Progress
Total Bytes To Transfer	All bits in the status field	C-prog-mask
P (page select)		
Current Offset		
TP (transaction position)		
T-count (transaction count)		

NOTE

TP and *T-count* are used only for Host to Device (OUT) endpoints.

If software has budgeted the schedule of this data stream with a frame wrap case, then it must initialize the *siTD.Back Pointer* field to reference a valid siTD and will have the *siTD.Back Pointer.T-bit* in the *siTD.Back Pointer*

field set to a zero. Otherwise, software must set the *siTD.Back Pointer.T-bit* in the *siTD.Back Pointer* field to a one. The host controller's rules for interpreting when to use the *siTD.Back Pointer* field are listed below. These rules apply only when the siTD's *Active* bit is a one and the *SplitXState* is Do Complete Split.

- When *cMicroFrameBit* is a 1h and the *siTDX.Back Pointer.T-bit* is a zero, or
- If *cMicroFrameBit* is a 2h and *siTDX.S-mask[0]* is a zero

When either of these conditions apply, then the host controller must use the transaction state from *siTD_{X-1}*.

In order to access *siTD_{X-1}*, the host controller reads on-chip the siTD referenced from *siTD_X.Back Pointer*.

The host controller must save the entire state from *siTD_X* while processing *siTD_{X-1}*. This is to accommodate for case 2b processing. The host controller must not recursively walk the list of *siTD.Back Pointers*.

If *siTD_{X-1}* is active (*Active* bit is a one and *SplitXStat* is Do Complete Split), then both Test A and Test B are applied as described above. If these criteria to execute a complete-split are met, the host controller executes the complete split and evaluates the results as described above. The transaction state (see [Table 11-49](#)) of *siTD_{X-1}* is appropriately advanced based on the results and written back to memory. If the resultant state of *siTD_{X-1}*'s *Active* bit is a one, then the host controller returns to the context of *siTD_X*, and follows its next pointer to the next schedule item. No updates to *siTD_X* are necessary.

If *siTD_{X-1}* is active (*Active* bit is a one and *SplitXStat* is Do Start Split), then the host controller must set *Active* bit to a zero and *Missed Micro-Frame* status bit to a one and the resultant status written back to memory.

If *siTD_{X-1}*'s *Active* bit is a zero, (because it was zero when the host controller first visited *siTD_{X-1}* via *siTD_X*'s back pointer, it transitioned to zero as a result of a detected error, or the results of *siTD_{X-1}*'s complete-split transaction transitioned it to zero), then the host controller returns to the context of *siTD_X* and transitions its *SplitXState* to Do Start Split. The host controller then determines whether the case 2b start split boundary condition exists (that is, if *cMicroframeBit* is a 1b and *siTD_X.S-mask[0]* is a 1b). If this criterion is met the host controller immediately executes a start-split transaction and appropriately advances the transaction state of *siTD_X*, then follows *siTD_X.Next Pointer* to the next schedule item. If the criterion is not met, the host controller simply follows *siTD_X.Next Pointer* to the next schedule item. Note that in the case of a 2b boundary case, the split-transaction of *siTD_{X-1}* will have its *Active* bit set to zero when the host controller returns

to the context of $siTD_X$. Also, note that software should not initialize an siTD with *C-mask* bits 0 and 1 set to a one and an *S-mask* with bit zero set to a one. This scheduling combination is not supported and the behavior of the host controller is undefined.

11.1.3.3.12.3.7 Split Transaction for Isochronous - Processing Examples

There is an important difference between how the hardware/software manages the isochronous split transaction state machine and how it manages the asynchronous and interrupt split transaction state machines.

The asynchronous and interrupt split transaction state machines are encapsulated within a single queue head. The progress of the data stream depends on the progress of each split transaction. In some respects, the split-transaction state machine is sequenced via the Execute Transaction queue head traversal state machine (see [Figure 11-18](#)).

Isochronous is a pure time-oriented transaction/data stream. The interface data structures are optimized to efficiently describe transactions that need to occur at specific times. The isochronous split-transaction state machine must be managed across these time-oriented data structures. This means that system software must correctly describe the scheduling of split-transactions across more than one data structure.

Then the host controller must make the appropriate state transitions at the appropriate times, in the correct data structures.

For example, the table below illustrates a couple of frames worth of scheduling required to schedule a case 2a full-speed isochronous data stream.

Table 11-50. Example Case 2a - Software Scheduling siTDs for an IN Endpoint

siTDX		Micro-Frames								Initial
#	Masks	0	1	2	3	4	5	6	7	SplitXState
X	S-Mask	-	-	-	-	1	-	-	-	Do Start Split
	C-Mask	1	1	-	-	-	-	1	1	
X+1	S-Mask	-	-	-	-	1	-	-	-	Do Complete Split
	C-Mask	1	1					1	1	
X+2	S-Mask	-	-	-	-	1	-	-	-	Do Complete Split
	C-Mask	1	1					1	1	
X+3	S-Mask	Repeats previous pattern								Do Complete Split
	C-Mask									

This example shows the first three siTDs for the transaction stream. Because this is the case-2a frame-wrap case, *S-masks* of all siTDs for this endpoint have a value of 10h (a one bit in micro-frame 4) and *C-mask* value of C3h (one-bits in micro-frames 0,1, 6 and 7). Additionally, software ensures that the *Back Pointer* field of each siTD references the appropriate siTD data structure (and the *Back PointerT-bits* are set to zero).

The initial *SplitXState* of the first siTD is Do Start Split. The host controller will visit the first siTD eight times during frame X. The C-mask bits in micro-frames 0 and 1 are ignored because the state is Do Start Split. During micro-frame 4, the host controller determines that it can run a start-split (and does) and changes *SplitXState* to Do Complete Split. During micro-frames 6 and 7, the host controller executes complete-splits. Notice the siTD for frame X+1 has its *SplitXState* initialized to Do Complete Split. As the host controller continues to traverse the schedule during *H-Frame* X+1, it will visit the second siTD eight times. During micro-frames 0 and 1 it will detect that it must execute complete-splits.

During *H-Frame* X+1, micro-frame 0, the host controller detects that siTD_{X+1}'s *Back Pointer.T-bit* is a zero, saves the state of siTD_{X+1} and fetches siTD_X. It executes the complete split transaction using the transaction state of siTD_X. If the siTD_X split transaction is complete, siTD's *Active* bit is set to zero and results written back to siTD_X. The host controller retains the fact that siTD_X is retired and transitions the *SplitXState* in the siTD_{X+1} to Do Start Split. At this point, the host controller is prepared to execute the start-split for siTD_{X+1} when it reaches micro-frame 4. If the split-transaction completes early (transaction-complete is defined in Section [Periodic Isochronous - Do Complete Split](#)), that is, before all the scheduled complete-splits have been executed, the host controller will transition siTD_X.*SplitXState* to Do Start Split early and naturally skip the remaining scheduled complete-split transactions. For this example, siTD_{X+1} does not receive a DATA0 response until *H-Frame* X+2, micro-frame 1.

During *H-Frame* X+2, micro-frame 0, the host controller detects that siTD_{X+2}'s *Back Pointer.T-bit* is a zero, saves the state of siTD_{X+2} and fetches siTD_{X+1}. As described above, it executes another split transaction, receives an MDATA response, updates the transfer state, but does not modify the *Active* bit. The host controller returns to the context of siTD_{X+2}, and traverses its next pointer without any state change updates to siTD_{X+2}. S

During *H-Frame* X+2, micro-frame 1, the host controller detects siTD_{X+2}'s *S-mask[0]* is a zero, saves the state of siTD_{X+2} and fetches siTD_{X+1}. It executes another complete-split transaction, receives a DATA0 response, updates the transfer state and sets the *Active* bit to a zero. It returns to the state of siTD_{X+2} and changes its *SplitXState* to Do Start Split. At this point, the host controller is prepared to execute start-splits for siTD_{X+2} when it reaches micro-frame 4.

11.1.3.3.13 Host Controller Pause

When the host controller's *HCHalted* bit in the USBSTS register is a zero, the host controller is sending SOF (Start OF Frame) packets down all enabled ports.

When the schedules are enabled, the EHCI host controller will access the schedules in main memory each micro-frame. This constant pinging of main memory is known to create Arm platform power management problems for mobile systems. Specifically, mobile systems aggressively manage the state of the Arm platform, based on recent history usage. In the more aggressive power saving modes, the Arm platform can disable its caches. Current PC architectures assume that bus-master accesses to main memory must be cache-coherent. So, when bus masters are busy touching memory, the Arm platform power management software can detect this activity over time and inhibit the transition of the Arm platform into its lowest power savings mode. USB controllers are bus-masters and the frequency at which they access their memory-based schedules keeps the Arm platform power management software from placing the Arm platform into its lowest power savings state.

USB Host controllers don't access main memory when they are suspended. However, there are a variety of reasons why placing the USB controllers into suspend won't work, but they are beyond the scope of this document. The base requirement is that the USB controller needs to be kept out of main memory, while at the same time, the USB bus is kept from going into suspend.

EHCI controllers provide a large-grained mechanism that can be manipulated by system software to change the memory access pattern of the host controller. System software can manipulate the schedule enable bits in the USBCMD register to turn on/off the scheduling traversal. A software heuristic can be applied to implement an on/off duty cycle that allows the USB to make reasonable progress and allow the Arm platform power management to get the Arm platform into its lowest power state. This method is not intended to be applied at all times to throttle USB, but should only be applied in very specific configurations and usage loads. For example, when only a keyboard or mouse is attached to the USB, the heuristic could detect times when the USB is attempting to move data only very infrequently and can adjust the duty cycle to allow the Arm platform to reach its low power state for longer periods of time. Similarly, it could detect increases in the USB load and adjust the duty cycle appropriately, even to the point where the schedules are never disabled. The assumption here is that the USB is moving data and the Arm platform will be required to process the data streams.

It is suggested that in order to provide a complete solution for the system, the companion host controllers should also provide a similar method to allow system software to inhibit the companion host controller from accessing its shared memory based data structures (schedule lists or otherwise).

11.1.3.3.14 Port Test Modes -Host Operational Model

EHCI host controllers must implement the port test modes Test J_State, Test K_State, Test_Packet, Test Force_Enable, and Test SE0_NAK as described in the USB Specification Revision 2.0.

The system is only allowed to test ports that are owned by the EHCI controller (for example, *CF-bit* is a one and *PortOwner* bit is a zero). System software is allowed to have at most one port in test mode at a time. Placing more than one port in test mode will yield undefined results. The required, per port test sequence is (assuming the *CF-bit* in the USB_n_CONFIGFLAG register is a one):

- Disable the periodic and asynchronous schedules by setting the *Asynchronous Schedule Enable* and *Periodic Schedule Enable* bits in the USBCMD register to a zero.
- Place all enabled root ports into the suspended state by setting the *Suspend* bit in each appropriate USB_n_PORTSC register to a one.
- Set the *Run/Stop* bit in the USBCMD register to a zero and wait for the *HCHalted* bit in the USBSTS register, to transition to a one. Note that an EHCI host controller implementation may optionally allow port testing with the *Run/Stop* bit set to a one. However, all host controllers must support port testing with *Run/Stop* set to a zero and *HCHalted* set to a one.
- Set the *Port Test Control* field in the port under test PORTSC register to the value corresponding to the desired test mode. If the selected test is Test_Force_Enable, then the *Run/Stop* bit in the USBCMD register must then be transitioned back to one, in order to enable transmission of SOFs out of the port under test.
- When the test is complete, system software must ensure the host controller is halted (*HCHalted* bit is a one) then it terminates and exits test mode by setting *HCRreset* to a one.

11.1.3.3.15 Interrupts-Host Operational Model

The EHCI Host Controller hardware provides interrupt capability based on a number of sources.

There are several general groups of interrupt sources:

- Interrupts as a result of executing transactions from the schedule (success and error conditions),
- Host controller events (Port change events, etc.), and
- Host Controller error events

All transaction-based sources are maskable through the Host Controller's Interrupt Enable register (USBINTR, see Section). Additionally, individual transfer descriptors can be marked to generate an interrupt on completion. This section describes each interrupt source and the processing that occurs in response to the interrupt.

During normal operation, interrupts may be immediate or deferred until the next interrupt threshold occurs. The interrupt threshold is a tunable parameter via the *Interrupt Threshold Control* field in the USBCMD register. The value of this register controls when the host controller will generate an interrupt on behalf of normal transaction execution. When a transaction completes during an interrupt interval period, the interrupt signaling the completion of the transfer will not occur until the interrupt threshold occurs. For example, the default value is eight micro-frames. This means that the host controller will not generate interrupts any more frequently than once every eight micro-frames.

Section [Host System Error](#) details effects of a host system error.

If an interrupt has been scheduled to be generated for the current interrupt threshold interval, the interrupt is not signaled until after the status for the last complete transaction in the interval has been written back to host memory. This may sometimes result in the interrupt not being signaled until the next interrupt threshold.

Initial interrupt processing is the same, regardless of the reason for the interrupt. When an interrupt is signaled by the hardware, Arm platform control is transferred to host controller's USB interrupt handler. The precise mechanism to accomplish the transfer is OS specific. For this discussion it is just assumed that control is received. When the interrupt handler receives control, its first action is to read the USBSTS (USB Status Register). It then acknowledges the interrupt by clearing all of the interrupt status bits by writing ones to these bit positions. The handler then determines whether the interrupt is due to schedule processing or some other event. After acknowledging the interrupt, the handler (via an OS-specific mechanism), schedules a deferred procedure call (DPC) which will execute later. The DPC routine processes the results of the schedule execution. The precise mechanisms used are beyond the scope of this document.

Note: the host controller is not required to de-assert a currently active interrupt condition when software sets the interrupt enables (in the USBINTR register, see Section) to a zero. The only reliable method software should use for acknowledging an interrupt is by transitioning the appropriate status bits in the USBSTS register (Section) from a one to a zero.

11.1.3.3.15.1 Transfer/Transaction Based Interrupts

These interrupt sources are associated with transfer and transaction progress. They are all dependent on the next interrupt threshold.

11.1.3.3.15.1.1 Transaction Error

A transaction error is any error that caused the host controller to think that the transfer did not complete successfully.

The table below lists the events/responses that the host can observe as a result of a transaction. The effects of the error counter and interrupt status are summarized in the following paragraphs. Most of these errors set the *XactErr* status bit in the appropriate interface data structure.

There is a small set of protocol errors that relate only when executing a queue head and fit under the umbrella of a WRONG PID error that are significant to explicitly identify. When these errors occur, the *XactErr* status bit in the queue head is set and the *CErr* field is decremented. When the *PIDCode* indicates a SETUP, the following responses are protocol errors and result in *XactErr* bit being set to a one and the *CErr* field being decremented.

- *EPS* field indicates a high-speed device and it returns a Nak handshake to a SETUP.
- *EPS* field indicates a high-speed device and it returns a Nyet handshake to a SETUP.
- *EPS* field indicates a low- or full-speed device and the complete-split receives a Nak handshake.

Table 11-51. Summary of Transaction Errors

Event / Result	Queue Head/qTD/iTD/siTD Side-effects		USB Status Register (USBSTS)
	Cerr	Status Field	USBERRINT
CRC	-1	XactErr set to a one.	1 ¹
Timeout	-1	XactErr set to a one.	1 ¹
Bad PID ²	-1	XactErr set to a one.	1 ¹
Babble	N/A	Section Serial Bus Babble	1
Buffer Error	N/A	Section Data Buffer Error	

1. If occurs in a queue head, then *USBERRINT* is asserted only when *CErr* counts down from a one to a zero. In addition the queue is halted, see [Halting a Queue Head](#).
2. The host controller received a response from the device, but it could not recognize the PID as a valid PID.

11.1.3.3.15.1.2 Serial Bus Babble

When a device transmits more data on the USB than the host controller is expecting for this transaction, it is defined to be babbling. In general, this is called a *Packet Babble*.

When a device sends more data than the *Maximum Length* number of bytes, the host controller sets the *Babble Detected* bit to a one and halts the endpoint if it is using a queue head (see [Halting a Queue Head](#)). *Maximum Length* is defined as the minimum of *Total Bytes to Transfer* and *Maximum Packet Size*. The *CErr* field is not decremented for

a packet babble condition (only applies to queue heads). A babble condition also exists if IN transaction is in progress at High-speed EOF2 point. This is called a frame babble. A frame babble condition is recorded into the appropriate schedule data structure. In addition, the host controller must disable the port to which the frame babble is detected.

The *USBERRINT* bit in the USB_n_USBSTS register is set to a one and if the *USB Error Interrupt Enable* bit in the USB_n_USBINTR register is a one, then a hardware interrupt is signaled to the system at the next interrupt threshold. The host controller must never start an OUT transaction that will babble across a micro-frame EOF.

NOTE

When a host controller detects a data PID mismatch, it must either: disable the packet babble checking for the duration of the bus transaction or do packet babble checking based solely on *Maximum Packet Size*. The USB core specification defines the requirements on a data receiver when it receives a data PID mismatch (for example, expects a DATA0 and gets a DATA1 or visa-versa). In summary, it must ignore the received data and respond with an ACK handshake, in order to advance the transmitter's data sequence.

The EHCI interface allows System software to provide buffers for a Control, Bulk or Interrupt IN endpoint that are not an even multiple of the maximum packet size specified by the device. Whenever a device misses an ACK for an IN endpoint, the host and device are out of synchronization with respect to the progress of the data transfer. The host controller may have advanced the transfer to a buffer that is less than maximum packet size. The device will re-send its maximum packet size data packet, with the original data PID, in response to the next IN token. In order to properly manage the bus protocol, the host controller must disable the packet babble check when it observes the data PID mismatch.

11.1.3.3.15.1.3 Data Buffer Error

This event indicates that an overrun of incoming data or a underrun of outgoing data has occurred for this transaction.

This would generally be caused by the host controller not being able to access required data buffers in memory within necessary latency requirements. These conditions are not considered transaction errors, and do not effect the error count in the queue head. When these errors do occur, the host controller records the fact the error occurred by setting the *Data Buffer Error* bit in the queue head, iTD or siTD.

If the data buffer error occurs on a non-isochronous IN, the host controller will not issue a handshake to the endpoint. This will force the endpoint to resend the same data (and data toggle) in response to the next IN to the endpoint.

If the data buffer error occurs on an OUT, the host controller must corrupt the end of the packet so that it cannot be interpreted by the device as a good data packet. Simply truncating the packet is not considered acceptable. An acceptable implementation option is to 1's complement the CRC bytes and send them. There are other options suggested in the Transaction Translator section of the USB Specification Revision 2.0.

11.1.3.3.15.1.4 *USB Interrupt (Interrupt on Completion (IOC))*

Transfer Descriptors (iTDs, siTDs, and queue heads (qTDs)) contain a bit that can be set to cause an interrupt on their completion. The completion of the transfer associated with that schedule item causes the USB Interrupt (USBINT) bit in the USB_n_USBSTS register to be set to a one.

In addition, if a short packet is encountered on an IN transaction associated with a queue head, then this event also causes USBINT to be set to a one. If the USB Interrupt Enable bit in the USB_n_USBINTR register is set to a one, a hardware interrupt is signaled to the system at the next interrupt threshold. If the completion is because of errors, the *USBERRINT* bit in the USB_n_USBSTS register is also set to a one.

11.1.3.3.15.1.5 *Short Packet*

Reception of a data packet that is less than the endpoint's Max Packet size during Control, Bulk or Interrupt transfers signals the completion of the transfer. Whenever a short packet completion occurs during a queue head execution, the *USBINT* bit in the USB_n_USBSTS register is set to a one.

If the *USB Interrupt Enable* bit is set in the USB_n_USBINTR register, a hardware interrupt is signaled to the system at the next interrupt threshold.

11.1.3.3.15.2 **Host Controller Event Interrupts**

These interrupt sources are independent of the interrupt threshold (with the one exception being the Interrupt on Async Advance, see Section [Interrupt on Async Advance](#)).

11.1.3.3.15.2.1 *Port Change Events*

Port registers contain status and status change bits. When the status change bits are set to a one, the host controller sets the *Port Change Detect* bit in the USBSTS register to a one.

If the *Port Change Interrupt Enable* bit in the USB_n_USBINTR register is a one, then the host controller will issue a hardware interrupt. The port status change bits include:

- Connect Status Change
- Port Enable/Disable Change
- Over-current Change
- Force Port Resume

11.1.3.3.15.2.2 *Frame List Rollover*

This event indicates that the host controller has wrapped the frame list. The current programmed size of the frame list effects how often this interrupt occurs.

If the frame list size is 1024, then the interrupt will occur every 1024 milliseconds, if it is 512, then it will occur every 512 milliseconds, etc. When a frame list rollover is detected, the host controller sets the *Frame List Rollover* bit in the USB.USBSTS register to a one. If the *Frame List Rollover Enable* bit in the USB.USBINTR register is set to a one, the host controller issues a hardware interrupt. This interrupt is not delayed to the next interrupt threshold.

11.1.3.3.15.2.3 *Interrupt on Async Advance*

This event is used for deterministic removal of queue heads from the asynchronous schedule. Whenever the host controller advances the on-chip context of the asynchronous schedule, it evaluates the value of the *Interrupt on Async Advance Doorbell* bit in the USB.USBCMD register.

If it is a one, it sets the *Interrupt on Async Advance* bit in the USB.USBSTS register to a one. If the *Interrupt on Async Advance Enable* bit in the USB.USBINTR register is a one, the host controller issues a hardware interrupt at the next interrupt threshold. A detailed explanation of this feature is described in Section [Removing Queue Heads from Asynchronous Schedule](#).

11.1.3.3.15.2.4 *Host System Error*

The host controller is a bus master and any interaction between the host controller and the system may experience errors.

The type of host error may be catastrophic to the host controller (such as a Master Abort) making it impossible for the host controller to continue in a coherent fashion. In the presence of non-catastrophic host errors, such as parity errors, the host controller could potentially continue operation. The recommended behavior for these types of errors is to escalate it to a catastrophic error and halt the host controller. Host-based error must result in the following actions:

- The *Run/Stop* bit in the USB.USBCMD register is set to a zero.
- The following bits in the USB.USBSTS register are set:
 - *Host System Error* bit is to a one.
 - *HCHalted* bit is set to a one.
- If the *Host System Error Enable* bit in the USB.USBINTR register is a one, then the host controller will issue a hardware interrupt. This interrupt is not delayed to the next interrupt threshold. The following table summarizes the required actions taken on the various host errors.

Table 11-52. Summary Behavior of EHCI Host Controller on Host System Errors

Cycle Type	Master Abort	Target Abort	Data Phase Parity
Frame list pointer fetch (read)	Fatal	Fatal	Fatal [o]
siTD fetch (read)	Fatal	Fatal	Fatal [o]
siTD status write-back (write)	Fatal [o]	Fatal [o]	Fatal [o]
iTD fetch (read)	Fatal	Fatal	Fatal [o]
iTD status write-back (write)	Fatal [o]	Fatal [o]	Fatal [o]
qTD fetch (read)	Fatal	Fatal	Fatal [o]
qHD status write-back (write)	Fatal [o]	Fatal [o]	Fatal [o]
Data write	Fatal [o]	Fatal [o]	Fatal [o]
Data read	Fatal	Fatal	Fatal [o]

Potentially, a host controller implementation could continue operation without a halt. However, the recommended behavior is to halt the host controller.

NOTE

After a *Host System Error*, Software must reset the host controller through *HCRreset* in the USB.USBCMD register before re-initializing and restarting the host controller.

11.1.3.4 EHCI Deviation

For the purposes a dual-role Host/Device controller with support for On-The-Go applications, it is necessary to deviate from the EHCI specification. Enhanced Host Controller Interface Specification for Universal Serial Bus, Revision 0.95, November 2000, Intel Corporation. <http://www.intel.com>. Device operation & On-The-Go operation is not specified in the EHCI and thus the implementation supported in this core is proprietary.

The host mode operation of the core is near EHCI compatible with few minor differences documented in this section.

The particulars of the deviations occur in the areas summarized here:

- Embedded Transaction Translator - Allows direct attachment of FS and LS devices in host mode without the need for a companion controller.
- Device operation - In host mode the device operational registers are generally disabled and thus device mode is mostly transparent when in host mode. However, there are a couple exceptions documented in the following sections.
- Embedded design interface - This core does not have a PCI Interface and therefore the PCI configuration registers described in the EHCI specification are not applicable.
- On-The-Go Operation - This design includes an On-The-Go controller for Port #1.

11.1.3.4.1 Embedded Transaction Translator Function

The OTG controller supports directly connected full and low speed devices without requiring a companion controller by including the capabilities of a USB 2.0 high speed hub transaction translator.

Although there is no separate Transaction Translator block in the system, the transaction translator function normally associated with a high speed hub has been implemented within the DMA and Protocol engine blocks. The embedded transaction translator function is an extension to EHCI interface, but makes use of the standard data structures and operational models that exist in the EHCI specification to support full and low speed devices.

11.1.3.4.1.1 Capability Registers

The following additions have been added to the capability registers to support the embedded Transaction Translator Function:

- N_TT added to USB.HCSPARAMS - Host Control Structural Parameters
- N_PTT added to USB.HCSPARAMS - Host Control Structural Parameters

11.1.3.4.1.2 Operational Registers

The following additions have been added to the operational registers to support the embedded TT:

- Addition of two-bit Port Speed (PSPD) to the register.

11.1.3.4.1.3 Discovery-EHCI Deviation

In a standard EHCI controller design, the EHCI host controller driver detects a Full speed (FS) or Low speed (LS) device by noting if the port enable bit is set after the port reset operation.

The port enable will only be set in a standard EHCI controller implementation after the port reset operation and when the host and device negotiate a High-Speed connection (that is, Chirp completes successfully).

Because this controller has an embedded Transaction Translator, the port enable will always be set after the port reset operation regardless of the result of the host device chirp result and the resulting port speed will be indicated by the PSPD field in USB.PORTSCx.

Therefore, the standard EHCI host controller driver requires an alteration to handle directly connected Full and Low speed devices or hubs.

The change is a fundamental one in that is summarized in the following table.

Table 11-53. Summary of EHCI

Standard EHCI	EHCI with embedded Transaction Translator
After port enable bit is set following a connection and reset sequence, the device/hub is assumed to be HS.	After port enable bit is set following a connection and reset sequence, the device/hub speed is noted from USB.PORTSCx.
FS and LS devices are assumed to be downstream from a HS hub thus, all port-level control is performed through the Hub Class to the nearest Hub.	FS and LS device can be either downstream from a HS hub or directly attached. When the FS/LS device is downstream from a HS hub, then port-level control is done using the Hub Class through the nearest Hub. When a FS/LS device is directly attached, then port-level control is accomplished using USB.PORTSCx.
FS and LS devices are assumed to be downstream from a HS hub with HubAddr=X. [where HubAddr > 0 and HubAddr is the address of the Hub where the bus transitions from HS to FS/LS (ie. Split target hub)]	FS and LS device can be either downstream from a HS hub with HubAddr = X [HubAddr > 0] or directly attached [where HubAddr = 0 and HubAddr is the address of the Root Hub where the bus transitions from HS to FS/LS (ie. Split target hub is the root hub)]

11.1.3.4.1.4 Data Structures

The same data structures used for FS/LS transactions though a HS hub are also used for transactions through the Root Hub with sm embedded Transaction Translator.

Here it is demonstrated how the Hub Address and Endpoint Speed fields should be set for directly attached FS/LS devices and hubs:

1. QH (for direct attach FS/LS) - Async. (Bulk/Control Endpoints) Periodic (Interrupt)
 - Hub Address = 0
 - Transactions to direct attached device/hub.
 - QH.EPS = Port Speed
 - Transactions to a device downstream from direct attached FS hub.

- QH.EPS = Downstream Device Speed

NOTE

When QH.EPS = 01 (LS) and PORTSCx.PSPD = 00 (FS), a LS-pre-pid will be sent before the transmitting LS traffic.

Maximum Packet Size must be less than or equal 64 or undefined behaviour may result.

2. siTD (for direct attach FS) - Periodic (ISO Endpoint)

- All FS ISO transactions:
 - Hub Address = 0
 - siTD.EPS = 00 (full speed)
 - Maximum Packet Size must less than or equal to 1023 or undefined behaviour may result.

11.1.3.4.1.5 Operational Model

The operational models are well defined for the behavior of the Transaction Translator (see USB 2.0 specification. Universal Serial Bus Specification, Revision 2.0, April 2000, Compaq, Hewlett-Packard, Intel, Lucent, Microsoft, NEC, Philips. <http://www.usb.org>) and for the EHCI controller moving packets between system memory and a USB-HS hub. Because the embedded Transaction Translator exists within the host controller there is no physical bus between EHCI host controller driver and the USB FS/LS bus. These sections will briefly discuss the operational model for how the EHCI and Transaction Translator operational models are combined without the physical bus between. The following sections assume the reader is familiar with both the EHCI and USB 2.0 Transaction Translator operational models.

11.1.3.4.1.5.1 Micro-frame Pipeline

The EHCI operational model uses the concept of H-frames and B-frames to describe the pipeline between the Host (H) and the Bus (B). The embedded Transaction Translator shall use the same pipeline algorithms specified in the USB 2.0 specification for a Hub-based Transaction Translator.

All periodic transfers always begin at B-frame 0 (after SOF) and continue until the stored periodic transfers are complete. As an example of the micro-frame pipeline implemented in the embedded Transaction Translator, all periodic transfers that are tagged in EHCI to execute in H-frame 0 will be ready to execute on the bus in B-frame 0.

It is important to note that when programming the S-mask and C-masks in the EHCI data structures to schedule periodic transfers for the embedded Transaction Translator, the EHCI host controller driver must follow the same rules specified in EHCI for programming the S-mask and C-mask for downstream Hub-based Transaction Translators.

Once periodic transfers are exhausted, any stored asynchronous transfer will be moved. Asynchronous transfers are opportunistic in that they shall execute whenever possible and their operation is not tied to H-frame and B-frame boundaries with the exception that an asynchronous transfer can not babble through the SOF (start of B-frame 0.)

11.1.3.4.1.5.2 Split State Machines

The start and complete split operational model differs from EHCI slightly because there is no bus medium between the EHCI controller and the embedded Transaction Translator.

Where a start or complete-split operation would occur by requesting the split to the HS hub, the start/complete split operation is simple an internal operation to the embedded Transaction Translator. The following table summarizes the conditions where handshakes are emulated from internal state instead of actual handshakes to HS split bus traffic.

Table 11-54. Summary of the Conditions of Handshakes¹

Condition	Emulate TT Response
Start-Split: All asynchronous buffers full.	NAK
Start-Split: All periodic buffers full.	ERR
Start-Split: Success for start of Async. Transaction.	ACK
Start-Split: Start Periodic Transaction.	No Handshake (Ok)
Complete-Split: Failed to find transaction in queue.	Bus Time Out
Complete-Split: Transaction in Queue is Busy.	NYET
Complete-Split: Transaction in Queue is Complete.	[Actual Handshake from LS/FS device]

1. The un-shaded cells represent Start-Splits and the shaded cells represent Complete-Splits

11.1.3.4.1.5.3 Asynchronous Transaction Scheduling and Buffer Management

The following USB 2.0 specification items are implemented in the embedded Transaction Translator:

- Sequencing is provided & a packet length estimator ensures no full-speed/low-speed packet babbles into SOF time.
- Transaction tracking for 2 data pipes.

11.1.3.4.1.5.3.1 USB 2.0 - 11.17.3

- Sequencing is provided & a packet length estimator ensures no full-speed/low-speed packet babbles into SOF time.

11.1.3.4.1.5.3.2 USB 2.0 - 11.17.4

- Transaction tracking for 2 data pipes.

11.1.3.4.1.5.4 Periodic Transaction Scheduling and Buffer Management

The following USB 2.0 specification items are implemented in the embedded Transaction Translator:

- Abort of pending start-splits
 - EOF (and not started in micro-frames 6)
 - Idle for more than 4 micro-frames
- Abort of pending complete-splits
 - EOF
 - Idle for more than 4 micro-frames
- Transaction tracking for up to 16 data pipes.
- Complete-split transaction searching.

NOTE

There is no data schedule mechanism for these transactions other than the micro-frame pipeline. The embedded TT assumes the number of packets scheduled in a frame does not exceed the frame duration (1 ms) or else undefined behavior may result.

11.1.3.4.1.5.4.1 USB 2.0 - 11.18.6.[1-2]

- Abort of pending start-splits
 - EOF (and not started in micro-frames 6)
 - Idle for more than 4 micro-frames
- Abort of pending complete-splits
 - EOF
 - Idle for more than 4 micro-frames

11.1.3.4.1.5.4.2 USB 2.0 - 11.18.[7-8]

- Transaction tracking for up to 16 data pipes.
- Complete-split transaction searching.

NOTE

There is no data schedule mechanism for these transactions other than the micro-frame pipeline. The embedded TT assumes

the number of packets scheduled in a frame does not exceed the frame duration (1 ms) or else undefined behavior may result.

11.1.3.4.1.5.5 *Multiple Transaction Translators*

The maximum number of embedded Transaction Translators that is currently supported is one as indicated by the N_TT field in the register.

11.1.3.4.2 **Device Operation**

The co-existence of a device operational controller within the host controller has little effect on EHCI compatibility for host operation except as noted in this section.

11.1.3.4.2.1 **USB_USBMODE Register**

Given that the dual-role controller is initialized in neither host nor device mode, the [USB Device Mode \(USB_nUSBMODE\)](#) register must be programmed for host operation before the EHCI host controller driver can begin EHCI host operations.

11.1.3.4.2.2 **Non-Zero Fields the Register File**

Some of the reserved fields and reserved addresses in the capability registers and operational register have use in device mode, the following must be adhered to:

- Write operations to all EHCI reserved fields (some of which are device fields) with the operation registers should always be written to zero. This is an EHCI requirement of the device controller driver that must be adhered to.
- Read operations by the host controller must properly mask EHCI reserved fields (some of which are device fields) because fields that are used exclusive for device are undefined in host mode .

11.1.3.4.2.3 **SOF Interrupt**

This SOF Interrupt used for device mode is shared as a free running 125us interrupt for host mode.

EHCI does not specify this interrupt but it has been added for convenience and as a potential software time base. See [USB Status Register \(USB_nUSBSTS\)](#) and [Interrupt Enable Register \(USB_nUSBINTR\)](#) registers.

11.1.3.4.3 Embedded Design Interface

This is an Embedded USB Host Controller as defined by the EHCI specification and thus does not implement the PCI configuration registers.

11.1.3.4.3.1 Frame Adjust Register

Given that the optional PCI configuration registers are not included in this implementation, there is no corresponding bit level timing adjustments like is provided by the Frame Adjust register in the PCI configuration registers. Starts of micro-frames are timed precisely to 125 us using the transceiver clock as a reference clock. That is, a 60 Mhz transceiver clock for 8-bit physical interfaces & full-speed serial interfaces or 30 Mhz transceiver clock for 16-bit physical interfaces.

11.1.3.4.4 Miscellaneous variations from EHCI

11.1.3.4.4.1 Programmable Physical Interface Behaviour

This design supports multiple Physical interfaces which can operate in differing modes when the core is configured with software programmable Physical Interface Modes. Software programmability allows the selection of the Physical interface part during the board design phase instead of during the chip design phase. The control bits for selecting the Physical Interface operating mode have been added to the [Port Status & Control \(USB_nPORTSC1\)](#) register providing a capability that is not defined by EHCI.

11.1.3.4.4.2 Discovery

11.1.3.4.4.2.1 Port Reset

The port connect methods specified by EHCI require setting the port reset bit in the [Port Status & Control \(USB_nPORTSC1\)](#) register for a duration of 10ms. Due to the complexity required to support the attachment of devices that are not high speed there are counter already present in the design that can count the 10ms reset pulse to alleviate the requirement of the software to measure this duration. Therefore, the basic connection is then summarized as the following:

- [Port Change Interrupt] Port connect change occurs to notify the host controller driver that a device has attached.
- Software shall write a '1' to reset the device.
- Software shall write a '0' to reset the device after 10 ms.

- This step, which is necessary in a standard EHCI design, may be omitted with this implementation. Should the EHCI host controller driver attempt to write a '0' to the reset bit while a reset is in progress, the write will simple be ignored and the reset will continue until completion.
- [Port Change Interrupt] Port enable change occurs to notify the host controller that the device is now operational and at this point the port speed has been determined.

11.1.3.4.4.2.2 Port Speed Detection

After the port change interrupt indicates that a port is enabled, the EHCI stack should determine the port speed. Unlike the EHCI implementation, which will re-assign the port owner for any device that does not connect at High-Speed, this host controller supports direct attach of non High-Speed devices.

Therefore, the following differences are important regarding port speed detection:

- Port Owner is read-only and always reads 0.
- A 2-bit Port Speed indicator has been added to PORTSC to provide the current operating speed of the port to the host controller driver.
- A 1-bit High Speed indicator has been added to PORTSC to signify that the port is in High-Speed vs. Full/Low Speed - *This information is redundant with the 2-bit Port Speed indicator above.*

11.1.3.4.4.3 Port Test Mode

Port Test Control mode behaves fully as described in EHCI. An alternate host controller driver procedure is not necessary or supported.

11.1.3.5 Device Data Structures

This section defines the interface data structures used to communicate control, status, and data between Device Controller Driver (DCD) Software and the Device Controller.

The data structure definitions in this chapter support a 32-bit memory buffer address space. The interface consists of device Queue Heads and Transfer Descriptors.

NOTE

Software must ensure that no interface data structure reachable by the Device Controller spans a 4K-page boundary.

The data structures defined in the chapter are (from the device controller's perspective) a mix of read-only and read/ writable fields. The device controller must preserve the read-only fields on all data structure writes.

The figure below shows the organization of the EndPoint Queue Head.

Figure 11-28. EndPoint Queue Head Organization

Endpoint queue heads are arranged in an array in a continuous area of memory pointed to by the USB.ENDPOINTLISTADDR pointer. The even -numbered device queue heads in the list support receive endpoints (OUT/SETUP) and the odd-numbered queue heads in the list are used for transmit endpoints (IN/INTERRUPT). The device controller will index into this array based upon the endpoint number received from the USB bus. All information necessary to respond to transactions for all primed transfers is contained in this list so the Device Controller can readily respond to incoming requests without having to traverse a linked list.

NOTE

The Endpoint Queue Head List must be aligned to a 2k boundary.

11.1.3.5.1 Endpoint Queue Head (dQH)

The device Endpoint Queue Head (dQH) is where all transfers for a given endpoint are managed. The dQH is a 48-byte data structure, but must be aligned on 64-byte boundaries.

During priming of an endpoint, the dTD (device transfer descriptor) is copied into the overlay area of the dQH, which starts at the nextTD pointer DWord and continues through the end of the buffer pointers DWords. After a transfer is complete, the dTD status DWord is updated in the dTD pointed to by the currentTD pointer. While a packet is in progress, the overlay area of the dQH is used as a staging area for the dTD so that the Device Controller can access needed information with little minimal latency.

Table 11-55. Endpoint Queue Head (dQH)

Host Controller Read/Write

Host Controller Read Only

11.1.3.5.1.1 Endpoint Capabilities/Characteristics

This DWord specifies static information about the endpoint, in other words, this information does not change over the lifetime of the endpoint. Device Controller software should not attempt to modify this information while the corresponding endpoint is enabled.

[Table 11-56](#) describes the endpoint capabilities.

Table 11-56. Endpoint Capabilities/Characteristics

Bit	Description
31-30	Mult. This field is used to indicate the number of packets executed per transaction description as given by the following: 00 - Execute N Transactions as demonstrated by the USB variable length packet protocol where N is computed using the Maximum Packet Length (dQH) and the Total Bytes field (dTD) 01 Execute 1 Transaction. 10 Execute 2 Transactions. 11 Execute 3 Transactions. NOTE: Non-ISO endpoints must set Mult="00". ISO endpoints must set Mult="01", "10", or "11" as needed.
29	Zero Length Termination Select. This bit is used to indicate when a zero length packet is used to terminate transfers where the total transfer length is a multiple of the Maximum Packet Length. This bit is not relevant for Isochronous 0 - Enable zero length packet to terminate transfers equal to a multiple of the Maximum Packet Length. (default). 1 - Disable the zero length packet on transfers that are equal in length to a multiple Maximum Packet Length.
28-27	Reserved. These bits reserved for future use and should be set to zero.
26-16	Maximum Packet Length. This directly corresponds to the maximum packet size of the associated endpoint (wMaxPacketSize). The maximum value this field may contain is 0x400 (1024).
15	Interrupt On Setup (IOS). This bit is used on control type endpoints to indicate if USBINT is set in response to a setup being received.
14-0	Reserved. Bits reserved for future use and should be set to zero.

11.1.3.5.1.2 Transfer Overlay-Endpoint Queue Head

The seven DWords in the overlay area represent a transaction working space for the device controller.

The general operational model is that the device controller can detect whether the overlay area contains a description of an active transfer. If it does not contain an active transfer, then it will not read the associated endpoint.

After an endpoint is readied, the dTD will be copied into this queue head overlay area by the device controller. Until a transfer is expired, software must not write the queue head overlay area or the associated transfer descriptor. When the transfer is complete, the device controller will write the results back to the original transfer descriptor and advance the queue.

See dTD for a description of the overlay fields.

11.1.3.5.1.3 Current dTD Pointer

The current dTD pointer is used by the device controller to locate the transfer in progress. This word is for Device Controller (hardware) use only and should not be modified by DCD software.

The following table describes the dTD Pointer.

Table 11-57. Next dTD Pointer

Bit	Description
31-5	Current dTD. This field is a pointer to the dTD that is represented in the transfer overlay area. This field will be modified by the Device Controller to next dTD pointer during endpoint priming or queue advance.
4-0	Reserved. Bit reserved for future use and should be set to zero.

11.1.3.5.1.4 Set-up Buffer

The set-up buffer is dedicated storage for the 8-byte data that follows a set-up PID.

NOTE

Each endpoint has a TX and an RX dQH associated with it, and only the RX queue head is used for receiving setup data packets.

The following table describes the Multiple Mode Control.

Table 11-58. Multiple Mode Control (HCCPARAMS)

DWord	Bits	Description
1	31-0	Setup Buffer 0. This buffer contains bytes 3 to 0 of an incoming setup buffer packet and is written by the device controller to be read by software.
2	31-0	Setup Buffer 1. This buffer contains bytes 7 to 4 of an incoming setup buffer packet and is written by the device controller to be read by software.

11.1.3.5.2 Endpoint Transfer Descriptor (dTD)

The dTD describes to the device controller the location and quantity of data to be sent/received for a given transfer.

The DCD should not attempt to modify any field in an active dTD except the Next Like Pointer, which should only be modified as described in section [Managing Transfers with Transfer Descriptors](#).

Table below shows the Endpoint Transfer Descriptor (dTD).

Table 11-59. Endpoint Transfer Descriptor (dTD)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Buffer Pointer (Page 2)	Reserved
Buffer Pointer (Page 3)	Reserved
Buffer Pointer (Page 4)	Reserved

Host Controller Read/Write

Host Controller Read Only

The following table describes the dTD Pointer.

Table 11-60. Next dTD Pointer

Bit	Description
31-5	Next Transfer Element Pointer. This field contains the physical memory address of the next dTD to be processed. The field corresponds to memory address signals [31:5], respectively.
4-1	Reserved. Bits reserved for future use and should be set to zero.
0	Terminate (T). 1=pointer is invalid. 0=Pointer is valid (points to a valid Transfer Element Descriptor). This bit indicates to the Device Controller that there are no more valid entries in the queue.

The following table describes the dTD Token.

Table 11-61. dTD Token

Bit	Description
31	Reserved. Bit reserved for future use and should be set to zero.
30-16	<p>Total Bytes. This field specifies the total number of bytes to be moved with this transfer descriptor. This field is decremented by the number of bytes actually moved during the transaction and only on the successful completion of the transaction.</p> <p>The maximum value software may store in the field is 5*4K (5000H). This is the maximum number of bytes 5 page pointers can access. Although it is possible to create a transfer up to 20K this assumes the 1st offset into the first page is 0. When the offset cannot be predetermined, crossing past the 5th page can be guaranteed by limiting the total bytes to 16K**. Therefore, the maximum recommended transfer is 16K (4000H).</p> <p>If the value of the field is zero when the host controller fetches this transfer descriptor (and the active bit is set), the device controller executes a zero-length transaction and retires the transfer descriptor.</p> <p>It is not a requirement for IN transfers that Total Bytes To Transfer be an even multiple of <i>Maximum Packet Length</i>. If software builds such a transfer descriptor for an IN transfer, the last transaction will always be less than <i>Maximum Packet Length</i>.</p>
15	Interrupt On Complete (IOC). This bit is used to indicate if USBINT is to be set in response to device controller being finished with this dTD.
14-12	Reserved. Bits reserved for future use and should be set to zero.

Table continues on the next page...

Table 11-61. dTD Token (continued)

11-10	<p>Multiplier Override (MultiO). This field can be used for transmit ISO's (ie. ISO-IN) to override the multiplier in the QH. This field must be zero for all packet types that are not transmit-ISO.</p> <p>Example:</p> <p>if QH.multiplier = 3; Maximum packet size = 8; Total Bytes = 15; MultiO = 0 [default]</p> <p>Three packets are sent: {Data2(8); Data1(7); Data0(0)}</p> <p>if QH.multiplier = 3; Maximum packet size = 8; Total Bytes = 15; MultiO = 2</p> <p>Two packets are sent: {Data1(8); Data0(7)}</p> <p>For maximal efficiency, software should compute MultiO = greatest integer of (Total Bytes / Max. Packet Size) except for the case when Total Bytes = 0; then MultiO should be 1.</p> <p>Note: Non-ISO and Non-TX endpoints must set MultiO = "00".</p>
9-8	Reserved. Bits reserved for future use and should be set to zero.
7-0	<p>Status. This field is used by the Device Controller to communicate individual command execution states back to the Device Controller software. This field contains the status of the last transaction performed on this qTD. The bit encodings are:</p> <p>Bit Status Field Description</p> <p>7 Active.</p> <p>6 Halted.</p> <p>5 Data Buffer Error.</p> <p>3 Transaction Error.</p> <p>4, 2, 0 Reserved.</p>

The table below describes the dTD Buffer Page Pointer List.

Table 11-62. dTD Buffer Page Pointer List

Bit	Description
31-12	Buffer Pointer. Selects the page offset in memory for the packet buffer. Non virtual memory systems will typically set the buffer pointers to a series of incrementing integers.
0,11-0	Current Offset. Offset into the 4kb buffer where the packet is to begin.
1,10-0	Frame Number. Written by the device controller to indicate the frame number in which a packet finishes. This is typically be used to correlate relative completion times of packets on an ISO endpoint.

11.1.3.6 Device Operational Model

The function of the device operation is to transfer a request in the memory image to and from the Universal Serial Bus.

Using a set of linked list transfer descriptors, pointed to by a queue head, the device controller will perform the data transfers. The following sections explain the use of the device controller from the device controller driver (DCD) point-of-view and further describe how specific USB bus events relate to status changes in the device controller programmer's interface.

11.1.3.6.1 Device Controller Initialization

After hardware reset, the device is disabled until the Run/Stop bit is set to a '1'. In the disabled state, the pull-up on the USB D+ is not active which prevents an attach event from occurring. At a minimum, it is necessary to have the queue heads setup for endpoint zero before the device attach occurs.

Shortly after the device is enabled, a USB reset will occur followed by setup packet arriving at endpoint 0. A Queue head must be prepared so that the device controller can store the incoming setup packet.

In order to initialize a device, the software should perform the following steps:

- Set Controller Mode in the USB.USBMODE register to device mode.

NOTE

Transitioning from host mode to device mode requires a device controller reset before modifying USB.USBMODE.

- Allocate and Initialize device queue heads in system memory.
 - Minimum: Initialize device queue heads 0 Tx & 0 Rx.

NOTE

All device queue heads for control endpoints must be initialized before the endpoint is enabled. Non-Control device queue heads before the endpoint can be used.

- For information on device queue heads, refer to section [Device Data Structures](#).
- Configure USB.ENDPOINTLISTADDR Pointer.
 - For additional information on USB.ENDPOINTLISTADDR, refer to the register table.
- Enable the microprocessor interrupt associated with the USB core.
 - Recommended: enable all device interrupts including: USBINT, USBERRINT, Port Change Detect, USB Reset Received, DCSuspend.
 - For a list of available interrupts refer to the [Interrupt Enable Register \(USB_nUSBINTR\)](#) and the [USB Status Register \(USB_nUSBSTS\)](#) register tables.
- Set Run/Stop bit to Run Mode.

- After the Run bit is set and the device is connected to a host, a Bus Reset will be issued by host downstream port. The DCD must monitor the reset event and adjust the software state as described in the Bus Reset section of the Port State and Control section below.

NOTE

Endpoint 0 is designed as a control endpoint only and does not need to be configured using `ENDPTCTRL0` register.

It is also not necessary to prime Endpoint 0 initially because the first packet received will always be a setup packet. The contents of the first setup packet will require a response in accordance with USB device framework (Chapter 9) command set.

11.1.3.6.2 Port State and Control

From a chip or system reset, the device controller enters the *powered* state. A transition from the *powered* state to the *attach* state occurs when the Run/Stop bit is set to a '1'.

After receiving a reset on the bus, the port will enter the *defaultFS* or *defaultHS* state in accordance with the reset protocol described in Appendix C.2 of the USB Specification Rev. 2.0.

The following state diagram depicts the state of a USB 2.0 device.

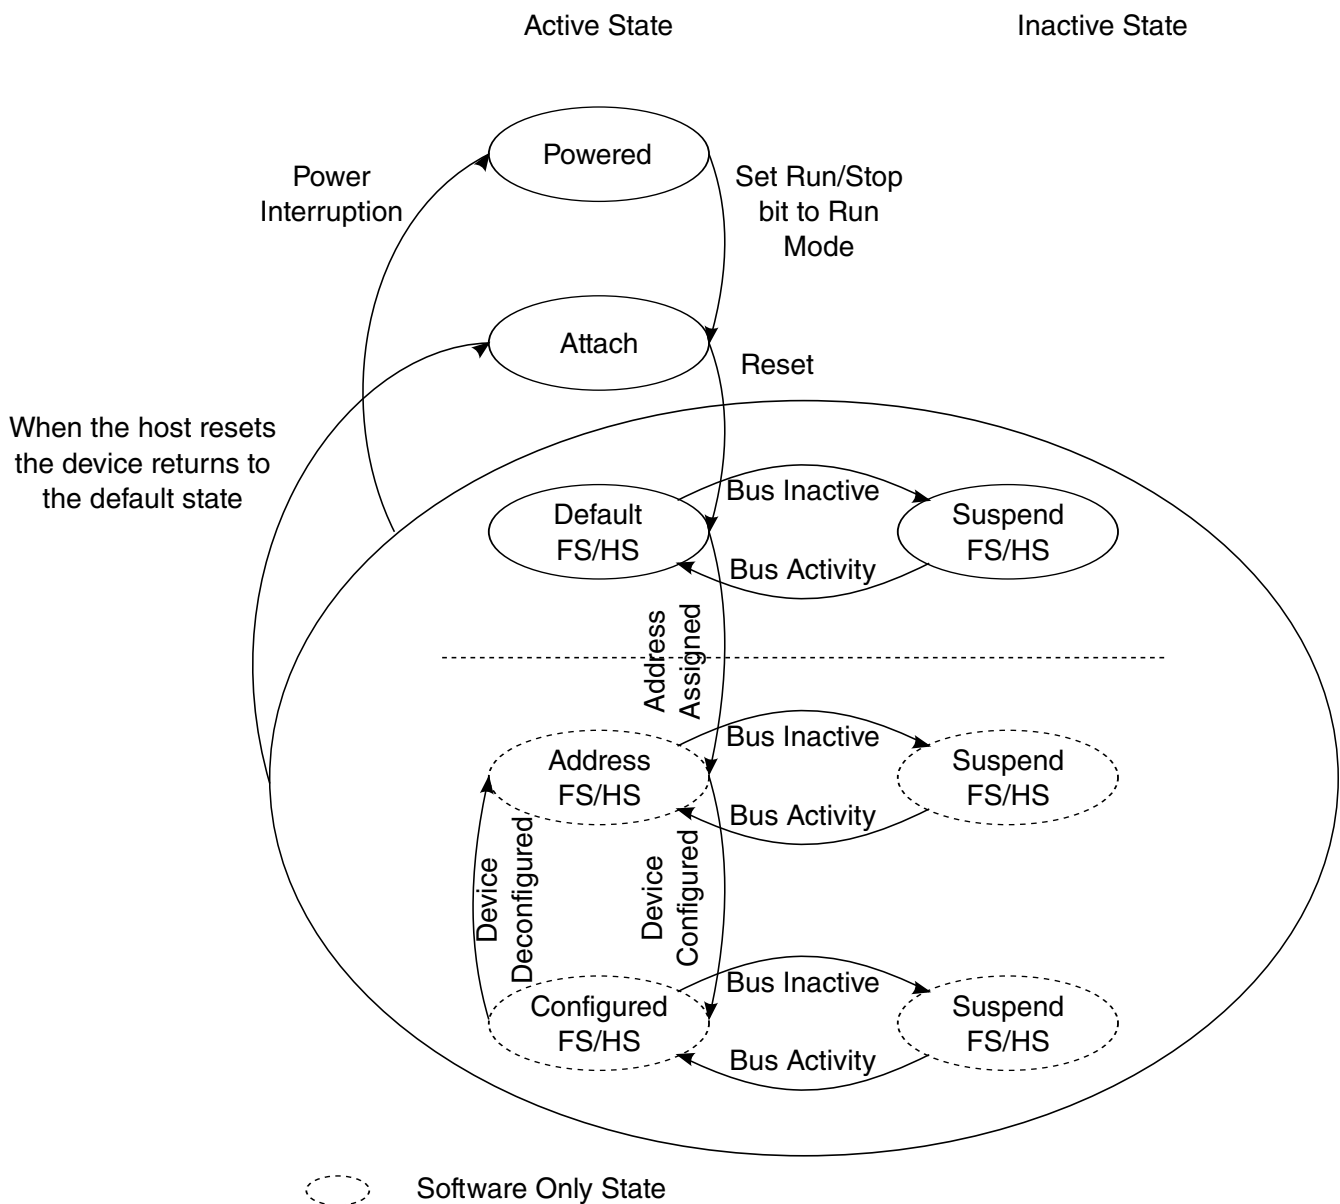

Figure 11-29. Device State Diagram

States *powered*, *attach*, *defaultFS/HS*, *suspendFS/HS* are implemented in the device controller and are communicated to the DCD using the following status bits:

The following table describes the Device Controller State Information Bits.

Table 11-63. Device Controller State Information Bits

Bit	Register
DCSuspend	
USB Reset Received	
Port Change Detect	
High-Speed Port	

It is the responsibility of the DCD to maintain a state variable to differentiate between the *DefaultFS/HS* state and the *Address/Configured* states. Change of state from *Default* to *Address* and the *Configured* states is part of the enumeration process described in the device framework section of the USB 2.0 Specification.

As a result of entering the *Address* state, the device address register (DEVICEADDR) must be programmed by the DCD.

Entry into the *Configured* indicates that all endpoints to be used in the operation of the device have been properly initialized by programming the USB_UOG_ENDPTCTRLx registers and initializing the associated queue heads.

11.1.3.6.2.1 Bus Reset

A bus reset is used by the host to initialize downstream devices.

When a bus reset is detected, the device controller will renegotiate its attachment speed, reset the device address to 0, and notify the DCD by interrupt (assuming the USB Reset Interrupt Enable is set). After a reset is received, all endpoints (except endpoint 0) are disabled and any primed transactions will be cancelled by the device controller. The concept of priming will be clarified below, but the DCD must perform the following tasks when a reset is received:

Clear all setup token semaphores by reading the [Endpoint Status \(USB_nENDPTSTAT\)](#) register and writing the same value back to the [Endpoint Status \(USB_nENDPTSTAT\)](#) register.

Clear all the endpoint complete status bits by reading the [Endpoint Complete \(USB_nENDPTCOMPLETE\)](#) register and writing the same value back to the [Endpoint Complete \(USB_nENDPTCOMPLETE\)](#) register.

Cancel all primed status by waiting until all bits in the [Endpoint Prime \(USB_nENDPTPRIME\)](#) are 0 and then writing 0xFFFFFFFF to [Endpoint Flush \(USB_nENDPTFLUSH\)](#).

Read the reset bit in the [Port Status & Control \(USB_nPORTSC1\)](#) register and make sure that it is still active. A USB reset will occur for a minimum of 3 ms and the DCD must reach this point in the reset cleanup before end of the reset occurs, otherwise a hardware reset of the device controller is recommended (rare.)

- A hardware reset can be performed by writing a one to the device controller reset bit in the USBCMD reset. Note: a hardware reset will cause the device to detach from the bus by clearing the Run/Stop bit. Thus, the DCD must completely re-initialize the device controller after a hardware reset.

Free all allocated dTDs because they will no longer be executed by the device controller. If this is the first time the DCD is processing a USB reset event, then it is likely that no dTDs have been allocated.

At this time, the DCD may release control back to the OS because no further changes to the device controller are permitted until a Port Change Detect is indicated.

After a Port Change Detect, the device has reached the default state and the DCD can read the [Port Status & Control \(USB_nPORTSC1\)](#) to determine if the device is operating in FS or HS mode. At this time, the device controller has reached normal operating mode and DCD can begin enumeration according to the USB Chapter 9 - Device Framework.

NOTE

The device DCD may use the FS/HS mode information to determine the bandwidth mode of the device

In some applications, it may not be possible to enable one or more pipes while in FS mode. *Beyond the data rate issue, there is no difference in DCD operation between FS and HS modes.*

11.1.3.6.2.2 Suspend/Resume

The details of suspend and resume are explained in these sections.

11.1.3.6.2.2.1 Suspend

Suspend Description

In order to conserve power, USB devices automatically enter the suspended state when the device has observed no bus traffic for a specified period. When suspended, the USB device maintains any internal status, including its address and configuration. Attached devices must be prepared to suspend at any time they are powered, regardless of if they have been assigned a non-default address, are configured, or neither. Bus activity may cease due to the host entering a suspend mode of its own. In addition, a USB device shall also enter the suspended state when the hub port it is attached to is disabled.

A USB device exits suspend mode when there is bus activity. A USB device may also request the host to exit suspend mode or selective suspend by using electrical signaling to indicate remote wakeup. The ability of a device to signal remote wakeup is optional. If the USB device is capable of remote wakeup signaling, the device must support the ability of the host to enable and disable this capability. When the device is reset, remote wakeup signaling must be disabled.

Suspend Operational Model

The device controller moves into the suspend state when suspend signaling is detected or activity is missing on the upstream port for more than a specific period. After the device controller enters the suspend state, the DCD is notified by an interrupt (assuming *DC Suspend Interrupt* is enabled). When the *DCSuspend* bit in the [Port Status & Control \(USB_nPORTSC1\)](#) is set to a '1', the device controller is suspended.

DCD response when the device controller is suspended is application specific and may involve switching to low power operation.

Information on the bus power limits in suspend state can be found in USB 2.0 specification.

NOTE

Review system level clocking issues defined in section (Ref: Signals-Clocking) for the clocking requirements of a suspended device controller.

11.1.3.6.2.2.2 Resume

If the device controller is suspended, its operation is resumed when any non-idle signaling is received on its upstream facing port. In addition, the device can signal the system to resume operation by forcing resume signaling to the upstream port.

Resume signaling is sent upstream by writing a '1' to the Resume bit in the in the [Port Status & Control \(USB_nPORTSC1\)](#) while the device is in suspend state. Sending resume signal to an upstream port should cause the host to issue resume signaling and bring the suspended bus segment (one more devices) back to the active condition.

NOTE

Before resume signaling can be used, the host must enable it by using the Set Feature command defined in device framework (chapter 9) of the USB 2.0 Specification.

11.1.3.6.3 Managing Endpoints

The USB 2.0 specification defines an endpoint, also called a device endpoint or an address endpoint as a uniquely addressable portion of a USB device that can source or sink data in a communications channel between the host and the device.

The endpoint address is specified by the combination of the endpoint number and the endpoint direction.

The channel between the host and an endpoint at a specific device represents a data pipe. Endpoint 0 for a device is always a *control* type data channel used for device discovery and enumeration. Other types of endpoints support by USB include *bulk*, *interrupt*, and

isochronous. Each endpoint type has specific behavior related to packet response and error handling. More detail on endpoint operation can be found in the USB 2.0 specification.

The USB OTG device controller hardware supports up to 8 endpoint numbers.

Each endpoint direction is essentially independent and can be configured with differing behavior in each direction. For example, the DCD can configure endpoint 1-IN to be a bulk endpoint and endpoint 1-OUT to be an isochronous endpoint. This helps to conserve the total number of endpoints required for device operation. The only exception is that control endpoints must use both directions on a single endpoint number to function as a control endpoint. Endpoint 0 is, for example, is always a control endpoint and uses the pair of directions.

Each endpoint direction requires a *queue head* allocated in memory. To support the 8 endpoint numbers, 16 *queue heads* are required. The operation of an endpoint and use of *queue heads* are described later in this document.

11.1.3.6.3.1 Endpoint Initialization

After hardware reset, all endpoints except endpoint zero are uninitialized and disabled. The DCD must configure and enable each endpoint by writing to configuration bit in the USB_UOG_ENDPTCTRLx register.

Each 32-bit USB_UOG_ENDPTCTRLx is split into an upper and lower half. The lower half of USB_UOG_ENDPTCTRLx is used to configure the receive or OUT endpoint and the upper half is likewise used to configure the corresponding transmit or IN endpoint. Control endpoints must be configured the same in both the upper and lower half of the USB_UOG_ENDPTCTRLx register otherwise the behavior is undefined. The following table shows how to construct a configuration word for endpoint initialization. The following table shows the fields and values for the Device Controller Endpoint initialization.

Table 11-64. Device Controller Endpoint Initialization

Field	Value
Data Toggle Reset	1
Data Toggle Inhibit	0
Endpoint Type	00 Control 01 Isochronous 10 Bulk 11 Interrupt
Endpoint Stall	0

11.1.3.6.3.2 Stalling

There are two occasions where the device controller may need to return to the host a STALL.

The first occasion is the functional stall, which is a condition set by the DCD as described in the USB 2.0 device framework. A functional stall is only used on non-control endpoints and can be enabled in the device controller by setting the endpoint stall bit in the USB_UOG_ENDPTCTRLx register associated with the given endpoint and the given direction. In a functional stall condition, the device controller will continue to return STALL responses to all transactions occurring on the respective endpoint and direction until the endpoint stall bit is cleared by the DCD.

A protocol stall, unlike a function stall, is used on control endpoints is automatically cleared by the device controller at the start of a new control transaction (setup phase). When enabling a protocol stall, the DCD should enable the stall bits (both directions) as a pair. A single write to the USB_UOG_ENDPTCTRLx register can ensure that both stall bits are set at the same instant.

NOTE

Any write to the USB_UOG_ENDPTCTRLx register during operational mode must preserve the endpoint type field (that is, perform a read-modify-write).

The following table shows the response matrix for the Device Controller Stall.

Table 11-65. Device Controller Stall Response Matrix

USB Packet	Endpoint Stall Bit.	Effect on STALL bit.	USB Response
SETUP packet received by a non-control endpoint.	N/A	None.	STALL
IN/OUT/PING packet received by a non-control endpoint.	'1'	None.	STALL
IN/OUT/PING packet received by a non-control endpoint.	'0'	None.	ACK/ NAK/ NYET
SETUP packet received by a control endpoint.	N/A	Cleared	ACK
IN/OUT/PING packet received by a control endpoint	'1'	None	STALL
IN/OUT/PING packet received by a control endpoint.	'0'	None.	ACK/ NAK/ NYET

11.1.3.6.3.3 Data Toggle

Data toggle is a mechanism to maintain data coherency between host and device for any given data pipe.

For more information on data toggle, refer to the USB 2.0 specification.

11.1.3.6.3.3.1 Data Toggle Reset

The DCD may reset the data toggle state bit and cause the data toggle sequence to reset in the device controller by writing a '1' to the data toggle reset bit in the USB_UOG_ENDPTCTRLx register.

This should only be necessary when configuring/initializing an endpoint or returning from a STALL condition.

11.1.3.6.3.3.2 Data Toggle Inhibit

NOTE

This feature is for test purposes only and should never be used during normal device controller operation.

Setting the *data toggle Inhibit bit* active ('1') causes the device controller to ignore the data toggle pattern that is normally sent and accept all incoming data packets regardless of the data toggle state.

In normal operation, the device controller checks the DATA0/DATA1 bit against the data toggle to determine if the packet is valid. If Data PID does not match the data toggle state bit maintained by the device controller for that endpoint, the Data toggle is considered not valid. If the data toggle is not valid, the device controller assumes the packet was already received and discards the packet (not reporting it to the DCD). To prevent the host controller from re-sending the same packet, the device controller will respond to the error packet by acknowledging it with either an ACK or NYET response.

11.1.3.6.3.3.3 Priming Transmit Endpoints

Priming a transmit endpoint will cause the device controller to fetch the device transfer descriptor (dTD) for the transaction pointed to by the device queue head (dQH).

After the dTD is fetched, it will be stored in the dQH until the device controller completes the transfer described by the dTD. Storing the dTD in the dQH allows the device controller to fetch the operating context needed to handle a request from the host without the need to follow the linked list, starting at the dQH when the host request is received.

After the device has loaded the dTD, the leading data in the packet is stored in a FIFO in the device controller. This FIFO is split into virtual channels so that the leading data can be stored for any endpoint up to the maximum number of endpoints configured at device synthesis time.

After a priming request is complete, an endpoint state of primed is indicated in the USB_UOG_ENDPTSTATUS register. For a primed transmit endpoint, the device controller can respond to an IN request from the host and meet the stringent bus turnaround time of High Speed USB.

Because only the leading data is stored in the device controller FIFO, it is necessary for the device controller to begin filling in behind leading data after the transaction starts. The FIFO must be sized to account for the maximum latency that can be incurred by the system memory bus. More information about FIFO sizing is presented in section .

11.1.3.6.3.3.4 *Priming Receive Endpoints*

Priming receive endpoints is identical to priming of transmit endpoints from the point of view of the DCD. At the device controller the major difference in the operational model is that there is no data movement of the leading packet data simply because the data is to be received from the host.

Note as part of the architecture, the FIFO for the receive endpoints is not partitioned into multiple channels like the transmit FIFO. Thus, the size of the RX FIFO does not scale with the number of endpoints.

11.1.3.6.4 **Operational Model For Packet Transfers**

All transactions on the USB bus are initiated by the host and in turn, the device must respond to any request from the host within the turnaround time stated in the USB 2.0 Specification.

At USB 1.1 Full or Low Speed rates, this turnaround time was significant and the USB 1.1 device controllers were architected so that the device controller could access main memory or interrupt a host protocol processor in order to respond to the USB 1.1 transaction. The architecture of the USB 2.0 device controller must be different because same methods will not meet USB 2.0 High-speed turnaround time requirements by simply increasing clock rate.

A USB host will send requests to the device controller in an order that can not be precisely predicted as a single pipeline, so it is not possible to prepare a single packet for the device controller to execute. However, the order of packet requests is predictable when the endpoint number and direction is considered. For example, if endpoint 3 (transmit direction) is configured as a bulk pipe, then we can expect the host will send IN

requests to that endpoint. This device controller is architected in such a way that it can prepare packets for each endpoint/direction in anticipation of the host request. The process of preparing the device controller to send or receive data in response to host initiated transaction on the bus is referred to as "priming" the endpoint. This term will be used throughout the following documentation to describe the device controller operation so the DCD can be architected properly use priming. Further, note that the term "flushing" is used to describe the action of clearing a packet that was queued for execution.

11.1.3.6.4.1 Interrupt/Bulk Endpoint Operational Model

The behaviors of the device controller for interrupt and bulk endpoints are identical.

All valid IN and OUT transactions to bulk pipes will handshake with a NAK unless the endpoint had been primed. Once the endpoint has been primed, data delivery will commence.

A dTD will be retired by the device controller when the packets described in the transfer descriptor have been completed. Each dTD describes N packets to be transferred according to the USB Variable Length transfer protocol. The formula and table on the following page describe how the device controller computes the number and length of the packets to be sent/received by the USB vary according to the total number of bytes and maximum packet length.

With Zero Length Termination (ZLT) = 0

$N = \text{INT}(\text{Number Of Bytes}/\text{Max. Packet Length}) + 1$

With Zero Length Termination (ZLT) = 1

$N = \text{MAXINT}(\text{Number Of Bytes}/\text{Max. Packet Length})$

Table 11-66. Variable Length Transfer Protocol Example (ZLT = 0)

Bytes (dTD)	Max. Packet Length (dQH)	N	P1	P2	P3
511	256	2	256	255	
512	256	3	256	256	0
512	512	2	512	0	

Table 11-67. Variable Length Transfer Protocol Example (ZLT = 1)

Bytes (dTD)	Max. Packet Length (dQH)	N	P1	P2	P3
511	256	2	256	255	
512	256	2	256	256	
512	512	1	512		

NOTE

The MULT field in the dQH must be set to "00" for bulk, interrupt, and control endpoints.

TX-dTD is complete when:

- All packets described dTD were successfully transmitted. *** Total bytes in dTD will equal zero when this occurs.

RX-dTD is complete when:

- All packets described in dTD were successfully received. *** Total bytes in dTD will equal zero when this occurs.
- A short packet (number of bytes < maximum packet length) was received. *** This is a successful transfer completion; DCD must check Total Bytes in dTD to determine the number of bytes that are remaining. From the total bytes remaining in the dTD, the DCD can compute the actual bytes received.
- A long packet was received (number of bytes > maximum packet size) OR (total bytes received > total bytes specified). *** This is an error condition. The device controller will discard the remaining packet, and set the Buffer Error bit in the dTD. In addition, the endpoint will be flushed and the USBERR interrupt will become active.

On the successful completion of the packet(s) described by the dTD, the active bit in the dTD will be cleared and the next pointer will be followed when the Terminate bit is clear. When the Terminate bit is set, the device controller will flush the endpoint/direction and cease operations for that endpoint/direction.

On the unsuccessful completion of a packet (see long packet above), the dQH will be left pointing to the dTD that was in error. In order to recover from this error condition, the DCD must properly reinitialize the dQH by clearing the active bit and update the nextTD pointer before attempting to re-prime the endpoint.

NOTE

All packet level errors such as a missing handshake or CRC error will be retried automatically by the device controller.

There is no required interaction with the DCD for handling such errors.

11.1.3.6.4.1.1 *Interrupt/Bulk Endpoint Bus Response Matrix*

The table below shows the response matrix for Interrupt/Bulk Endpoint Bus.

Table 11-68. Interrupt/Bulk Endpoint Bus Response Matrix

	Stall	Not Primed	Primed	Underflow	Overflow
Setup	Ignore	Ignore	Ignore	N/A	N/A
In	STALL	NAK	Transmit	BS Error	N/A
Out	STALL	NAK	Receive + NYET/ACK	N/A	NAK
Ping	STALL	NAK	ACK	N/A	N/A
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore

NOTE

BS Error = Force Bit Stuff Error

NYET/ACK - NYET unless the Transfer Descriptor has packets remaining according to the USB variable length protocol then ACK.

SYSERR - System error should never occur when the latency FIFOs are correctly sized and the DCD is responsive.

11.1.3.6.4.2 Control Endpoint Operation Model

This section details the setup phase, data phase, status phase, and the control endpoint bus response matrix.

11.1.3.6.4.2.1 Setup Phase

All requests to a control endpoint begin with a setup phase followed by an optional data phase and a required status phase. The device controller will always accept the setup phase unless the setup lockout is engaged.

The setup lockout will engage so that future setup packets are ignored. Lockout of setup packets ensures that while software is reading the setup packet stored in the queue head, that data is not written as it is being read potentially causing an invalid setup packet.

The setup lockout mechanism can be disabled and a new tripwire type semaphore will ensure that the setup packet payload is extracted from the queue head without being corrupted by an incoming setup packet. This is the preferred behavior because ignoring repeated setup packets due to long software interrupt latency would be a compliance issue.

- Disable Setup Lockout by writing 1 to Setup Lockout Mode (SLOM) in [USB Device Mode \(USB_nUSBMODE\)](#). (once at initialization). Setup lockout is not necessary when using the tripwire as described below.

NOTE

Leaving the Setup Lockout Mode As 0 will result in pre-2.3 hardware behavior.

- After receiving an interrupt and inspecting [Endpoint Setup Status \(USB_nENDPTSETUPSTAT\)](#) to determine that a setup packet was received on a particular pipe:
 - a. Write 1 to clear corresponding bit [Endpoint Setup Status \(USB_nENDPTSETUPSTAT\)](#).
 - b. Write 1 to Setup Tripwire (SUTW) in [USB Command Register \(USB_nUSBCMD\)](#) register.
 - c. Duplicate contents of dQH.SetupBuffer into local software byte array.
 - d. Read Setup TripWire (SUTW) in [USB Command Register \(USB_nUSBCMD\)](#) register. (if set - continue; if cleared - goto 2)
 - e. Write 0 to clear Setup Tripwire (SUTW) in [USB Command Register \(USB_nUSBCMD\)](#) register.
 - f. Process setup packet using local software byte array copy and execute status/handshake phases.

NOTE

After receiving a new setup packet the status and/or handshake phases may still be pending from a previous control sequence. These should be flushed & deallocated before linking a new status and/or handshake dTD for the most recent setup packet.

11.1.3.6.4.2.2 Data Phase

Following the setup phase, the DCD must create a device transfer descriptor for the data phase and prime the transfer.

After priming the packet, the DCD must verify a new setup packet has not been received by reading the USB.ENDPTSETUPSTAT register immediately verifying that the prime had completed. A prime will complete when the associated bit in the [Endpoint Prime \(USB_nENDPTPRIME\)](#) register is zero and the associated bit in the [Endpoint Status \(USB_nENDPTSTAT\)](#) register is a one. If a prime fails, ie. The [Endpoint Prime \(USB_nENDPTPRIME\)](#) bit goes to zero and the [Endpoint Status \(USB_nENDPTSTAT\)](#) bit is not set, then the prime has failed. This can only be due to improper setup of the dQH, dTD or a setup arriving during the prime operation. If a new setup packet is indicated after the ENDPTPRIME bit is cleared, then the transfer descriptor can be freed and the DCD must reinterpret the setup packet.

Should a setup arrive after the data stage is primed, the device controller will automatically clear the prime status ([Endpoint Status \(USB_nENDPTSTAT\)](#)) to enforce data coherency with the setup packet.

NOTE

- The MULT field in the dQH must be set to "00" for bulk, interrupt, and control endpoints.
- Error handling of data phase packets is the same as bulk packets described previously.

11.1.3.6.4.2.3 Status Phase

Similar to the data phase, the DCD must create a transfer descriptor (with byte length equal zero) and prime the endpoint for the status phase.

The DCD must also perform the same checks of the USB.ENDPTSETUPSTAT as described above in the data phase.

NOTE

- The MULT field in the dQH must be set to 00 for bulk, interrupt, and control endpoints.
- Error handling of data phase packets is the same as bulk packets described previously.

11.1.3.6.4.2.4 Control Endpoint Bus Response Matrix

Shown in the following table is the device controller response to packets on a control endpoint according to the device controller state.

The table below shows the response matrix for the Control Endpoint Bus.

Table 11-69. Control Endpoint Bus Response Matrix

Token Type	Endpoint State					Setup Lockout
	Stall	Not Primed	Primed	Underflow	Overflow	
Setup	ACK	ACK	ACK	N/A	SYSEERR	
In	STALL	NAK	Transmit	BS Error	N/A	N/A
Out	STALL	NAK	Receive + NYET/ACK	N/A	NAK	N/A
Ping	STALL	NAK	ACK	N/A	N/A	N/A
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore	Ignore

BS Error = Force Bit Stuff Error

NYET/ACK - NYET unless the Transfer Descriptor has packets remaining according to the USB variable length protocol then ACK.

SYSERR - System error should never occur when the latency FIFOs are correctly sized and the DCD is responsive.

11.1.3.6.4.3 Isochronous Endpoint Operational Model

Isochronous endpoints are used for real-time scheduled delivery of data and their operational model is significantly different than the host throttled Bulk, Interrupt, and Control data pipes.

Real time delivery by the device controller will be accomplished by the following:

- Exactly MULT Packets per (micro) Frame are transmitted/received. Note: MULT is a two-bit field in the device Queue Head. The variable length packet protocol is not used on isochronous endpoints.
- NAK responses are not used. Instead, zero length packets are sent in response to an IN request to an unprimed endpoints. For unprimed RX endpoints, the response to an OUT transaction is to ignore the packet within the device controller.
- Prime requests always schedule the transfer described in the dTD for the next (micro) frame. If the ISO-dTD is still active after that frame, then the ISO-dTD will be held ready until executed or canceled by the DCD.

An EHCI compatible host controller uses the periodic frame list to schedule data exchanges to Isochronous endpoints. The operational model for device mode does not use such a data structure. Instead, the same dTD used for Control/Bulk/Interrupt endpoints is also used for isochronous endpoints. The difference is in the handling of the dTD.

The first difference between bulk and ISO-endpoints is that priming an ISO-endpoint is a delayed operation such that an endpoint will become primed only after a SOF is received. After the DCD writes the prime bit, the prime bit will be cleared as usual to indicate to software that the device controller completed a priming the dTD for transfer. Internal to the design, the device controller hardware masks that prime start until the next frame boundary. This behavior is hidden from the DCD but occurs so that the device controller can match the dTD to a specific (micro)frame.

Another difference with isochronous endpoints is that the transaction must wholly complete in a (micro)frame. Once an ISO transaction is started in a (micro)frame it will retire the corresponding dTD when MULT transactions occur or the device controller finds a fulfillment condition.

The transaction error bit set in the status field indicates a fulfillment error condition. When a fulfillment error occurs, the frame after the transfer failed to complete wholly, the device controller will force retire the ISO-dTD and move to the next ISO-dTD.

It is important to note that fulfillment errors are only caused due to partially completed packets. If no activity occurs to a primed ISO-dTD, the transaction will stay primed indefinitely. This means it is up to software discard transmit ISO-dTDs that pile up from a failure of the host to move the data.

Finally, the last difference with ISO packets is in the data level error handling. When a CRC error occurs on a received packet, the packet is not retried similar to bulk and control endpoints. Instead, the CRC is noted by setting the *Transaction Error* bit and the data is stored as usual for the application software to sort out.

- TX Packet Retired
 - MULT counter reaches zero.
 - Fulfillment Error [*Transaction Error* bit is set]
 - # Packets Occurred > 0 AND # Packets Occurred < MULT

NOTE

For TX-ISO, MULT Counter can be loaded with a lesser value in the dTD Multiplier Override field in hardware versions 2.3 and later. If the Multiplier Override is zero, the MULT Counter is initialized to the Multiplier in the QH.

- RX Packet Retired:
 - MULT counter reaches zero.
 - Non-MDATA Data PID is received**
 - ** Exit criteria only valid in hardware version 2.3 or later. Previous to hardware version 2.3, any PID sequence that did not match the MULT field exactly would be flagged as a transaction error due to PID mismatch or fulfillment error.
 - Overflow Error:
 - Packet received is > maximum packet length. [*Buffer Error* bit is set]
 - Packet received exceeds total bytes allocated in dTD. [*Buffer Error* bit is set]
 - Fulfillment Error [*Transaction Error* bit is set]
 - # Packets Occurred > 0 AND # Packets Occurred < MULT
 - CRC Error [*Transaction Error* bit is set]

NOTE

For ISO, when a dTD is retired, the next dTD is primed for the next frame. For continuous (micro)frame to (micro)frame

operation the DCD should ensure that the dTD linked-list is out ahead of the device controller by at least two (micro)frames.

11.1.3.6.4.3.1 Isochronous Pipe Synchronization

When it is necessary to synchronize an isochronous data pipe to the host, the (micro) frame number (USB_UOG_FRINDEX register) can be used as a marker.

To cause a packet transfer to occur at a specific (micro) frame number [N], the DCD should interrupt on SOF during frame N-1. When the USB_UOG_FRINDEX=N-1, the DCD must write the prime bit. The device controller will prime the isochronous endpoint in (micro) frame N-1 so that the device controller will execute delivery during (micro) frame N.

NOTE

Priming an endpoint towards the end of (micro) frame N-1 will not guarantee delivery in (micro) frame N. The delivery may actually occur in (micro) frame N+1 if device controller does not have enough time to complete the prime before the SOF for packet N is received.

11.1.3.6.4.3.2 Isochronous Endpoint Bus Response Matrix

The following table shows the response matrix for the Isochronous Endpoint Bus.

Table 11-70. Isochronous Endpoint Bus Response Matrix

	Stall	Not Primed	Primed	Underflow	Overflow
Setup	STALL	STALL	STALL	N/A	N/A
In	NULL Packet	NULL Packet	Transmit	BS Error	N/A
Out	Ignore	Ignore	Receive	N/A	Drop Packet
Ping	Ignore	Ignore	Ignore	Ignore	Ignore
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore

1. BS Error = Force Bit Stuff Error

NULL Packet = Zero Length Packet

11.1.3.6.5 Managing Queue Heads

The following figure shows the End Point Queue Head.

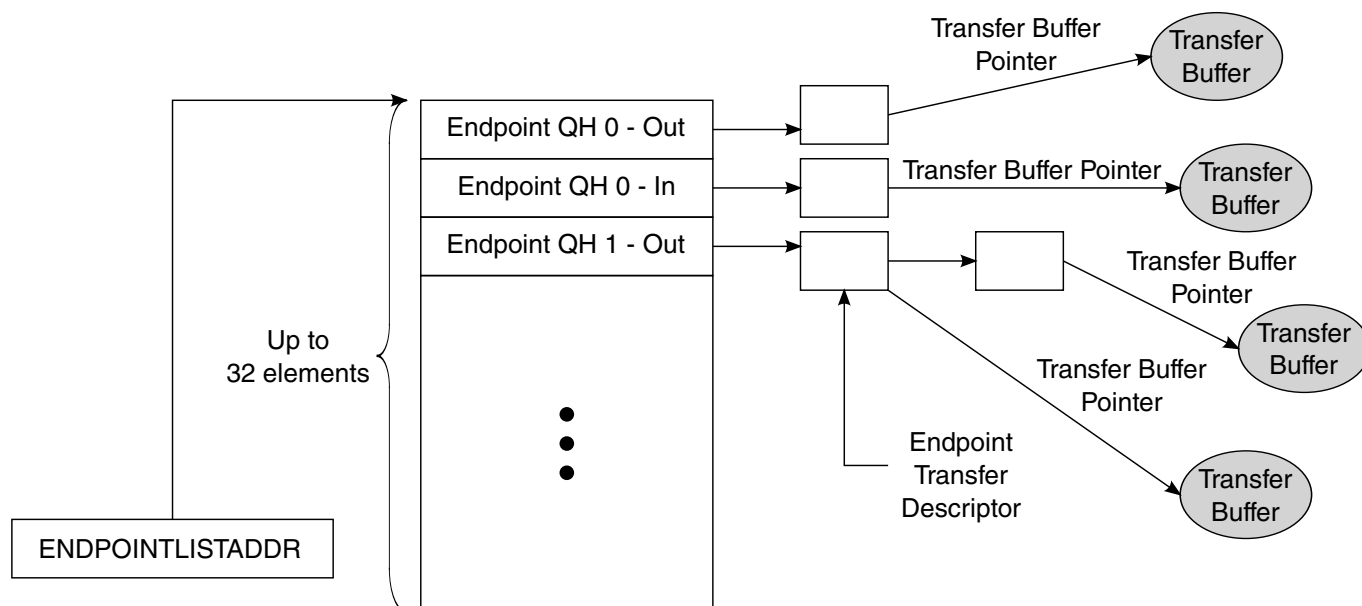

Figure 11-30. End Point Queue Head Diagram

The device queue head (dQH) points to the linked list of transfer tasks, each depicted by the device Transfer Descriptor (dTD). An area of memory pointed to by USB.ENDPOINTLISTADDR contains a group of all dQH's in a sequential list as shown in [Figure 11-30](#). The even elements in the list of dQH's are used for receive endpoints (OUT/SETUP) and the odd elements are used for transmit endpoints (IN/INTERRUPT). Device transfer descriptors are linked head to tail starting at the queue head and ending at a terminate bit. Once the dTD has been retired, it will no longer be part of the linked list from the queue head. Therefore, software is required to track all transfer descriptors because pointers will no longer exist within the queue head once the dTD is retired (see section [Software Link Pointers](#)).

In addition to the current and next pointers and the dTD overlay examined in section [Operational Model For Packet Transfers](#), the dQH also contains the following parameters for the associated endpoint: Multiplier, Maximum Packet Length, Interrupt On Setup. The complete initialization of the dQH including these fields is demonstrated in the next section.

11.1.3.6.5.1 Queue Head Initialization

One device queue head must be initialized for each active endpoint.

To initialize a device queue head:

- Write the wMaxPacketSize field as required by the USB Chapter 9 or application specific protocol.
- Write the multiplier field to 0 for control, bulk, and interrupt endpoints. For ISO endpoints, set the multiplier to 1,2, or 3 as required bandwidth and in conjunction with the USB Chapter 9 protocol.

NOTE

In FS mode, the multiplier field can only be 1 for ISO endpoints.

- Write the next dTD Terminate bit field to 1.
- Write the Active bit in the status field to 0.
- Write the Halt bit in the status field to 0.

NOTE

The DCD must only modify dQH if the associated endpoint is not primed and there are no outstanding dTD's.

11.1.3.6.5.2 Operational Model For Setup Transfers

As discussed in section [Control Endpoint Operation Model](#), setup transfer requires special treatment by the DCD. A setup transfer does not use a dTD but instead stores the incoming data from a setup packet in an 8-byte buffer within the dQH.

Upon receiving notification of the setup packet, the DCD should handle the setup transfer as demonstrated here:

1. Copy setup buffer contents from dQH - RX to software buffer.
2. Acknowledge setup backup by writing a "1" to the corresponding bit in ENDPTSETUPSTAT.

NOTE

- The acknowledge must occur before continuing to process the setup packet.
 - After the acknowledge has occurred, the DCD must not attempt to access the setup buffer in the dQH - RX. Only the local software copy should be examined.
3. Check for pending data or status dTD's from previous control transfers and flush if any exist as discussed in section [Flushing/De-priming an Endpoint](#).
 4. Decode setup packet and prepare data phase [optional] and status phase transfer as required by the USB Chapter 9 or application specific protocol.

NOTE

It is possible for the device controller to receive setup packets before previous control transfers complete. Existing control packets in progress must be flushed and the new control packet completed.

11.1.3.6.6 Managing Transfers with Transfer Descriptors**11.1.3.6.6.1 Software Link Pointers**

It is necessary for the DCD software to maintain head and tail pointers to the for the linked list of dTDs for each respective queue head.

This is necessary because the dQH only maintains pointers to the current working dTD and the next dTD to be executed. The operations described in next section for managing dTD will assume the DCD can use reference the head and tail of the dTD linked list. The following figure shows the Software Link Pointers.

Figure 11-31. Software Link Pointers

NOTE

To conserve memory, the reserved fields at the end of the dQH can be used to store the Head & Tail pointers, but it still remains the responsibility of the DCD to maintain the pointers.

11.1.3.6.6.2 Building a Transfer Descriptor

Before a transfer can be executed from the linked list, a dTD must be built to describe the transfer.

Use the following procedure for building dTDs.

Allocate 8-DWord dTD block of memory aligned to 8-DWord boundaries. Example: bit address 4:0 would be equal to "00000"

Write the following fields:

1. Initialize first 7 DWords to 0.
2. Set the terminate bit to 1.
3. Fill in total bytes with transfer size.
4. Set the interrupt on complete if desired.
5. Initialize the status field with the active bit set to 1 and all remaining status bits set to 0.
6. Fill in buffer pointer page 0 and the current offset to point to the start of the data buffer.
7. Initialize buffer pointer page 1 through page 4 to be one greater than each of the previous buffer pointer.

11.1.3.6.6.3 Executing A Transfer Descriptor

To safely add a dTD, the DCD must follow this procedure which will handle the event where the device controller reaches the end of the dTD list at the same time a new dTD is being added to the end of the list.

Determine whether the link list is empty: Check DCD driver to see if pipe is empty (internal representation of linked-list should indicate if any packets are outstanding).

- Case 1: Link list is empty
 - a. Write dQH next pointer AND dQH terminate bit to 0 as a single DWord operation.
 - b. Clear active & halt bit in dQH (in case set from a previous error).
 - c. Prime endpoint by writing 1 to correct bit position in .
- Case 2: Link list is not empty
 - a. Add dTD to end of linked list.
 - b. Read correct prime bit in - if 1 DONE.
 - c. Set ATDTW bit in USBCMD register to 1.
 - d. Read correct status bit in . (store in tmp. variable for later)
 - e. Read ATDTW bit in USBCMD register.
 - If 0 goto 3.
 - If 1 continue to 6.
 - f. Write ATDTW bit in USBCMD register to 0.
 - g. If status bit read in (3) is 1 DONE.
 - h. If status bit read in (3) is 0 then Goto Case 1: Step 1.

11.1.3.6.6.4 Transfer Completion

After a dTD has been initialized and the associated endpoint primed the device controller will execute the transfer upon the host-initiated request. The DCD will be notified with a USB interrupt if the Interrupt On Complete bit was set or alternately, the DCD can poll the endpoint complete register to find when the dTD had been executed. After a dTD has been executed, DCD can check the status bits to determine success or failure.

NOTE

Multiple dTD can be completed in a single endpoint complete notification. After clearing the notification, DCD must search the dTD linked list and retire all dTDs that have finished (Active bit cleared).

By reading the status fields of the completed dTDs, the DCD can determine if the transfers completed successfully. Success is determined with the following combination of status bits:

- Active = 0
- Halted = 0
- Transaction Error = 0
- Data Buffer Error = 0

Should any combination other than the one shown above exist, the DCD must take proper action. Transfer failure mechanisms are indicated in the [Device Error Matrix](#).

In addition to checking the status bit the DCD must read the Transfer Bytes field to determine the actual bytes transferred. When a transfer is complete, the Total Bytes transferred is by decremented by the actual bytes transferred. For Transmit packets, a packet is only complete after the actual bytes reaches zero, but for receive packets, the host may send fewer bytes in the transfer according the USB variable length packet protocol.

11.1.3.6.6.5 Flushing/De-priming an Endpoint

It is necessary for the DCD to flush to de-prime one more endpoints on a USB device reset or during a broken control transfer.

There may also be application specific requirements to stop transfers in progress. The following procedure can be used by the DCD to stop a transfer in progress:

1. Write a '1' to the corresponding bit(s) in .
2. Wait until all bits in are '0'.

- Software note: this operation may take a large amount of time depending on the USB bus activity. It is not desirable to have this wait loop within an interrupt service routine.
3. Read to ensure that for all endpoints commanded to be flushed, that the corresponding bits are now '0'. If the corresponding bits are '1' after step #2 has finished, then the flush failed as described in the following:
- Explanation: In very rare cases, a packet is in progress to the particular endpoint when commanded flush using . A safeguard is in place to refuse the flush to ensure that the packet in progress completes successfully. The DCD may need to repeatedly flush any endpoints that fail to flush by repeating steps 1-3 until each endpoint is successfully flushed.

11.1.3.6.6 Device Error Matrix

The following table summarizes packet errors that are not automatically handled by the Device Controller.

Table 11-71. Device Error Matrix

Error	Direction	Packet Type	Data Buffer Error Bit	Transaction Error Bit
Overflow **	RX	Any	1	0
ISO Packet Error	RX	ISO	0	1
ISO Fulfillment Error	Both	ISO	0	1

Notice that the device controller handles all errors on Bulk/Control/Interrupt Endpoints except for a data buffer overflow. However, for ISO endpoints, errors packets are not retried and errors are tagged as indicated. The table below describes the errors.

Table 11-72. Error Descriptions

Error	Description
Overflow	Number of bytes received exceeded max. packet size or total buffer length. ** This error will also set the Halt bit in the dQH and if there are dTDs remaining in the linked list for the endpoint, then those will not be executed.
ISO Packet Error	CRC Error on received ISO packet. Contents not guaranteed to be correct.
ISO Fulfillment Error	Host failed to complete the number of packets defined in the dQH mult field within the given (micro)frame. For scheduled data delivery the DCD may need to readjust the data queue because a fulfillment error will cause Device Controller to cease data transfers on the pipe for one (micro)frame. During the "dead" (micro)frame, the Device Controller reports error on the pipe and primes for the following frame.

11.1.3.6.7 Servicing Interrupts

The interrupt service routine must consider that there are high-frequency, low-frequency operations, and error operations and order accordingly.

11.1.3.6.7.1 High-Frequency Interrupts

High frequency interrupts in particular should be handled in the order below. The most important of these is listed first because the DCD must acknowledge a setup buffer in the timeliest manner possible.

The table below describes the High frequency interrupt events.

Table 11-73. High Frequency Interrupt Events

Execution Order	Interrupt	Action
1a	USB Interrupt - USB.ENDPTSETUPSTATUS	Copy contents of setup buffer and acknowledge setup packet (as indicated in Figure 11-30 shows the End Point Queue Head). Process setup packet according to USB 2.0 Chapter 9 or application specific protocol.
1b	USB Interrupt ¹ - USB.ENDPTCOMPLETE	Handle completion of dTD as indicated in Figure 11-30 shows the End Point Queue Head.
2	SOF Interrupt	Action as deemed necessary by application. This interrupt may not have a use in all applications.

1. It is likely that multiple interrupts to stack up on any call to the Interrupt Service Routine AND during the Interrupt Service Routine.

11.1.3.6.7.2 Low-Frequency Interrupts

The low frequency interrupts can be handled in any order because they do not occur often in comparison to the high-frequency interrupts.

The table below shows the Low frequency interrupt events.

Table 11-74. Low Frequency Interrupt Events

Interrupt	Action
Port Change	Change software state information.
Sleep Enable (Suspend)	Change software state information. Low power handling as necessary.
Reset Received	Change software state information. Abort pending transfers.

11.1.3.6.7.3 Error Interrupts

Error interrupts will be least frequent and should be placed last in the interrupt service routine.

The following table shows the error interrupt events.

Table 11-75. Error Interrupt Events

Interrupt	Action
USB Error Interrupt	This error is redundant because it combines USB Interrupt and an error status in the dTD. The DCD will more aptly handle packet-level errors by checking dTD status field upon receipt of USB Interrupt (w/ USB.ENDPTCOMPLETE).
System Error	Unrecoverable error. Immediate Reset of core; free transfers buffers in progress and restart the DCD.

11.1.4 USB Non-Core Memory Map/Register Definition

There are two kinds of registers in the USB module: USB core registers and USB non-core registers.

USB core registers are used to control USB core functions, and more independent of USB features. Each USB controller core has its own core registers.

USB non-core registers are additional to USB core registers, and more dependent on USB features. i.MX series products vary in non-core registers.

This section describes only the USB non-core registers. For detailed descriptions of USB core registers, please refer to [Register Interface](#).

NOTE

- For reserved bits, please preserve the value when writing (read its reset value, then write this value back)
- "USB_UOG1_", "USB_UOG2_" prefix in register name indicates it is a core register for OTG1/OTG2 controller core respectively.
- USBNC_USB_" prefix in register name indicates it is a USB non-core register.

Field	Description
	1 Low active (low on this signal represents an overcurrent condition) 0 High active (high on this signal represents an overcurrent condition)
7 OVER_CUR_DIS	Disable Overcurrent Detection 1 Disables overcurrent detection 0 Enables overcurrent detection
Reserved	This field is reserved.

11.1.4.2 USBNC_n_CTRL2

The USB_OTGx_PHY_CTRL2 register allows observation of the UTMI Clock Valid status along with control of selected inputs to the USB OTG PHY transceiver.

Some of these input signals may be used for USB out-of-band signaling. Customers should use caution when overriding any UTMI signals since that will interfere with normal USB data communication.

Address: 32E4_0000h base + 204h offset + (65536d × i), where i=0d to 1d

Field	Description
VBUS_SOURCE_SEL	VBUS source select used to detect a VBUS wakeup event. This bit field is for UTMI OTG PHY only (UH core and HSIC PHY have no such feature). 2'b00 vbus_valid others sess_valid

11.1.4.3 USB OTG PHY Configuration Register 1 (USBNC_n_PHY_CFG1)

The USB_OTGx_PHY_CFG1 register allows control of selected inputs to the USB OTG PHY.

Most of these signals are used for parametric tuning of the USB transceiver functions.

One signal is used to allow persistent control of the USB_OTG1_CHD_B external pin.

Address: 32E4_0000h base + 230h offset + (65536d × i), where i=0d to 1d

Customers should not change the value of this bit field. 000 9.6 MHz 001 10 MHz 010 12 MHz 011 19.2 MHz 100 20 MHz 101 24 MHz (only valid setting for this SOC) 110 Reserved 111 50 MHz
0 COMMONONN	Common Block Power-Down Control This signal controls the power-down signals in the Bias and PLL blocks when the USB OTG PHY is in Suspend or Sleep modes. 0 In Suspend or Sleep modes, the Bias and PLL blocks remain powered 1 In Suspend or Sleep modes, the Bias and PLL blocks are powered down 0

11.1.4.4 USB OTG PHY Configuration Register 2 (USBNC_n_PHY_CFG2)

The USB_OTGx_PHY_CFG2 register allows control of selected inputs to the USB OTG PHY.

Most of these signals are used for configuration of VBUS detection, ADP (Attach Detection Protocol), and Battery Charging ACA (Accessory Charging Adaptor) functions.

Address: 32E4_0000h base + 234h offset + (65536d × i), where i=0d to 1d

USBNC_n_PHY_CFG2 field descriptions

Field	Description
31–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 DRVVBUS0	VBUS Valid Comparator Enable This signal controls the USB OTG PHY VBUS Valid comparator which indicates whether the voltage on the USB_OTG*_VBUS pin is below the VBUS Valid threshold. The VBUS Valid threshold is nominally 4.75V on this USB PHY. The VBUS Valid threshold can be adjusted using the USBNC_OTGn_PHY_CFG1[OTGTUNE0] bit field. Status of the VBUS Valid comparator, when it is enabled, is reported on the USBNC_OTGn_PHY_STATUS[VBUS_VLD] bit. When OTGDISABLE0 (USBNC_USB_OTGx_PHY_CFG2[10]) is set to 1'b0 and DRVVBUS0 is set to 1'b1, the Bandgap circuitry and VBUS Valid comparator are powered, even in Suspend or Sleep mode. DRVVBUS0 should be reset to 1'b0 when the internal VBUS Valid comparator is not required, to reduce quiescent current in Suspend or Sleep mode. 0 The VBUS Valid comparator is disabled 1 The VBUS Valid comparator is enabled
15 VBUSVLDEXT	External VBUS Valid Indicator

USBNC_n_PHY_CFG2 field descriptions (continued)

Field	Description
	0 The OTG block is powered up 1 The OTG block is powered down
9 TXBITSTUFFENH0	High-Byte Transmit Bit-Stuffing Enable This controller signal controls bit stuffing on DATAINH[7:0] when OPMODE[1:0] = 2'b11. For more information on the use of this setting see UTMI+ Specification Section 2.2.1.12 . 0 Bit stuffing is disabled 1 Bit stuffing is enabled
8 TXBITSTUFFEN0	Low-Byte Transmit Bit-Stuffing Enable This controller signal controls bit stuffing on DATAIN[7:0] when OPMODE[1:0] = 2'b11. For more information on the use of this setting see UTMI+ Specification Section 2.2.1.12 . 0 Bit stuffing is disabled 1 Bit stuffing is enabled
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 LOOPBACKENB0	Loopback Test Enable This signal places the USB OTG PHY in Loopback mode, which enables the receive and transmit logic concurrently. Loopback mode is for test purposes only; it cannot be used for normal operation. 0 During data transmission, the receive logic is disabled 1 During data transmission, the receive logic is enabled
5 SLEEPM0	Sleep Mode Assertion Asserting this signal places the USB OTG PHY in Sleep mode according to the USB 2.0 Link Power Management (LPM) addendum to the USB 2.0 specification. In Sleep mode, the transmitter is tri-stated and the USB OTG PHY circuits used in this SOC are powered down. Note: The USB controller used in this SOC does not support LPM operation. Leave this bit set to 1'b1 for normal operation. 0 Sleep mode 1 Normal operating mode
4 ACAENB0	ACA USB_OTG*_ID Pin Resistance Detection Enable This signal enables the circuitry to detect resistance on the USB_OTG*_ID pin if the USB cable is connected to an ACA (Accessory Charger Adaptor). When ACAENB0 is set to 1'b1, IDPULLUP0 (USB_OTGSC[26]) is overridden and set to 1'b0 internally to the USB OTG PHY. The RID* results are reported in USBNC_USB_OTGx_PHY_STATUS[28:24]. 0 Disables detection of resistance on the USB_OTG*_ID pin 1 Enables detection of resistance on the USB_OTG*_ID pin
3 DCDENB	Data Contact Detection Enable This signal enables current sourcing on the USB_OTG*_DP pin and pull-down resistance on the USB_OTG*_DN pin for Data Contact Detect (DCD) per the USB Battery Charging Specification revision 1.2.

Table continues on the next page...

USBNC_n_PHY_CFG2 field descriptions (continued)

Field	Description
	<p>Note: During normal USB operation of the USB OTG PHY, set this signal to 1'b0.</p> <p>0 I_{DP_SRC} current and R_{DM_DWN} pull-down resistance are disabled</p> <p>1 I_{DP_SRC} current and R_{DM_DWN} pull-down resistance are enabled</p>
2 VDATSRCENB0	<p>Battery Charging Source Select</p> <p>This signal is used to enable the VD*_SRC voltage source and ID*_SINK current sink per the USB Battery Charging Specification revision 1.2.</p> <p>Pin selection for the voltage source and the current sink are controlled by USBNC_USB_OTGx_PHY_CFG2[0].</p> <p>Note: During normal USB operation of the USB OTG PHY, set this signal to 1'b0.</p> <p>0 VD*_SRC and ID*_SINK are disabled</p> <p>1 VD*_SRC and ID*_SINK are enabled</p>
1 VDATDETENB0	<p>Battery Charging Detection Comparator Enable</p> <p>This signal is used to enable the charge detection comparator circuit per the USB Battery Charging Specification revision 1.2.</p> <p>Results are reported by using the CHRGET status in USBNC_USB_OTGx_PHY_STATUS[CHRGDET]. The Comparator connection to USB_OTG*_D* pins is configured by USBNC_USB_OTGx_PHY_CFG2[CHRGSEL].</p> <p>NOTE: During normal USB operation of the USB OTG PHY, set this signal to 1'b0.</p> <p>0 Battery Charging detection comparator connected to USB_OTG*_D* pin is disabled</p> <p>1 Battery Charging detection comparator connected to USB_OTG*_D* pin is enabled</p>
0 CHRGSEL	<p>Battery Charging Source Select</p> <p>This signal is used to select the Battery Charging detection connections per the USB Battery Charging Specification revision 1.2. It determines which of USB_OTG*_DP / USB_OTG*_DN has the VD*_SRC voltage source and which has the ID*_SINK current sink.</p> <p>Results are reported in USBNC_USB_OTGx_PHY_STATUS[29].</p> <p>Note: During normal USB operation of the USB OTG PHY, set this signal to 1'b0.</p> <p>0 VDP_SRC is connected to USB_OTG*_DP and IDM_SINK is connected to USB_OTG*_DN. Used for Primary Detection.</p> <p>1 VDM_SRC is connected to USB_OTG*_DN and IDP_SINK is connected to USB_OTG*_DP. Used for Secondary Detection.</p>

11.1.4.5 USB OTG PHY Status Register (USBNC_n_PHY_STATUS)

The USB_OTGx_PHY_STATUS register allows visibility of selected outputs of the USB OTG PHY.

These signals are used for some VBUS detection, ADP (Attach Detection Protocol), and Battery Charging ACA (Accessory Charging Adaptor) functions.

Universal Serial Bus Controller (USB)

USBx_nGPTIMER0LD field descriptions

Field	Description
31–24 -	This field is reserved. Reserved
GPTLD	General Purpose Timer Load Value These bit fields are loaded to GPTCNT bits when GPTRST bit is set '1b'. This value represents the time in microseconds minus 1 for the timer duration.

Table continues on the next page...

USB_x_nGPTIMER0LD field descriptions (continued)

Field	Description
	Example: for a one millisecond timer, load 1000-1=999 or 0x0003E7. NOTE: Max value is 0xFFFFF or 16.777215 seconds.

11.1.5.8 General Purpose Timer #0 Controller (USB_x_nGPTIMER0CTRL)

This register contains the control for this countdown timer and a data field can be queried to determine the running count value. This timer has granularity on 1 us and can be programmed to a little over 16 seconds. There are two counter modes which are described in the register table below. When the timer counter value transitions to zero, an interrupt could be generated if enable.

Interrupt status bit is TI0 bit in n_USBSTS register (See [USB Status Register \(USB_nUSBSTS\)](#)), interrupt enable bit is TIE0 bit in n_USBINTR register. (See [Interrupt Enable Register \(USB_nUSBINTR\)](#) .)

Address: Base address + 84h offset + (65536d × i), where i=0d to 1d

Field	Description
31–3 -	This field is reserved. Reserved
AHBBRST	AHB master interface Burst configuration These bits control AHB master transfer type sequence (or priority). NOTE: This register overrides n_BURSTSIZE register when its value is not zero. 000 Incremental burst of unspecified length only 001 INCR4 burst, then single transfer 010 INCR8 burst, INCR4 burst, then single transfer 011 INCR16 burst, INCR8 burst, INCR4 burst, then single transfer 100 Reserved, don't use 101 INCR4 burst, then incremental burst of unspecified length 110 INCR8 burst, INCR4 burst, then incremental burst of unspecified length 111 INCR16 burst, INCR8 burst, INCR4 burst, then incremental burst of unspecified length

11.1.5.12 Capability Registers Length (USBx_nCAPLENGTH)

The Capability Registers Length register contains the address offset to the Operational registers relative to the CAPLENGTH register.

Address: Base address + 100h offset + (65536d × i), where i=0d to 1d

USBx_nCAPLENGTH field descriptions

Field	Description
CAPLENGTH	These bits are used as an offset to add to register base to find the beginning of the Operational Register. Default value is '40h'.

11.1.5.13 Host Controller Interface Version (USBx_nHCVERSION)

This is a 2-byte register containing a BCD encoding of the EHCI revision number supported by this host controller. The most significant byte of this register represents a major revision and the least significant byte is the minor revision.

Address: Base address + 102h offset + (65536d × i), where i=0d to 1d

USBx_nHCVERSION field descriptions

Field	Description
HCVERSION	Host Controller Interface Version Number Default value is '10h', which means EHCI rev1.0.

11.1.5.14 Host Controller Structural Parameters (USBx_nHCSPARAMS)

The following figure shows the port steering logic capabilities of Host Control Structural Parameters (n_HCSPARAMS).

Address: Base address + 104h offset + (65536d × i), where i=0d to 1d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

USBx_nHCSPARAMS field descriptions

Field	Description
31–28 -	This field is reserved. Reserved
27–24 N_TT	Number of Transaction Translators (N_TT). Default value '0000b' This field indicates the number of embedded transaction translators associated with the USB2.0 host controller. These bits would be set to '0001b' for Multi-Port Host, and '0000b' for Single-Port Host.
23–20 N_PTT	Number of Ports per Transaction Translator (N_PTT). Default value '0000b' This field indicates the number of ports assigned to each transaction translator within the USB2.0 host controller. These bits would be set to equal N_PORTS for Multi-Port Host, and '0000b' for Single-Port Host.
19–17 -	This field is reserved. Reserved
16 PI	Port Indicators (P INDICATOR) This bit indicates whether the ports support port indicator control. When set to one, the port status and control registers include a read/writeable field for controlling the state of the port indicator This bit is "1b" in all controller core.
15–12 N_CC	Number of Companion Controller (N_CC). This field indicates the number of companion controllers associated with this USB2.0 host controller. These bits are '0000b' in all controller core. 0 There is no internal Companion Controller and port-ownership hand-off is not supported. 1 There are internal companion controller(s) and port-ownership hand-offs is supported.

Table continues on the next page...

USBx_nHCSPARAMS field descriptions (continued)

Field	Description
11–8 N_PCC	<p>Number of Ports per Companion Controller</p> <p>This field indicates the number of ports supported per internal Companion Controller. It is used to indicate the port routing configuration to the system software.</p> <p>For example, if N_PORTS has a value of 6 and N_CC has a value of 2 then N_PCC could have a value of 3. The convention is that the first N_PCC ports are assumed to be routed to companion controller 1, the next N_PCC ports to companion controller 2, etc. In the previous example, the N_PCC could have been 4, where the first 4 are routed to companion controller 1 and the last two are routed to companion controller 2. The number in this field must be consistent with N_PORTS and N_CC.</p> <p>These bits are '0000b' in all controller core.</p>
7–5 -	<p>This field is reserved.</p> <p>Reserved</p>
4 PPC	<p>Port Power Control</p> <p>This field indicates whether the host controller implementation includes port power control. A one indicates the ports have port power switches. A zero indicates the ports do not have port power switches. The value of this field affects the functionality of the Port Power field in each port status and control register</p>
N_PORTS	<p>Number of downstream ports. This field specifies the number of physical downstream ports implemented on this host controller. The value of this field determines how many port registers are addressable in the Operational Register.</p> <p>Valid values are in the range of 1h to Fh. A zero in this field is undefined.</p> <p>These bits are always set to '0001b' because all controller cores are Single-Port Host.</p>

11.1.5.15 Host Controller Capability Parameters (USBx_nHCCPARAMS)

This register identifies multiple mode control (time-base bit functionality), addressing capability.

Address: Base address + 108h offset + (65536d × i), where i=0d to 1d

USBx_nHCCPARAMS field descriptions

Field	Description
31–16 -	This field is reserved. Reserved
15–8 EECP	EHCI Extended Capabilities Pointer. This field indicates the existence of a capabilities list. A value of 00h indicates no extended capabilities are implemented. A non-zero value in this register indicates the offset in PCI configuration space of the first EHCI extended capability. The pointer value must be 40h or greater if implemented to maintain the consistency of the PCI header defined for this class of device. NOTE: These bits are set '00h' in all controller core.
7–4 IST	Isochronous Scheduling Threshold. This field indicates, relative to the current position of the executing host controller, where software can reliably update the isochronous schedule. When bit [7] is zero, the value of the least significant 3 bits indicates the number of micro-frames a host controller can hold a set of isochronous data structures (one or more) before flushing the state. When bit [7] is a one, then host software assumes the host controller may cache an isochronous data structure for an entire frame. These bits are set '00h' in all controller core.
3 -	This field is reserved. Reserved

Table continues on the next page...

USBx_nHCCPARAMS field descriptions (continued)

Field	Description
2 ASP	<p>Asynchronous Schedule Park Capability</p> <p>If this bit is set to a one, then the host controller supports the park feature for high-speed queue heads in the Asynchronous Schedule. The feature can be disabled or enabled and set to a specific level by using the <i>Asynchronous Schedule Park Mode Enable</i> and <i>Asynchronous Schedule Park Mode Count</i> fields in the USBCMD register.</p> <p>NOTE: ASP bit reset value: '00b' for OTG controller core, '11b' for Host-only controller core.</p>
1 PFL	<p>Programmable Frame List Flag</p> <p>If this bit is set to zero, then the system software must use a frame list length of 1024 elements with this host controller. The USBCMD register Frame List Size field is a read-only register and must be set to zero.</p> <p>If set to a one, then the system software can specify and use a smaller frame list and configure the host controller via the USBCMD register Frame List Size field. The frame list must always be aligned on a 4K-page boundary. This requirement ensures that the frame list is always physically contiguous.</p> <p>This bit is set '1b' in all controller core.</p>
0 ADC	<p>64-bit Addressing Capability</p> <p>This bit is set '0b' in all controller core, no 64-bit addressing capability is supported.</p>

11.1.5.16 Device Controller Interface Version (USBx_nDCIVERSION)

This register indicates the two-byte BCD encoding of the device controller interface version number.

Address: Base address + 120h offset + (65536d × i), where i=0d to 1d

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Field	Description
	0x20 32 micro-frames 0x40 64 micro-frames
15 FS_2	<p>Frame List Size - (Read/Write or Read Only). [host mode only]</p> <p>This field is Read/Write only if Programmable Frame List Flag in the HCCPARAMS registers is set to one.</p> <p>This field specifies the size of the frame list that controls which bits in the Frame Index Register should be used for the Frame List Current index.</p> <p>NOTE: This field is made up from USBCMD bits 15, 3 and 2.</p> <p>Value Meaning</p> <p>000 1024 elements (4096 bytes) Default value 001 512 elements (2048 bytes) 010 256 elements (1024 bytes) 011 128 elements (512 bytes) 100 64 elements (256 bytes) 101 32 elements (128 bytes) 110 16 elements (64 bytes) 111 8 elements (32 bytes)</p>
14 ATDTW	<p>Add dTD TripWire - Read/Write. [device mode only]</p> <p>This bit is used as a semaphore to ensure proper addition of a new dTD to an active (primed) endpoint's linked list. This bit is set and cleared by software.</p> <p>This bit would also be cleared by hardware when state machine is hazard region for which adding a dTD to a primed endpoint may go unrecognized.</p>
13 SUTW	<p>Setup TripWire - Read/Write. [device mode only]</p> <p>This bit is used as a semaphore to ensure that the setup data payload of 8 bytes is extracted from a QH by the DCD without being corrupted. If the setup lockout mode is off (SLOM bit in USB core register n_USBMODE, see USB Device Mode (USB_nUSBMODE)) then there is a hazard when new setup data arrives while the DCD is copying the setup data payload from the QH for a previous setup packet. This bit is set and cleared by software.</p> <p>This bit would also be cleared by hardware when a hazard detected.</p>
12 -	This field is reserved. Reserved
11 ASPE	<p>Asynchronous Schedule Park Mode Enable - Read/Write.</p> <p>If the <i>Asynchronous Park Capability</i> bit in the HCCPARAMS register is a one, then this bit defaults to a 1h and is R/W. Otherwise the bit must be a zero and is RO. Software uses this bit to enable or disable Park mode. When this bit is one, Park mode is enabled. When this bit is a zero, Park mode is disabled.</p> <p>NOTE: ASPE bit reset value: '0b' for OTG controller core, '1b' for Host-only controller core.</p>
10 -	This field is reserved. Reserved
9–8 ASP	<p>Asynchronous Schedule Park Mode Count - Read/Write.</p> <p>If the <i>Asynchronous Park Capability</i> bit in the HCCPARAMS register is a one, then this field defaults to 3h and is R/W. Otherwise it defaults to zero and is Read-Only. It contains a count of the number of successive transactions the host controller is allowed to execute from a high-speed queue head on the</p>

Table continues on the next page...

USB_x_nUSBCMD field descriptions (continued)

Field	Description
	Asynchronous schedule before continuing traversal of the Asynchronous schedule. Valid values are 1h to 3h. Software must not write a zero to this bit when <i>Park Mode Enable</i> is a one as this will result in undefined behavior. This field is set to 3h in all controller core.
7 -	This field is reserved. Reserved
6 IAA	Interrupt on Async Advance Doorbell - Read/Write. This bit is used as a doorbell by software to tell the host controller to issue an interrupt the next time it advances asynchronous schedule. Software must write a 1 to this bit to ring the doorbell. When the host controller has evicted all appropriate cached schedule states, it sets the Interrupt on Async Advance status bit in the USBSTS register. If the Interrupt on Sync Advance Enable bit in the USBINTR register is one, then the host controller will assert an interrupt at the next interrupt threshold. The host controller sets this bit to zero after it has set the Interrupt on Sync Advance status bit in the USBSTS register to one. Software should not write a one to this bit when the asynchronous schedule is inactive. Doing so will yield undefined results. This bit is only used in host mode. Writing a one to this bit when device mode is selected will have undefined results.
5 ASE	Asynchronous Schedule Enable - Read/Write. Default 0b. This bit controls whether the host controller skips processing the Asynchronous Schedule. Only the host controller uses this bit. Values Meaning 0 Do not process the Asynchronous Schedule. 1 Use the ASYNCLISTADDR register to access the Asynchronous Schedule.
4 PSE	Periodic Schedule Enable- Read/Write. Default 0b. This bit controls whether the host controller skips processing the Periodic Schedule. Only the host controller uses this bit. Values Meaning 0 Do not process the Periodic Schedule 1 Use the PERIODICLISTBASE register to access the Periodic Schedule.
3-2 FS_1	See description at bit 15
1 RST	Controller Reset (RESET) - Read/Write. Software uses this bit to reset the controller. This bit is set to zero by the Host/Device Controller when the reset process is complete. Software cannot terminate the reset process early by writing a zero to this register. Host operation mode: When software writes a one to this bit, the Controller resets its internal pipelines, timers, counters, state machines etc. to their initial value. Any transaction currently in progress on USB is immediately terminated. A USB reset is not driven on downstream ports. Software should not set this bit to a one when the HCHalted bit in the USBSTS register is a zero. Attempting to reset an actively running host controller will result in undefined behavior. Device operation mode:

Table continues on the next page...

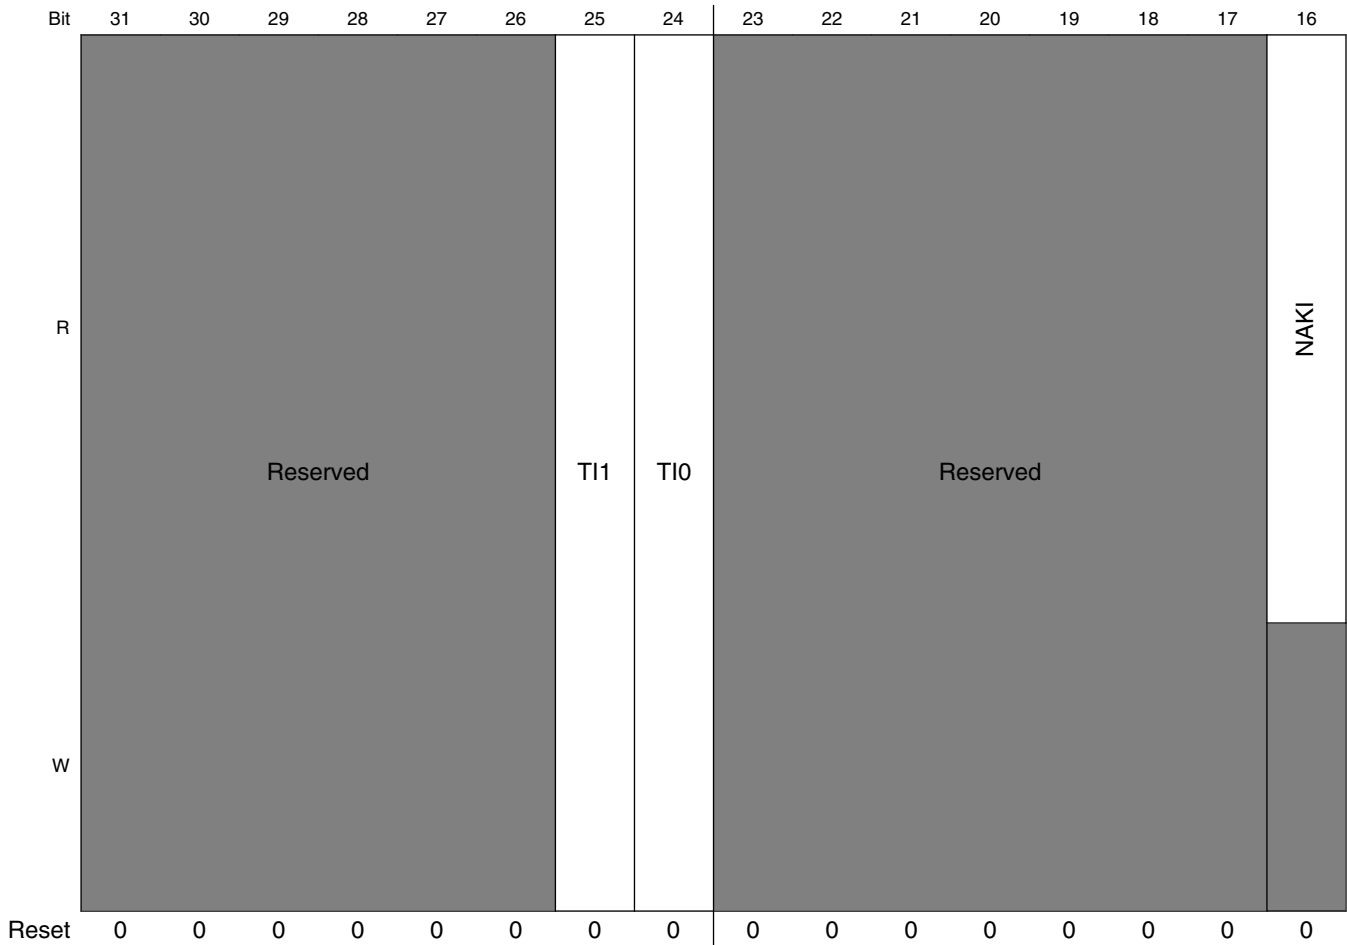

USBx_nUSBCMD field descriptions (continued)

Field	Description
	When software writes a one to this bit, the Controller resets its internal pipelines, timers, counters, state machines etc. to their initial value. Writing a one to this bit when the device is in the attached state is not recommended, because the effect on an attached host is undefined. In order to ensure that the device is not in an attached state before initiating a device controller reset, all primed endpoints should be flushed and the USBCMD Run/Stop bit should be set to 0.
0 RS	<p>Run/Stop (RS) - Read/Write. Default 0b. 1=Run. 0=Stop.</p> <p>Host operation mode:</p> <p>When set to '1b', the Controller proceeds with the execution of the schedule. The Controller continues execution as long as this bit is set to a one. When this bit is set to 0, the Host Controller completes the current transaction on the USB and then halts. The HC Halted bit in the status register indicates when the Controller has finished the transaction and has entered the stopped state. Software should not write a one to this field unless the controller is in the Halted state (that is, HCHalted in the USBSTS register is a one).</p> <p>Device operation mode:</p> <p>Writing a one to this bit will cause the controller to enable a pull-up on D+ and initiate an attach event. This control bit is not directly connected to the pull-up enable, as the pull-up will become disabled upon transitioning into high-speed mode. Software should use this bit to prevent an attach event before the controller has been properly initialized. Writing a 0 to this will cause a detach event.</p>

11.1.5.19 USB Status Register (USBx_nUSBSTS)

This register indicates various states of the Host/Device Controller and any pending interrupts. This register does not indicate status resulting from a transaction on the serial bus.

Address: Base address + 144h offset + (65536d × i), where i=0d to 1d

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

USBx_nUSBSTS field descriptions

Field	Description
31–26 -	This field is reserved. Reserved
25 TI1	General Purpose Timer Interrupt 1(GPTINT1)--R/WC. This bit is set when the counter in the GPTIMER1CTRL register transitions to zero, writing a one to this bit will clear it.
24 TI0	General Purpose Timer Interrupt 0(GPTINT0)--R/WC. This bit is set when the counter in the GPTIMER0CTRL register transitions to zero, writing a one to this bit clears it.
23–17 -	This field is reserved. Reserved
16 NAKI	NAK Interrupt Bit--RO. This bit is set by hardware when for a particular endpoint both the TX/RX Endpoint NAK bit and corresponding TX/RX Endpoint NAK Enable bit are set. This bit is automatically cleared by hardware when all Enabled TX/RX Endpoint NAK bits are cleared.
15 AS	Asynchronous Schedule Status - Read Only. This bit reports the current real status of the Asynchronous Schedule. When set to zero the asynchronous schedule status is disabled and if set to one the status is enabled. The Host Controller is not required to immediately disable or enable the Asynchronous Schedule when software transitions the Asynchronous Schedule Enable bit in the USBCMD register. When this bit and the Asynchronous Schedule Enable bit are the same value, the Asynchronous Schedule is either enabled (1) or disabled (0). Only used in the host operation mode.
14 PS	Periodic Schedule Status - Read Only.

Table continues on the next page...

USBx_nUSBSTS field descriptions (continued)

Field	Description
	<p>This bit reports the current real status of the Periodic Schedule. When set to zero the periodic schedule is disabled, and if set to one the status is enabled. The Host Controller is not required to immediately disable or enable the Periodic Schedule when software transitions the Periodic Schedule Enable bit in the USBCMD register. When this bit and the Periodic Schedule Enable bit are the same value, the Periodic Schedule is either enabled (1) or disabled (0).</p> <p>Only used in the host operation mode.</p>
13 RCL	<p>Reclamation - Read Only.</p> <p>This is a read-only status bit used to detect an empty asynchronous schedule.</p> <p>Only used in the host operation mode.</p>
12 HCH	<p>HCHalted - Read Only.</p> <p>This bit is a zero whenever the Run/Stop bit is a one. The Controller sets this bit to one after it has stopped executing because of the Run/Stop bit being set to 0, either by software or by the Controller hardware (for example, an internal error).</p> <p>Only used in the host operation mode.</p> <p>Default value is '0b' for OTG core, and '1b' for Host1/Host2/Host3 core.</p> <p>This is because OTG core is not operating as host in default. Please see CM bit in USB_n_USBMODE register.</p> <p>NOTE: HCH bit reset value: '0b' for OTG controller core, '1b' for Host-only controller core.</p>
11 -	<p>This field is reserved.</p> <p>Reserved</p>
10 ULPII	<p>ULPI Interrupt - R/WC.</p> <p>This bit will be set '1b' by hardware when there is an event completion in ULPI viewport.</p> <p>This bit is usable only if the controller support UPLI interface mode.</p>
9 -	<p>This field is reserved.</p> <p>Reserved</p>
8 SLI	<p>DCSuspend - R/WC.</p> <p>When a controller enters a suspend state from an active state, this bit will be set to a one. The device controller clears the bit upon exiting from a suspend state.</p> <p>Only used in device operation mode.</p>
7 SRI	<p>SOF Received - R/WC.</p> <p>When the device controller detects a Start Of (micro) Frame, this bit will be set to a one. When a SOF is extremely late, the device controller will automatically set this bit to indicate that an SOF was expected. Therefore, this bit will be set roughly every 1ms in device FS mode and every 125ms in HS mode and will be synchronized to the actual SOF that is received.</p> <p>Because the device controller is initialized to FS before connect, this bit will be set at an interval of 1ms during the prelude to connect and chirp.</p> <p>In host mode, this bit will be set every 125us and can be used by host controller driver as a time base.</p> <p>Software writes a 1 to this bit to clear it.</p>
6 URI	<p>USB Reset Received - R/WC.</p> <p>When the device controller detects a USB Reset and enters the default state, this bit will be set to a one. Software can write a 1 to this bit to clear the USB Reset Received status bit.</p> <p>Only used in device operation mode.</p>

Table continues on the next page...

USBx_nUSBSTS field descriptions (continued)

Field	Description
5 AAI	<p>Interrupt on Async Advance - R/WC.</p> <p>System software can force the host controller to issue an interrupt the next time the host controller advances the asynchronous schedule by writing a one to the Interrupt on Async Advance Doorbell bit in the n_USBCMD register. This status bit indicates the assertion of that interrupt source.</p> <p>Only used in host operation mode.</p>
4 SEI	<p>System Error- R/WC.</p> <p>This bit is will be set to '1b' when an Error response is seen to a read on the system interface.</p>
3 FRI	<p>Frame List Rollover - R/WC.</p> <p>The Host Controller sets this bit to a one when the Frame List Index rolls over from its maximum value to zero. The exact value at which the rollover occurs depends on the frame list size. For example, If the frame list size (as programmed in the Frame List Size field of the USB_n_USBCMD register) is 1024, the Frame Index Register rolls over every time FRINDEX [13] toggles. Similarly, if the size is 512, the Host Controller sets this bit to a one every time FHINDEX [12] toggles.</p> <p>Only used in host operation mode.</p>
2 PCI	<p>Port Change Detect - R/WC.</p> <p>The Host Controller sets this bit to a one when on any port a Connect Status occurs, a Port Enable/Disable Change occurs, or the Force Port Resume bit is set as the result of a J-K transition on the suspended port.</p> <p>The Device Controller sets this bit to a one when the port controller enters the full or high-speed operational state. When the port controller exits the full or high-speed operation states due to Reset or Suspend events, the notification mechanisms are the USB Reset Received bit and the DCSuspend bits respectively.</p>
1 UEI	<p>USB Error Interrupt (USBERRINT) - R/WC.</p> <p>When completion of a USB transaction results in an error condition, this bit is set by the Host/Device Controller. This bit is set along with the USBINT bit, if the TD on which the error interrupt occurred also had its interrupt on complete (IOC) bit set.</p> <p>The device controller detects resume signaling only.</p>
0 UI	<p>USB Interrupt (USBINT) - R/WC.</p> <p>This bit is set by the Host/Device Controller when the cause of an interrupt is a completion of a USB transaction where the Transfer Descriptor (TD) has an interrupt on complete (IOC) bit set.</p> <p>This bit is also set by the Host/Device Controller when a short packet is detected. A short packet is when the actual number of bytes received was less than the expected number of bytes.</p>

11.1.5.20 Interrupt Enable Register (USBx_nUSBINTR)

The interrupts to software are enabled with this register. An interrupt is generated when a bit is set and the corresponding interrupt source is active. The USB Status register (n_USBSTS) still shows interrupt sources even if they are disabled by the n_USBINTR register, allowing polling of interrupt events by the software.

Table continues on the next page...

USBx_nUSBINTR field descriptions (continued)

Field	Description
	When this bit is one, and the UPI bit in the n_USBSTS register is one, host controller will issue an interrupt at the next interrupt threshold.
18 UAIE	USB Host Asynchronous Interrupt Enable When this bit is one, and the UAI bit in the n_USBSTS register is one, host controller will issue an interrupt at the next interrupt threshold.
17 -	This field is reserved. Reserved
16 NAKE	NAK Interrupt Enable When this bit is one and the NAKI bit in n_USBSTS register is a one the controller will issue an interrupt.
15–11 -	These bits are reserved and should be set to zero.
10 ULPIE	ULPI Interrupt Enable When this bit is one and the UPLI bit in n_USBSTS register is a one the controller will issue an interrupt. This bit is usable only if the controller support UPLI interface mode.
9 -	This field is reserved. Reserved
8 SLE	Sleep Interrupt Enable When this bit is one and the SLI bit in n_n_USBSTS register is a one the controller will issue an interrupt. Only used in device operation mode.
7 SRE	SOF Received Interrupt Enable When this bit is one and the SRI bit in n_USBSTS register is a one the controller will issue an interrupt.
6 URE	USB Reset Interrupt Enable When this bit is one and the URI bit in n_USBSTS register is a one the controller will issue an interrupt. Only used in device operation mode.
5 AAE	Async Advance Interrupt Enable When this bit is one and the AAI bit in n_USBSTS register is a one the controller will issue an interrupt. Only used in host operation mode.
4 SEE	System Error Interrupt Enable When this bit is one and the SEI bit in n_USBSTS register is a one the controller will issue an interrupt. Only used in host operation mode.
3 FRE	Frame List Rollover Interrupt Enable When this bit is one and the FRI bit in n_USBSTS register is a one the controller will issue an interrupt. Only used in host operation mode.
2 PCE	Port Change Detect Interrupt Enable When this bit is one and the PCI bit in n_USBSTS register is a one the controller will issue an interrupt.
1 UEE	USB Error Interrupt Enable When this bit is one and the UEI bit in n_USBSTS register is a one the controller will issue an interrupt.
0 UE	USB Interrupt Enable When this bit is one and the UI bit in n_USBSTS register is a one the controller will issue an interrupt.

11.1.5.21 USB Frame Index (USBx_nFRINDEX)

This register is used by the host controller to index the periodic frame list. The register updates every 125 microseconds (once each micro-frame). Bits [N: 3] are used to select a particular entry in the Periodic Frame List during periodic schedule execution. The number of bits used for the index depends on the size of the frame list as set by system software in the Frame List Size field in the n_USBCMD register.

This register must be written as a DWord. Byte writes produce undefined results. This register cannot be written unless the Host Controller is in the 'Halted' state as indicated by the HCHalted bit. A write to this register while the Run/Stop hit is set to a one produces undefined results. Writes to this register also affect the SOF value.

In device mode this register is read only and, the device controller updates the FRINDEX [13:3] register from the frame number indicated by the SOF marker. Whenever a SOF is received by the USB bus, FRINDEX [13:3] will be checked against the SOF marker. If FRINDEX [13:3] is different from the SOF marker, FRINDEX [13:3] will be set to the SOF value and FRINDEX [2:0] will be set to zero (that is, SOF for 1 ms frame). If FRINDEX [13:3] is equal to the SOF value, FRINDEX [2:0] will be increment (that is, SOF for 125 us micro-frame.).

Address: Base address + 14Ch offset + (65536d × i), where i=0d to 1d

USBx_nFRINDEX field descriptions

Field	Description
31–14 -	This field is reserved. Reserved
FRINDEX	Frame Index. The value, in this register, increments at the end of each time frame (micro-frame). Bits [N: 3] are used for the Frame List current index. This means that each location of the frame list is accessed 8 times (frames or micro-frames) before moving to the next index. The following illustrates values of N based on the value of the Frame List Size field in the USBCMD register, when used in host mode. USBCMD [Frame List Size] Number Elements N In device mode the value is the current frame number of the last frame transmitted. It is not used as an index. In either mode bits 2:0 indicate the current microframe. 000 (1024) 12 001 (512) 11

11.1.5.22 Frame List Base Address (USBx_nPERIODICLISTBASE)

Host Controller only

This 32-bit register contains the beginning address of the Periodic Frame List in the system memory. HCD loads this register prior to starting the schedule execution by the Host Controller. The memory structure referenced by this physical memory pointer is assumed to be 4-Kbyte aligned. The contents of this register are combined with the Frame Index Register (USB_n_FRINDEX) to enable the Host Controller to step through the Periodic Frame List in sequence.

Address: Base address + 154h offset + (65536d × i), where i=0d to 1d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

USBx_nDEVICEADDR field descriptions

Field	Description
31–25 USBADR	Device Address. These bits correspond to the USB device address
24 USBADRA	Device Address Advance. Default=0. When this bit is '0', any writes to USBADR are instantaneous. When this bit is written to a '1' at the same time or before USBADR is written, the write to the USBADR field is staged and held in a hidden register. After an IN occurs on endpoint 0 and is ACKed, USBADR will be loaded from the holding register. Hardware will automatically clear this bit on the following conditions: 1) IN is ACKed to endpoint 0. (USBADR is updated from staging register). 2) OUT/SETUP occur to endpoint 0. (USBADR is not updated). 3) Device Reset occurs (USBADR is reset to 0). NOTE: After the status phase of the SET_ADDRESS descriptor, the DCD has 2 ms to program the USBADR field. This mechanism will ensure this specification is met when the DCD can not write of the device address within 2ms from the SET_ADDRESS status phase. If the DCD writes the USBADR with USBADRA=1 after the SET_ADDRESS data phase (before the prime of the status phase), the USBADR will be programmed instantly at the correct time and meet the 2ms USB requirement.
-	This field is reserved. Reserved

11.1.5.24 Next Asynch. Address (USBx_nASYNCLISTADDR)

Host Controller only

This 32-bit register contains the address of the next asynchronous queue head to be executed by the host. Bits [4:0] of this register cannot be modified by the system software and will always return a zero when read.

Address: Base address + 158h offset + (65536d × i), where i=0d to 1d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

USBx_nBURSTSIZE field descriptions

Field	Description
31–17 -	This field is reserved. Reserved
16–8 TXPBURST	Programmable TX Burst Size. Default value is determined by TXBURST bits in n_HWTXBUF. This register represents the maximum length of a the burst in 32-bit words while moving data from system memory to the USB bus.
RXPBURST	Programmable RX Burst Size. Default value is determined by TXBURST bits in n_HWRXBUF. This register represents the maximum length of a the burst in 32-bit words while moving data from the USB bus to system memory.

11.1.5.27 TX FIFO Fill Tuning (USBx_nTXFILLTUNING)

The fields in this register control performance tuning associated with how the host controller posts data to the TX latency FIFO before moving the data onto the USB bus. The specific areas of performance include the how much data to post into the FIFO and an estimate for how long that operation should take in the target system.

Definitions:

T_0 = Standard packet overhead

T_1 = Time to send data payload

T_{ff} = Time to fetch packet into TX FIFO up to specified level.

T_s = Total Packet Flight Time (send-only) packet

$T_s = T_0 + T_1$

T_p = Total Packet Time (fetch and send) packet

$T_p = T_{ff} + T_0 + T_1$

Upon discovery of a transmit (OUT/SETUP) packet in the data structures, host controller checks to ensure T_p remains before the end of the [micro]frame. If so it proceeds to pre-fill the TX FIFO. If at anytime during the pre-fill operation the time remaining the [micro]frame is $< T_s$ then the packet attempt ceases and the packet is tried at a later time. Although this is not an error condition and the host controller will eventually recover, a

mark will be made the scheduler health counter to note the occurrence of a "back-off" event. When a back-off event is detected, the partial packet fetched may need to be discarded from the latency buffer to make room for periodic traffic that will begin after the next SOF. Too many back-off events can waste bandwidth and power on the system bus and thus should be minimized (not necessarily eliminated). Back-offs can be minimized with use of the `n_TSCHHEALTH` (T_{ff}) described below.

NOTE

The reset value could vary from instance to instance. Please see the detail in bit field description and ignore reset value in summary table in this case!

Address: Base address + 164h offset + (65536d × i), where i=0d to 1d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W	Reserved																Reserved			TXSCHHEALTH				TXSCHOH								
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	1	0	0	0

USB_x_nTXFILLTUNING field descriptions

Field	Description
31–22 -	This field is reserved. Reserved
21–16 TXFIFOTHRES	FIFO Burst Threshold. (Read/Write) This register controls the number of data bursts that are posted to the TX latency FIFO in host mode before the packet begins on to the bus. The minimum value is 2 and this value should be as low as possible to maximize USB performance. A higher value can be used in systems with unpredictable latency and/or insufficient bandwidth where the FIFO may underrun because the data transferred from the latency FIFO to USB occurs before it can be replenished from system memory. This value is ignored if the Stream Disable bit in USB _n _USBMODE register is set. Default value is '00h' for OTG controller core, and '02h' for Host-only controller core.
15–13 -	This field is reserved. Reserved
12–8 TXSCHHEALTH	Scheduler Health Counter. (Read/Write To Clear) This register increments when the host controller fails to fill the TX latency FIFO to the level programmed by TXFIFOTHRES before running out of time to send the packet before the next Start-Of-Frame. This health counter measures the number of times this occurs to provide feedback to selecting a proper TXSCHOH. Writing to this register will clear the counter and this counter will max. at 31. Default value is for OTG controller core, and '00h' for Host-only controller core.
TXSCHOH	Scheduler Overhead. (Read/Write) [Default = 0] This register adds an additional fixed offset to the schedule time estimator described above as T_{ff} . As an approximation, the value chosen for this register should limit the number of back-off events captured in the TXSCHHEALTH to less than 10 per second in a highly utilized bus. Choosing a value that is too high for this register is not desired as it can needlessly reduce USB utilization. The time unit represented in this register is 1.267us when a device is connected in High-Speed Mode. The time unit represented in this register is 6.333us when a device is connected in Low/Full Speed Mode. Default value is '08h' for OTG controller core, and '00h' for Host-only controller core.

0 CF	Configure Flag Host software sets this bit as the last action in its process of configuring the Host Controller. This bit controls the default port-routing control logic. 0 Port routing control logic default-routes each port to an implementation dependent classic host controller. 1 Port routing control logic default-routes all ports to this host controller.

11.1.5.31 Port Status & Control (USBx_nPORTSC1)

Host Controller

A host controller could implement one to eight port status and control registers. The number is determined by N_PORTS bits in HWSPARAMs register (please see [Host Controller Structural Parameters \(USB_nHCSPARAMS\)](#)). Software could read this parameter register to determine how many ports need service.

All controller cores on this product are Single-Port, so there is only one port status and control register for each controller core.

This register is only reset by power on reset or controller core reset. The initial conditions of a port are:

- No device connected
- Port disabled

If the port supports power control, this state remains until port power is supplied (by software).

Device Controller

A controller operating in device mode has only port register one (PORTSC1) and it does not support power control in that mode. Port control in device mode is only used for status port reset, suspend, and current connect status. It is also used to initiate test mode or force signaling and allows software to put the PHY into low power suspend mode and disable the PHY clock.

USBx_nPORTSC1 field descriptions (continued)

Field	Description
15–14 PIC	<p>Port Indicator Control - Read/Write. Default = 0b.</p> <p>Writing to this field has no effect if the P_INDICATOR bit in the HCSPARAMS register is a zero.</p> <p>Refer to the USB Specification Revision 2.0 for a description on how these bits are to be used.</p> <p>This field is zero if <i>Port Power</i> is zero.</p> <p>Bit Value Meaning</p> <p>00 Port indicators are off</p> <p>01 Amber</p> <p>10 Green</p> <p>11 Undefined</p>
13 PO	<p>Port Owner-Read/Write. Default = 0.</p> <p>This bit unconditionally goes to a 0 when the configured bit in the CONFIGFLAG register makes a 0 to 1 transition. This bit unconditionally goes to 1 whenever the Configured bit is zero. System software uses this field to release ownership of the port to a selected host controller (in the event that the attached device is not a high-speed device). Software writes a one to this bit when the attached device is not a high-speed device. A one in this bit means that an internal companion controller owns and controls the port.</p> <p>Port owner handoff is not supported in all controller cores, therefore this bit will always be 0.</p>
12 PP	<p>Port Power (PP)-Read/Write or Read Only.</p> <p>The function of this bit depends on the value of the Port Power Switching (PPC) field in the HCSPARAMS register. The behavior is as follows:</p> <p>PPC</p> <p>PP Operation</p> <p>0</p> <p>1b <i>Read Only</i> - Host controller does not have port power control switches. Each port is hard-wired to power.</p> <p>1</p> <p>1b/0b - <i>Read/Write</i>. Host/OTG controller requires port power control switches. This bit represents the current setting of the switch (0=off, 1=on). When power is not available on a port (that is, PP equals a 0), the port is non-functional and will not report attaches, detaches, etc.</p> <p>When an over-current condition is detected on a powered port and PPC is a one, the PP bit in each affected port may be transitional by the host controller driver from a one to a zero (removing power from the port).</p> <p>This feature is implemented in all controller cores (PPC = 1).</p>
11–10 LS	<p>Line Status-Read Only. These bits reflect the current logical levels of the D+ (bit 11) and D- (bit 10) signal lines.</p> <p>In host mode, the use of linestate by the host controller driver is not necessary (unlike EHCI), because the port controller state machine and the port routing manage the connection of LS and FS.</p> <p>In device mode, the use of linestate by the device controller driver is not necessary.</p> <p>The encoding of the bits are:</p> <p>Bits [11:10] Meaning</p> <p>00 SE0</p> <p>10 J-state</p>

Table continues on the next page...

USB_x_nPORTSC1 field descriptions (continued)

Field	Description
	01 K-state 11 Undefined
9 HSP	High-Speed Port - Read Only. Default = 0b. When the bit is one, the host/device connected to the port is in high-speed mode and if set to zero, the host/device connected to the port is not in a high-speed mode. NOTE: HSP is redundant with PSPD(bit 27, 26) but remained for compatibility.
8 PR	Port Reset - Read/Write or Read Only. Default = 0b. In Host Mode: Read/Write. 1=Port is in Reset. 0=Port is not in Reset. Default 0. When software writes a one to this bit the bus-reset sequence as defined in the USB Specification Revision 2.0 is started. <i>This bit will automatically change to zero after the reset sequence is complete. This behavior is different from EHCI where the host controller driver is required to set this bit to a zero after the reset duration is timed in the driver.</i> In Device Mode: This bit is a read only status bit. Device reset from the USB bus is also indicated in the USBSTS register. This field is zero if <i>Port Power</i> (Port Status & Control (USB_nPORTSC1)) is zero.
7 SUSP	Suspend - Read/Write or Read Only. Default = 0b. 1=Port in suspend state. 0=Port not in suspend state. In Host Mode: Read/Write. Port Enabled Bit and Suspend bit of this register define the port states as follows: Bits [Port Enabled, Suspend] Port State 0x Disable 10 Enable 11 Suspend When in suspend state, downstream propagation of data is blocked on this port, except for port reset. The blocking occurs at the end of the current transaction if a transaction was in progress when this bit was written to 1. In the suspend state, the port is sensitive to resume detection. Note that the bit status does not change until the port is suspended and that there may be a delay in suspending a port if there is a transaction currently in progress on the USB. The host controller will unconditionally set this bit to zero when software sets the <i>Force Port Resume</i> bit to zero. The host controller ignores a write of zero to this bit. If host software sets this bit to a one when the port is not enabled (that is, <i>Port enabled</i> bit is a zero) the results are undefined. This field is zero if <i>Port Power</i> (Port Status & Control (USB_nPORTSC1)) is zero in host mode. In Device Mode: Read Only. In device mode this bit is a read only status bit.
6 FPR	Force Port Resume -Read/Write. 1= Resume detected/driven on port. 0=No resume (K-state) detected/driven on port. Default = 0. In Host Mode: Software sets this bit to one to drive resume signaling. The Host Controller sets this bit to one if a J-to-K transition is detected while the port is in the Suspend state. When this bit transitions to a one because a J-to-K transition is detected, the <i>Port Change Detect</i> bit in the USBSTS register is also set to one. <i>This bit</i>

Table continues on the next page...

USB_nPORTSC1 field descriptions (continued)

Field	Description
	<p><i>will automatically change to zero after the resume sequence is complete. This behavior is different from EHCI where the host controller driver is required to set this bit to a zero after the resume duration is timed in the driver.</i></p> <p>Note that when the Host controller owns the port, the resume sequence follows the defined sequence documented in the USB Specification Revision 2.0. The resume signaling (Full-speed 'K') is driven on the port as long as this bit remains a one. This bit will remain a one until the port has switched to the high-speed idle. Writing a zero has no effect because the port controller will time the resume operation, clear the bit the port control state switches to HS or FS idle.</p> <p>This field is zero if <i>Port Power</i>(Port Status & Control (USB_nPORTSC1)) is zero in host mode.</p> <p>This bit is not-EHCI compatible.</p> <p>In Device mode:</p> <p>After the device has been in Suspend State for 5ms or more, software must set this bit to one to drive resume signaling before clearing. The Device Controller will set this bit to one if a J-to-K transition is detected while the port is in the Suspend state. The bit will be cleared when the device returns to normal operation. Also, when this bit will be cleared because a K-to-J transition detected, the <i>Port Change Detect</i> bit in the USBSTS register is also set to one.</p>
5 OCC	<p>Over-current Change-R/WC. Default=0.</p> <p>This bit is set '1b' by hardware when there is a change to Over-current Active. Software can clear this bit by writing a one to this bit position.</p>
4 OCA	<p>Over-current Active-Read Only. Default 0.</p> <p>This bit will automatically transition from one to zero when the over current condition is removed.</p> <p>1 This port currently has an over-current condition 0 This port does not have an over-current condition.</p>
3 PEC	<p>Port Enable/Disable Change-R/WC. 1=Port enabled/disabled status has changed. 0=No change. Default = 0.</p> <p>In Host Mode:</p> <p>For the root hub, this bit is set to a one only when a port is disabled due to disconnect on the port or due to the appropriate conditions existing at the EOF2 point (See Chapter 11 of the USB Specification). Software clears this by writing a one to it.</p> <p>This field is zero if <i>Port Power</i>(Port Status & Control (USB_nPORTSC1)) is zero.</p> <p>In Device mode:</p> <p>The device port is always enabled, so this bit is always '0b'.</p>
2 PE	<p>Port Enabled/Disabled-Read/Write. 1=Enable. 0=Disable. Default 0.</p> <p>In Host Mode:</p> <p>Ports can only be enabled by the host controller as a part of the reset and enable. Software cannot enable a port by writing a one to this field. Ports can be disabled by either a fault condition (disconnect event or other fault condition) or by the host software. Note that the bit status does not change until the port state actually changes. There may be a delay in disabling or enabling a port due to other host controller and bus events.</p> <p>When the port is disabled, (0b) downstream propagation of data is blocked except for reset.</p> <p>This field is zero if <i>Port Power</i>(Port Status & Control (USB_nPORTSC1)) is zero in host mode.</p> <p>In Device Mode:</p> <p>The device port is always enabled, so this bit is always '1b'.</p>

Table continues on the next page...

USB_x_nPORTSC1 field descriptions (continued)

Field	Description
1 CSC	<p>Connect Status Change-R/WC. 1 =Change in Current Connect Status. 0=No change. Default 0.</p> <p>In Host Mode:</p> <p>Indicates a change has occurred in the port's Current Connect Status. The host/device controller sets this bit for all changes to the port device connect status, even if system software has not cleared an existing connect status change. For example, the insertion status changes twice before system software has cleared the changed condition, hub hardware will be 'setting' an already-set bit (that is, the bit will remain set). Software clears this bit by writing a one to it.</p> <p>This field is zero if <i>Port Power</i>(Port Status & Control (USB_nPORTSC1)) is zero in host mode.</p> <p>In Device Mode:</p> <p>This bit is undefined in device controller mode.</p>
0 CCS	<p>Current Connect Status-Read Only.</p> <p>In Host Mode:</p> <p>1=Device is present on port. 0=No device is present. Default = 0. This value reflects the current state of the port, and may not correspond directly to the event that caused the <i>Connect Status Change</i> bit (Bit 1) to be set.</p> <p>This field is zero if <i>Port Power</i>(Port Status & Control (USB_nPORTSC1)) is zero in host mode.</p> <p>In Device Mode:</p> <p>1=Attached. 0=Not Attached. Default=0. A one indicates that the device successfully attached and is operating in either high speed or full speed as indicated by the High Speed Port bit in this register. A zero indicates that the device did not attach successfully or was forcibly disconnected by the software writing a zero to the Run bit in the USBCMD register. It does not state the device being disconnected or suspended.</p>

11.1.5.32 On-The-Go Status & control (USB_x_nOTGSC)

This register is available only in OTG controller core. It has four sections:

- OTG Interrupt enables (Read/Write)
- OTG Interrupt status (Read/Write to Clear)
- OTG Status inputs (Read Only)
- OTG Controls (Read/Write)

The status inputs are debounced using a 1 ms time constant. Values on the status inputs that do not persist for more than 1 ms does not cause an update of the status input register, or cause an OTG interrupt.

See also [USB Device Mode \(USB_nUSBMODE\)](#) register.

Address: Base address + 1A4h offset + (65536d × i), where i=0d to 1d

USB_x_nOTGSC field descriptions

Field	Description
31 -	This field is reserved. Reserved
30 DPIE	Data Pulse Interrupt Enable
29 EN_1MS	1 millisecond timer Interrupt Enable - Read/Write
28 BSEIE	B Session End Interrupt Enable - Read/Write. Setting this bit enables the B session end interrupt.
27 BSVIE	B Session Valid Interrupt Enable - Read/Write. Setting this bit enables the B session valid interrupt.
26 ASVIE	A Session Valid Interrupt Enable - Read/Write. Setting this bit enables the A session valid interrupt.
25 AVVIE	A VBus Valid Interrupt Enable - Read/Write. Setting this bit enables the A VBus valid interrupt.
24 IDIE	USB ID Interrupt Enable - Read/Write. Setting this bit enables the USB ID interrupt.
23 -	This field is reserved. Reserved
22 DPIS	Data Pulse Interrupt Status - Read/Write to Clear. This bit is set when data bus pulsing occurs on DP or DM. Data bus pulsing is only detected when USBMODE.CM = Host (11) and PORTSC1(0)[PP] = 0. Software must write a one to clear this bit.
21 STATUS_1MS	1 millisecond timer Interrupt Status - Read/Write to Clear. This bit is set once every millisecond. Software must write a one to clear this bit.
20 BSEIS	B Session End Interrupt Status - Read/Write to Clear. This bit is set when VBus has fallen below the B session end threshold. Software must write a one to clear this bit.
19 BSVIS	B Session Valid Interrupt Status - Read/Write to Clear. This bit is set when VBus has either risen above or fallen below the B session valid threshold. Software must write a one to clear this bit.
18 ASVIS	A Session Valid Interrupt Status - Read/Write to Clear. This bit is set when VBus has either risen above or fallen below the A session valid threshold. Software must write a one to clear this bit.
17 AVVIS	A VBus Valid Interrupt Status - Read/Write to Clear. This bit is set when VBus has either risen above or fallen below the VBus valid threshold on an A device. Software must write a one to clear this bit.
16 IDIS	USB ID Interrupt Status - Read/Write. This bit is set when a change on the ID input has been detected. Software must write a one to clear this bit.

Table continues on the next page...

USB_x_nOTGSC field descriptions (continued)

Field	Description
15 -	This field is reserved. Reserved
14 DPS	Data Bus Pulsing Status - Read Only. A '1' indicates data bus pulsing is being detected on the port.
13 TOG_1MS	1 millisecond timer toggle - Read Only. This bit toggles once per millisecond.
12 BSE	B Session End - Read Only. Indicates VBus is below the B session end threshold.
11 BSV	B Session Valid - Read Only. Indicates VBus is above the B session valid threshold.
10 ASV	A Session Valid - Read Only. Indicates VBus is above the A session valid threshold.
9 AVV	A VBus Valid - Read Only. Indicates VBus is above the A VBus valid threshold.
8 ID	USB ID - Read Only. 0 = A device, 1 = B device
7-6 -	This field is reserved. Reserved
5 IDPU	ID Pullup - Read/Write This bit provide control over the ID pull-up resistor; 0 = off, 1 = on [default]. When this bit is 0, the ID input will not be sampled.
4 DP	Data Pulsing - Read/Write. Setting this bit causes the pullup on DP to be asserted for data pulsing during SRP.
3 OT	OTG Termination - Read/Write. This bit must be set when the OTG device is in device mode, this controls the pulldown on DM.
2 -	This field is reserved. Reserved
1 VC	VBUS Charge - Read/Write. Setting this bit causes the VBus line to be charged. This is used for VBus pulsing during SRP.
0 VD	VBUS_Discharge - Read/Write. Setting this bit causes VBus to discharge through a resistor.

11.1.5.33 USB Device Mode (USBx_nUSBMODE)

Address: Base address + 1A8h offset + (65536d × i), where i=0d to 1d

USBx_nUSBMODE field descriptions

Field	Description
31–16 -	This field is reserved. Reserved
15 -	This field is reserved. Reserved
14–5 -	This field is reserved. Reserved
4 SDIS	<p>Stream Disable Mode. (0 - Inactive [default]; 1 - Active)</p> <p>Device Mode: Setting to a '1' disables double priming on both RX and TX for low bandwidth systems. This mode ensures that when the RX and TX buffers are sufficient to contain an entire packet that the standard double buffering scheme is disabled to prevent overruns/underruns in bandwidth limited systems. Note: In High Speed Mode, all packets received are responded to with a NYET handshake when stream disable is active.</p> <p>Host Mode: Setting to a '1' ensures that overruns/underruns of the latency FIFO are eliminated for low bandwidth systems where the RX and TX buffers are sufficient to contain the entire packet. Enabling stream disable also has the effect of ensuring the TX latency is filled to capacity before the packet is launched onto the USB.</p> <p>NOTE: Time duration to pre-fill the FIFO becomes significant when stream disable is active. See TX FIFO Fill Tuning (USB_nTXFILLTUNING) and TTTTFFILLTUNING [MPH Only] to characterize the adjustments needed for the scheduler when using this feature.</p>

Table continues on the next page...

USBx_nUSBMODE field descriptions (continued)

Field	Description
	NOTE: The use of this feature substantially limits the overall USB performance that can be achieved.
3 SLOM	Setup Lockout Mode. In device mode, this bit controls behavior of the setup lock mechanism. See Control Endpoint Operation Model . 0 Setup Lockouts On (default); 1 Setup Lockouts Off (DCD requires use of Setup Data Buffer Tripwire in USB Command Register (USB_nUSBCMD) .
2 ES	Endian Select - Read/Write. This bit can change the byte alignment of the transfer buffers to match the host microprocessor. The bit fields in the microprocessor interface and the data structures are unaffected by the value of this bit because they are based upon the 32-bit word. Bit Meaning 0 Little Endian [Default] 1 Big Endian
CM	Controller Mode - R/WO. Controller mode is defaulted to the proper mode for host only and device only implementations. For those designs that contain both host & device capability, the controller defaults to an idle state and needs to be initialized to the desired operating mode after reset. For combination host/device controllers, this register can only be written once after reset. If it is necessary to switch modes, software must reset the controller by writing to the <i>RESET</i> bit in the USBCMD register before reprogramming this register. For OTG controller core, reset value is '00b'. For Host-only controller core, reset value is '11b'. 00 Idle [Default for combination host/device] 01 Reserved 10 Device Controller [Default for device only controller] 11 Host Controller [Default for host only controller]

11.1.5.34 Endpoint Setup Status (USBx_nENDPTSETUPSTAT)

Address: Base address + 1ACh offset + (65536d × i), where i=0d to 1d

USBx_nENDPTSETUPSTAT field descriptions

Field	Description
31–16 -	This field is reserved. Reserved
ENDPTSETUPSTAT	Setup Endpoint Status. For every setup transaction that is received, a corresponding bit in this register is set to one. Software must clear or acknowledge the setup transfer by writing a one to a respective bit after it has read the setup data from Queue head. The response to a setup packet as in the order of operations and total response time is crucial to limit bus time outs while the setup lock our mechanism is engaged. See Managing Endpoints in the Device Operational Model. This register is only used in device mode.

11.1.5.35 Endpoint Prime (USBx_nENDPTPRIME)

This register is only used in device mode.

When software sets the prime bit for a given endpoint, the device controller loads the transfer descriptor, pointed to by the queue head, such that the endpoint is ready to transmit or receive when the host sends a request (IN/OUT token). The endpoint will NAK all requests from the host until the endpoint is primed. The controller will automatically re-prime the endpoint with a new transfer descriptor when one is found via the next_dtd pointer of the current transfer descriptor. Hence, the prime bit must only be set by software when a descriptor is added to the queue head.

Address: Base address + 1B0h offset + (65536d × i), where i=0d to 1d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table continues on the next page...

USB_x_nENDPTCTRL0 field descriptions (continued)

Field	Description
22–20 -	This field is reserved. Reserved
19–18 TXT	TX Endpoint Type - Read/Write 00 - Control Endpoint0 is fixed as a Control End Point.
17 -	This field is reserved. Reserved
16 TXS	TX Endpoint Stall - Read/Write 0 End Point OK [Default] 1 End Point Stalled Software can write a one to this bit to force the endpoint to return a STALL handshake to the Host. It continues returning STALL until the bit is cleared by software or it is automatically cleared upon receipt of a new SETUP request. After receiving a SETUP request, this bit will continue to be cleared by hardware until the associated ENDPTSETUPSTAT bit is cleared. NOTE: There is a slight delay (50 clocks max.) between the endptsetupstat being cleared and hardware continuing to clear this bit. In most systems it is unlikely the DCD software will observe this delay. However, should the dcd observe that the stall bit is not set after writing a one to it then follow this procedure: continually write this stall bit until it is set or until a newsetup has been received by checking the associated endptsetupstat bit.
15–8 -	This field is reserved. Reserved
7 RXE	RX Endpoint Enable 1 Enabled Endpoint0 is always enabled.
6–4 -	This field is reserved. Reserved
3–2 RXT	RX Endpoint Type - Read/Write 00 Control Endpoint0 is fixed as a Control End Point.
1 -	This field is reserved. Reserved
0 RXS	RX Endpoint Stall - Read/Write 0 End Point OK. [Default] 1 End Point Stalled Software can write a one to this bit to force the endpoint to return a STALL handshake to the Host. It continues returning STALL until the bit is cleared by software or it is automatically cleared upon receipt of a new SETUP request. After receiving a SETUP request, this bit will continue to be cleared by hardware until the associated ENDPTSETUPSTAT bit is cleared.

Table continues on the next page...

USBx_nENDPTCTRL0 field descriptions (continued)

Field	Description
	NOTE: There is a slight delay (50 clocks max.) between the endptsetupstat being cleared and hardware continuing to clear this bit. In most systems it is unlikely the dcd software will observe this delay. However, should the dcd observe that the stall bit is not set after writing a one to it then follow this procedure: continually write this stall bit until it is set or until a newsetup has been received by checking the associated endptsetupstat bit.

11.1.5.40 Endpoint Control 1 (USBx_nENDPTCTRL1)

This is endpoint control register for endpoint 1 in device operation mode.

NOTE

If one endpoint direction is enabled and the paired endpoint of opposite direction is disabled then the unused direction type must be changed from the default control-type to any other type (that is Bulk-type). leaving an unconfigured endpoint control causes undefined behavior for the data pid tracking on the active endpoint/direction.

11.1.5.46 Endpoint Control 7 (USBx_nENDPTCTRL7)

This is endpoint control register for endpoint 7 in device operation mode.

NOTE

If one endpoint direction is enabled and the paired endpoint of opposite direction is disabled then the unused direction type must be changed from the default control-type to any other type (that is Bulk-type). leaving an unconfigured endpoint control causes undefined behavior for the data pid tracking on the active endpoint/direction.

Address: Base address + 1DCh offset + (65536d × i), where i=0d to 1d

11.2 Universal Serial Bus 2.0 PHY (USB2_PHY)

11.2.1 Overview

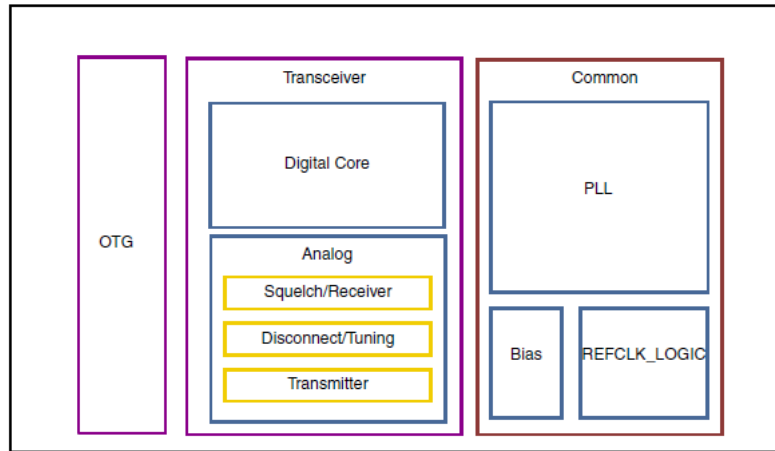

The USB 2.0 PHY, connects a USB OTG controller to a USB system. This chapter provides an introduction to the USB 2.0 PHY and its features.

NOTE

The information within this block guide is Synopsys Proprietary. Used with permission.

11.2.1.1 Block Diagram

The following figure shows the USB 2.0 PHY functional block diagram for a one-port macro.

11.2.1.2 Features

The USB 2.0 PHY provides the following features.

General Features:

- Implements low power dissipation while active, idle, or on standby
- Fully integrates high-, full-, and low-speed (Host mode only) termination and signal switching
- Implements one parallel data interface and clock for high-, full-, and low-speed (Host mode only) USB data transfers
- Provides on-chip PLL to reduce clock noise and eliminate the need for an external clock generator
- Provides Universal Asynchronous Receiver/Transmitter (UART) support to enable the USB 2.0 PHY to receive and transmit asynchronous, serial data

USB 2.0 Features:

- Supports 480-Mbps high-speed, 12-Mbps full-speed, and 1.5-Mbps low-speed (Host mode only) data transmission rates
- Supports 8/16-bit unidirectional parallel interfaces for HS, FS, and LS (Host mode only) modes of operation, in accordance with the UTMI+ specification
- Provides dual (HS/FS) mode host support
- Implements data recovery from serial data on the USB connector
- Implements SYNC/End-of-Packet (EOP) generation and checking
- Implements Non Return to Zero Invert (NRZI) encoding and decoding Implements logic to support suspend, sleep, resume, and remote wakeup operations
- Supports battery charging to enable devices to draw current in excess of the USB 2.0 specification for charging and/or powering up from dedicated charging ports or charging downstream ports

11.2.1.3 Interfaces

Each USB 2.0 PHY port has three distinct external interfaces:

- USB Data Plus (D+) and Data Minus (D–) lines: These lines are USB 1.1 and 2.0 specification compliant. The USB 2.0 PHY supports high-speed, 480-Mbps transfers, as well as USB 1.1 full-speed and low-speed transfers through the USB.
- USB 2.0 Transceiver Macrocell Interface (UTMI+): The USB 2.0 PHY supports the following modes through the UTMI+:
 - High-Speed (HS)
 - Full-Speed (FS)
 - Low-Speed Preamble (LS Preamble)

The UTMI+ contains a receive port, a transmit port, and associated control lines to interface with a USB host controller or device controller. The receive and transmit ports can be configured as 8/16-bit parallel ports for all applicable modes of operation.

- Serial interface: This is the USB 1.1 controller interface that supports full-speed (FS-Serial mode) and low-speed (LS-Serial mode) data transmission rates to and from a USB 1.1 controller.

The USB 2.0 PHY handles low-level USB protocol and signaling. The USB 2.0 PHY supports SYNC detection, data serialization and deserialization, and data recovery.

11.2.1.4 Standards Compliance

The USB 2.0 PHY complies with the following standards:

- Universal Serial Bus Specification, Revision 2.0, with a High-Speed (HS) Transmit to Receive Inter-Packet Delay requirement of 38 bit-times provided by the UTMI specification version 1.05.
- Battery Charging Specification, Revision 1.2, USB Implementers Forum, Inc.
- On-The-Go and Embedded Host Supplement to the USB Revision 2.0 Specification, Revision 2.0, USB Implementers Forum, Inc. ADP (Attach Detach Protocol) is not supported.
- UTMI+ Specification, Revision 1.0 (Level 3)

11.2.2 Architecture

This section describes the high-level architecture of the USB 2.0 PHY.

11.2.2.1 Block Descriptions

The USB 2.0 PHY provides the following features.

As shown in [Block Diagram](#), the USB 2.0 PHY consists of three basic components: the Common block, Transceiver block, and OTG block.

- Common block: This block contains circuitry that provides biasing and reference clocks for each Transceiver block.
- Transceiver block: This block contains circuitry for data processing and transfers.
- OTG block: This block contains circuitry to initiate the Session Request Protocol (SRP) and the Host Negotiation Protocol (HNP).

11.2.2.1.1 Common Block

The Common block contains the Phase-Locked Loop (PLL), Bias, and REFCLK_LOGIC blocks.

11.2.2.1.1.1 Phase-Locked Loop

The PLL takes a reference clock from the REFCLK_LOGIC block and outputs 16 equally-spaced (in time) phases that are propagated to the digital core for use in its Delay-Locked Loop (DLL) clock and data recovery circuit.

To limit power-supply-induced jitter, internal regulators supply power to all jitter-sensitive circuitry in the PLL such as the charge pump, oscillator, and frequency divider.

11.2.2.1.1.2 Bias

The Bias block provides bias references to the analog circuitry in both the Common and Transceiver blocks.

11.2.2.1.1.3 REFCLK_LOGIC

The REFCLK_LOGIC block performs all mode control, multiplexing, and division of core clock sources. The output clocks from the REFCLK_LOGIC block are divide by 1, 2, or 5 versions of the input clock, and these output clocks are provided to the digital core and the PLL block. The REFCLK_LOGIC block accepts 9.6-, 10-, 12-, 19.2-, 20-, 24-,

and 50-MHz core clock input frequencies. Dividers in the REFCLK_LOGIC block, whose division rates are set by top-level ports, convert the reference clock frequency to the PLL reference.

11.2.2.1.2 Transceiver Block

The Transceiver block comprises the Analog block and the digital core, which control the transmit, receive, disconnect detection, squelch detection, and automatic tuning functions.

11.2.2.1.2.1 Analog Block

The Analog block comprises the Squelch/Receiver, Disconnect/Tuning, and Transmitter blocks.

11.2.2.1.2.2 Squelch/Receiver Block

This block combines the squelch detection and receiver functions.

The Receiver regulator provides power to the Squelch/Receiver block's core-voltage circuitry and Disconnect/Tuning block's core-voltage circuitry.

11.2.2.1.2.3 Disconnect/Tuning Block

This block employs a low-offset comparator to perform host disconnect detection.

In addition, the comparator is used in the high-speed transmit DC level tuning algorithm. To ensure that temperature changes do not affect the tuned DC level, this tuning algorithm is run at each Start-of-Frame (SOF) transmission or reception. Furthermore, the Disconnect/Tuning block contains the control circuitry for the ANALOGTEST pin.

11.2.2.1.2.4 Transmitter Block

The Transmitter block contains drivers for all three speed modes in the USB protocol: HS mode at 480 Mbps, FS mode at 12 Mbps, and LS mode at 1.5 Mbps.

This block also includes automatically tuned 45- Ω resistors that set the HS input and output impedance, 1.5-k Ω D+ device pull-up resistor for FS operation, and 15-k Ω D+ and D- host pull-down resistors for FS and LS operations. The USB 2.0 PHY does not integrate a 1.5-k Ω D- device pull-up resistor for LS operation, because according to the USB 2.0 specification, an HS-capable device cannot support LS device operation.

11.2.2.1.3 OTG Block

The OTG block enables A-devices and B-devices to initiate the Session Request Protocol (SRP), and dualrole devices to initiate the Host Negotiation Protocol (HNP).

11.2.3 External Signals

The following table describes the external signals.

Table 11-76. External Signals

Signal	I/O	Description
FREECLK	O	Free-Running UTMI+ Clock Function: This controller signal is valid only if the USB 2.0 PHY is used as a downstream-facing port. In Suspend or Sleep mode, the state of FREECLK is indeterminate.
PHYCLOCK<#>	O	UTMI+ Clock Function: This controller signal clocks parallel receive and transmit data on the UTMI+.
CHGDET<#>	O	Battery Charger Detection Output Function: Indicates whether the voltage level on DP<#> or DM<#> is greater than VDAT_REF as defined in the Battery Charger specification.
VBUS0	IO	USB 5-V Signal Function: The PHY VBUS0 pin must not connect directly to the 5v VBUS voltage on the USB2.0 link. The PHY VBUS0 pin must be isolated by an external resistor (REXT1) so that the PHY VBUS0 pin sees a lower voltage. A charge pump external to the USB 2.0 PHY must provide power to this pin. If VBUS0 is not used, leave it floating.
ID0	IO	USB Mini-Receptacle Identifier or Alternate Test Point for DC Points Probes Inside USB 2.0 PHY Function: This signal differentiates a mini-A from a mini-B plug or between the ACA ID resistances. If this signal is not used, internal resistance pulls the signal's voltage level up to VDD18<#> when IDPULLUP0 is high.
DP<#>	IO	USB D+ Signal

Table continues on the next page...

Table 11-76. External Signals (continued)

Signal	I/O	Description
		Function: In normal operation, DP<#> carries USB data to and from the USB 2.0 PHY. In HS operation, this pin receives/transmits a maximum of 800 mV or 400 mV nominally. In FS or LS operation, this pin receives/transmits 3.3 V nominally.
DM<#>	IO	USB D– Signal Function: In normal operation, DP<#> carries USB data to and from the USB 2.0 PHY. In HS operation, this pin receives/transmits a maximum of 800 mV or 400 mV nominally. In FS or LS operation, this pin receives/transmits 3.3 V nominally.
TXRTUNE	IO	Transmitter Resistor Tune Pin Function: This analog signal connects to an external resistor (REXT2) that adjusts the USB 2.0 PHY's high-speed source impedance.
DVDD	I	Digital Power Supply Function: Digital power supply from the PHY's I/O power pads.
VDD33<#>	I	3.3-V Analog Power Supply Function: Analog power supply.
VDD18<#>	I	1.8V Analog Power Supply Function: Analog power supply
VSSA<#>	I	Ground Supply Function: Ground supply for the Common, Transceiver, and OTG blocks.
REFCLOUT	O	Buffered Version of CLKCORE Function: This output clock is a buffered version of the reference clock (CLKCORE).
CLKCORE	I	On-Chip Reference Clock Source Function: This clock signal enables the USB 2.0 PHY to accept a corevoltage reference clock on this pin. If this signal is not used, tie it to ground.
CLK48MOHCI	O	48-MHz Reference Clock for Open Host Controller Interface (OHCI) Function: This 48-MHz reference output clock signal can be used by logic external to the USB 2.0 PHY. This signal does not control any UTMI+ input or output and is derived from the USB 2.0 PHY's internal PLL's 480-MHz output

Table continues on the next page...

Table 11-76. External Signals (continued)

Signal	I/O	Description
		<p>through an internal divide-by-10 circuit. This signal starts pulsing when the PLL is locked and stops pulsing when the PLL is powered down in Suspend or Sleep mode. Setting the COMMONONN input to 1'b0 prevents the PLL from being powered down in Suspend or Sleep mode. Therefore, CLK48MOHCI continues to toggle while COMMONONN is asserted, even in Suspend or Sleep mode. The peak output jitter on CLK48MOHCI is ± 200 ps.</p> <p>Notes:</p> <ul style="list-style-type: none"> • When using this output as a clock signal for external logic, ensure that CLK48MOHCI has its own clock tree. • Setting COMMONONN to 1'b0 causes the PLL to remain powered, even in Suspend or Sleep mode. The resultant current draw of approximately 15 mA might affect suspend current limits, especially for bus-powered devices. • CLK48MOHCI is a 50% duty cycle output. • Loading effects on this pin are specified in the .lib timing models. • When the internal PLL is powered down in Suspend or Sleep mode, the CLK48MOHCI output settles down to either logic 1 or logic 0. Therefore, CLK48MOHCI is not appropriate as a clock signal for external latch-based logic.
CLK12MOHCI	O	<p>12-MHz Reference Clock for OHCI</p> <p>Function: This 12-MHz reference output clock signal can be used by logic external to the USB 2.0 PHY. This signal does not control any UTMI+ input or output and is derived from the USB 2.0 PHY's internal PLL's 480-MHz output through an internal divide-by-40 circuit. This signal starts pulsing when the PLL is locked and stops pulsing when the PLL is powered down in Suspend or Sleep mode. Setting the COMMONONN input to 1'b0 prevents the PLL from being powered down in Suspend or Sleep mode. Therefore, CLK12MOHCI continues to toggle while COMMONONN</p>

Table continues on the next page...

Table 11-76. External Signals (continued)

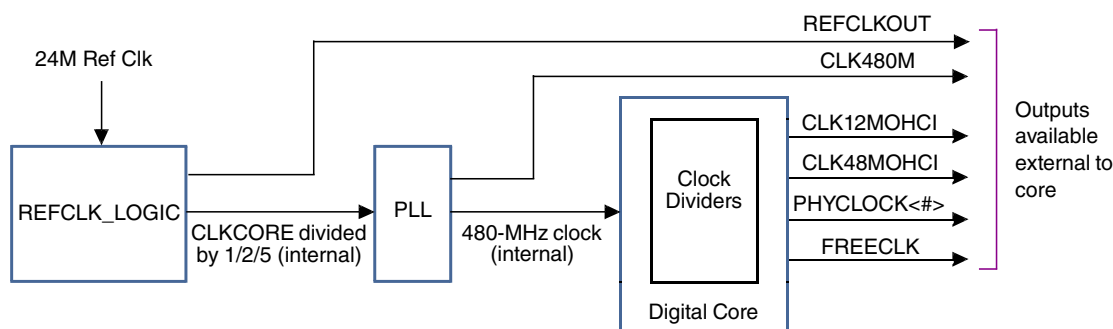

Signal	I/O	Description
		<p>is asserted, even in Suspend or Sleep mode. The peak output jitter on CLK12MOHCI is ± 200 ps.</p> <p>Notes:</p> <ul style="list-style-type: none"> When using this output as a clock signal for external logic, ensure that CLK12MOHCI has its own clock tree. Setting COMMONONN to 1'b0 causes the PLL to remain powered, even in Suspend or Sleep mode. The resultant current draw of approximately 15 mA might affect suspend current limits, especially for bus-powered devices. CLK12MOHCI is a 50% duty cycle output. Loading effects on this pin are specified in the .lib timing models. When the internal PLL is powered down in Suspend or Sleep mode, the CLK12MOHCI output settles down to either logic 1 or logic 0. Therefore, CLK12MOHCI is not appropriate as a clock signal for external latch-based logic.
CLK480M	O	<p>480-MHz Buffered Output Clock From PLL</p> <p>Function: This 480-MHz clock is a buffered output clock from the PLL that can be used by logic external to the USB 2.0 PHY. Setting the COMMONONN input to 1'b0 prevents the PLL from being powered down in Suspend and Sleep modes. Therefore, CLK480M continues to toggle while COMMONONN is asserted, even in Suspend or Sleep mode.</p> <p>Notes:</p> <ul style="list-style-type: none"> When using this output as a clock signal for external logic, ensure that CLK480M has its own clock tree. Setting COMMONONN to 1'b0 causes the PLL, REFCLK_LOGIC, and Bias blocks to remain powered, even in Suspend or UART/Autoresume mode. The resultant current draw of approximately 15 mA might affect suspend current limits, especially for bus-powered devices.

Table 11-76. External Signals

Signal	I/O	Description
		<ul style="list-style-type: none"> • CLK480M has a 40/60 duty cycle output with 100 ps peak-to-peak jitter. • Loading effects on this pin are specified in the .lib timing models. • When the internal PLL is powered down, the state and frequency of CLK480M is indeterminate. • During a POR, the state and frequency of CLK480M is indeterminate. • When the PLL is not locked, the state and frequency of CLK480M is indeterminate. Gating circuitry for CLK480M must be external to the USB 2.0 PHY, because the PHYCLOCK<#> output starts pulsing only after the PLL is locked.

11.2.4 Clock Generation

The following figure shows the USB 2.0 PHY clock generation and distribution architecture, and the functional behavior of blocks that generate various clocks in the USB 2.0 PHY.

**Figure 11-32. Clock Generation**

11.2.5 OTG 2.0 Settings and Usage

This section describes the settings and usage of the USB 2.0 PHY's OTG 2.0 functionality.

11.2.5.1 OTG Block Overview

The OTG block enables A-devices and B-devices to initiate the Session Request Protocol (SRP), and dualrole devices to initiate the Host Negotiation Protocol (HNP).

Comparators

The OTG block includes two voltage comparators, session request protocol circuitry, and ID detection circuitry.

- **VBUS Valid comparator:** This comparator enables an A-device to determine if the voltage on VBUS is above the VBUS Valid threshold for valid operation.
- **VBUS Detect comparator:** This comparator detects when a session is being started (that is, when the voltage on VBUS is above the Session Valid threshold).

ID Detection Circuitry

The ID Detection circuitry senses the ID line's condition to indicate which type of plug is connected. The ID Accessory Charger Adapter (ACA) detection circuitry complies with the Battery Charging specification requirements. For more information about these requirements, refer to the Battery Charging specification.

11.2.6 Charge Pump Connection

An off-chip charge pump is required to provide power to the USB 2.0 PHY VBUS0 pin. Figure 6-5 shows the charge pump connection to the USB 2.0 PHY.

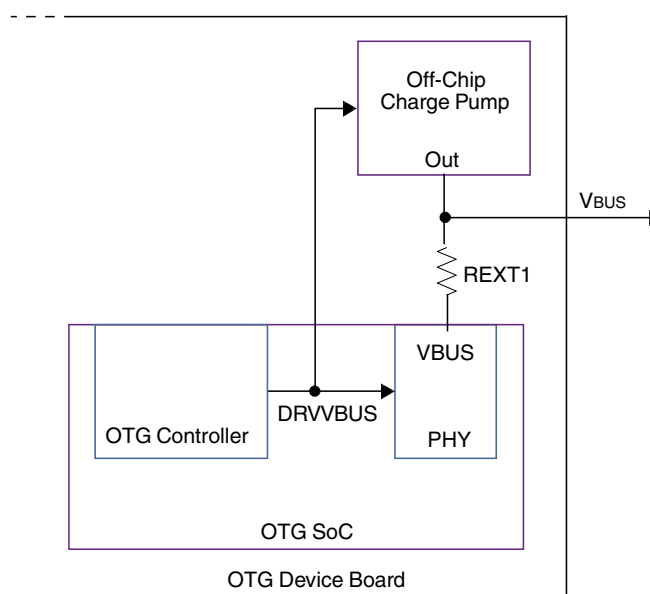

Figure 11-33. Charge Pump Connection

The charge pump's output is connected directly to VBUS on the device board. The USB 2.0 PHY's VBUS0 pin is connected to VBUS with series resistor (REXT1). The charge pump's DRVVBUS0 input is an output of the OTG HNP finite state machine and an input to the USB 2.0 PHY.

The VBUS0 pin presents a worst-case core-side load of 500 fF. This worst-case load is a small addition to the overall capacitance budget that includes the external capacitive load due to routing, pads, package, board traces, and receivers.

11.2.7 Pad/Package/Board Connections

Figure 11-34. Pad/Package/Board Connections

11.2.8 Pad Implementation Requirements

Customers must ensure that all USB pads meet the criteria in the following table.

Table 11-77. Maximum Pad/Package/Board Requirements

Signal	Signal Description	Series Resistancea (Ω) ¹	Series Inductance (nH)	Capacitancea (pF) ¹	5-V Tolerance Needed	Worst-Case Interconnect Metal DC Current Handling Requirements (mA)
ID0	USB mini-receptacle identifier	1	4	5	N	1
VBUS0	USB mini-receptacle VBUS	1	4	5	N	8
VDD33<#>	Macro supply	1	4	-	N	35
VSSA<#> ²	Macro supply	1	4	-	N	50
VDD18<#><#>	Macro supply	1	4	-	N	35
DP<#>	Analog signal	1	4	5	Y	30
DM<#>	Analog signal	1	4	5	Y	30
TXRTUNE	Analog signal	1	4	5 ³	N	15
DVDD	Digital-core supply	1	4	-	N	15
<p>The simplest way to construct the pad ring is to use the following pad types:</p> <ul style="list-style-type: none"> • VDD33: 3.3-V analog power supply pad • VDD18<#>: 1.8-VVREG analog power supply pad • VSSA<#>: ground supply pad • DVDD: Core power pad • DP, DM, VBUS: 5-V tolerant analog pads • TXRTUNE, ID: 1.8-V analog pads • VBUS0: 3.3-V analog pad 						

1. Total resistance/capacitance of the ESD I/O pad, package, bondwire (if applicable), board trace, and USB connector must not exceed specified value.
2. The PHY macro has multiple VSSA<#> pins. The total impedance between all the instances of the VSSA node and the board ground should be less than the value mentioned in this table.
3. Total capacitance of the package and board trace must not exceed specified value.

11.2.9 Device Initialization

According to the USB 2.0 specification, a host must provide 100 ms between first detecting the D+ line at a high state and initiating a USB reset (SE0). The device pulling up the D+ line is expected to complete initialization within the 100-ms interval and be ready to respond to the host.

If the device requires more than 100 ms to initialize the device might connect the D+ resistance prior to initialization. After the 100-ms interval, the host initiates a USB reset. If the D+ pull-up resistance is enabled and remains enabled after the 100-ms interval, and if the device has not completed initialization, the device does not respond to the host correctly, and the transaction times out.

11.2.10 Tuning

The USB 2.0 PHY has an internal tuning circuit that ensures that the driver's impedance is within the USB 2.0 specification.

The USB 2.0 PHY performs two types of tuning:

- Incremental tuning: Incremental tuning occurs during an EOP, SOF, or SYNC pattern.
- Full tuning: Full tuning occurs during a power-on reset or after resume operation.

11.3 PCI Express (PCIe)

11.3.1 Overview

This PCI Express dual mode (DM) controller provides a solution to implement a PCI Express port for a PCI Express root complex or endpoint application. A complete PCI Express port solution includes the controller, an analog PHY macro, and application logic to source and sink data.

NOTE

The information within this block guide is Synopsys Proprietary. Used with permission.

Figure 11-35. PCIe Application

11.3.1.1 Features

The PCI Express DM controller supports:

- Latency Tolerance Reporting (LTR)
- Address Translation Services (ATS) by your application
- Page Request Services (PRS) by your application
- Completion Timeout Ranges
- ID-Based Ordering (IDO) by your application
- PASID
- L1 Substates (L1SS)

- Extended Tag Support
- Resizable BAR (RBAR) with Expanded RBAR support,
- Separate Refclk with Independent Spread Spectrum Clocking (SRIS)
- Lightweight Notifications (LN)
- Readiness Notifications (RN)
- PCI Express Active State Power Management (ASPM)
- PCI Express Advanced Error Reporting (AER) with Multiple Header Logging
- PCI Express Advanced Error Reporting (AER)
- Vital Product Data (VPD)
- x1 lane

11.3.1.2 Standards

The PCIe controller implements the following standards:

- *PCI Express Base Specification, Revision 4.0, Version 0.7*
- Access to this specification requires membership in PCI-SIG.
- *PCI Local Bus Specification, Revision 3.0*
- Access to this specification requires membership in PCI-SIG.
- *PCI Bus Power Management Specification, Revision 1.2* Access to this specification requires membership in PCI-SIG.
- *PCI Express Card Electromechanical Specification, Revision 1.1* Access to this specification requires membership in PCI-SIG.

11.3.2 Functional Description

11.3.2.1 Link Establishment

The controller implements the LTSSM function according to the *PCI Express Base Specification, Revision 4.0, Version 0.7. .*

11.3.2.1.1 Transmit TLP Processing

The following section describe the flow of transmit TLPs through the controller.

NOTE

The controller does not check the TLP for errors.

The PCIe controller ensures transmitted TLP Payload sizes are less than or equal to the maximum payload size limit.

11.3.2.1.1.1 Transmit TLP Arbitration

TLPs and DLLPs have equal priorities during transmit arbitration as shown in the figure below. The priority of TLP types and DLLP types are shown in tables below.

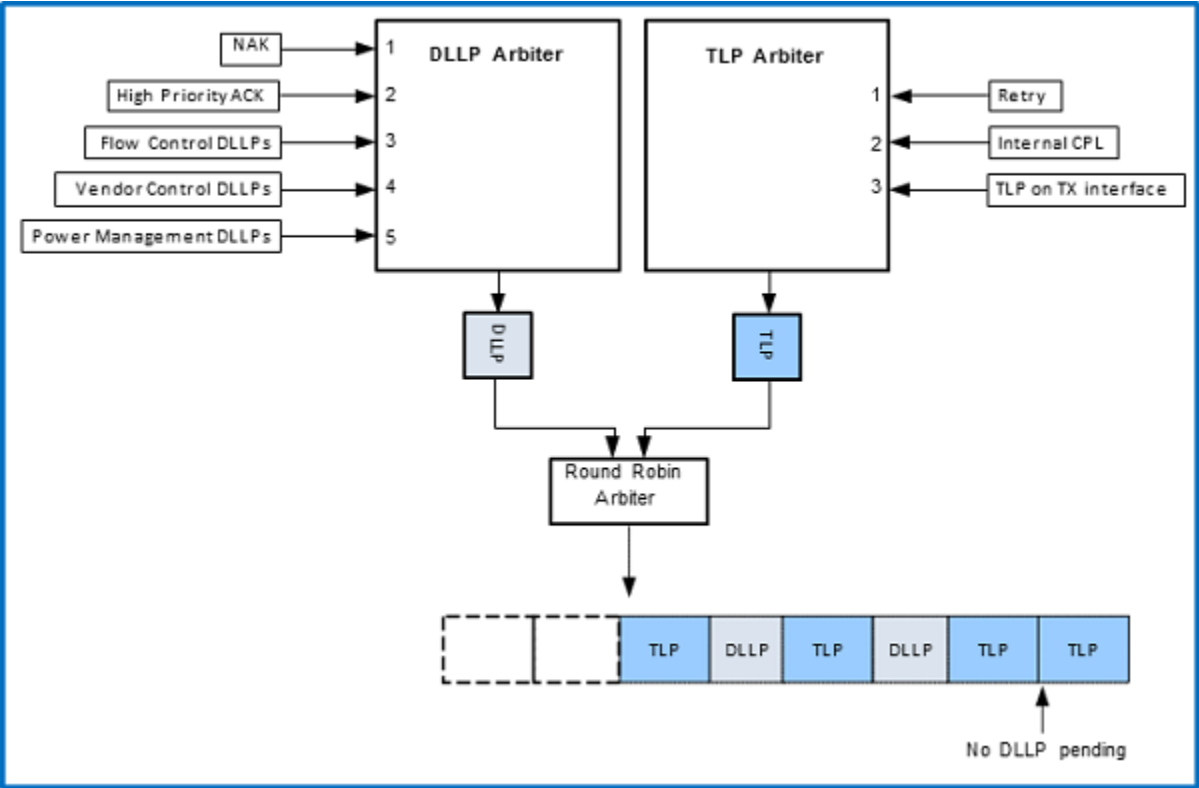

Figure 11-36. Transmit TLP/DLLP Arbitration

Table 11-78. TLP Arbitration Priority (1= Highest, 4= Lowest)

Priority	TLP Type
1	Completion of any TLP currently in progress
2	Retry buffer retransmissions
3	TLPs from the transaction layer (in the following order of priority): <ul style="list-style-type: none">• Messages generated by the controller (including by your application through the MSI interface)• Upstream ports: Completions generated by the controller (including memory or I/O mapped application register space) for Type 0 configuration read and write requests, or responses to error conditions (unsupported requests)• Downstream ports: Completions generated by the controller for unsupported requests or completer aborts
4	TLPs on the AXI Master/Slave interface

Table 11-79. DLLP Arbitration Priority (1= Highest, 6 = Lowest)

Priority	DLLP Type
1	Completion of any DLLP currently in progress
2	NAK DLLP

Table continues on the next page...

Table 11-79. DLLP Arbitration Priority (1= Highest, 6 = Lowest) (continued)

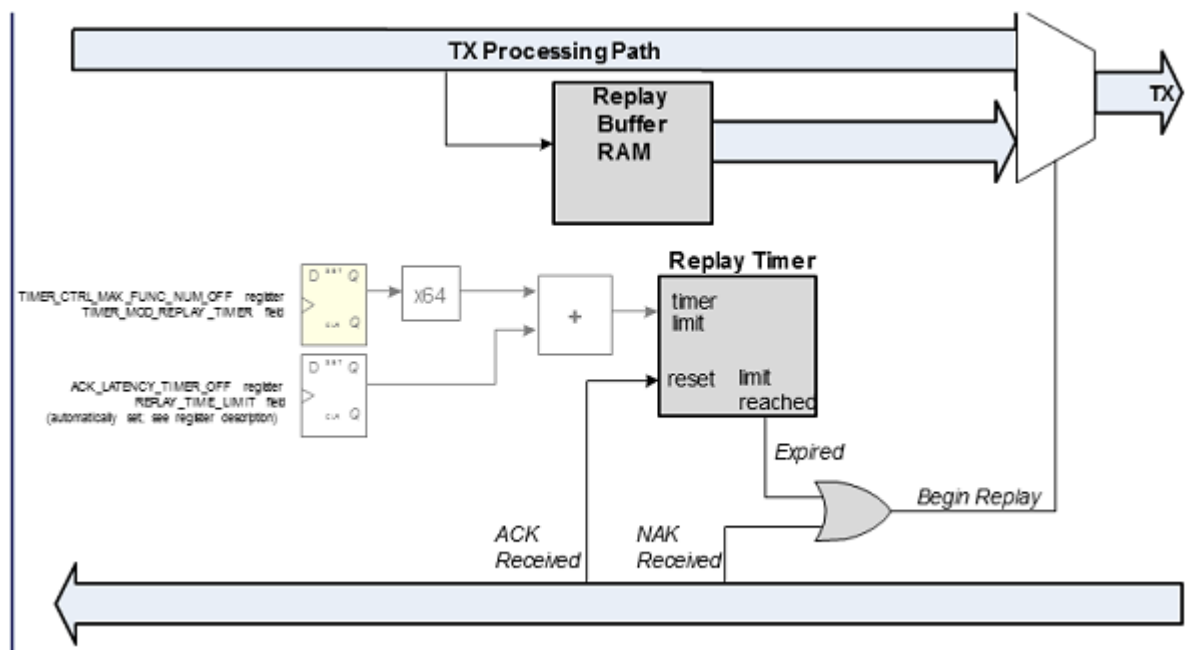

3	High Priority ACK DLLP
4	Flow Control DLLP
5	Vendor Specific Message DLLP
6	Power management or any other Low Priority DLLP

11.3.2.1.1.1 Effects of Flow Control Credits On Transmit Client Arbitration

The controller checks that enough flow control (FC) credits are available in the remote device for the specific type of transaction (posted, non-posted, completion) before allowing a transmission of a TLP. TLPs that passed the credit check are arbitrated according to the supported arbitration method. Internally generated completions and messages are also gated by the arbitration logic, though at highest priority, and must also pass the FC credit test before they are accepted for transmission.

11.3.2.1.1.2 Transmit Replay

You can modify the time-out value of the replay buffer as shown in the figure below. For a typical system, you do not have to modify the default settings, unless the remote device is executing unexpected replays.

Figure 11-37. Replay Buffer And Time (Representative)

11.3.2.1.2 Receive TLP Processing

This section describes the flow of received TLPs through the controller.

11.3.2.1.2.1 Receive Filtering

The controller contains a filter module that is responsible for the following tasks:

- Determine the status of a received TLP using filtering rules.
- Determine the destination of a received TLP based on the filtering status.
- Indicate the status of the received TLP using outputs.
- Report Errors to AER registers based on filter results. When more than one type of error is detected, Error Pollution, of the *PCI Express Base Specification, Revision 4.0, Version 0.7* is followed.
- The controller filters and routes received TLPs according to a set of rules determined by the TLP type based on the *PCI Express Base Specification, Revision 4.0, Version 0.7* and user-configurable filtering options.

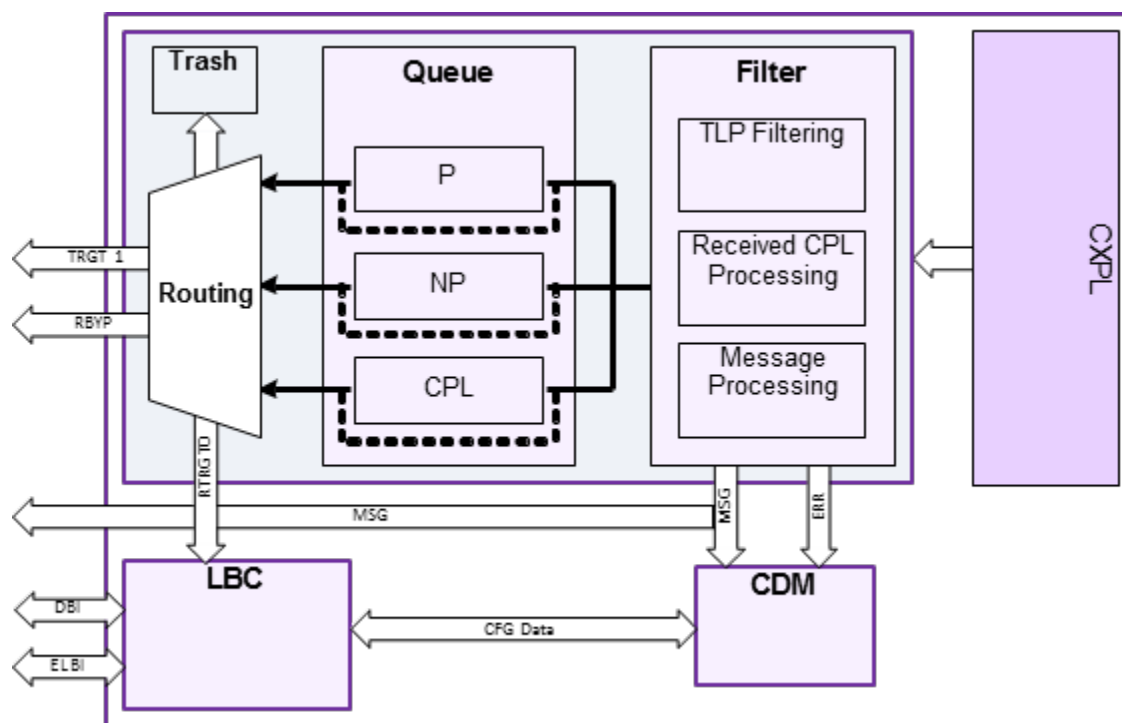

Figure 11-38. RADM Block Diagram

The following general rules apply to all incoming TLPs that are not malformed. For details on what happens to malformed TLPs, see "Error Detection for Received TLPs" By default:

- For a function in device power states D1, D2, and D3hot, the controller only accepts CFG and MSG requests TLPs for that function. All other incoming request types for that function are treated as unsupported requests (UR).
- When the controller detects an error in a received TLP, it normally performs the following:
 - Discards the TLP
 - Generates a completion (for non-posted requests) with the completion status set to CA or UR
 - Sets the status in the PCI-compatible Status register
 - Sets the status in the AER registers
 - Generates an error message (upstream port only)

All error-free MSG requests are decoded internally, signaled on the SII interface and then dropped. When you want to have the decoded message also sent to the application interface, then see “Routing of Received Messages”.

11.3.2.1.2.2 Receive Routing

This section discusses how the RADM routes different TLP types to different receive interfaces depending on TLP type and filter result. TRGT1 refers to the AXI interface. TRGT0 refers to the internal interface used to access the CDM registers or the ELBI in an upstream port.

11.3.2.1.2.2.1 EP Mode Routing Overview

The possible destinations of a posted or non-posted request TLP are TRGT1 interface, TRGT0 interface and Discard. By default:

- CFG requests are routed to TRGT0 and then to CDM through the LBC.
- BAR-matched MEM and I/O requests are routed to TRGT1.
- MSG requests are decoded internally, signaled on the SII interface, and then terminated.

Figure 11-39. EP Mode Routing

11.3.2.1.2.2.2 RC Mode Routing Overview

The possible destinations of a posted or non-posted request are TRGT1 and Discard. By default:

- MEM requests outside of the memory range and prefetchable memory range as determined by the corresponding Base and Limit fields in the Type-1 header are routed to TRGT1.
- MSG requests are decoded internally, signaled on the SII interface, and then terminated.
- An RC does not expect to receive CFG or I/O requests.
- BARs should be disabled and not used.

The possible destinations of a completion TLP are TRGT1 and Discard.

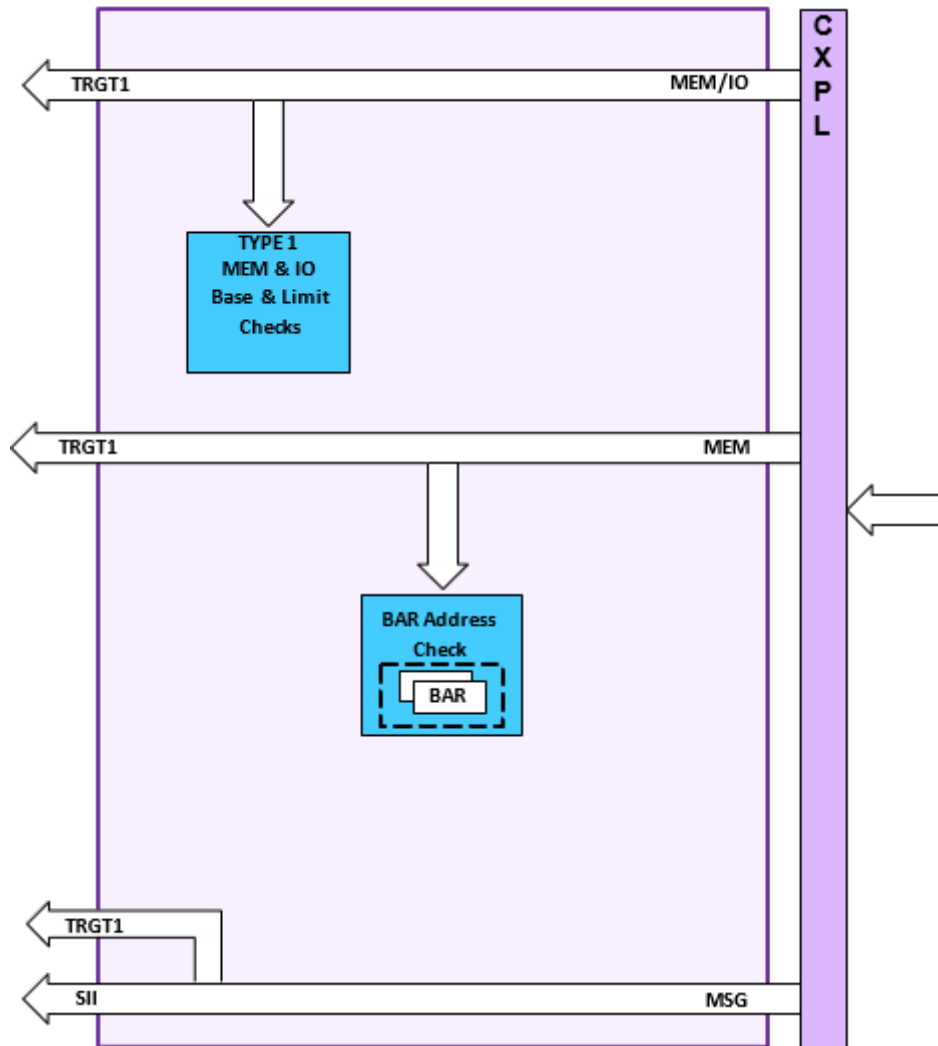

Figure 11-40. Default Request TLP Routing (Assuming no TLPs with CA/CRS/UR Error Status)

11.3.2.1.2.3 Error Handling

The controller supports the Baseline Capabilities, AER capabilities, and Advisory Non-Fatal Error Messaging as specified in section "Error Signaling and Logging" of the *PCI Express Base Specification, Revision 4.0, Version 0.7*. These include Correctable and Uncorrectable (Fatal and Non-Fatal) errors. For an RC port, the reporting of most errors is internal to the root port. No external error notifications are generated. One exception to this (for example) is unsupported request (UR) completion status.

11.3.2.1.2.3.1 Error Detection for Received TLPs

The controller performs all mandatory error detections, the error reporting mechanism based on the PCI Express Base Specification, Revision 4.0, Version 0.7. When the controller detects an error in a received TLP, it normally performs the following:

- Discards the TLP
- Generates a completion (for non-posted requests) with the completion status set to CA or UR
- Sets the status in the PCI-compatible status register
- Sets the status in the AER registers
- Generates an error MSG (upstream port only)

11.3.2.1.2.3.2 AER Multiple Header Logging

The controller supports the AER multiple header logging as specified in Section, "Multiple Error Handling (Advanced Error Reporting Capability)" of the *PCI Express Base Specification, Revision 4.0, Version 0.7*.

11.3.2.1.2.3.3 Physical Functions

By default, each physical function only logs the first header that caused an error. Per physical function, the controller implements a FIFO queue that interfaces with the AER Header Log registers (HDR_LOG_i_OFF). A valid queue entry is never overwritten. When the queue is full and your software does not read the header log registers fast enough, new header log information will be missed.

11.3.2.1.2.3.4 Virtual Functions

By default, each virtual function only logs the first header that caused an error. Each VF in each physical function has the exact same header log queue depth. Per VF, the controller implements a queue that interfaces with the AER Header Log registers (VF_HDR_LOG_i_OFF). A valid queue entry is never overwritten. When the queue is full and your software does not read the header log registers fast enough, new header log information will be missed.

The depth of each shared queue is identical for all PFs . The queue is not a FIFO, it is just a resource-saving mechanism, and each VF can randomly access it's own header logs independently of other VFs.

Table 11-80. Shared VF Header Log Full Behavior

VF First Error Pointer Status	VF Shared Header Log Status	Core Actions
----------------------------------	--------------------------------	--------------

Table continues on the next page...

Table 11-80. Shared VF Header Log Full Behavior (continued)

Invalid	Full	<ul style="list-style-type: none"> • A read to the Header Log returns all 1's. • A read to the "TLP Prefix Log Present" bit indicates '0'. • The controller sets the Uncorrectable Error Status Register according to the First Error Pointer.
Valid	Full	<ul style="list-style-type: none"> • The controller sets the Uncorrectable Error Status Register according to the First Error Pointer that is associated with the rejected TLP. • The Header log can be cleared or updated to the next stored header log, if one exists, by writing to the bit of the Uncorrectable Status Error Register pointed to by the First Error Pointer. • This applies to both when a normally displayed TLP Header is present in the Header Log Register or when an overflow condition is shown on the Uncorrectable Status Error Register.

11.3.2.1.3 Register Module and Data Bus Interface (DBI)

11.3.2.1.3.1 Overview

The Local Bus Controller (LBC) module provides a mechanism for a link partner (in upstream mode) or a local CPU (through the DBI) to access:

- Internal registers (in the CDM)
- External application registers connected externally to the ELBI
- In RC mode:
 - There is no PCIe wire access to the CDM registers and ELBI.
 - There is full DBI access to the CDM registers and ELBI.
- The controller has 4096 bytes of register PCIe configuration and port logic space per function. The controller also has a common iATU and DMA configuration register space for all functions. The controller register space is fully accessible from the DBI without any restrictions.

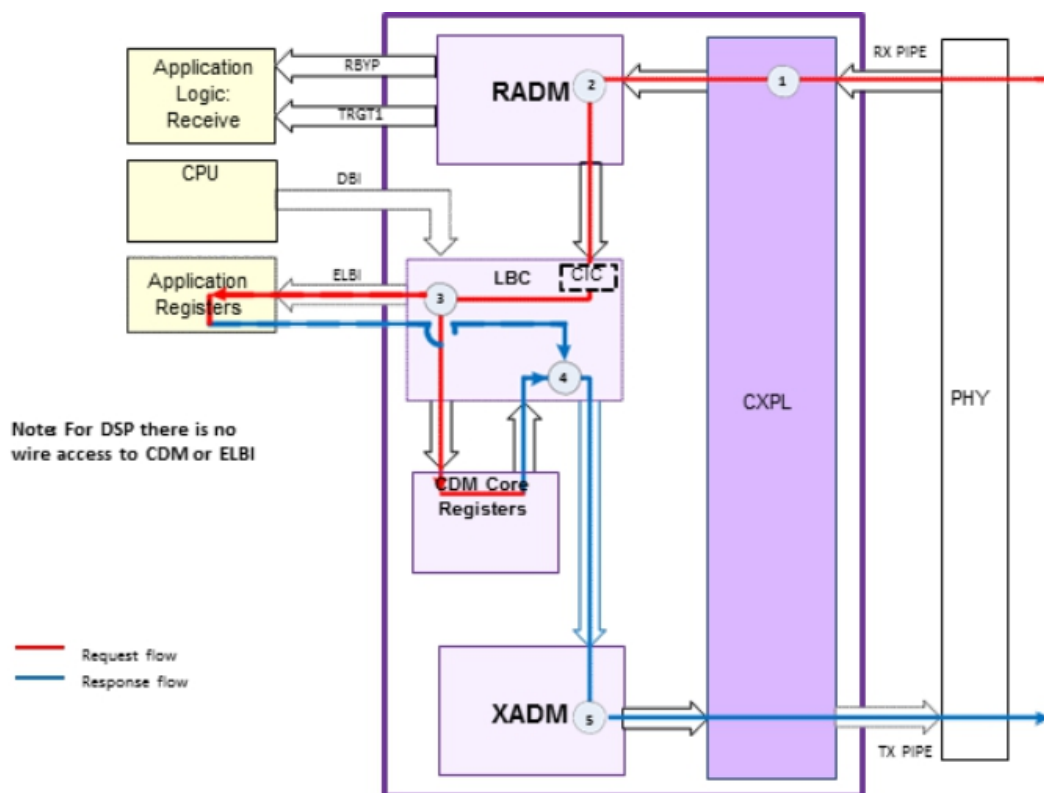

NOTE

Please refer to the Memory Map for the assigned space for the PCIe controller.

Table 11-81. EP Mode Port Region Access

Register Location		CDM					ELBI
Register Type		PCI-SIG		Port Logic			User
		Normal	Shadow	Misc	IATU	DMA	User
Access Details	CDM/ELBI Selector Bit ¹ Value	0	0	0	1	1	1
	CS2 Selector Bit Value	0	1	0	1	1	0
DBI/Wire Access Allowed							
DBI		Y	Y	Y	Y	Y	Y
Wire	CFG Request	Y	-	Y	-	-	Y
	BAR Matched MEM Request	-	-	Y ²	Y	Y	Y ⁻¹

1. Selector bit locations are configuration-dependent.
2. IO request also supported.

PCIe Wire Access to CDM Registers or ELB(USP)

- ① Incoming request from PCIe remote link partner
- ② Request is filtered and routed by RADM through TRGT0 to LBC
- ③ LBC forwards the request to external registers(through ELBI) or internal registers in CDM
- ④ LBC forms completion TLPs with response received from ELBI or internal registers in CDM
- ⑤ PCIe controller transmits response completion to remote link partner

Figure 11-41. PCIe Wire Access to CDM Registers or ELB

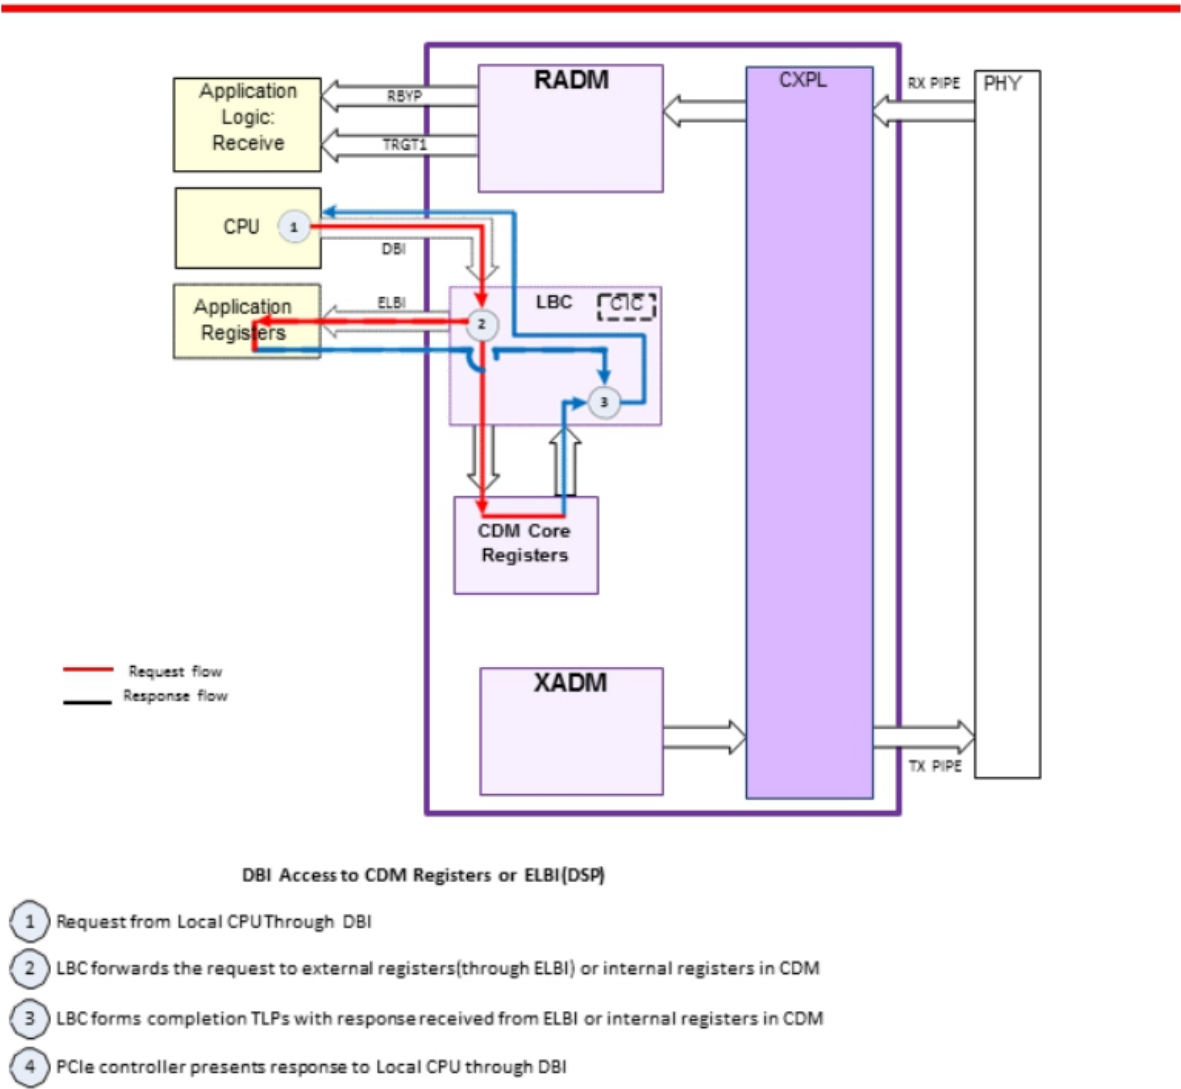

Figure 11-42. DBI Access to CDM Registers or ELBI

11.3.2.1.3.2 CDM Register Space Layout

11.3.2.1.3.2.1 Overview

The controller has 4096(0x1000) bytes of register PCIe configuration and port logic space per function. The controller also has a common iATU and DMA configuration register space for all functions. The controller register space is fully accessible from the DBI without any restrictions. Please see the Memory Map for the register base address assignment.

Table 11-82. Port Region Access

Register Location	CDM	ELBI
-------------------	-----	------

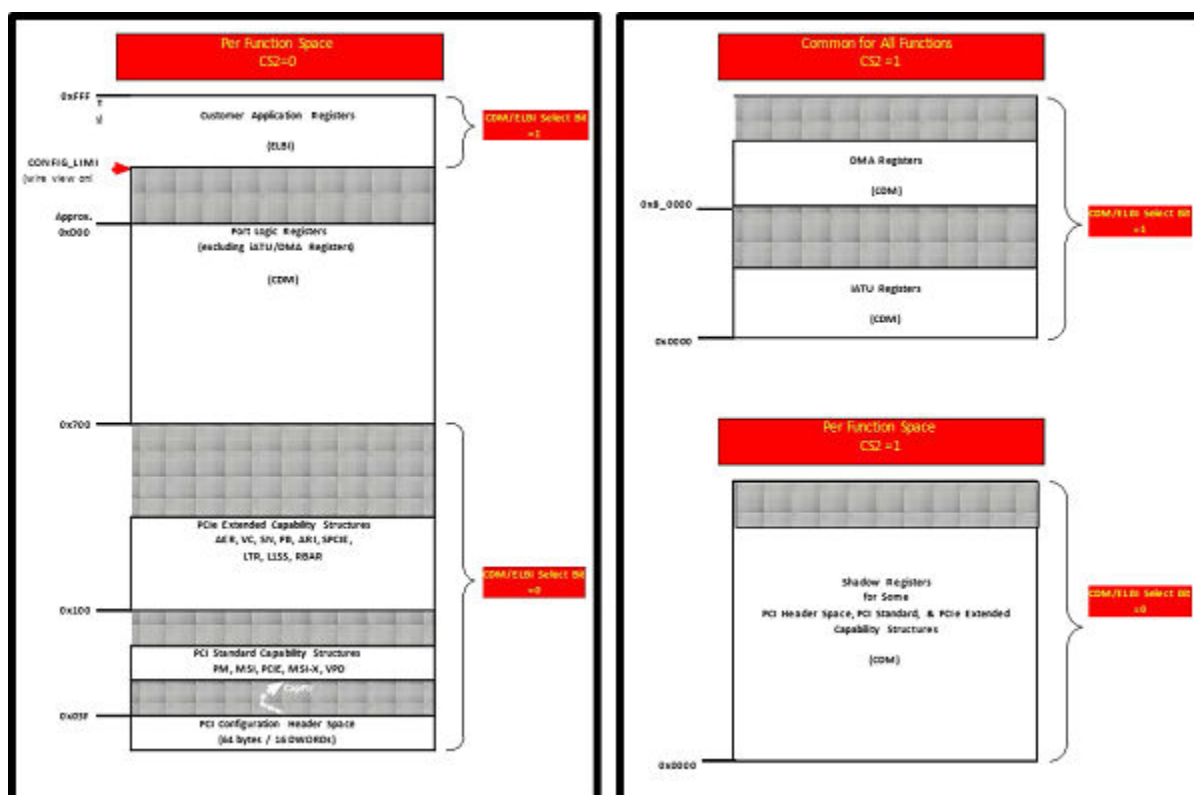

Table continues on the next page...

Table 11-82. Port Region Access (continued)

Register Type		PCI-SIG		Port Logic			User
		Normal	Shadow	Misc	IATU	DMA	User
Access Details	CDM/ELBI Selector Bit ¹ Value	0	0	0	1	1	1
	CS2 Selector Bit Value	0	1	0	1	1	0
DBI/Wire Access Allowed							
DBI		Y	Y	Y	Y	Y	Y
Wire	CFG Request	Y	-	Y	-	-	Y
	BAR Matched MEM Request	-	-	Y ²	Y	Y	Y ⁻¹

1. Selector bit locations are configuration-dependent.

2. IO request also supported.

**Figure 11-43. Controller Configuration Space Layout (EP Mode)**

Figure 11-44. Controller Configuration Space Layout: (RC Mode)

Wire Access (Upstream Ports Only):

- Any CFG > CONFIG_LIMIT goes to TRGT1 or ELBI
- Any MEM/IO captured by a BAR whose interface target is TRGT0 goes to ELBI
- Any MEM captured by BAR_n ($n = \text{UNROLL_BAR_NUM}$) when
- ENABLE_MEM_MAP_UNROLL_{DMA/IATU}_REG=1, whose interface target is TRGT0, and whose address falls into the range defined in "Memory Mapping iATU and DMA Port Logic Registers" goes to the IATU/DMA registers.

DBI Access (Upstream and Downstream Ports):

- No concept of MEM/IO/CFG
- Uses the specified address bit to route the access to ELBI or CDM
- No restrictions regarding what spaces can be accessed or not

11.3.2.1.3.2.2 Core Configuration Space Registers

- CDM Registers
 - PCI Configuration Header and Capability Registers:
 - The *PCI configuration header and capability registers* in the previous diagrams are PCIe controller configuration registers specified by the *PCI Express Base Specification, Revision 4.0, Version 0.7*. Access from the PCIe wire is possible with CFG requests (upstream ports). These registers are fully accessible from the DBI without any restrictions.

- Port Logic Registers:
 - The port logic (PL) registers are configuration registers which are not specified by the *PCI Express Base Specification, Revision 4.0, Version 0.7*. Access from the PCIe wire is normally with CFG requests. These registers are fully accessible from the DBI without any restrictions.
- iATU and DMA Port Logic Registers:
 - This memory space is dedicated for iATU and DMA configuration registers. Access from the PCIe wire is with specific BAR matched MEM requests. These registers are fully accessible from the DBI without any restrictions.

11.3.2.1.3.3 Data Bus Interface (DBI)

11.3.2.1.3.3.1 Overview

The DBI can access all 4096 bytes (1024 DWORDs) of the PCI Express configuration space per function. DBI can also access iATU and DMA configuration space. This address space is fully accessible from the DBI without any restrictions.

11.3.2.1.3.4 Features and Limitations

The following limitations exist for the LBC.

- CDM Access Restrictions:
 - Maximum payload Length = 1 DWORD.
 - PCIe MEM requests with Length > 1 are processed as completer abort.
 - PCIe MEM requests with Length = 0 are processed as completer abort.
 - PCIe IO or CFG requests with Length != 1 are processed as malformed TLPs.
- ELBI Access Restrictions:
 - CS2 bit must be 1'b0.
 - PCIe MEM requests with Length = 0 are processed as completer abort.
 - PCIe IO or CFG requests with Length != 1 are processed as malformed TLPs.
 - Does not support "Atomic Operations (AtomicOps)"
 - Does not support TPH. Core does not forward the TPH bits to the ELBI.
 - Data (Read)
- DBI Data/Address Port Widths (with no AXI bridge):
 - Data: 32 bit
 - Address: 32 bit

11.3.2.1.3.4.1 Additional AXI DBI Limitations

The following limitations exist when you configure the controller to use the AXI bridge module.

- The DBI address must be a DWORD address.
- AXI transfer widths of 8, 16, and 32 bits are supported. The AXI dedicated/shared DBI interface returns an error response to requests with width greater than 32 bits. The type of error response is programmable through AMBA_ERROR_RESPONSE_DEFAULT_OFF register1.
- For AHB you get an error response whenever the size is not equal to 32 bits.
- The CDM only supports 32-bit data access. The AXI dedicated/shared DBI interface returns an error response to multi beat requests. The type of error response is programmable through AMBA_ERROR_RESPONSE_DEFAULT_OFF register.
- Byte access within a DWORD for DBI requests is not possible for AHB.
- Byte access within a DWORD for DBI WRITE requests is possible for AXI (not for AHB)
 - Dedicated DBI: The write strobes dbi_wstrb[3:0] are sent to the LBC.
 - Shared DBI: The relevant four strobes from slv_wstrb are sent to the LBC

A zero-byte write over DBI is processed as a read and should never be issued. The AXI dedicated/shared DBI slave drops a zero-byte write before it reaches the internal (native controller) DBI and returns an error response. The type of error response is programmable through AMBA_ERROR_RESPONSE_DEFAULT_OFF register.

The type of error response returned by the AXI dedicated/shared DBI slave is the same as that programmed for UR completions in the AMBA_ERROR_RESPONSE_DEFAULT_OFF register.

11.3.2.1.4 Flow Control

The flow control mechanism is divided into two phases: initialization and update. The controller automatically performs both of these phases with minimal support required from your application. By default the RADM is responsible for returning flow control credits when it reads data out of the receive queues.

11.3.2.1.5 Completion Timeout Ranges

Timeout ranges are supported as defined in the *PCI Express Base Specification, Revision 4.0, Version 0.7*. The controller supports all ranges. The Device Control 2 Register has a default equal to the default in the specification: 0000b Default range: 50 us to 50 ms. When the default is used, then the timeout is in Range B: 0101b: 16 ms to 55 ms. This range was chosen for the default because the *PCI Express Base Specification, Revision*

4.0, *Version 0.7* states, "It is strongly recommended that the completion Timeout mechanism not expire in less than 10 ms". The table below illustrates the specification values versus the PCI Express controller values for the ranges.

NOTE

As the PCIe specification states, This mechanism is intended to be activated only when there is no reasonable expectation that the completion is returned, and should never occur under normal operating conditions.

Table 11-83. Comparison of PCIe Specification and PCIe Core Completion Timeout Ranges

Range	Encoding	Spec Minimum	Spec Maximum	PCIe controller Minimum	PCIe controller Maximum
Default	0000b	50 us	50 ms	28 ms	45 ms
A	0001b	50 us	100 us	65 us	99 ms
A	0010b	1 ms	10 ms	4.1 ms	6.2 ms
B	0101b	16 ms	55 ms	28 ms	44 ms
B	0110b	65 ms	210 ms	86 ms	131 ms
C	1001b	260 ms	900 ms	260 ms	390 ms
C	1010b	1s	3.5 s	1.8 s	2.8 s
D	1101b	4s	13 s	5.4 s	8.2 s
D	1110b	17s	64 s	38 s	58 s

11.3.2.1.6 Crosslink

Crosslink allows a downstream port to be connected to another downstream port or an upstream port to be connected to another upstream port. When a crosslink capable port negotiates a crosslink connection, the port changes its behavior accordingly. For this reason crosslink is supported in the DM controller because it contains the functionality for both upstream and downstream support.

Crosslink provides more than simply the ability to connect two like ports together. For instance, a DM operating in EP mode that negotiates a crosslink connection switches to RC mode and follows all of the *PCI Express Base Specification, Revision 4.0, Version 0.7* rules for an RC.

11.3.2.2 DMA Controller

This section describes the embedded multichannel DMA controller.

11.3.2.2.1 DMA Overview

The RC system CPU, or the EP application CPU, can offload the transferring of large blocks of data to the embedded DMA controller, leaving the CPU free to perform other tasks. It can simultaneously perform the following types of memory transactions (as shown in the figure 'System Level View of DMA'):

DMA write: Transfer (copy) of a block of data from local (application) memory to remote (link partner) memory.

DMA read: Transfer (copy) of a block of data from remote (link partner) memory to local (application) memory.

Therefore the DMA supports full duplex operation, processing read and write transfers at the same time, and in parallel with normal (non-DMA) traffic. Upon completion of a DMA transfer or an error, the DMA optionally interrupts the local CPU or sends an interrupt MWr (IMWr) to the remote CPU.

In linked list mode, the DMA fetches the transfer control information (called channel context) for each transfer (block), from a list of DMA elements that you have constructed in local memory.

11.3.2.2.2 DMA Architecture

This section describes the architecture of the DMA.

11.3.2.2.2.1 Architecture Overview

A DMA write and read channel operate independently to maximize the performance of the DMA read and write data transfers over the PCIe link. DMA with multiple read channels uses a weighted round robin (WRR) arbitration scheme to select the next read channel to be serviced. The same applies for multiple write channels.

Figure 11-45. System Level View of DMA

11.3.2.2.2.1.1 DMA Read Transfer

The DMA injects multiple MRd requests of size less than or equal to the minimum of {Max Read Request Size, Max Payload Size} into the outbound request path, directed toward the remote link partner. The DMA converts the read responses into write requests, that it then transmits to the local application. When the DMA data transfer is complete, the CPU is notified. For a read transfer, the SAR is the address of the remote memory, and the DAR is the address of the local memory.

11.3.2.2.2.1.2 DMA Write Transfer

The DMA injects multiple MRd requests of size less than or equal to Max_Payload_Size into the inbound request path, directed toward the local application. The DMA converts the read responses into MWr TLPs, that it then transmits to the remote link partner. When the DMA data transfer is complete, the CPU is notified. For a write transfer, the SAR is the address of the local memory, and the DAR is the address of the remote memory.

11.3.2.2.2 Interrupts and Error Handling

11.3.2.2.2.1 Interrupt Handling

The DMA generates two interrupts per channel:

Done: The DMA successfully completes the transfer.

Abort: The DMA fails to complete the transfer, or an error occurs during the transfer.

The interrupt handling mechanism is different for linked list (LL) mode (than non LL mode), and there are also some differences between the read and write channels.

11.3.2.2.2.2 Non Linked List Mode

You enable the local and remote interrupts through the local and remote interrupt enable (LIE and RIE) bits:

DMA_CH_CONTROL1_OFF_WRCH_0.lie and
DMA_CH_CONTROL1_OFF_WRCH_0.rie.

In the write channel, there is only one error condition that results in an abort interrupt. For more details, see "Linked List Mode". You mask, clear, and read the status of each of the two interrupts (done and abort) through the DMA interrupt registers as indicated in figure 'Write Interrupt Generation - Non Linked List Mode - Shown For Write Channel #0'.

In the read channel, there are five error conditions that results in an abort interrupt. For more details, see "Linked List Mode". You mask and clear each of the two interrupts (done and abort) through the DMA interrupt registers as indicated in figure 'Read Interrupt Generation - Non Linked List Mode - Shown For Read Channel #0'. However, you can read the status of each of the five abort errors (that contribute to the abort interrupt) through DMA_READ_ERR_STATUS_LOW_OFF and DMA_READ_ERR_STATUS_HIGH_OFF.

Figure 11-46. Write Interrupt Generation - Non Linked List Mode - Shown For Write Channel #0

If you want a remote interrupt and not a local interrupt then:

- Set LIE and RIE
- Mask the local interrupt using the mask register

This will allow you to poll the status register to distinguish a DONE from an ABORT

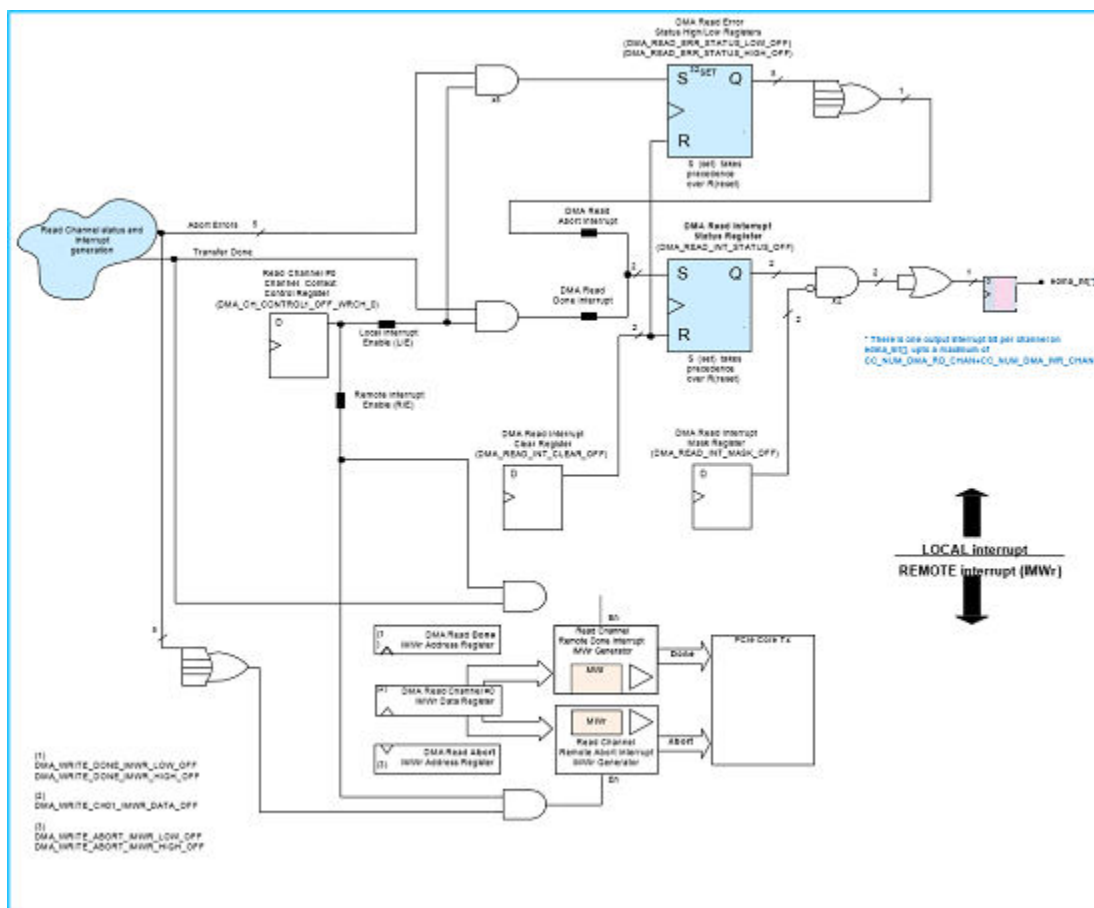

Figure 11-47. Read Interrupt Generation - Non Linked List Mode - Shown For Read Channel #0

11.3.2.2.2.3 Linked List Mode

The LIE and RIE bits in the LL element enable the channel done interrupts (local and remote). The LLLAIE and LLRAIE bits of the DMA_WRITE_LINKED_LIST_ERR_EN_OFF/DMA_READ_LINKED_LIST_ERR_EN_OFF registers enable the channel abort interrupts (local and remote). In the write channel, there are two error conditions that results in an abort interrupt. For more details, see "Linked List Mode". You mask and clear each of the two interrupts (done and abort) through the DMA interrupt registers as indicated in the figure below. You can read the status of each of the two abort errors (that contribute to the abort interrupt) through the DMA_WRITE_ERR_STATUS_OFF register.

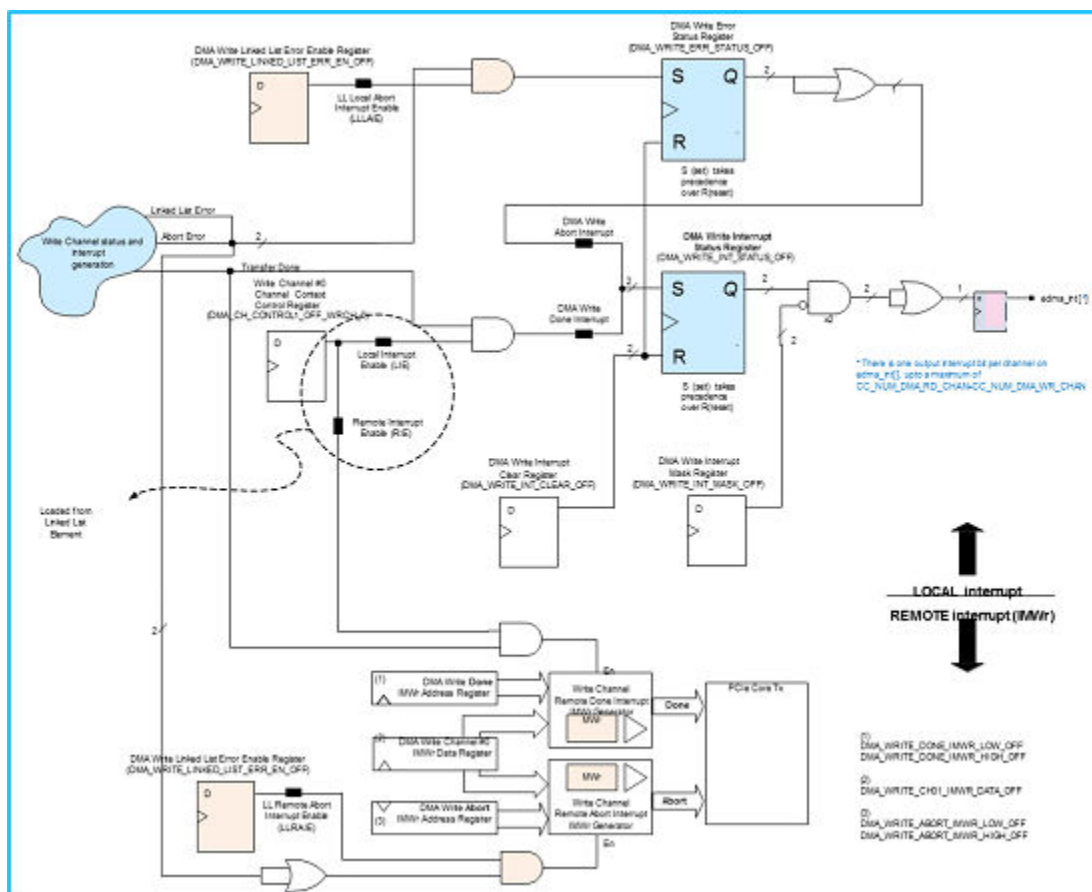

Figure 11-48. Write Interrupt Generation - Linked List Mode - Shown For Write Channel #0

In the read channel, there are six error conditions that results in an abort interrupt. For more details, see "Linked List Mode". You mask and clear each of the two interrupts (done and abort) through the DMA interrupt registers as indicated in the figure below. You can read the status of each of the six abort errors (that contribute to the abort interrupt) through the DMA_READ_ERR_STATUS_LOW_OFF and DMA_READ_ERR_STATUS_HIGH_OFF registers.

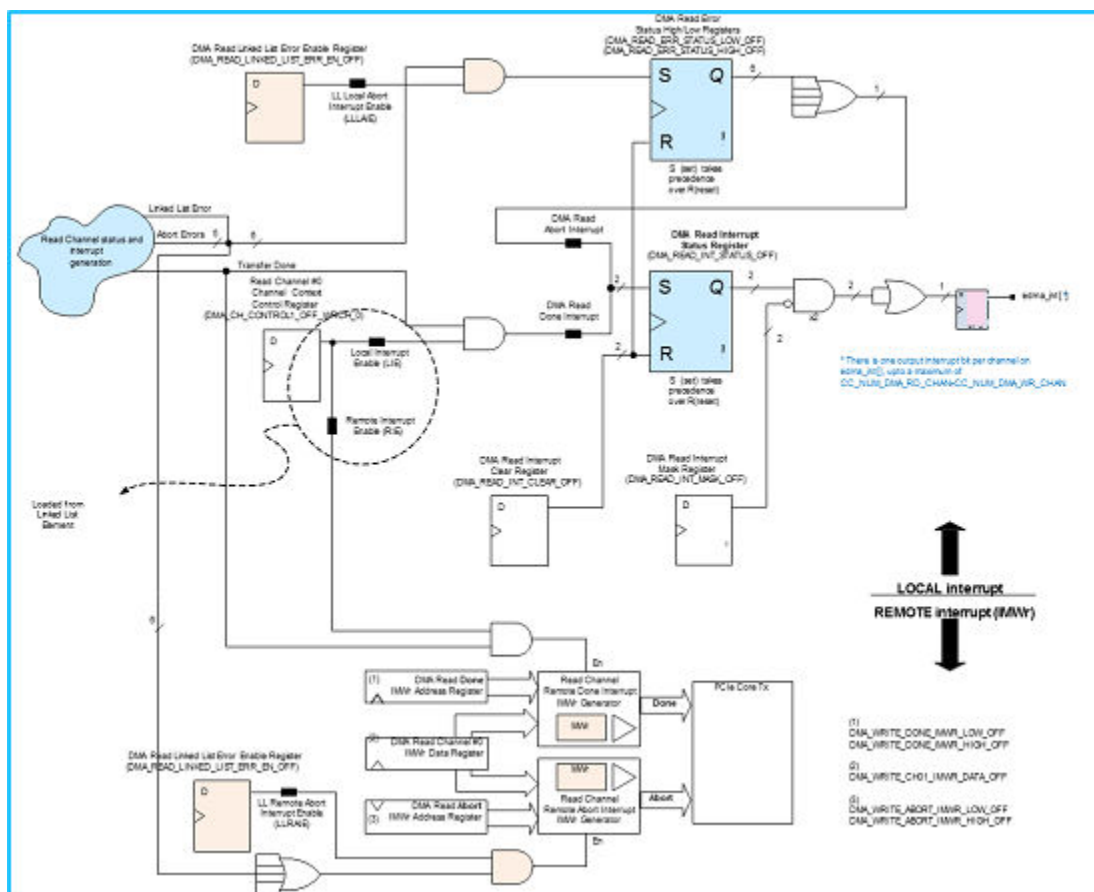

Figure 11-49. Read Interrupt Generation - Linked List Mode - Shown For Read Channel #0

NOTE

In non-linked list mode, LIE acts as a global switch. However when in linked list mode, LIE is just local to the current linked list element and the global switch is LLLAIE.

NOTE

If the DMA driver is running on the host and the interrupt service routine is reading local interrupts to determine if the transfer is successful, then you must set LIE and RIE in the same element and you should mask or ignore the local interrupt pin. Setting RIE and LIE in element A followed by RIE (only) in element B is not a verified usage scenario.

11.3.2.2.3 Linked List Mode

The DMA provides a linked list (LL) mode to efficiently move data from source to destination with minimal intervention from the local CPU. This mode provides an alternative to programming the DMA multiple times to transfer multiple blocks of data. The programming information (address, size, and so on) for each block of memory is pre-programmed by your software into a LL element (also known as a descriptor) in local memory. Each element (called a data element) in the LL structure (called a transfer list) can transfer up to 4 GB of data. You enable LL operation for a channel, by setting the LLE field of the DMA_CH_CONTROL1_OFF_WRCH_0 (Replace WRCH with RDCH for a read channel) register to 1. You can enable LL mode independently for each channel. When you enable LL for more than one channel, then you must have a separate LL structure in local memory for each channel. Your application must produce the LL element structure in local memory as shown in the figure below. Normally, all of the elements are contiguous (one after the other) in memory, and each element has six DWORDs containing the information about the block of data to be transferred. You program the channel context registers (DMA_LL_LOW_REG_WRCH_0 and DMA_LL_HIGH_OFF_WRCH_0) with the location of where you have placed the LL element structure in local memory.

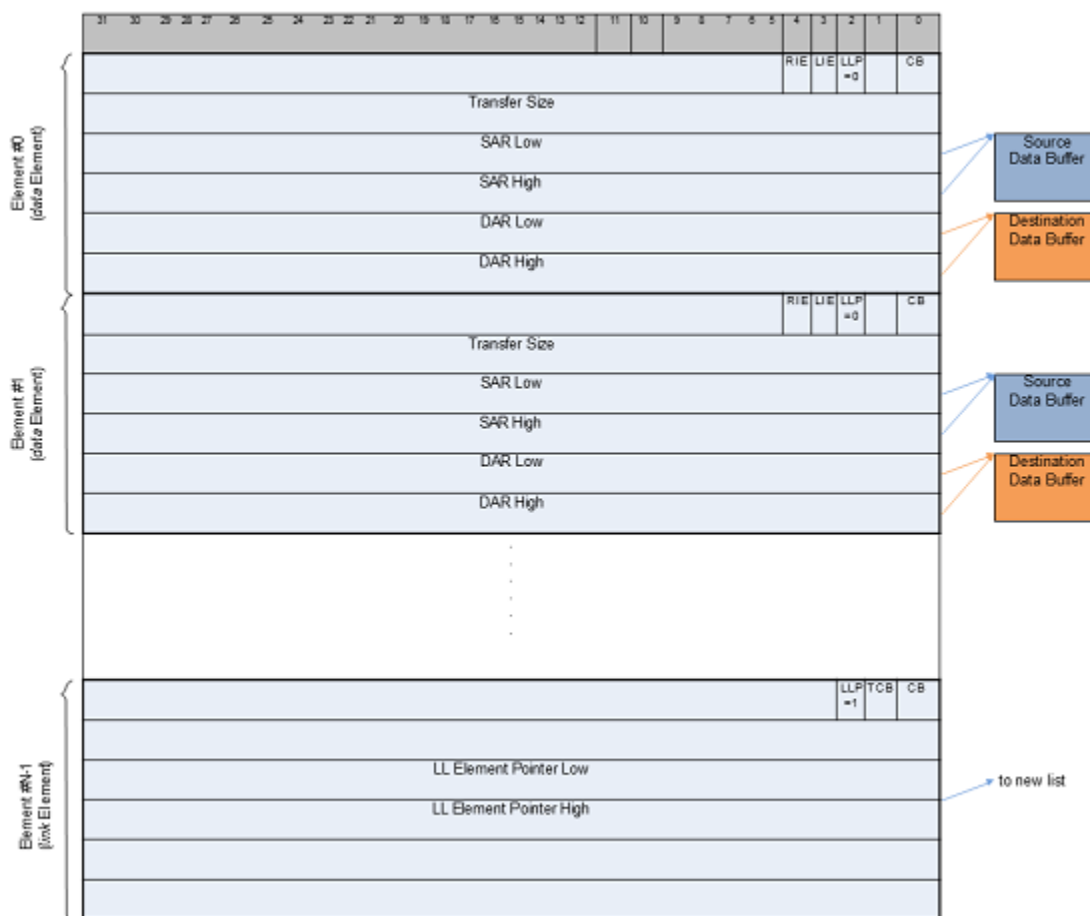

Figure 11-50. Linked List Element/Descriptor Structure in Local Memory with N Elements

When you start the DMA transfer (by writing to the DMA Write Doorbell Register `DMA_WRITE_DOORBELL_OFF` or DMA Read Doorbell Register `DMA_READ_DOORBELL_OFF`), the DMA reads (consumes) each element from local memory, and loads the information (SAR, DAR, size, and so on) from that element into the channel context registers in the DMA. These channel context registers determine the operation of the channel that the DMA controller is currently servicing. The DMA then proceeds to transfer the block of data (as defined by the element), and when it is finished, reads the next element from local memory. Normally, all of the elements are contiguous (one after the other) in memory, with the starting address defined in the channel context DMA Linked List Pointer Low Register `DMA_LL_P_LOW_OFF_WRCH_0`. When you want to jump in local memory to another element list (or recycle the consumed elements), then you set the LLP bit in the element (for example, link element #N-1 in figure shown)), specify the location of the next element structure using the LL Element Pointer DWORDs (as indicated in the figure), and, set TCB to 1 (for recycling) or to 0 (to jump to another list).

11.3.2.2.3.1 Relationship Between Element DWORDs and Channel Context Registers

Notice the similarity between a data element and the DMA Channel Context registers for each channel. Each element has six DWORDs as in figure 'Linked List Element/Descriptor Structure in Local Memory with N Elements'. There are eight channel context registers (DWORDs) for a channel. The DMA loads the six element DWORDs into the following channel context:

- CB, LLP, LIE, and RIE fields of the DMA Channel Control 1 register.
- DMA Transfer Size
- DMA SAR Low and DMA SAR High
- DMA DAR Low and DMA DAR High

The definitions of the element DWORD bit fields are the same as the DMA Channel Context registers described in the "DMA Software Register Map", with the exception of the LIE and RIE bits. The LIE and RIE bits in a LL element, only enable the done interrupt. In non-LL mode, the RIE and LIE bits (in the channel context registers) enable the done and abort interrupts.

When the LLP field of the first DWORD in the element is set to 1, the element is a link element. The DMA only loads the following information into the channel context registers:

- CB, TCB, and LLP bits of the first DWORD. The LIE and RIE bits are not defined in a link element.
- LL Element Pointer (3rd and 4th DWORDs) into the DMA Linked List Pointer registers (DMA_LL- P_LOW_REG_WRCH_0 and DMA_LL- P_HIGH_REG_WRCH_0).

Linked List Operation

- When you enable linked list operation (DMA_CH_CONTROL1_OFF_WRCH_0.LL = 1b1), then the DMA overwrites the following DMA channel context registers with the following information from linked list data elements:
 - The CB, LLP, LIE, and RIE fields of the DMA Channel Control 1 register.
 - DMA Transfer Size
 - DMA SAR Low & High
 - DMA DAR Low & High
- The structure of a link element is different to that of the data element. A data element has no TCB field. A link element has no LIE or RIE fields. It has no SAR, DAR, or Transfer Size DWORDs, but has LL Element Pointer DWORDs instead of the SAR DWORDs.
- The LIE and RIE bits in a LL element, only enable the done interrupt. In non-LL mode, the RIE and LIE bits enable the done and abort interrupts. For more information, see "Interrupts and Error Handling".

11.3.2.2.3 Using the DMA

This section describes how to use the DMA. It can simultaneously perform the following types of memory transactions:

- DMA write : Transfer (copy) of a block of data from local memory to remote memory
- DMA read : Transfer (copy) of a block of data from remote memory to local memory

Therefore the DMA supports full duplex operation, processing read and write transfers at the same time, and in parallel with normal (non-DMA) traffic. Upon completion of a DMA transfer or an error, the DMA sends an interrupt MWr (IMWr).

The channels are named read channel 7..0 and write channel 7..0. Each channel is programmed using a number of registers.

11.3.2.2.3.1 Source and Destination Address Registers (SAR, DAR)

The DMA channel context SAR and DAR registers (DMA_SAR_LOW_OFF_WRCH_01 / DMA_SAR_HIGH_OFF_WRCH_0 / DMA_DAR_LOW_OFF_WRCH_0 / DMA_DAR_HIGH_OFF_WRCH_0) provide support for remote-to-local, and local-to-remote PCIe address mapping. You program the start of the local and remote data buffers using these registers, and the DMA increments the SAR and DAR as the DMA transfer progresses. For a write transfer, the SAR is the address of the local memory, and the DAR is the address of the remote memory, as shown in Figure 'Write Transfer: SAR and DAR for Write Channel 0'.

Figure 11-51. Write Transfer: SAR and DAR for Write Channel 0

For a read transfer, the SAR is the address of the remote memory, and the DAR is the address of the local memory, as shown in the figure below.

Figure 11-52. Read Transfer: SAR and DAR for Read Channel 0

The presence of the DMA controller does not affect:

- Normal filtering rules for inbound TLPs (for example, BAR checking in an Endpoint, as described in “Receive Filtering”)
- The operation of any internal or external address translation as described in “Internal Address Translation Unit (iATU)”.

NOTE

When you do not want the iATU to translate outbound requests that are generated by the internal DMA module, then you must implement one of the following approaches:

- Ensure that the combination of DMA channel programming and iATU control register programming, causes no translation of DMA traffic to be done in the iATU.
- Activate the DMA bypass mode to allow request TLPs which are initiated by the DMA controller to pass through the iATU untranslated. You can activate DMA bypass mode by setting the DMA Bypass field of the iATU Control 2 Register (IATU_REGION_CTRL_2_OFF_2_OUTBOUND_0).

11.3.2.2.3.2 DMA Transfer Size Register

You program the DMA transfer size using the DMA Transfer Size Register (DMA_TRANSFER_SIZE_OFF_WRCH_0). The DMA decrements the value in this register as the DMA transfer progresses. You can read this register at any time to determine the number of bytes remaining to be transferred. When all bytes are successfully transferred, the result is zero. The DMA transfer size can be of any value from one byte, up to a maximum of 4 GB.

11.3.2.2.3.3 Starting The DMA Transfer

After you program the DMA controller registers (including writing to the DMA Read Engine Enable or DMA Write Engine Enable register), you start a DMA transfer by writing the channel number to the Doorbell Number field of the DMA Write Doorbell Register (DMA_WRITE_DOORBELL_OFF) or DMA Read Doorbell Register (DMA_READ_DOORBELL_OFF). You can program and start both a read and a write transfer at the same time. The DMA supports full duplex operation, processing read and write transfers at the same time and in parallel with normal (non-DMA) traffic. You can program and start any number of channels in the DMA controller sequentially or simultaneously.

Sequentially: configure and start a channel, and then configure and start another channel

Simultaneously: configure multiple channels, and then start multiple channels

NOTE

You must not write to any of the context registers for a particular channel after you start the channel by writing the channel number to the Doorbell Number field of the DMA Write Doorbell Register (DMA_WRITE_DOORBELL_OFF) or DMA Read Doorbell Register (DMA_READ_DOORBELL_OFF).

11.3.2.2.3.4 Detecting the End of The DMA Transfer

If a DMA transfer proceeds without any errors, it stops automatically when finished.

11.3.2.2.3.4.1 Detecting End of Transfer without Errors

The normal end of a DMA transfer is detected by any of the following methods:

- Done local interrupt (pin) asserted.
- Done remote interrupt (IMWr) received.

- Channel status field of the Channel Control 1 register is Stopped, and the DMA Transfer Size register is 0x0.
- Polling of the DMA Write Interrupt Status Register (DMA_WRITE_INT_STATUS_OFF) or DMA Read Interrupt Status Register (DMA_READ_INT_STATUS_OFF).

11.3.2.2.3.4.2 Detecting End of Transfer with Errors

The abnormal end of a DMA transfer is detected by any of the following methods:

- Abort local interrupt (pin) asserted.
- Abort remote interrupt (IMWr) received.
- Polling of the DMA Write Interrupt Status Register (DMA_WRITE_INT_STATUS_OFF) or DMA Read Interrupt Status Register (DMA_READ_INT_STATUS_OFF).
- Channel Status field of the Channel Control 1 register is halted. When the DMA controller detects an error, it forces the DMA to stop issuing requests for the channel. It also sets the channel status field of the Channel Control 1 register to halted, generates an abort interrupt (if enabled), and sends an abort IMWr (if enabled). The DMA Transfer Size register indicates the remaining number bytes to be transferred, except when there is an AXI write error during a DMA read transfer. For more details, see table 'Possible Sources of an Error during a DMA Read Transfer'.
- Channel Status field of the Channel Control 1 register is Stopped, and the DMA Transfer Size register is not 0x0. You have prematurely stopped this channel as described in “Stopping the DMA Transfer (Software Stop)”.

11.3.2.2.3.5 Stopping the DMA Transfer (Software Stop)

You can manually abort (stop) the DMA transfer by writing the channel number to the Doorbell Number field and writing 1 to the Stop field in DMA_WRITE_DOORBELL_OFF. This causes the DMA to:

- Place the channel in a Stopped state.
- The channel Status field in DMA_CH_CONTROL1_OFF_WRCH_0 is Stopped and the value in DMA_TRANSFER_SIZE_OFF_WRCH_0 will not be 0x0.
- Wait for all outstanding pending transactions.
- Assert the abort interrupt (if it is enabled) in DMA_WRITE_INT_STATUS_OFF.

You might do this as part of error handling which is described in “Error Handling Assistance by Remote Software”, which is only necessary during software development if you incorrectly program the DMA write channel DAR. You might also do this as part of a function level reset (FLR). FLR does not directly affect the DMA transfer so you must manually stop the DMA transfer before initiating an FLR.

Use This Feature With Caution in Linked List Mode

You should not use the STOP feature in operational mode. It is only a debug feature and has associated hazards.

- Before setting the Stop bit, you must read the channel status field (CS) of the DMA Channel Control 1 register to ensure that the corresponding channel is Running (transferring data). To eliminate the possibility of a race condition between these two actions (read and write), you should confirm the presence of the abort bit in the DMA Write Interrupt Status Register (DMA_WRITE_INT_STATUS_OFF) or DMA Read Interrupt Status Register (DMA_READ_INT_STATUS_OFF) and check the status of any fatal error if some other event has occurred.
- After a Stop event, you cannot seamlessly resume the transfer again because the DMA will not carry on exactly from the point that it was stopped at. Therefore you must setup and start the complete channel context again, including the
 - linked list pointer
 - linked list structure in memory
 - related PCS and CCS values

11.3.2.2.3.6 TLP Generator Header Control

You must program bits [31:12] of the DMA Channel Control 1 Register (DMA_CH_CONTROL1_REG_WRCH_0/DMA_CH_CONTROL1_OFF_RDCH_0), so that the DMA TLP generator correctly sets the TC, RO, NS, AT, and FN TLP header fields for any TLPs that it generates. When SRIOV is enabled, then you must also program DMA_CH_CONTROL2_OFF_WRCH_0/DMA_CH_CONTROL2_OFF_RDCH_0.

11.3.2.2.3.7 DMA Software Register Map

This section discusses the grouping and access methods of the DMA registers. The following registers are present when the DMA is enabled.

The DMA Global Registers control the global settings

Table 11-84. DMA Global Registers

Name	Description
0x8_0000 +0x000	DMA Arbitration Scheme for TRGT1 Interface
+0x008	Number of DMA Channels
+0x00C	DMA Write Engine Enable
+0x010	DMA Write Doorbell
+0x018	DMA Write Engine Channel Arbitration Weight Low
+0x01C	DMA Write Engine Channel Arbitration Weight High
+0x02C	DMA Read Engine Enable
+0x030	DMA Read Doorbell
+0x034	DMA Global Read Control
+0x038	DMA Read Engine Channel Arbitration Weight Low
+0x03C	DMA Read Engine Channel Arbitration Weight High

The DMA Interrupt Registers control the generation of local interrupts and remote IMW_r. The IMW_r addresses and data are stored in RAM.

Table 11-85. DMA Interrupt Registers

Byte Offset	Description
0x8_0000 +0x4C	DMA Write Interrupt Status
+0x50	Not used (RsvdP).
+0x54	DMA Write Interrupt Mask
+0x58	DMA Write Interrupt Clear
+0x5C	DMA Write Error Status
+0x60	DMA Write Done IMW _r Address Low
+0x64	DMA Write Done IMW _r Address High
+0x68	DMA Write Abort IMW _r Address Low
+0x6C	DMA Write Abort IMW _r Address High
+0x70	DMA Write Channels 1 and 0 IMW _r Data
+0x84	DMA Write Channels 3 and 2 IMW _r Data
+0x88	DMA Write Channels 5 and 4 IMW _r Data
+0x8C	DMA Write Channels 7 and 6 IMW _r Data
+0x90	DMA Write Linked List Error Enable
up to +0x9C	Not used (RsvdP).
+0xA0	DMA Read Interrupt Status
+0xA4	Not used (RsvdP).
+0xA8	DMA Read Interrupt Mask
+0xAC	DMA Read Interrupt Clear
+0xB0	Not used (RsvdP).
+0xB4	DMA Read Error Status Low
+0xB8	DMA Read Error Status High

Table continues on the next page...

Table 11-85. DMA Interrupt Registers (continued)

up to +0xC0	Not used (RsvdP).
+0xC4	DMA Read Linked List Error Enable
+0xC8	Not used (RsvdP).
+0xCC	DMA Read Done IMWr Address Low
+0xD0	DMA Read Done IMWr Address High
+0xD4	DMA Read Abort IMWr Address Low
+0xD8	DMA Read Abort IMWr Address High
+0xDC	DMA Read Channels 1 and 0 IMWr Data
+0xE0	DMA Read Channels 3 and 2 IMWr Data
+0xE4	DMA Read Channels 5 and 4 IMWr Data
+0xE8	DMA Read Channels 7 and 6 IMWr Data

DMA Channel Context Registers: these registers (which are stored in RAM) are for the control and status information that is specific to each channel. There is a set of registers for each channel.

Table 11-86. DMA Channel Context Registers for Each Channel

Byte Offset	Description
DMA Channel Context	
$0x8_0000 + 0x200*i + 0x100*(WR RD)b$	DMA Channel Control 1 Register
$+0x004*i + 0x200*i + 0x100*(WR RD)$	DMA Channel Control 2 Register
$+0x008*i + 0x200*i + 0x100*(WR RD)$	DMA Transfer Size
$+0x00C*i + 0x200*i + 0x100*(WR RD)$	DMA SAR Low
$+0x010*i + 0x200*i + 0x100*(WR RD)$	DMA SAR High
$+0x014*i + 0x200*i + 0x100*(WR RD)$	DMA DAR Low
$+0x018*i + 0x200*i + 0x100*(WR RD)$	DMA DAR High
$+0x01C*i + 0x200*i + 0x100*(WR RD)$	DMA Linked List Pointer Low
$+0x020*i + 0x200*i + 0x100*(WR RD)$	DMA Linked List Pointer High

a. i is the number of channels

b. WR=0 | RD=1

11.3.2.2.3.7.1 Implementation of Channel Context Registers

- The channel context registers are stored in RAM whose contents are automatically initialized after power-on.
 - Therefore, you must program every “register” value as the default is undefined

- You must program all fields marked Reserved to 1'b0
- These registers are not affected by any of the reset signals
- You must not write to any of the context registers for a particular channel after you start the channel by writing the channel number to the Doorbell Number field of the DMA Write Doorbell Register (DMA_WRITE_DOORBELL_OFF) or DMA Read Doorbell Register (DMA_READ_DOORBELL_OFF).

Linked List Operation

When you enable linked list operation (Linked List Enable field of DMA Channel Control 1 Register (DMA_CH_CONTROL1_OFF_WRCH_0) to 1b1), the DMA overwrites the following DMA channel context registers with the following information from linked list data elements:

- The CB, LLP, LIE, and RIE fields of the DMA Channel Control 1 register.
- DMA Transfer Size
- DMA SAR Low
- DMA SAR High
- DMA DAR Low
- DMA DAR High

NOTE

- The structure of a link element is different to that of the data element. A data element has no TCB field. A link element has no LIE or RIE fields. It has no SAR, DAR, or Transfer Size DWORDs, but has LL Element Pointer DWORDs instead of the SAR DWORDs. For more details, see Relationship Between Element DWORDs and Channel Context Registers.
- The LIE and RIE bits in a LL element, only enable the Done interrupt. In non-LL mode, the RIE and LIE bits enable the Done and Abort interrupts. For more information, see Interrupts and Error Handling.

11.3.2.2.3.8 Programming Examples

This section provides a programming and operation flow for each of the following scenarios:

- 1 MB Write Transfer On Write Channel #0 Initiated by Local CPU (Non LL mode)
- 1 MB Read Transfer On Read Channel #0 Initiated by Local CPU (Non LL mode)
- 1 MB Write Transfer On Write Channel #5 Initiated by Remote CPU (Non LL mode)

- 1 MB Read Transfer On Read Channel #5 Initiated by Remote CPU (Non LL mode)
- Linked List Mode Programming Example (Write Channel #0)

NOTE

The order in which the registers in the following examples are programmed is not important, except for the Doorbell register, which initiates the DMA transfer. Therefore, to start both a "1 MB Write Transfer On Write Channel #0 Initiated by Local CPU (Non LL mode)" and a "1 MB Read Transfer On Read Channel #0 Initiated by Local CPU (Non LL mode)" by executing the commands on the table. If, as mentioned in "Starting The DMA Transfer" , you want both channels to start at (approximately) the same time, then do not execute the last command (at 0x280) in the table 'DMA Register Setup' until after you have executed all the commands in table.

NOTE

You must enable the DMA before you start a DMA channel. Therefore you must write '1' to DMA Read Engine Enable or DMA Write Engine Enable register before you write '1' to the DMA Read Doorbell or DMA Write Doorbell register.

11.3.2.2.3.8.1 1 MB Write Transfer On Write Channel #0 Initiated by Local CPU (Non LL mode)

In this example, the IMWr generation is disabled, as the local CPU initiates the DMA transfer. The local CPU is interrupted using the edma_int bus. The SAR is the address of the local memory, and the DAR is the address of the remote memory, as shown in the figure below. The table below provides the programming details for this example transfer.

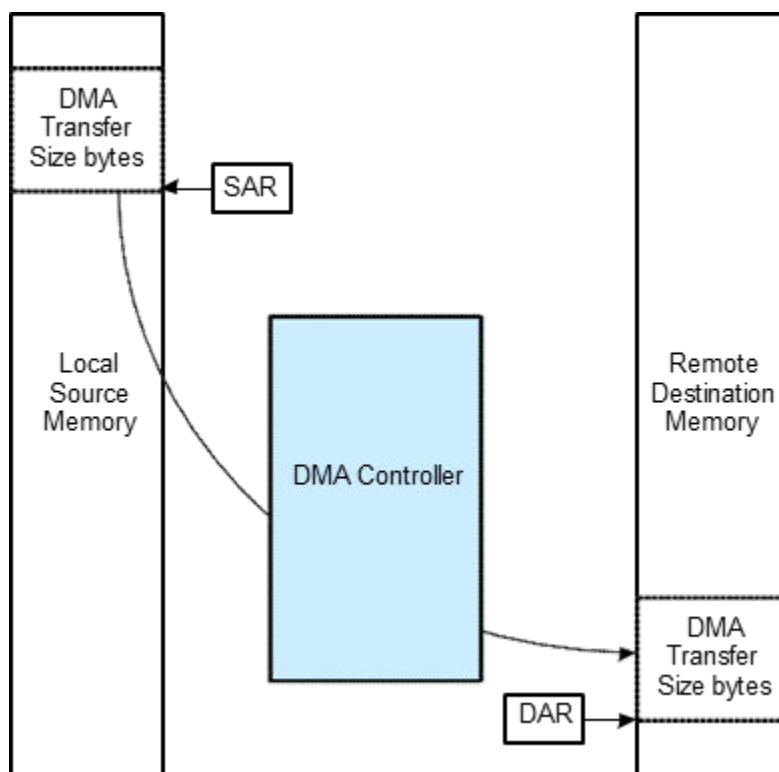

Figure 11-53. 1 MB Write DMA Transfer from 0xBEEF_BEE0 to 0xCAFE_CAF0

Table 11-87. 1 MB Write DMA Transfer from 0xBEEF_BEE0 to 0xCAFE_CAF0

Address (0x8_0000+)	Name	Value
0x00C	DMA Write Engine Enable You must not write 0 to this register. Even temporarily writing 0 to this register resets the DMA logic. For more details, see DMA Write Engine Enable Register (DMA_WRITE_ENGINE_EN_OFF).	0x1
0x054	DMA Write Interrupt Mask	0x0
0x200	DMA Channel Control 1 register <ul style="list-style-type: none"> Local Interrupt Enable (LIE) =1 Remote Interrupt Enable (RIE) =0 AT, RO, NS, TC, Function Number =0 	0x04000008

11.3.2.2.3.8.3 1 MB Write Transfer On Write Channel #5 Initiated by Remote CPU (Non LL mode)

In this example, the local interrupt generation is disabled, as the remote CPU initiates the DMA transfer. The remote CPU is interrupted using an IMWr. The SAR is the address of the local memory, and the DAR is the address of the remote memory, as shown in the figure below. The table below provides the programming details for this example transfer.

11.3.2.2.3.8.5 Linked List Mode Programming Example (Write Channel #0)

This write channel example corresponds to figure 'Example Producer (Software) - Consumer (DMA) Synchronization Flow', with the following features:

- Recycled linked list (LL) of nine data elements and one link element.
- Transfer is initiated by local CPU.
- Each data element corresponds to a 1 MB (0x0010_0000) write transfer.
- The SARs for each element are separated by 2 MB (0x0020_0000). The DAR for each element are separated by 16 MB (0x0100_0000). The SAR is the address of the local memory, and the DAR is the address of the remote memory, as shown in the figure below.
- The LL transfer list is located at address 0x0000_0200 in local memory.
- No remote interrupt is generated so the IMWr generation is disabled, as the local CPU initiates the DMA transfer. The local CPU is interrupted using the edma_int bus.
- There is a Watermark interrupt at element #5, and an Empty interrupt at element #8. Both of these interrupts are done interrupts (as opposed to abort interrupts).

You should familiarize yourself with the Linked List Flow for Producer and Consumer as shown in Figure 'Linked List Flow for Producer and Consumer'. These are the main steps for this process in this example:

Step 1: Create TL in local memory:

- Create the 10 elements as per Table 'Linked List Element Initial Setup'.
 - For elements 0, 1, 2, 3, 4, 6, 7: RIE, LIE, LLP, CB =0,0,0,1
 - For element 5: RIE, LIE, LLP, CB =0,1,0,1 □ For element 8: RIE, LIE, LLP, CB =0,1,0,1 □ For element 9: LLP, TCB, CB =1,1,0
- For more details, see “PCS-CCS-CB-TCB Producer-Consumer Synchronization” and “Linked List Mode”

Step 2: Program and Start DMA:

- Configure and start the DMA registers as per Table 'DMA Register Setup'.

Step 4: Wait for done interrupt and recycle TL

- For more details, see “Using Interrupts for Linked List Producer-Consumer Synchronization”
- When recycling elements, consider “Element Recycling”

NOTE

If the DMA driver is running on the host and the interrupt service routine is reading local interrupts to determine if the transfer is successful, then you must set LIE and RIE in the same element and you should mask or ignore the local interrupt pin. Setting RIE and LIE in element A followed by RIE (only) in element B is not a verified usage scenario.

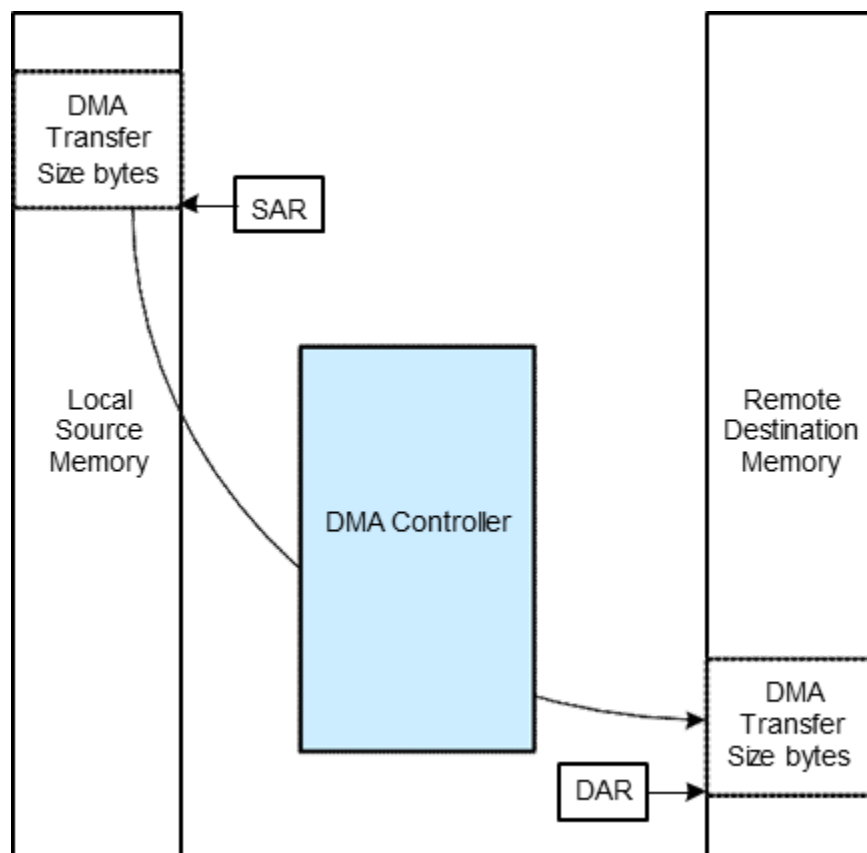

Figure 11-57. 1 MB Write DMA Transfer from SAR to DAR

11.3.2.2.4 Advanced DMA Information and Operation

This section discusses advanced features and operation of the DMA.

11.3.2.2.4.1 Overview

The DMA write and read channels operate independently to maximize the performance of the DMA read and write data transfers over the PCIe link.

The DMA can simultaneously perform the following types of memory transactions:

- DMA write: transfer (copy) of a block of data from local memory to remote memory
- DMA read: transfer (copy) of a block of data from remote memory to local memory

After you have programmed and started a DMA transfer (see "Using the DMA"), the DMA transfers the data as described in "**DMA Write Transfer**" and "**DMA Read Transfer**"

11.3.2.2.4.2 DMA Ordering

The DMA assumes that all DMA read channel data must be written to the local application memory in strict address order. For a DMA read transfer, each original outgoing request has a unique PCIe tag. The remote link partner or intermediate switch does not have to preserve the order of CPLs corresponding to such individual requests. When the DMA receives the CPLs out of order, it reorders that data in the "Read Buffer" as described in "**DMA Read Transfer**". DMA write transfer data is sourced from the local application memory and sent to the remote memory in address order.

11.3.2.2.4.3 Error Handling

The DMA supports full AXI and PCIe error handling in conjunction with the PCIe controller. The tables below list the possible sources of an error for DMA read and write transfers.

Table 11-93. Possible Sources of an Error during a DMA Read Transfer

Source	Type	Description
Application Write Error Detected	Fatal	<p>The DMA read channel has received an error response from the AXI bus at the bridge master interface (or TRGT1 interface when the AXI bridge is not used) while writing posted data to it. This error is fatal.</p> <ul style="list-style-type: none"> • You must restart the transfer from the beginning because the channel context is corrupted.

Table continues on the next page...

Table 11-93. Possible Sources of an Error during a DMA Read Transfer (continued)

		<ul style="list-style-type: none"> • The MWr is not rolled back. • The AXI bridge master does not report this error to software through error logging or MSG. <p>NOTE: During linked list mode, the Application Write Error only corrupts the current element in the linked list. This is because the DMA does not fetch the next element from local memory until it has completely finished transferring the current block of data (as defined by the current linked list element). Finished implies that your application has successfully acknowledged (without ERROR) all of the MWr requests.</p>
Unsupported Request (UR)	Non-fatal	The DMA read channel has received a PCIe UR CPL status from the remote device in response to the MRd request.
Completer Abort (CA)	Non-fatal	The DMA read channel has received a PCIe CA CPL status from the remote device in response to the MRd request.
CPL Time Out	Non-fatal	The DMA read channel has timed-out while waiting for the remote device to respond to the MRd request, or a malformed CplD has been received.
Data Poisoning	Fatal	The DMA read channel has detected data poisoning in the CPL from the remote device in response to the MRd request. The DMA read channel will drop the completion and then be halted.
Linked List Element Fetch Error Detected	Fatal	The DMA read channel has received an error response from the AXI bus (or TRGT1 interface when the AXI bridge is not used) while reading a linked list element from local memory.

Table 11-94. Possible Sources of an Error during a DMA Write Transfer

Source	Type	Description
Application Read Error Detected	Fatal	<p>The DMA write channel has received an error response from the AXI bus at the bridge master interface (or TRGT1 interface when the AXI bridge is not used) while reading data from it.</p> <ul style="list-style-type: none"> • The response TLP is discarded by the DMA and is not converted to an outbound MWr TLP.

Table continues on the next page...

Table 11-94. Possible Sources of an Error during a DMA Write Transfer (continued)

		<ul style="list-style-type: none"> • The UR or CA CPL status TLP generated by the bridge is discarded by the DMA. • The AXI bridge master does not report this error to software through error logging or MSG.
Linked List Element Fetch Error Detected	Fatal	<p>The DMA write channel has received an error response from the AXI bus at the bridge master interface (or TRGT1 interface when the AXI bridge is not used) while reading a linked list element from local memory.</p> <ul style="list-style-type: none"> • The UR or CA CPL status TLP generated by the bridge is discarded by the DMA. • The AXI bridge master1 does not report this (or for non-DMA traffic) error to software through error logging or MSG.

When the DMA detects an error, it performs the following actions (for the channel with the error):

- Stops issuing new requests to the remote link partner.
- Stops issuing new requests.
 - All data in the “Read Buffer”, that was received before the error was detected, is valid. In the case of a non-fatal error, this is reflected in the DMA Transfer Size Register DMA_TRANSFER_SIZE_OFF_WRCH_0.
 - All data in the read buffer (for that channel), that was received after the error was detected, is discarded.
- Places the DMA channel in a halted state (channel status field of the DMA Channel Control 1 Register is halted).
- Waits for all outstanding requests and CPLs to complete.
- Generates the abort interrupt or IMWr, if enabled, as outlined in “Interrupt Handling”.

For a DMA read transfer, you can read the DMA Read Error Status High Register (DMA_READ_ERR_STATUS_HIGH_OFF) and DMA Read Error Status Low Register (DMA_READ_ERR_STATUS_LOW_OFF) to identify the source of the error. For a DMA write transfer (in linked list mode only), you can read the DMA Write Error Status Register (DMA_WRITE_ERR_STATUS_OFF) to identify the source of the error. After your software has finished error and interrupt routine handling for Non-Fatal errors, you can request the DMA to continue processing (for the channel with the error) by:

1. Reprogramming the SAR based on the number of bytes remaining in the DMA Transfer Size register
2. Writing the channel number to the Doorbell Number field of the DMA Write Doorbell Register (DMA_WRITE_DOORBELL_OFF) or DMA Read Doorbell Register (DMA_READ_DOORBELL_REG).

NOTE

You cannot continue after a Fatal Error is detected, as the channel context is corrupted. Any actions that were in progress are not rolled back. To exit from this condition, you need to Soft Reset the complete DMA controller, as described in DMA Write Engine Enable Register (DMA_WRITE_ENGINE_EN_OFF) and DMA Read Engine Enable Register (DMA_READ_ENGINE_EN_OFF).

When an error occurs in linked list mode, the next LL element is not fetched from local memory. DMA Linked List Pointer Low Register (DMA_LL_P_LOW_OFF_WRCH_0) is not incremented by the DMA, but remains pointing to the element that caused the error.

11.3.2.2.4.3.1 Error Handling Assistance by Remote Software

During a DMA write transfer, the DMA is not aware of MWr errors that are detected in the remote device, because an MWr is a posted request and has no corresponding completion TLP. In these cases, your remote CPU must manually abort the DMA transfer by writing the channel number to the Doorbell Number field, and 1 to the Stop field of the DMA Write Doorbell Register (DMA_WRITE_DOORBELL_OFF). This causes the DMA to:

- Place the channel in a stopped state. The channel Status field of the DMA Channel Control 1 Register (DMA_CH_CONTROL1_OFF_WRCH_0) is stopped and the DMA Transfer Size register is not 0x0.
- Wait for all outstanding pending transactions.
- Assert the abort interrupt if it is enabled

11.3.2.2.4.4 Linked List Operation

This section describes the detailed operation of the DMA in linked list (LL) mode. It also discusses how the software should produce LL elements¹, and how the DMA and software maintain synchronization.

11.3.2.2.4.4.1 LL Operation Overview

You should first read "Linked List Mode" for an overview of LL mode. In this section, a normal LL operation called recycling2 is described in detail. The process is described for a write channel, but it is possible to have duplicate processes running in parallel for other write or read channels. In this process interrupts are used to trigger the producer (software) to recycle elements. Typically a Watermark interrupt (positioned near the middle of the transfer list (TL)) and an Empty interrupt (in the last data element) are used by setting LIE in these two elements to '1'.

The steps in this process are:

1. Software creates a LL element structure called a TL in local memory consisting of N-1 data elements and one link element.

The link elements "LL Element Pointer Low/High DWORDs"(as shown in Linked List Element figure in Linked List Mode topic) are programmed to point back to the beginning of the first data element.

One of the data elements (near the middle of the TL) is programmed to generate a "Watermark" interrupt.

The last data element is programmed to generate an "Empty" interrupt.

2. Software programs the DMA with the location of the TL. This is done by writing to the DMA Linked List Pointer Low Register (DMA_LL_P_L_LOW_OFF_WRCH_0) and DMA Linked List Pointer High Register (DMA_LL_P_H_HIGH_OFF_WRCH_0).
3. Software starts the DMA process by ringing the write channel Doorbell. This is done by writing to the DMA Write Doorbell Register (DMA_WRITE_DOORBELL_OFF).

The solid purple loop L1 in [Figure 11-58](#) corresponds to steps 1-3.

4. The DMA reads (**consumes**) each data element from local memory, and if the CB and CCS bits match, loads the information (SAR, DAR, size, and so on) from that data element into the channel context registers. These context registers determine the operation of the channel that the DMA is currently servicing. The DMA executes the check for the CB/CCS match after it has evaluated TCB and toggled CCS. The DMA always loads link elements into the channel context.

NOTE

If the DMA stops on a link element, then your software must set the DMA Linked List Pointer registers, and restart the DMA process by ringing the doorbell.

With recycling, the same LL structure is used over and over again. Another mode of operation would be to jump to a new LL element structure when the current one is consumed.

Figure 11-58. Linked List Flow for Producer and Consumer

5. The DMA then proceeds to transfer the block of data (as defined by the element), and when it is finished, reads the next element from local memory.

The solid green loop L2 in [Figure 11-58](#) corresponds to steps 4-5.

6. The last element in the list (called a link element, and indicated by having its LLP field set to 1) is not used to transfer a block of data.

It causes the DMA to effectively repeat the task in step 4.

Its TCB is typically set to 1. This causes the DMA to toggle its CCS bit, and the software to toggle its PCS bit. The software and DMA use the "PCS-CCS-CB-TCB" producer-consumer synchronization mechanism to ensure that:

Software does not recycle elements that have not yet being consumed by the DMA

DMA correctly recognizes and consumes recycled elements. The solid red loop L4 in [Figure 11-58](#) corresponds to step 6.

7. Upon reception of the interrupt (mentioned in step 1), the software starts to recycle the TL.

Software reprograms each data element with new DMA transfer information.

The software and DMA use the "PCS-CCS-CB-TCB" producer-consumer synchronization mechanism described later in this section.

The dashed purple loop L3 in [Figure 11-58](#) corresponds to step 7.

8. As some point, the software wants to terminate the complete DMA process, by not recycling any more elements. The DMA recognizes this condition when $CB \neq CCS$, and sets the channel status to stopped

The dashed red loop L5 in [Figure 11-58](#) corresponds to step 8.

11.3.2.2.4.4.2 Using Interrupts for Linked List Producer-Consumer Synchronization

When the DMA is finished with an element, the DMA checks the LIE bit, before reading the next LL element. For more details, see circled step A in [Figure 11-58](#). When the LIE is set, then the DMA does not assert the "done" interrupt immediately, but sets an internal interrupt pending flag (LIEP). It asserts the actual done interrupt after the next data element has been read from system memory. For more details, see circled step B in [Figure 11-58](#). This automatic internal process of delaying the interrupt avoids a race condition between the DMA and software when the LIE bit is set in an element.

Your software should set the "Watermark" interrupt early to schedule the recycling of the consumed elements. Placing the Watermark interrupt too far down in the list, combined with a slow element recycling process in your application; ensures that the DMA returns to the start of the LL before your software has recycled it. The DMA channel STOPS, and you have to restart it by writing to its Doorbell. Typically a "Watermark interrupt" (positioned near the middle of the TL) and an Empty interrupt (in the last data element) are used by setting LIE in these two elements to 1b1. Upon reception of the interrupt, the software starts to recycle the TL.

Operational interrupts are always "done" interrupts. For more details, see "Interrupts and Error Handling"

NOTE

The DMA processes the remote interrupt enable (RIE) bit in the LL element in the same way as the LIE. Therefore, everywhere that LIE and edma_int are mentioned in this section can be interpreted to mean LIE and edma_int, or RIE and IMWr.

11.3.2.2.4.4.3 PCS-CCS-CB-TCB Producer-Consumer Synchronization

The software and DMA use the "PCS-CCS-CB-TCB" producer-consumer synchronization mechanism to ensure that software does not recycle elements that have not yet being consumed by the DMA, and that the DMA correctly recognizes and consumes recycled elements. This process, which is shared between the DMA and the software, is illustrated through an example producer-consumer flow in the figure below.

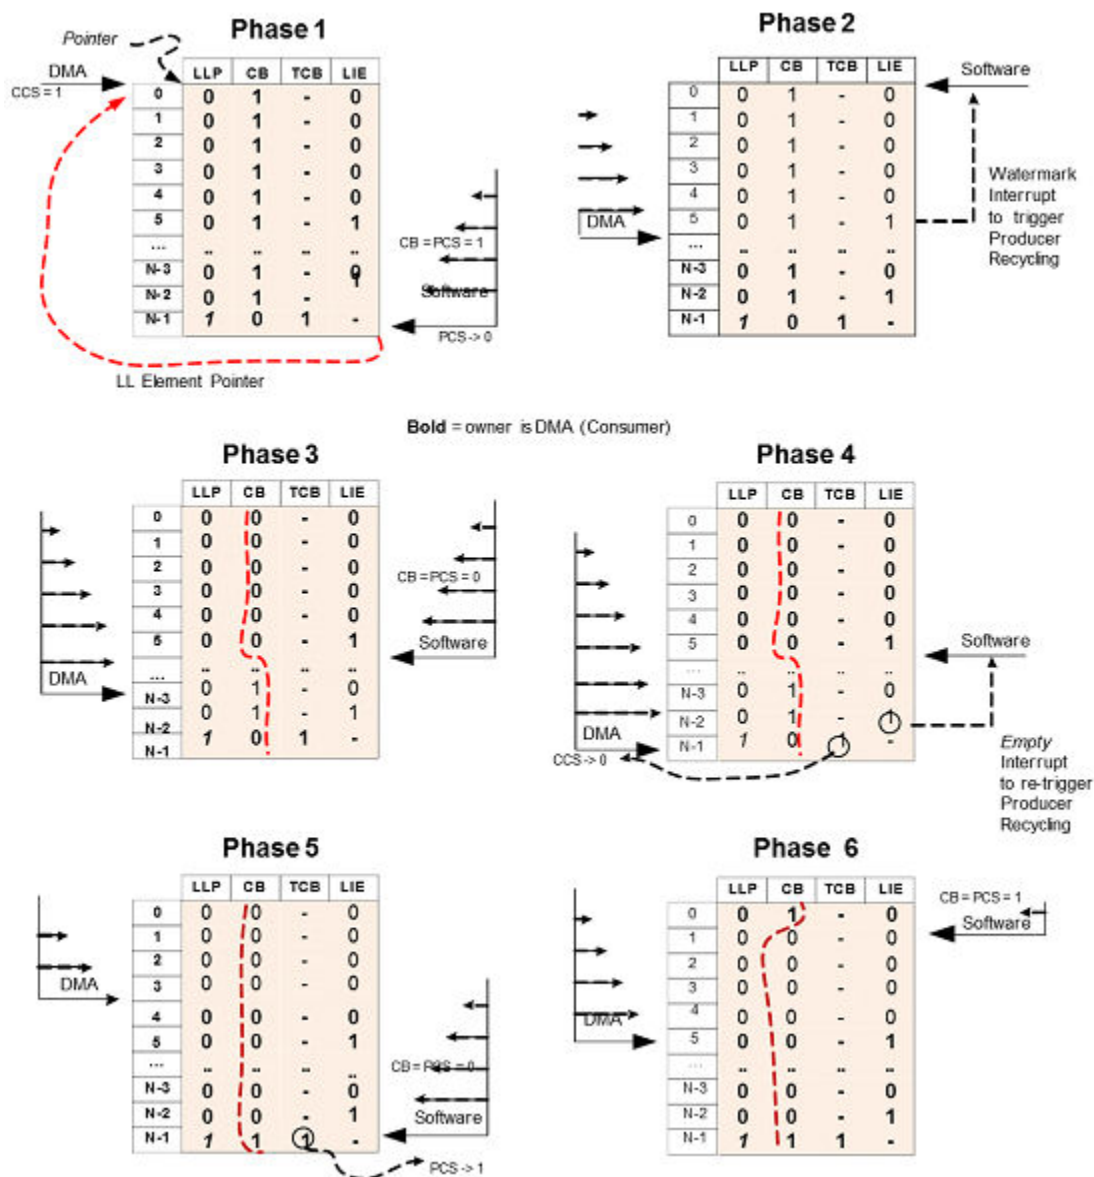

Figure 11-59. Example Producer (Software) - Consumer (DMA) Synchronization Flow

Before looking at the example in detail, it is useful to note that the DMA performs the following two tests as part of this process:

- Consumer-Owned Element, or Transfer List (TL) Empty Test

The solid red loop L4 in the [Figure 11-58](#) corresponds to this test. The Cycle Bit (CB) of DMA Channel Control 1 Register (DMA_CH_CONTROL1_OFF_WRCH_0) (which was loaded from the LL element) is tested against the DMA Consumer Cycle State (CCS) bit of the same register. When CB = CCS, the element is owned by the consumer (DMA) and the data transfer

is executed. When $CB \neq CCS$, the TL is empty and the DMA sets channel Status (CS) in DMA Channel Control 1 Register (DMA_CH_CONTROL1_OFF_WRCH_0) to "Stopped".

- Toggle Cycle Bit (TCB) Test

The Dashed Red Loop Marked L5 in [Figure 11-58](#) corresponds to this test. When the Toggle Cycle Bit (TCB) of the DMA Channel Control 1 Register (DMA_CH_CONTROL1_OFF_WRCH_0) (which was loaded from the LL element) is set to 1, the DMA toggles the CCS bit of the DMA Channel Control 1 Register (DMA_CH_CONTROL1_OFF_WRCH_0) to be $\sim CB$. The producer (software) also performs a similar action on its local variable "Producer Cycle Status" (PCS), as it sets $PCS = \sim PCS$. The TCB field is only valid in the last LL element (the link element). Toggling the PCS and CCS flags in this manner synchronizes the consumer to the producer.

The example in [Figure 11-59](#) has the following six phases:

1. The software builds the transfer list for the write (or read) channel, according to the steps outlined in the circled step C in [Figure 11-58](#). For each element, $CB = PCS = CCS = 1$. The exception to this is the link element where CB is set to the next iteration value because the link element is always loaded into the channel context.
 - The link element points to the start of the TL and its TCB bit is 1. Software toggles its PCS variable.
 - Software writes the location of the TL into the channel context LL Pointer register.
 - Software rings the write channel Doorbell.
2. The DMA starts processing elements. After processing element 5 (and fetching the next element), the DMA asserts a Watermark "done" interrupt to signal the software to start recycling elements.
3. The software is recycling elements. It reads the channel context DMA Linked List Pointer Low Register (DMA_LL_P_LOW_OFF_WRCH_0) and DMA Linked List Pointer High Register (DMA_LL_P_HIGH_OFF_WRCH_0), and recycles elements up to this location in the TL. It sets CB for each element to be PCS. The Dashed Purple Loop Marked L3 in [Figure 11-58](#) corresponds to this activity. The DMA continues processing (consuming) elements as before.
4. The DMA then asserts an Empty "done" interrupt (from the LIE bit in the last data element at the end of TL that was set in the previous phase) to indicate to the software, to start recycling elements again. The DMA reaches the end of the TL, and as the TCB is set to 1, it toggles its CCS bit to 0 ($\sim CB$). For more details, see circled step D in [Figure 11-58](#).
5. The software reads the channel context DMA Linked List Pointer Low Register (DMA_LL_P_LOW_REG_WRCH_0) and DMA Linked List Pointer High Register

(DMA_LL_P_HIGH_OFF_WRCH_0), and recycles elements up to this location in the TL. It sets CB for each element to be PCS. As it recycles the link element, it detects that TCB is set to 1. It toggles its internal variable PCS to 0, and the initial TL has been fully recycled. The DMA starts processing the recycled elements.

6. The DMA continues processing (consuming) elements as before. Software did not have to ring the Doorbell, as the first element was already recycled before the DMA started processing it. The software might continue recycling from the top of the list, if the DMA had already returned to the top of the list when the software read the channel context DMA Linked List Pointer Low Register (DMA_LL_P_LOW_OFF_WRCH_0) and DMA Linked List Pointer High Register (DMA_LL_P_HIGH_OFF_WRCH_0), in step 5. If not, it starts recycling again when the DMA processes element 4 and the DMA asserts a Watermark “done” interrupt.

11.3.2.2.4.4.4 *Element Recycling*

When your software is recycling elements, it should program the first DWORD (control bits) in the [Figure 11-50](#) only after the other DWORDs have been programmed. In addition, it should set the CB bit (to ~PCS) within this DWORD only after the other bits in this DWORD have been set. This programming sequence avoids the DMA incorrectly fetching an element that software is currently recycling.

When the software is finished recycling it must check the channel context status (CS). When CS is "Stopped", the software must ring the channel Doorbell again. For more details, see circled step E in [Figure 11-46](#). If your element recycling process was fast enough, then the DMA will seamlessly move from processing the last old element to the first new element, without the need for the software to ring the channel Doorbell again. To eliminate the possibility of a race condition between these two actions (read and write), you should first confirm the presence of the "done" interrupt bit in the DMA Write Interrupt Status Register (DMA_WRITE_INT_STATUS_OFF) or DMA Read Interrupt Status Register (DMA_READ_INT_STATUS_OFF) and also check the DMA Linked List Pointer Low Register (DMA_LL_P_LOW_REG_WRCH_0) to confirm that it is pointing to the correct location.

11.3.2.2.4.4.5 *Link Down Recovery*

During normal operation when the link goes down, the controller generates a "link reset" request. A

high-to-low transition on link_req_rst_not indicates that the PCIe controller is requesting external logic to reset the PCIe controller because the PHY link is down. For more details, see "Hot Reset". To determine the progress of the linked list operation when the

link went down, you can read the contents of the channel context DMA Linked List Pointer Low Register (DMA_LLPOW_OFF_WRCH_0) and DMA Linked List Pointer High Register (DMA_LLPHIGH_OFF_WRCH_0).

11.3.3 Memory Map and Register Definition

This section includes the PCIe module memory map and detailed descriptions of all registers.

11.3.3.1.2 Device ID and Vendor ID Register. (TYPE1_DEV_ID_VEND_ID_REG)

11.3.3.1.2.1 Offset

Register	Offset
TYPE1_DEV_ID_VEND_ID_REG	0h

11.3.3.1.2.2 Diagram

11.3.3.1.2.3 Fields

Field	Function
31-16 DEVICE_ID	Device ID. The Device ID register identifies the particular Function. This identifier is allocated by the vendor. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.
15-0 VENDOR_ID	Vendor ID. The Vendor ID register identifies the manufacturer of the Function. Valid vendor identifiers are allocated by the PCI-SIG to ensure uniqueness. It is not permitted to populate this register with a value of FFFFh, which is an invalid value for Vendor ID. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.

11.3.3.1.3 Status and Command Register. (TYPE1_STATUS_COMMAND_REG)

11.3.3.1.3.1 Offset

Register	Offset
TYPE1_STATUS_COMMAND_REG	4h

11.3.3.1.3.2 Diagram

11.3.3.1.3.3 Fields

Field	Function
31 DETECTED_PA RITY_ERROR	Detected Parity Error. This bit is set by a Function whenever it receives a Poisoned TLP, regardless of the state the Parity Error Response bit in the Command register. The bit is set when the Poisoned TLP is received by a Function's primary side.
30 SIGNALED_SY S_ERROR	Signaled System Error. This bit is set when a Function sends an ERR_FATAL or ERR_NONFATAL Message, and the SERR# Enable bit in the Command register is 1b.
29 RCVD_MASTE R_ABORT	Received Master Abort. This bit is set when a Requester receives a Completion with Unsupported Request Completion status. The bit is set when the Unsupported Request is received by a Function's primary side.
28 RCVD_TARGET _ABORT	Received Target Abort. This bit is set when a Requester receives a Completion with Completer Abort Completion status. The bit is set when the Completer Abort is received by a Function's primary side.
27 SIGNALED_TA RGET_ABORT	Signaled Target Abort. This bit is set when a Function completes a Posted or Non-Posted Request as a Completer Abort error. This applies to a Function when the Completer Abort was generated by its primary side.
26-25	DEVSEL Timing. This field was originally described in the PCI Local Bus Specification. Its functionality does not apply to PCI Express. The controller hardwires it to 00b.

Table continues on the next page...

PCI Express (PCIe)

Field	Function
DEV_SEL_TIMING	
24 MASTER_DPE	Master Data Parity Error. This bit is set by a Function if the Parity Error Response bit in the Command register is 1b and either of the following two conditions occurs: - Port receives a Poisoned Completion going downstream - Port transmits a Poisoned Request upstream If the Parity Error Response bit is 0b, this bit is never set.
23 FAST_B2B_CAP	Fast Back-to-Back Transactions Capable. This bit was originally described in the PCI Local Bus Specification. Its functionality does not apply to PCI Express. The controller hardwires this bit to 0b.
22 RSVDP_22	Reserved for future use.
21 FAST_66MHZ_CAP	66 MHz Capable. This bit was originally described in the PCI Local Bus Specification. Its functionality does not apply to PCI Express. The controller hardwires this bit to 0b.
20 CAP_LIST	Capabilities List. Indicates the presence of an Extended Capability list item. Since all PCI Express device Functions are required to implement the PCI Express Capability structure, the controller hardwires this bit to 1b.
19 INT_STATUS	Interrupt Status. When set, indicates that an INTx emulation interrupt is pending internally in the Function. INTx emulation interrupts forwarded by Functions from the secondary side are not reflected in this bit. Setting the Interrupt Disable bit has no effect on the state of this bit. For Functions that do not generate INTx interrupts, the controller hardwires this bit to 0b.
18-17 RSVDP_17	Reserved for future use.
16 —	Reserved.
15-11 RESERV	Reserved.
10 INT_EN	Interrupt Disable. Controls the ability of a Function to generate INTx emulation interrupts. When set, Functions are prevented from asserting INTx interrupts. Note: - Any INTx emulation interrupts already asserted by the Function must be deasserted when this bit is set. INTx interrupts use virtual wires that must, if asserted, be deasserted using the appropriate Deassert_INTx message(s) when this bit is set. - Only the INTx virtual wire interrupt(s) associated with the Function(s) for which this bit is set are affected. - For Functions that generate INTx interrupts on their own behalf, this bit is required. This bit has no effect on interrupts forwarded from the secondary side. For Functions that do not generate INTx interrupts on their own behalf this bit is optional. If this bit is not implemented, the controller hardwires it to 0b.
9 RSVDP_9	Reserved for future use.
8 SERREN	SERR# Enable. When set, this bit enables reporting upstream of Non-fatal and Fatal errors detected by the Function. Note: The errors are reported if enabled either through this bit or through the PCI Express specific bits in the Device Control register. For more details see the "Error Registers" section of the PCI Express Specification. In addition, this bit controls transmission by the primary interface of ERR_NONFATAL and ERR_FATAL error Messages forwarded from the secondary interface. This bit does not affect the transmission of forwarded ERR_COR messages.
7 IDSEL	IDSEL Stepping/Wait Cycle Control. This bit was originally described in the PCI Local Bus Specification. Its functionality does not apply to PCI Express. The controller hardwires this bit to 0b.
6 PERREN	Parity Error Response. This bit controls the logging of poisoned TLPs in the Master Data Parity Error bit in the Status register. For more details see the "Error Registers" section of the PCI Express Specification.

Table continues on the next page...

Field	Function
5 VGAPS	VGA Palette Snoop. This bit was originally described in the PCI Local Bus Specification and the PCI-to-PCI Bridge Architecture Specification. Its functionality does not apply to PCI Express. The controller hardwires this bit to 0b.
4 MWI_EN	Memory Write and Invalidate. This bit was originally described in the PCI Local Bus Specification and the PCI-to-PCI Bridge Architecture Specification. Its functionality does not apply to PCI Express. The controller hardwires this bit to 0b. For PCI Express to PCI/PCI-X Bridges, refer to the PCI Express to PCI/PCI-X Bridge Specification for requirements for this register.
3 SCO	Special Cycle Enable. This bit was originally described in the PCI Local Bus Specification. Its functionality does not apply to PCI Express. The controller hardwires this bit to 0b.
2 BME	Bus Master Enable. This bit controls forwarding of Memory or I/O requests by a port in the Upstream direction. When this bit is 0b, Memory and I/O Requests received at a Root Port must be handled as Unsupported Requests (UR) For Non-Posted Requests a Completion with UR completion status must be returned. This bit does not affect forwarding of Completions in either the Upstream or Downstream direction. The forwarding of Requests other than Memory or I/O Requests is not controlled by this bit.
1 MSE	Memory Space Enable. This bit controls a Function's response to Memory Space accesses received on its primary side. - When set, the Function is enabled to decode the address and further process Memory Space accesses. - When clear, all received Memory Space accesses are caused to be handled as Unsupported Requests. You cannot write to this register if your configuration has no MEM bars; that is, the internal signal has_mem_bar =0. Note: The access attributes of this field are as follows: - Dbi: !has_mem_bar ? RO : RW
0 IO_EN	IO Space Enable. This bit controls a Function's response to I/O Space accesses received on its primary side. - When set, the Function is enabled to decode the address and further process I/O Space accesses. - When clear, all received I/O accesses are caused to be handled as Unsupported Requests. You cannot write to this register if your configuration has no IO bars; that is, the internal signal has_io_bar =0. Note: The access attributes of this field are as follows: - Dbi: !has_io_bar ? RO : RW

11.3.3.1.4.3 Fields

Field	Function
31-24 BASE_CLASS_CODE	Base Class Code. A code that broadly classifies the type of operation the Function performs. Encodings for base class, are provided in the PCI Code and ID Assignment Specification. All unspecified encodings are reserved. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.
23-16 SUBCLASS_CODE	Sub-Class Code. Specifies a base class sub-class, which identifies more specifically the operation of the Function. Encodings for sub-class are provided in the PCI Code and ID Assignment Specification. All unspecified encodings are reserved. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.
15-8 PROGRAM_INTERFACE	Programming Interface. This field identifies a specific register level programming interface (if any) so that device independent software can interact with the Function. Encodings for interface are provided in the PCI Code and ID Assignment Specification. All unspecified encodings are reserved. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.
7-0 REVISION_ID	Revision ID. The value of this field specifies a Function specific revision identifier. The value is chosen by the vendor. Zero is an acceptable value. The Revision ID should be viewed as a vendor defined extension to the Device ID. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.

11.3.3.1.5 Header Type, Latency Timer, and Cache Line Size Register. (TYPE1_HDR_TYPE_LAT_CACHE_LINE_SIZE_REG)

Register	Offset
TYPE1_HDR_TYPE_LAT_CACHE_LINE_SIZE_REG	Ch

11.3.3.1.5.2 Diagram

11.3.3.1.5.3 Fields

Field	Function
31-24 —	Reserved.
23 MULTI_FUNC	Multi-Function Device. - When set, indicates that the device may contain multiple Functions, but not necessarily. Software is permitted to probe for Functions other than Function 0. - When clear, software must not probe for Functions other than Function 0 unless explicitly indicated by another mechanism, such as an ARI or SR-IOV Capability structure. Except where stated otherwise, it is recommended that this bit be set if there are multiple Functions, and clear if there is only one Function. Note: This register field is sticky.
22-16 HEADER_TYPE	Header Layout. This field identifies the layout of the second part of the predefined header. The controller uses 000 0001b encoding. The encoding 000 0010b is reserved. This encoding was originally described in the PC Card Standard Electrical Specification and is used in previous versions of the programming model. Careful consideration should be given to any attempt to repurpose it.
15-8 LATENCY_MASTER_TIMER	Latency Timer. This register is also referred to as Primary Latency Timer. The Latency Timer was originally described in the PCI Local Bus Specification and the PCI-to-PCI Bridge Architecture Specification. Its functionality does not apply to PCI Express. The controller hardwires this register to 00h.
7-0 CACHE_LINE_SIZE	Cache Line Size. The Cache Line Size register is programmed by the system firmware or the operating system to system cache line size. However, legacy conventional PCI software may not always be able to program this register correctly especially in the case of Hot-Plug devices. This read-write register is implemented for legacy compatibility purposes but has no effect on any PCI Express device behavior.

11.3.3.1.6 Secondary Latency Timer, Subordinate Bus Number, Secondary Bus Number, and Primary Bus Number Register. (SEC_LAT_TIMER_SUB_BUS_SEC_BUS_PRI_BUS_REG)

11.3.3.1.6.1 Offset

11.3.3.1.6.3 Fields

Field	Function
31-24 SEC_LAT_TIMER	Secondary Latency Timer. This register does not apply to PCI Express. The controller hardwires it to 00h.
23-16 SUB_BUS	Subordinate Bus Number. The Subordinate Bus Number register is used to record the bus number of the highest numbered PCI bus segment which is behind (or subordinate to) the bridge. Configuration software programs the value in this register. The bridge uses this register in conjunction with the Secondary Bus Number register to determine when to respond to and pass on a Type 1 configuration transaction on the primary interface to the secondary interface.
15-8 SEC_BUS	Secondary Bus Number. The Secondary Bus Number register is used to record the bus number of the PCI bus segment to which the secondary interface of the bridge is connected. Configuration software programs the value in this register. The bridge uses this register to determine when to respond to and convert a Type 1 configuration transaction on the primary interface into a Type 0 transaction on the secondary interface.
7-0 PRIM_BUS	Primary Bus Number. This register is not used by PCI Express Functions. It is implemented for compatibility with legacy software.

11.3.3.1.7 Secondary Status, and I/O Limit and Base Register. (SEC_STAT_IO_LIMIT_IO_BASE_REG)

11.3.3.1.7.1 Offset

Register	Offset
SEC_STAT_IO_LIMIT_ IO_BASE_REG	1Ch

11.3.3.1.7.2 Function

Secondary Status, and I/O Limit and Base Register. The I/O Limit and I/O Base registers are optional and define an address range that is used by the bridge to determine when to forward I/O transactions from one interface to the other. If a bridge does not implement an I/O address range, then both the I/O Limit and I/O Base registers must be implemented as read-only registers that return zero when read. If a bridge supports an I/O address range, then these registers must be initialized by configuration software so default states are not specified.

11.3.3.1.7.3 Diagram

11.3.3.1.7.4 Fields

Field	Function
31 SEC_STAT_DP E	Detected Parity Error. This bit is set by a Function when a Poisoned TLP is received by its secondary side, regardless of the state the Parity Error Response Enable bit in the Bridge Control register.
30 SEC_STAT_RC VD_SYS_ERR	Received System Error. This bit is set when the secondary side of a Function receives an ERR_FATAL or ERR_NONFATAL message.
29 SEC_STAT_RC VD_MSTR_ABR T	Received Master Abort. This bit is set when the secondary side of a Function (for requests initiated by the Type 1 header Function itself) receives a Completion with Unsupported Request Completion status.
28 SEC_STAT_RC VD_TRGT_ABR T	Received Target Abort. This bit is set when the secondary side of a Function (for requests initiated by the Type 1 header Function itself) receives a Completion with Completer Abort Completion status.
27 SEC_STAT_SIG _TRGT_ABRT	Signaled Target Abort. This bit is set when the secondary side of the Function (for Requests completed by the Type 1 header Function itself) completes a Posted or Non-Posted request as a Completer Abort error.
26-25 RSVDP_25	Reserved for future use.
24 SEC_STAT_MD PE	Master Data Parity Error. This bit is set by a Function if the Parity Error Response Enable bit in the Bridge Control register is set, and either of the following two conditions occurs: - Port receives a Poisoned Completion coming Upstream - Port transmits a Poisoned Request Downstream If the Parity Error Response Enable bit is clear, this bit is never set.
23 RSVDP_23	Reserved for future use.
22-16 SEC_STAT_RE SERV	Reserved.
15-12 IO_LIMIT	I/O Limit Address. These bits correspond to the address[15:12] of IO address range. For the purpose of address decoding, the bridge assumes that the lower 12 address bits, address[11:0], of the I/O limit address (not implemented in the I/O Limit register) are FFFh. The I/O Limit register can be programmed to a smaller value than the I/O Base register, if there are no I/O addresses on the secondary side of the bridge. In this case, the bridge will not forward any I/O transactions from the primary bus to the secondary and will forward all I/O transactions from the secondary bus to the primary bus.
11-9 IO_RESERV1	Reserved.
8 IO_DECODE_BIT8	I/O Addressing Encode (IO Limit Address). This bit encodes the IO addressing capability of the bridge. IO_DECODE_BIT8 indicates the following: - 0h: The bridge supports only 16-bit I/O addressing (for ISA compatibility). For the purpose of address decoding, the bridge assumes that the upper 16 address bits, Address[31:16], of the I/O limit address (not implemented in I/O Limit register) are zero. Note: The bridge must still perform a full 32-bit decode of the I/O address (that is, check that Address[31:16] are 0000h). In this case, the I/O address range supported by the bridge will be restricted to the first 64 KB of I/O Space (0000 0000h to 0000 FFFFh). - 01h: The bridge supports 32-bit I/O address decoding, and the I/O Limit Upper 16 Bits hold the upper 16 bits, corresponding to Address[31:16], of the 32-bit Limit address. In this case, system configuration software is permitted to locate the I/O address range supported by the bridge

Table continues on the next page...

Field	Function
	anywhere in the 4-GB I/O Space. Note: The 4-KB alignment and granularity restrictions still apply when the bridge supports 32-bit I/O addressing. Note: The access attributes of this field are as follows: - Dbi: R
7-4 IO_BASE	I/O Base Address. These bits correspond to the address[15:12] of IO address range. For the purpose of address decoding, the bridge assumes that the lower 12 address bits, address[11:0], of the I/O base address (not implemented in the I/O Base register) are zero.
3-1 IO_RESERV	Reserved.
0 IO_DECODE	I/O Addressing Encode (IO Base Address) This bit encodes the IO addressing capability of the bridge. IO_DECODE indicates the following: - 0h: The bridge supports only 16-bit I/O addressing (for ISA compatibility). For the purpose of address decoding, the bridge assumes that the upper 16 address bits, Address[31:16], of the I/O base address (not implemented in I/O base register) are zero. Note: The bridge must still perform a full 32-bit decode of the I/O address (that is, check that Address[31:16] are 0000h). In this case, the I/O address range supported by the bridge will be restricted to the first 64 KB of I/O Space (0000 0000h to 0000 FFFFh). - 01h: The bridge supports 32-bit I/O address decoding, and the I/O Base Upper 16 Bits hold the upper 16 bits, corresponding to Address[31:16], of the 32-bit Base address. In this case, system configuration software is permitted to locate the I/O address range supported by the bridge anywhere in the 4-GB I/O Space. Note: The 4-KB alignment and granularity restrictions still apply when the bridge supports 32-bit I/O addressing. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R

11.3.3.1.8 Memory Limit and Base Register. (MEM_LIMIT_MEM_BASE_REG)

11.3.3.1.8.1 Offset

Register	Offset
MEM_LIMIT_MEM_BASE_REG	20h

11.3.3.1.8.2 Function

Memory Limit and Base Register. The Memory Limit and Memory Base registers define a memory mapped address range which is used by the bridge to determine when to forward memory transactions from one interface to the other. If there is no prefetchable memory space, and there is no memory-mapped space on the secondary side of the bridge, then the bridge will not forward any memory transactions from the primary bus to the secondary bus and will forward all memory transactions from the secondary bus to the primary bus.

11.3.3.1.8.3 Diagram

11.3.3.1.8.4 Fields

Field	Function
31-20 MEM_LIMIT	Memory Limit Address. These bits correspond to the upper 12 address bits, Address[31:20], of 32-bit addresses. For the purpose of address decoding, the bridge assumes that the lower 20 address bits, Address[19:0], of the memory limit address (not implemented in the Memory Limit register) are F FFFFh. The Memory Limit register must be programmed to a smaller value than the Memory Base register if there is no memory-mapped address space on the secondary side of the bridge.
19-16 MEM_LIMIT_RE SERV	Reserved.
15-4 MEM_BASE	Memory Base Address. These bits correspond to the upper 12 address bits, Address[31:20], of 32-bit addresses. For the purpose of address decoding, the bridge assumes that the lower 20 address bits, Address[19:0], of the memory base address (not implemented in the Memory Base register) are zero.
3-0 MEM_BASE_R ESERV	Reserved.

11.3.3.1.9 Prefetchable Memory Limit and Base Register. (PREF_MEM_LIMIT_PREF_MEM_BASE_REG)

11.3.3.1.9.1 Offset

Register	Offset
PREF_MEM_LIMIT_P REF_MEM_BASE_REG	24h

11.3.3.1.9.2 Function

Prefetchable Memory Limit and Base Register. The Prefetchable Memory Limit and Prefetchable Memory Base registers must indicate that 64-bit addresses are supported, as defined in PCI-to-PCI Bridge Architecture Specification. The Prefetchable Memory Limit and Prefetchable Memory Base registers are optional. They define a prefetchable memory address range which is used by the bridge to determine when to forward memory transactions from one interface to the other (see the PCI-to-PCI Bridge Architecture Specification for additional details).

11.3.3.1.9.3 Diagram

11.3.3.1.9.4 Fields

Field	Function
31-20 PREF_MEM_LIMIT	Prefetchable Memory Limit Address. If the Prefetchable Memory Limit register indicates support for 32-bit addressing, then the Prefetchable Limit Upper 32 Bits register is implemented as a read-only register that returns zero when read. If the Prefetchable Memory Limit registers indicate support for 64-bit addressing, then the Prefetchable Limit Upper 32 Bits register is implemented as a read/write register which must be initialized by configuration software. If a 64-bit prefetchable memory address range is supported, the Prefetchable Limit Upper 32 Bits register specifies the upper 32 bits, corresponding to Address[63:32], of the 64-bit limit addresses which specify the prefetchable memory address range.
19-17 PREF_RESERV1	Reserved.
16 PREF_MEM_LIMIT_DECODE	Prefetchable Memory Limit Decode. This bit encodes whether or not the bridge supports 64-bit addresses. The value of PREF_MEM_LIMIT_DECODE indicates the following: - 0b: Indicates that the bridge supports only 32 bit addresses - 1b: Indicates that the bridge supports 64 bit addresses. Prefetchable Limit Upper 32 Bits registers holds the rest of the 64-bit prefetchable limit address.
15-4 PREF_MEM_BASE	Prefetchable Memory Base Address. If the Prefetchable Memory Base register indicates support for 32-bit addressing, then the Prefetchable Base Upper 32 Bits register is implemented as a read-only register that returns zero when read. If the Prefetchable Memory Base register indicates support for 64-bit addressing, then the Prefetchable Limit Upper 32 Bits register is implemented as a read/write register which must be initialized by configuration software. If a 64-bit prefetchable memory address range is supported, the Prefetchable Base Upper 32 Bits register specifies the upper 32 bits, corresponding to Address[63:32], of the 64-bit base addresses which specify the prefetchable memory address range.
3-1 PREF_RESERV	Reserved.
0 PREF_MEM_DECODE	Prefetchable Memory Base Decode. This bit encodes whether or not the bridge supports 64-bit addresses. The value of PREF_MEM_DECODE indicates the following: - 0b: Indicates that the bridge supports only 32 bit addresses. - 1b: Indicates that the bridge supports 64 bit addresses. Prefetchable Base Upper 32 Bits registers holds the rest of the 64-bit prefetchable base address. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.

11.3.3.1.10 Prefetchable Base Upper 32 Bits Register. (PREF_BASE_UPPER_REG)

11.3.3.1.10.1 Offset

Register	Offset
PREF_BASE_UPPER_REG	28h

11.3.3.1.10.2 Function

Prefetchable Base Upper 32 Bits Register. The Prefetchable Base Upper 32 Bits register is an optional extension to the Prefetchable Memory Base register.

11.3.3.1.10.3 Diagram

11.3.3.1.10.4 Fields

Field	Function
31-0 PREF_MEM_BASE_UPPER	Prefetchable Base Upper 32 Bit. If the Prefetchable Memory Base register indicates support for 32-bit addressing, then this register is implemented as read-only register that returns zero when read. If the Prefetchable Memory Base register indicate support for 64-bit addressing, then this register is implemented as read/write register which must be initialized by configuration software. This register specifies the upper 32 bits, corresponding to Address[63:32], of the 64-bit base addresses which specify the prefetchable memory address range. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R

11.3.3.1.11 Prefetchable Limit Upper 32 Bits Register. (PREF_LIMIT_UPPER_REG)

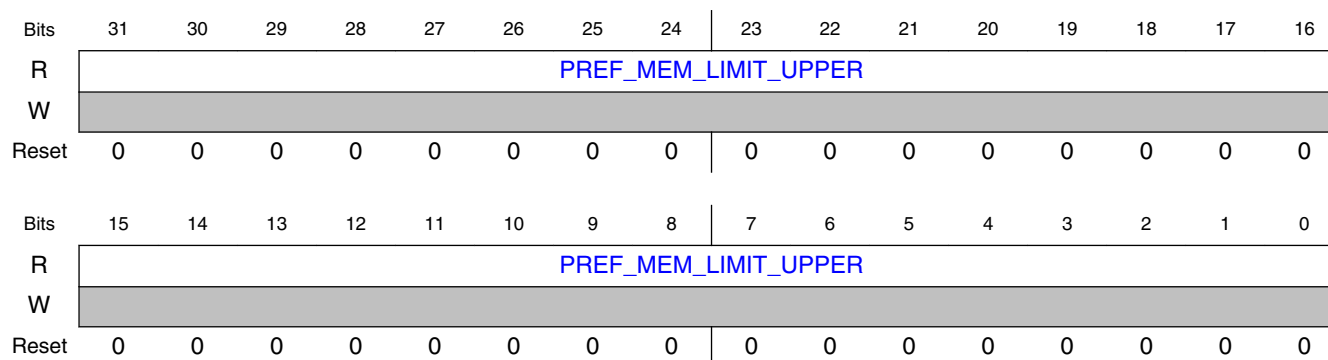

11.3.3.1.11.1 Offset

Register	Offset
PREF_LIMIT_UPPER_REG	2Ch

11.3.3.1.11.2 Function

Prefetchable Limit Upper 32 Bits Register. The Prefetchable Limit Upper 32 Bits register is an optional extension to the Prefetchable Memory Limit register.

11.3.3.1.11.3 Diagram

11.3.3.1.11.4 Fields

Field	Function
31-0 PREF_MEM_LIMIT_UPPER	Prefetchable Limit Upper 32 Bit. If the Prefetchable Memory Limit register indicate support for 64-bit addressing, then this register is implemented as read/write register which must be initialized by configuration software. This register specifies the upper 32 bits, corresponding to Address[63:32], of the 64-bit base addresses which specify the prefetchable memory address range. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R

11.3.3.1.12 I/O Limit and Base Upper 16 Bits Register. (IO_LIMIT_UPPER_I O_BASE_UPPER_REG)

11.3.3.1.12.1 Offset

Register	Offset
IO_LIMIT_UPPER_IO_ BASE_UPPER_REG	30h

11.3.3.1.12.2 Function

I/O Limit and Base Upper 16 Bits Register. The I/O Limit Upper 16 Bits and I/O Base Upper 16 Bits registers are optional extensions to the I/O Limit and I/O Base registers.

11.3.3.1.12.3 Diagram

11.3.3.1.12.4 Fields

Field	Function
31-16 IO_LIMIT_UPPER	I/O Limit Upper 16 Bits. If the I/O Limit register indicates support for 16-bit I/O address decoding, then this register is implemented as a read-only register which return zero when read. If the I/O Limit register indicates support for 32-bit I/O addressing, then this register must be initialized by configuration software. If 32-bit I/O address decoding is supported, this register specifies the upper 16 bits, corresponding to Address[31:16], of the 32-bit limit address, that specify the I/O address range. See the PCI-to-PCI Bridge Architecture Specification for additional details). Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R
15-0 IO_BASE_UPPER	I/O Base Upper 16 Bits. If the I/O Base register indicates support for 16-bit I/O address decoding, then this register is implemented as a read-only register which return zero when read. If the I/O base register indicates support for 32-bit I/O addressing, then this register must be initialized by configuration software. If 32-bit I/O address decoding is supported, this register specifies the upper 16 bits, corresponding to Address[31:16], of the 32-bit base address, that specify the I/O address range. See the PCI-to-PCI Bridge Architecture Specification for additional details. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R

11.3.3.1.13 Capabilities Pointer Register. (TYPE1_CAP_PTR_REG)

11.3.3.1.13.1 Offset

Register	Offset
TYPE1_CAP_PTR_REG	34h

11.3.3.1.13.2 Diagram

11.3.3.1.13.3 Fields

Field	Function
31-8 RSVDP_8	Reserved for future use.
7-0 CAP_POINTER	Capabilities Pointer. This register is used to point to a linked list of capabilities implemented by this Function. Since all PCI Express Functions are required to implement the PCI Express Capability structure, this register must point to a valid capability structure and either this structure is the PCI Express Capability structure, or a subsequent list item points to the PCI Express Capability structure. The bottom two bits are Reserved and must be set to 00b. Software must mask these bits off before using this register as a pointer in Configuration Space to the first entry of a linked list of new capabilities. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.

11.3.3.1.14 Expansion ROM Base Address Register. (TYPE1_EXP_ROM_BASE_REG)

11.3.3.1.14.1 Offset

Register	Offset
TYPE1_EXP_ROM_BASE_REG	38h

11.3.3.1.14.2 Function

Expansion ROM Base Address Register. This register is defined to handle the base address and size information for this expansion ROM. The mask for this ROM BAR exists (if implemented) as a shadow register at this address. The assertion of CS2 (that is, assert the dbi_cs2 input, or the CS2 address bit for the AXI bridge) is required to write to the second register at this address.

11.3.3.1.14.3 Diagram

11.3.3.1.14.4 Fields

Field	Function
31-11 EXP_ROM_BASE_ADDRESS	Expansion ROM Base Address. Upper 21 bits of the Expansion ROM base address. The number of bits (out of these 21) that a Function actually implements depends on how much address space the Function requires. The mask for this ROM BAR exists (if implemented) as a shadow register at this address. The assertion of CS2 (that is, assert the dbi_cs2 input, or the CS2 address bit for the AXI bridge) is required to write to the second register at this address. Note: The access attributes of this field are as follows: - Dbi: R/W
10-1 RSVDP_1	Reserved for future use.
0 ROM_BAR_ENABLE	Expansion ROM Enable. This bit controls whether or not the Function accepts accesses to its expansion ROM. When this bit is 0b, the Function's expansion ROM address space is disabled. When the bit is 1b, address decoding is enabled using the parameters in the other part of the Expansion ROM Base Address register. The Memory Space Enable bit in the Command register has precedence over the Expansion ROM Enable bit. A Function must claim accesses to its expansion ROM only if both the Memory Space Enable bit and the Expansion ROM Enable bit are set. Note: The access attributes of this field are as follows: - Dbi: R/W

11.3.3.1.15 Bridge Control, Interrupt Pin, and Interrupt Line Register. (BRIDGE_CTRL_INT_PIN_INT_LINE_REG)

11.3.3.1.15.1 Offset

Register	Offset
BRIDGE_CTRL_INT_PIN_INT_LINE_REG	3Ch

11.3.3.1.15.2 Diagram

11.3.3.1.15.3 Fields

Field	Function
31-23 BRIDGE_CTRL_RESERV	Reserved.
22 SBR	Secondary Bus Reset. Setting this bit triggers a hot reset on the corresponding PCI Express Port. Software must ensure a minimum reset duration (Trst) as defined in the PCI Local Bus Specification. Software and systems must honor first-access-following-reset timing requirements, unless the Readiness Notifications mechanism is used or if the Immediate Readiness bit in the relevant Function's Status Register register is set. Port configuration registers must not be changed, except as required to update Port status.
21 MSTR_ABORT_MODE	Master Abort Mode. This bit was originally described in the PCI-to-PCI Bridge Architecture Specification. Its functionality does not apply to PCI Express. The controller hardwires this bit to 0b. Note: The access attributes of this field are as follows: - Dbi: R/W
20 VGA_16B_DEC	VGA 16 bit decode. This bit only has meaning if VGA Enable bit is set. This bit enables system configuration software to select between 10-bit and 16-bit I/O address decoding for all VGA I/O register accesses that are forwarded from primary to secondary. The following actions are taken based on the value of the VGA_16B_DEC bit: - 0b: Execute 10-bit address decodes on VGA I/O accesses - 1b:

Table continues on the next page...

Field	Function
	Execute 16-bit address decodes on VGA I/O accesses For Functions that do not support VGA, the controller hardwires this bit to 0b. Note: The access attributes of this field are as follows: - Dbi: R
19 VGA_EN	VGA Enable. Modifies the response by the bridge to VGA compatible addresses. If the VGA Enable bit is set, the bridge will positively decode and forward the following accesses on the primary interface to the secondary interface (and, conversely, block the forwarding of these addresses from the secondary to primary interface): - Memory accesses in the range 000A 0000h to 000B FFFFh - I/O addresses in the first 64 KB of the I/O address space (Address[31:16] are 0000h) where Address[9:0] are in the ranges 3B0h to 3BBh and 3C0h to 3DFh (inclusive of ISA address aliases determined by the setting of VGA 16-bit Decode) If the VGA Enable bit is set, forwarding of these accesses is independent of the I/O address range and memory address ranges defined by the I/O Base and Limit registers, the Memory Base and Limit registers, and the Prefetchable Memory Base and Limit registers of the bridge. (Forwarding of these accesses is also independent of the setting of the ISA Enable bit (in the Bridge Control register) when the VGA Enable bit is set. Forwarding of these accesses is qualified by the I/O Space Enable and Memory Space Enable bits in the Command register.) The following actions are taken based on the value of the VGA_EN bit: - 0b: Do not forward VGA compatible memory and I/O addresses from the primary to the secondary interface (addresses defined above) unless they are enabled for forwarding by the defined I/O and memory address ranges - 1b: Forward VGA compatible memory and I/O addresses (addresses defined above) from the primary interface to the secondary interface (if the I/O Space Enable and Memory Space Enable bits are set) independent of the I/O and memory address ranges and independent of the ISA Enable bit For Functions that do not support VGA, the controller hardwires this bit to 0b. Note: The access attributes of this field are as follows: - Dbi: R
18 ISA_EN	ISA Enable. Modifies the response by the bridge to ISA I/O addresses. This applies only to I/O addresses that are enabled by the I/O Base and I/O Limit registers and are in the first 64 KB of I/O address space (0000 0000h to 0000 FFFFh). If this bit is set, the bridge will block any forwarding from primary to secondary of I/O transactions addressing the last 768 bytes in each 1-KB block. In the opposite direction (secondary to primary), I/O transactions will be forwarded if they address the last 768 bytes in each 1-KB block. The following actions are taken based on the value of the ISA_EN bit: - 0b: Forward downstream all I/O addresses in the address range defined by the I/O Base and I/O Limit registers - 1b: Forward upstream ISA I/O addresses in the address range defined by the I/O Base and I/O Limit registers that are in the first 64 KB of PCI I/O address space (top 768 bytes of each 1-KB block).
17 SERR_EN	SERR# Enable. This bit controls forwarding of ERR_COR, ERR_NONFATAL and ERR_FATAL from secondary to primary.
16 PERE	Parity Error Response Enable. This bit controls the logging of poisoned TLPs in the Master Data Parity Error bit in the Secondary Status register.
15-8 INT_PIN	Interrupt PIN. The Interrupt Pin register register that identifies the legacy interrupt Message(s) the Function uses. Valid values are: - 01h, 02h, 03h, and 04h: map to legacy interrupt Messages for INTA, INTB, INTC, and INTD respectively. - 00h: indicates that the Function uses no legacy interrupt Message(s). - 05h through FFh: Reserved. PCI Express defines one legacy interrupt Message for a single Function device and up to four legacy interrupt Messages for a multi-Function device. For a single Function device, only INTA may be used. Any Function on a multi-Function device can use any of the INTx Messages. If a device implements a single legacy interrupt Message, it must be INTA; if it implements two legacy interrupt Messages, they must be INTA and INTB; and so forth. For a multi-Function device, all Functions may use the same INTx Message or each may have its own (up to a maximum of four Functions) or any combination thereof. A single Function can never generate an interrupt request on more than one INTx Message. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
7-0 INT_LINE	Interrupt Line. The Interrupt Line register communicates interrupt line routing information. The register must be implemented by any Function that uses an interrupt pin. Values in this register are programmed by system software and are system architecture specific. The Function itself does not use this value; rather the value in this register is used by device drivers and operating systems.

11.3.3.1.16 Power Management Capabilities Register. (CAP_ID_NXT_PTR_REG)

11.3.3.1.16.1 Offset

Register	Offset
CAP_ID_NXT_PTR_REG	40h

11.3.3.1.16.2 Function

Power Management Capabilities Register. For a description of this standard PCIe register, see the PCI Express Specification.

11.3.3.1.16.3 Diagram

11.3.3.1.16.4 Fields

Field	Function
31-27 PME_SUPPORT	Power Management Event Support. For a description of this standard PCIe register field, see the PCI Express Specification. The read value from this field is the write value && (sys_aux_pwr_det, 1'b1, D2_SUPPORT, D1_SUPPORT, 1'b1), where D1_SUPPORT and D2_SUPPORT are fields in this register. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
26 D2_SUPPORT	D2 State Support. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
25 D1_SUPPORT	D1 State Support. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.

Table continues on the next page...

Field	Function
24-22 AUX_CURR	Auxiliary Current Requirements. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
21 DSI	Device Specific Initialization Bit. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
20 —	Reserved.
19 PME_CLK	PCI Clock Requirement. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
18-16 PM_SPEC_VER	Power Management Spec Version. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
15-8 PM_NEXT_POINTER	Next Capability Pointer. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
7-0 PM_CAP_ID	Power Management Capability ID. For a description of this standard PCIe register field, see the PCI Express Specification.

Field	Function
31 RSVDP_31	Reserved for future use.
30 RSVD	Reserved. For a description of this standard PCIe register field, see the PCI Express Specification.
29-25 PCIE_INT_MSG_NUM	PCIe Interrupt Message Number. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
24 PCIE_SLOT_IMP	PCIe Slot Implemented Valid. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R
23-20 PCIE_DEV_PORT_TYPE	PCIe Device/PortType. For a description of this standard PCIe register field, see the PCI Express Specification.
19-16 PCIE_CAP_REG	PCIe Capability Version Number. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
15-8 PCIE_CAP_NEXT_PTR	PCIe Next Capability Pointer. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
7-0 PCIE_CAP_ID	PCIe Capability ID. For a description of this standard PCIe register field, see the PCI Express Specification.

11.3.3.1.25 Device Capabilities Register. (DEVICE_CAPABILITIES_REG)

11.3.3.1.25.1 Offset

Register	Offset
DEVICE_CAPABILITIES_REG	74h

11.3.3.1.25.2 Function

Device Capabilities Register. For a description of this standard PCIe register, see the PCI Express Specification.

11.3.3.1.25.3 Diagram

11.3.3.1.25.4 Fields

Field	Function
31-16	Reserved for future use.

Table continues on the next page...

Field	Function
RSVDP_16	
15 PCIE_CAP_ROLE_BASED_ERROR_REPORT	Role-based Error Reporting Implemented. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
14-6 RSVDP_6	Reserved for future use.
5 PCIE_CAP_EXTENDED_TAG_SUPPORT	Extended Tag Field Supported. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
4-3 PCIE_CAP_PHANTOM_FUNCTION_SUPPORT	Phantom Functions Supported. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
2-0 PCIE_CAP_MAX_PAYLOAD_SIZE	Max Payload Size Supported. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.

11.3.3.1.26 Device Control and Status Register. (DEVICE_CONTROL_DEVICE_STATUS)

11.3.3.1.26.1 Offset

Register	Offset
DEVICE_CONTROL_DEVICE_STATUS	78h

11.3.3.1.26.2 Function

Device Control and Status Register. For a description of this standard PCIe register, see the PCI Express Specification.

31-22 RSVDP_22	Reserved for future use.

Table continues on the next page...

Field	Function
21 PCIE_CAP_TRANSPENDING	Transactions Pending Status. For a description of this standard PCIe register field, see the PCI Express Specification.
20 PCIE_CAP_AUX_POWER_DETECTED	Aux Power Detected Status. For a description of this standard PCIe register field, see the PCI Express Specification. This bit is derived by sampling the sys_aux_pwr_det input.
19 PCIE_CAP_UNSUPPORTED_REQ_DETECTED	Unsupported Request Detected Status. For a description of this standard PCIe register field, see the PCI Express Specification.
18 PCIE_CAP_FATAL_ERR_DETECTED	Fatal Error Detected Status. For a description of this standard PCIe register field, see the PCI Express Specification.
17 PCIE_CAP_NON_FATAL_ERR_DETECTED	Non-Fatal Error Detected Status. For a description of this standard PCIe register field, see the PCI Express Specification.
16 PCIE_CAP_CORRECTABLE_ERR_DETECTED	Correctable Error Detected Status. For a description of this standard PCIe register field, see the PCI Express Specification.
15 PCIE_CAP_INITIATE_FLR	Initiate Function Level Reset (for endpoints). For a description of this standard PCIe register field, see the PCI Express Specification.
14-12 PCIE_CAP_MAX_READ_REQ_SIZE	Max Read Request Size. For a description of this standard PCIe register field, see the PCI Express Specification.
11 PCIE_CAP_ENABLE_NO_SNOOP	Enable No Snoop. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: R
10 PCIE_CAP_AUX_POWER_PM_ENABLE	Aux Power PM Enable. For a description of this standard PCIe register field, see the PCI Express Specification. This bit is derived by sampling the sys_aux_pwr_det input. Note: This register field is sticky.
9 PCIE_CAP_PHANTOM_FUNC_ENABLE	Phantom Functions Enable. For a description of this standard PCIe register field, see the PCI Express Specification. The write value is gated with the PCIE_CAP_PHANTOM_FUNC_SUPPORT field of DEVICE_CAPABILITIES_REG. Note: The access attributes of this field are as follows: - Dbi: DEVICE_CAPABILITIES_REG.PCIE_CAP_PHANTOM_FUNC_SUPPORT ? RW : RO
8 PCIE_CAP_EXTENDED_TAG_ENABLE	Extended Tag Field Enable. For a description of this standard PCIe register field, see the PCI Express Specification. The write value is gated with the PCIE_CAP_EXT_TAG_SUPP field of DEVICE_CAPABILITIES_REG. Note: The access attributes of this field are as follows: - Dbi: DEVICE_CAPABILITIES_REG.PCIE_CAP_EXT_TAG_SUPP ? RW : RO

Table continues on the next page...

PCI Express (PCIe)

Field	Function
7-5 PCIE_CAP_MAX_PAYLOAD_SIZE_CS	Max Payload Size. Max_Payload_Size . This field sets maximum TLP payload size for the Function. Permissible values that can be programmed are indicated by the Max_Payload_Size Supported field (PCIE_CAP_MAX_PAYLOAD_SIZE) in the Device Capabilities register (DEVICE_CAPABILITIES_REG).
4 PCIE_CAP_ENABLE_REL_ORDER	Enable Relaxed Ordering. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: R/W
3 PCIE_CAP_UNSUPPORTED_REQUEST_REPORTING_ENABLE	Unsupported Request Reporting Enable. For a description of this standard PCIe register field, see the PCI Express Specification.
2 PCIE_CAP_FATAL_ERROR_REPORTING_ENABLE	Fatal Error Reporting Enable. For a description of this standard PCIe register field, see the PCI Express Specification.
1 PCIE_CAP_NON_FATAL_ERROR_REPORTING_ENABLE	Non-fatal Error Reporting Enable. For a description of this standard PCIe register field, see the PCI Express Specification.
0 PCIE_CAP_CORRECTABLE_ERROR_REPORTING_ENABLE	Correctable Error Reporting Enable. For a description of this standard PCIe register field, see the PCI Express Specification.

11.3.3.1.27 Link Capabilities Register. (LINK_CAPABILITIES_REG)

11.3.3.1.27.1 Offset

Register	Offset
LINK_CAPABILITIES_REGISTER	7Ch

11.3.3.1.27.2 Function

Link Capabilities Register. For a description of this standard PCIe register, see the PCI Express Specification.

11.3.3.1.27.3 Diagram

11.3.3.1.27.4 Fields

Field	Function
31-24 PCIE_CAP_PORT_NUM	Port Number. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R

Table continues on the next page...

PCI Express (PCIe)

Field	Function
23 RSVDP_23	Reserved for future use.
22 PCIE_CAP_AS PM_OPT_COM PLIANCE	ASPM Optionality Compliance. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R
21 PCIE_CAP_LIN K_BW_NOT_CA P	Link Bandwidth Notification Capable. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
20 PCIE_CAP_DLL _ACTIVE_REP_ CAP	Data Link Layer Link Active Reporting Capable. For a description of this standard PCIe register field, see the PCI Express Specification.
19 PCIE_CAP_SU RPRISE_DOWN _ERR_REP_CA P	Surprise Down Error Reporting Capable. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
18 PCIE_CAP_CL OCK_POWER_ MAN	Clock Power Management. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
17-15 PCIE_CAP_L1_ EXIT_LATENCY	L1 Exit Latency. For a description of this standard PCIe register field, see the PCI Express Specification. There are two each of these register fields, this one and a shadow one at the same address. The Common Clock bit (PCIE_CAP_COMMON_CLK_CONFIG) of the Link Control Register (LINK_CONTROL_LINK_STATUS_REG) determines which one is used by the controller and which one is accessed by a read request. Common Clock operation is enabled in the controller when you set the Common Clock bit (PCIE_CAP_COMMON_CLK_CONFIG) of the Link Control Register (LINK_CONTROL_LINK_STATUS_REG). The assertion of CS2 (that is, assert the dbi_cs2 input, or the CS2 address bit for the AXI bridge) is required to write to the shadow field at this location. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
14-12 PCIE_CAP_L0S _EXIT_LATENC Y	L0s Exit Latency. For a description of this standard PCIe register field, see the PCI Express Specification. There are two each of these register fields, this one and a shadow one at the same address. The Common Clock bit (PCIE_CAP_COMMON_CLK_CONFIG) of the Link Control Register (LINK_CONTROL_LINK_STATUS_REG) determines which one is used by the controller and which one is accessed by a read request. Common Clock operation is enabled in the controller when you set the Common Clock bit (PCIE_CAP_COMMON_CLK_CONFIG) of the Link Control Register (LINK_CONTROL_LINK_STATUS_REG). The assertion of CS2 (that is, assert the dbi_cs2 input, or the CS2 address bit for the AXI bridge) is required to write to the shadow field at this location. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
11-10 PCIE_CAP_AC TIVE_STATE_LI NK_PM_SUPP ORT	Level of ASPM (Active State Power Management) Support. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
9-4	Maximum Link Width. For a description of this standard PCIe register field, see the PCI Express Specification. In M-PCIe mode, the reset and dynamic values of this field are calculated by the controller.

Table continues on the next page...

Field	Function
PCIE_CAP_MAX_LINK_WIDTH	Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
3-0 PCIE_CAP_MAX_LINK_SPEED	Maximum Link Speed. For a description of this standard PCIe register field, see the PCI Express Specification. In M-PCIe mode, the reset and dynamic values of this field are calculated by the controller. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.

11.3.3.1.28.4 Fields

Field	Function
31	Link Autonomous Bandwidth Status. For a description of this standard PCIe register field, see the PCI Express Specification. The write value is gated with the PCIE_CAP_LINK_BW_NOT_CAP field in LINK_CAPABILITIES_REG.

Table continues on the next page...

Field	Function
PCIE_CAP_LINK_AUTO_BW_STATUS	
30 PCIE_CAP_LINK_BW_MAN_STATUS	Link Bandwidth Management Status. For a description of this standard PCIe register field, see the PCI Express Specification. The write value is gated with the PCIE_CAP_LINK_BW_NOT_CAP field in LINK_CAPABILITIES_REG.
29 PCIE_CAP_DLL_ACTIVE	Data Link Layer Active. For a description of this standard PCIe register field, see the PCI Express Specification.
28 PCIE_CAP_SLOT_CLK_CONFIG	Slot Clock Configuration. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R
27 PCIE_CAP_LINK_TRAINING	LTSSM is in Configuration or Recovery State. For a description of this standard PCIe register field, see the PCI Express Specification.
26 RSVDP_26	Reserved for future use.
25-20 PCIE_CAP_NEGOTIATED_LINK_WIDTH	Negotiated Link Width. For a description of this standard PCIe register field, see the PCI Express Specification.
19-16 PCIE_CAP_LINK_SPEED	Current Link Speed. For a description of this standard PCIe register field, see the PCI Express Specification.
15-14 PCIE_CAP_DRS_SIGNALING_CONTROL	DRS Signaling Control. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: LINK_CAPABILITIES2_REG.DRS_SUPPORTED ? RW : RO
13-12 RSVDP_12	Reserved for future use.
11 PCIE_CAP_LINK_AUTO_BW_INTERRUPT_ENABLE	Link Autonomous Bandwidth Management Interrupt Enable. For a description of this standard PCIe register field, see the PCI Express Specification. The write value is gated with the PCIE_CAP_LINK_BW_NOT_CAP field in LINK_CAPABILITIES_REG. Note: The access attributes of this field are as follows: - Dbi: LINK_CAPABILITIES_REG.PCIE_CAP_LINK_BW_NOT_CAP ? RW : RO
10 PCIE_CAP_LINK_BW_MAN_INTERRUPT_ENABLE	Link Bandwidth Management Interrupt Enable. For a description of this standard PCIe register field, see the PCI Express Specification. The write value is gated with the PCIE_CAP_LINK_BW_NOT_CAP field in LINK_CAPABILITIES_REG. Note: The access attributes of this field are as follows: - Dbi: LINK_CAPABILITIES_REG.PCIE_CAP_LINK_BW_NOT_CAP ? RW : RO
9 PCIE_CAP_HW_AUTO_WIDTH_DISABLE	Hardware Autonomous Width Disable. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: R/W
8	Enable Clock Power Management. For a description of this standard PCIe register field, see the PCI Express Specification. The write value is gated with the PCIE_CAP_CLOCK_POWER_MAN field in

Table continues on the next page...

PCI Express (PCIe)

Field	Function
PCIE_CAP_EN_CLK_POWER_MAN	LINK_CAPABILITIES_REG. Note: The access attributes of this field are as follows: - Dbi: LINK_CAPABILITIES_REG.PCIE_CAP_CLOCK_POWER_MAN ? RWS : ROS Note: This register field is sticky.
7 PCIE_CAP_EXTENDED_SYNC_H	Extended Synch. For a description of this standard PCIe register field, see the PCI Express Specification.
6 PCIE_CAP_COMMON_CLK_CONFIG	Common Clock Configuration. For a description of this standard PCIe register field, see the PCI Express Specification.
5 PCIE_CAP_RETRAIN_LINK	Initiate Link Retrain. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: see description
4 PCIE_CAP_LINK_DISABLE	Initiate Link Disable. For a description of this standard PCIe register field, see the PCI Express Specification. In a DSP that supports crosslink, the controller gates the write value with the CROSS_LINK_EN field in PORT_LINK_CTRL_OFF.
3 PCIE_CAP_RCB	Read Completion Boundary (RCB). Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R
2 RSVDP_2	Reserved for future use.
1-0 PCIE_CAP_ACTIVE_STATE_LINK_PM_CONTROL	Active State Power Management (ASPM) Control. Software must not enable L0s in either direction on a given Link unless components on both sides of the Link each support L0s; otherwise, the result is undefined. For a description of this standard PCIe register field, see the PCI Express Specification.

23-20 —	Reserved.
19-18 PCIE_CAP_OB FF_SUPPORT	(OBFF) Optimized Buffer Flush/fill Supported. For a description of this standard PCIe register field, see the PCI Express Specification.
17 PCIE_CAP2_10 _BIT_TAG_REQ _SUPPORT	10-Bit Tag Requester Supported. For a description of this standard PCIe register field, see the PCI Express Base Specification 4.0.
16 PCIE_CAP2_10 _BIT_TAG_CO MP_SUPPORT	10-Bit Tag Completer Supported. For a description of this standard PCIe register field, see the PCI Express Base Specification 4.0.
15-14 —	Reserved.
13 PCIE_CAP_TP H_CMPLT_SUP PORT_1	TPH Completer Supported Bit 1. For a description of this standard PCIe register field, see the PCI Express Specification.
12 PCIE_CAP_TP H_CMPLT_SUP PORT_0	TPH Completer Supported Bit 0. For a description of this standard PCIe register field, see the PCI Express Specification.
11 PCIE_CAP_LTR _SUPP	LTR Mechanism Supported. For a description of this standard PCIe register field, see the PCI Express Specification.
10 PCIE_CAP_NO _RO_EN_PR2P R_PAR	No Relaxed Ordering Enabled PR-PR Passing. For a description of this standard PCIe register field, see the PCI Express Specification.
9 PCIE_CAP_128 _CAS_CPL_SU PP	128 Bit CAS Completer Supported. For a description of this standard PCIe register field, see the PCI Express Specification.
8 PCIE_CAP_64_ ATOMIC_CPL_ SUPP	64 Bit AtomicOp Completer Supported. For a description of this standard PCIe register field, see the PCI Express Specification.
7 PCIE_CAP_32_ ATOMIC_CPL_ SUPP	32 Bit AtomicOp Completer Supported. For a description of this standard PCIe register field, see the PCI Express Specification.

Table continues on the next page...

Field	Function
6 PCIE_CAP_ATOMIC_ROUTING_SUPPORT	Atomic Operation Routing Supported. For a description of this standard PCIe register field, see the PCI Express Specification.
5 PCIE_CAP_ARI_FORWARD_SUPPORT	ARI Forwarding Supported. For a description of this standard PCIe register field, see the PCI Express Specification.
4 PCIE_CAP_CPL_TIMEOUT_DISABLE_SUPPORT	Completion Timeout Disable Supported. For a description of this standard PCIe register field, see the PCI Express Specification.
3-0 PCIE_CAP_CPL_TIMEOUT_RANGE	Completion Timeout Ranges Supported. For a description of this standard PCIe register field, see the PCI Express Specification.

11.3.3.1.34 Device Control 2 and Status 2 Register. (DEVICE_CONTROL2_DEVICE_STATUS2_REG)

11.3.3.1.34.1 Offset

Register	Offset
DEVICE_CONTROL2_DEVICE_STATUS2_REG	98h

11.3.3.1.34.2 Function

Device Control 2 and Status 2 Register. For a description of this standard PCIe register, see the PCI Express Specification.

11.3.3.1.34.3 Diagram

11.3.3.1.34.4 Fields

Field	Function
31-6 —	Reserved.
5 PCIE_CAP_ARI_FORWARD_SUPPORT_CS	ARI Forwarding Enable. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: R/W
4 PCIE_CAP_CPL_TIMEOUT_DISABLE	Completion Timeout Disable. For a description of this standard PCIe register field, see the PCI Express Specification.
3-0 PCIE_CAP_CPL_TIMEOUT_VALUE	Completion Timeout Value. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: R/W

11.3.3.1.35 Link Capabilities 2 Register. (LINK_CAPABILITIES2_REG)

11.3.3.1.35.1 Offset

Register	Offset
LINK_CAPABILITIES2_REG	9Ch

11.3.3.1.35.2 Function

Link Capabilities 2 Register. For a description of this standard PCIe register, see the PCI Express Specification.

11.3.3.1.35.3 Diagram

11.3.3.1.35.4 Fields

Field	Function
31 —	Reserved.
30-25 RSVDP_25	Reserved for future use.
24-23 —	Reserved.
22-9 RSVDP_9	Reserved for future use.
8 PCIE_CAP_CR OSS_LINK_SU PPORT	Cross Link Supported. For a description of this standard PCIe register field, see the PCI Express Specification.
7-1 PCIE_CAP_SU PPORT_LINK_S PEED_VECTOR	Supported Link Speeds Vector. For a description of this standard PCIe register field, see the PCI Express Specification. This field has a default of (PCIE_CAP_MAX_LINK_SPEED == 0100) ? 0001111 : (PCIE_CAP_MAX_LINK_SPEED == 0011) ? 0000111 : (PCIE_CAP_MAX_LINK_SPEED == 0010) ? 0000011 : 0000001 where PCIE_CAP_MAX_LINK_SPEED is a field in the LINK_CAPABILITIES_REG register.
0 RSVDP_0	Reserved for future use.

11.3.3.1.36 Link Control 2 and Status 2 Register. (LINK_CONTROL2_LINK_STATUS2_REG)**11.3.3.1.36.1 Offset**

Register	Offset
LINK_CONTROL2_LINK_STATUS2_REG	A0h

11.3.3.1.36.2 Function

Link Control 2 and Status 2 Register. For a description of this standard PCIe register, see the PCI Express Specification.

11.3.3.1.36.3 Diagram

11.3.3.1.36.4 Fields

Field	Function
31 DRS_MESSAGE_RECEIVED	DRS Message Received. For a description of this standard PCIe register field, see the PCI Express Base Specification 4.0. Note: The access attributes of this field are as follows: - Dbi: RW1C
30-28	Downstream Component Presence. For a description of this standard PCIe register field, see the PCI Express Base Specification 4.0.

Table continues on the next page...

PCI Express (PCIe)

Field	Function
DOWNSTREAM_COMPO_PRESENCE	
27-26 RSVDP_26	Reserved for future use.
25-17 —	Reserved.
16 PCIE_CAP_CURR_DEEMPHASIS	Current De-emphasis Level. For a description of this standard PCIe register field, see the PCI Express Specification. In M-PCIe mode this register is always 0x0. In C-PCIe mode, its contents are derived by sampling the PIPE
15-12 PCIE_CAP_COMPLIANCE_PRESSET	Sets Compliance Preset/De-emphasis for 5 GT/s and 8 GT/s. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: R/W (sticky) Note: This register field is sticky.
11 PCIE_CAP_COMPLIANCE_SOS	Sets Compliance Skip Ordered Sets transmission. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: R/W (sticky) Note: This register field is sticky.
10 PCIE_CAP_ENTER_MODIFIED_COMPLIANCE	Enter Modified Compliance. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: R/W (sticky) Note: This register field is sticky.
9-7 PCIE_CAP_TX_MARGIN	Controls Transmit Margin for Debug or Compliance. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
6 PCIE_CAP_SELECT_DEEMPHASIS	Controls Selectable De-emphasis for 5 GT/s. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.
5 PCIE_CAP_HW_AUTO_SPEED_DISABLE	Hardware Autonomous Speed Disable. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: R/W (sticky) Note: This register field is sticky.
4 PCIE_CAP_ENTER_COMPLIANCE	Enter Compliance Mode. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
3-0 PCIE_CAP_TARGET_LINK_SPEED	Target Link Speed. For a description of this standard PCIe register field, see the PCI Express Specification. In M-PCIe mode, the contents of this field are derived from other registers. Note: This register field is sticky.

11.3.3.1.37 Advanced Error Reporting Extended Capability Header. (AER_EXT_CAP_HDR_OFF)

11.3.3.1.37.1 Offset

Register	Offset
AER_EXT_CAP_HDR_OFF	100h

11.3.3.1.37.2 Function

Advanced Error Reporting Extended Capability Header. For a description of this standard PCIe register, see the PCI Express Specification.

11.3.3.1.37.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

11.3.3.1.37.4 Fields

Field	Function
31-20 NEXT_OFFSET	Next Capability Offset. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.
19-16 CAP_VERSION	Capability Version. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.
15-0 CAP_ID	AER Extended Capability ID. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.

11.3.3.1.38 Uncorrectable Error Status Register. (UNCORR_ERR_STATU S_OFF)

11.3.3.1.38.1 Offset

Register	Offset
UNCORR_ERR_STATU S_OFF	104h

11.3.3.1.38.2 Function

Uncorrectable Error Status Register. For a description of this standard PCIe register, see the PCI Express Specification.

11.3.3.1.38.3 Diagram

11.3.3.1.38.4 Fields

Field	Function
31-26 RSVDP_26	Reserved for future use.
25 TLP_PRFX_BLOCKED_ERR_STATU	TLP Prefix Blocked Error Status. For a description of this standard PCIe register field, see the PCI Express Specification. Note: Not supported.
24	Reserved.

Table continues on the next page...

PCI Express (PCIe)

Field	Function
—	
23 RSVDP_23	Reserved for future use.
22 INTERNAL_ER R_STATUS	Uncorrectable Internal Error Status. For a description of this standard PCIe register field, see the PCI Express Specification. The controller sets this bit when your application asserts app_err_bus[9]. It does not set this bit when it detects internal uncorrectable internal errors such as parity and ECC failures. You should use the outputs from these errors to drive the app_err_bus[9] input. For more details, see the "Data Integrity (Wire, Datapath, and RAM Protection)" section in the Databook.
21 —	Reserved.
20 UNSUPPORTED_REQ_ERR_STATUS	Unsupported Request Error Status. For a description of this standard PCIe register field, see the PCI Express Specification.
19 ECRC_ERR_STATUS	ECRC Error Status. For a description of this standard PCIe register field, see the PCI Express Specification.
18 MALF_TLP_ERR_STATUS	Malformed TLP Status. For a description of this standard PCIe register field, see the PCI Express Specification.
17 REC_OVERFLOW_ERR_STATUS	Receiver Overflow Status. For a description of this standard PCIe register field, see the PCI Express Specification.
16 UNEXP_CMPLT_ERR_STATUS	Unexpected Completion Status. For a description of this standard PCIe register field, see the PCI Express Specification.
15 CMPLT_ABORT_ERR_STATUS	Completer Abort Status. For a description of this standard PCIe register field, see the PCI Express Specification.
14 CMPLT_TIMEOUT_ERR_STATUS	Completion Timeout Status. For a description of this standard PCIe register field, see the PCI Express Specification.
13 FC_PROTOCOL_ERR_STATUS	Flow Control Protocol Error Status. For a description of this standard PCIe register field, see the PCI Express Specification.
12 POIS_TLP_ERR_STATUS	Poisoned TLP Status. For a description of this standard PCIe register field, see the PCI Express Specification.
11-6 RSVDP_6	Reserved for future use.
5	Surprise Down Error Status (Optional). For a description of this standard PCIe register field, see the PCI Express Specification.

Table continues on the next page...

Field	Function
SURPRISE_DOWN_ERR_STATUS	
4 DL_PROTOCOL_ERR_STATUS	Data Link Protocol Error Status. For a description of this standard PCIe register field, see the PCI Express Specification.
3-0 RSVDP_0	Reserved for future use.

11.3.3.1.39 Uncorrectable Error Mask Register. (UNCORR_ERR_MASK_OFF)

11.3.3.1.39.1 Offset

Register	Offset
UNCORR_ERR_MASK_OFF	108h

11.3.3.1.39.2 Function

Uncorrectable Error Mask Register. For a description of this standard PCIe register, see the PCI Express Specification.

11.3.3.1.39.3 Diagram

11.3.3.1.39.4 Fields

Field	Function
31-26 RSVDP_26	Reserved for future use.
25 TLP_PRFX_BLOCKED_ERR_MASK	TLP Prefix Blocked Error Mask. For a description of this standard PCIe register field, see the PCI Express Specification. Note: Not supported. Note: The access attributes of this field are as follows: - Dbi: R/W (sticky) Note: This register field is sticky.

Table continues on the next page...

Field	Function
24 ATOMIC_EGRESS_BLOCKED_ERR_MASK	AtomicOp Egress Block Mask (Optional). For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: R/W (sticky) Note: This register field is sticky.
23 RSVDP_23	Reserved for future use.
22 INTERNAL_ERROR_MASK	Uncorrectable Internal Error Mask (Optional). For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
21 —	Reserved.
20 UNSUPPORTED_REQUEST_ERROR_MASK	Unsupported Request Error Mask. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
19 ECRC_ERROR_MASK	ECRC Error Mask (Optional). For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: R/W (sticky) Note: This register field is sticky.
18 MALFORMED_TLP_ERROR_MASK	Malformed TLP Mask. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
17 RECEIVER_OVERFLOW_ERROR_MASK	Receiver Overflow Mask (Optional). For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
16 UNEXPECTED_COMPLETION_ERROR_MASK	Unexpected Completion Mask. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
15 COMPLETER_ABORT_ERROR_MASK	Completer Abort Error Mask (Optional). For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
14 COMPLETION_TIMEOUT_ERROR_MASK	Completion Timeout Error Mask. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
13 FLOW_CONTROL_PROTOCOL_ERROR_MASK	Flow Control Protocol Error Mask. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
12 POISONED_TLP_ERROR_MASK	Poisoned TLP Error Mask. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
11-6 RSVDP_6	Reserved for future use.
5	Surprise Down Error Mask. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi:

25 TLP_PRFX_BLK OCKED_ERR_S EVERITY	TLP Prefix Blocked Error Severity (Optional). For a description of this standard PCIe register field, see the PCI Express Specification. Note: Not supported. Note: The access attributes of this field are as follows: - Dbi: R/W (sticky) Note: This register field is sticky.

Table continues on the next page...

PCI Express (PCIe)

Field	Function
24 ATOMIC_EGRESS_BLOCKED_ERROR_SEVERITY	AtomicOp Egress Blocked Severity (Optional). For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: R/W (sticky) Note: This register field is sticky.
23 RSVDP_23	Reserved for future use.
22 INTERNAL_ERROR_SEVERITY	Uncorrectable Internal Error Severity (Optional). For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
21 —	Reserved.
20 UNSUPPORTED_REQUEST_ERROR_SEVERITY	Unsupported Request Error Severity. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
19 ECRC_ERROR_SEVERITY	ECRC Error Severity (Optional). For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: R/W (sticky) Note: This register field is sticky.
18 MALFORMED_TLP_ERROR_SEVERITY	Malformed TLP Severity. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
17 RECEIVER_OVERFLOW_ERROR_SEVERITY	Receiver Overflow Error Severity (Optional). For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
16 UNEXPECTED_COMPLETION_ERROR_SEVERITY	Unexpected Completion Error Severity. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
15 COMPLETER_ABORT_ERROR_SEVERITY	Completer Abort Error Severity (Optional). For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
14 COMPLETION_TIMEOUT_ERROR_SEVERITY	Completion Timeout Error Severity. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
13 FLOW_CONTROL_PROTOCOL_ERROR_SEVERITY	Flow Control Protocol Error Severity (Optional). For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
12 POISONED_TLP_ERROR_SEVERITY	Poisoned TLP Severity. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.

Table continues on the next page...

Field	Function
11-6 RSVDP_6	Reserved for future use.
5 SURPRISE_DOWN_ERR_SEVERITY	Surprise Down Error Severity (Optional). For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: LINK_CAPABILITIES_REG.PCIE_CAP_SURPRISE_DOWN_ERR_REP_CAP ? RW : RO Note: This register field is sticky.
4 DL_PROTOCOL_ERR_SEVERITY	Data Link Protocol Error Severity. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
3-0 RSVDP_0	Reserved for future use.

11.3.3.1.41 Correctable Error Status Register. (CORR_ERR_STATUS_OFF)

11.3.3.1.41.1 Offset

Register	Offset
CORR_ERR_STATUS_OFF	110h

11.3.3.1.41.2 Function

Correctable Error Status Register. For a description of this standard PCIe register, see the PCI Express Specification.

11.3.3.1.41.3 Diagram

11.3.3.1.41.4 Fields

Field	Function
31-16 RSVDP_16	Reserved for future use.
15 HEADER_LOG_OVERFLOW_STATUS	Header Log Overflow Error Status (Optional). For a description of this standard PCIe register field, see the PCI Express Specification.
14 CORRECTED_INT_ERR_STATUS	Corrected Internal Error Status (Optional). For a description of this standard PCIe register field, see the PCI Express Specification.
13 ADVISORY_NON_FATAL_ERR_STATUS	Advisory Non-Fatal Error Status. For a description of this standard PCIe register field, see the PCI Express Specification.
12	Replay Timer Timeout Status. For a description of this standard PCIe register field, see the PCI Express Specification.

Table continues on the next page...

Field	Function
RPL_TIMER_TIMEOUT_STATUSES	
11-9 RSVDP_9	Reserved for future use.
8 REPLAY_NO_ROLLOVER_STATUS	REPLAY_NUM Rollover Status. For a description of this standard PCIe register field, see the PCI Express Specification.
7 BAD_DLLP_STATUS	Bad DLLP Status. For a description of this standard PCIe register field, see the PCI Express Specification.
6 BAD_TLP_STATUS	Bad TLP Status. For a description of this standard PCIe register field, see the PCI Express Specification.
5-1 RSVDP_1	Reserved for future use.
0 RX_ERR_STATUS	Receiver Error Status (Optional). For a description of this standard PCIe register field, see the PCI Express Specification.

11.3.3.1.42 Correctable Error Mask Register. (CORR_ERR_MASK_OFF)

11.3.3.1.42.1 Offset

Register	Offset
CORR_ERR_MASK_OFF	114h

11.3.3.1.42.2 Function

Correctable Error Mask Register. For a description of this standard PCIe register, see the PCI Express Specification.

11.3.3.1.42.3 Diagram

11.3.3.1.42.4 Fields

Field	Function
31-16 RSVDP_16	Reserved for future use.
15 HEADER_LOG_OVERFLOW_MASK	Header Log Overflow Error Mask (Optional). For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
14 CORRECTED_INT_ERR_MASK	Corrected Internal Error Mask (Optional). For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
13 ADVISORY_NON_FATAL_ERR_MASK	Advisory Non-Fatal Error Mask. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
12 RPL_TIMER_TIMEOUT_MASK	Replay Timer Timeout Mask. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
11-9 RSVDP_9	Reserved for future use.

Table continues on the next page...

Field	Function
8 REPLAY_NO_ROLLOVER_MASK	REPLAY_NUM Rollover Mask. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
7 BAD_DLLP_MASK	Bad DLLP Mask. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
6 BAD_TLP_MASK	Bad TLP Mask. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
5-1 RSVDP_1	Reserved for future use.
0 RX_ERR_MASK	Receiver Error Mask (Optional). For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.

11.3.3.1.43 Advanced Error Capabilities and Control Register. (ADV_ERR_CAP_CTRL_OFF)

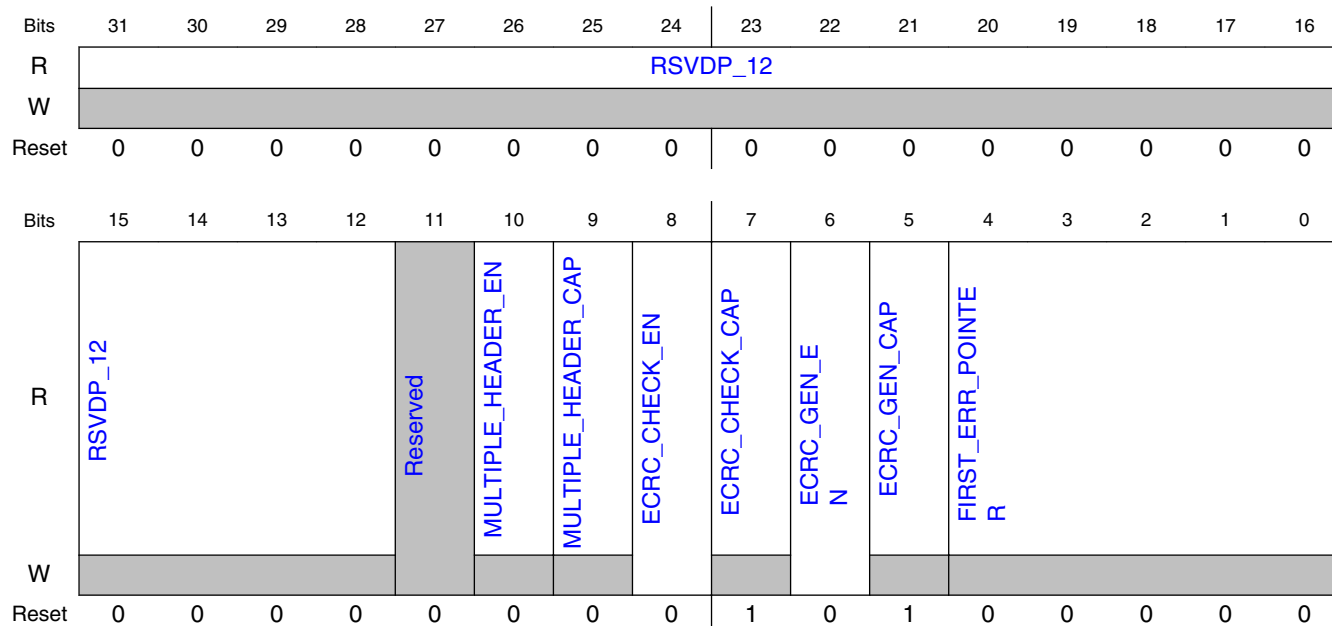

11.3.3.1.43.1 Offset

Register	Offset
ADV_ERR_CAP_CTRL_OFF	118h

11.3.3.1.43.2 Function

Advanced Error Capabilities and Control Register. For a description of this standard PCIe register, see the PCI Express Specification.

11.3.3.1.43.3 Diagram

11.3.3.1.43.4 Fields

Field	Function
31-12 RSVDP_12	Reserved for future use.
11 —	Reserved.
10 MULTIPLE_HEADER_EN	Multiple Header Recording Enable. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
9 MULTIPLE_HEADER_CAP	Multiple Header Recording Capable. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
8 ECRC_CHECK_EN	ECRC Check Enable. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
7 ECRC_CHECK_CAP	ECRC Check Capable. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
6 ECRC_GEN_EN	ECRC Generation Enable. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
5	ECRC Generation Capable. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.

Table continues on the next page...

Field	Function
ECRC_GEN_C AP	
4-0 FIRST_ERR_P OINTER	First Error Pointer. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.

11.3.3.1.44 Header Log Register 0. (HDR_LOG_0_OFF)

11.3.3.1.44.1 Offset

Register	Offset
HDR_LOG_0_OFF	11Ch

11.3.3.1.44.2 Function

Header Log Register 0. For a description of this standard PCIe register, see the PCI Express Specification.

11.3.3.1.47.4 Fields

Field	Function
31-24 FOURTH_DWORD_FOURTH_BYTE	Byte 3 of Header log register of Fourth 32 bit Data Word. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
23-16 FOURTH_DWORD_THIRD_BYTE	Byte 2 of Header log register of Fourth 32 bit Data Word. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
15-8 FOURTH_DWORD_SECOND_BYTE	Byte 1 of Header log register of Fourth 32 bit Data Word. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
7-0 FOURTH_DWORD_FIRST_BYTE	Byte 0 of Header log register of Fourth 32 bit Data Word. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.

11.3.3.1.48 Root Error Command Register. (ROOT_ERR_CMD_OFF)

11.3.3.1.48.1 Offset

Register	Offset
ROOT_ERR_CMD_OFF	12Ch

11.3.3.1.48.2 Function

Root Error Command Register. For a description of this standard PCIe register, see the PCI Express Specification.

11.3.3.1.48.3 Diagram

11.3.3.1.48.4 Fields

Field	Function
31-3 RSVDP_3	Reserved for future use.
2 FATAL_ERR_R EPORTING_EN	Fatal Error Reporting Enable. For a description of this standard PCIe register field, see the PCI Express Specification.
1 NON_FATAL_E RR_REPORTIN G_EN	Non-Fatal Error Reporting Enable. For a description of this standard PCIe register field, see the PCI Express Specification.
0 CORR_ERR_R EPORTING_EN	Correctable Error Reporting Enable. For a description of this standard PCIe register field, see the PCI Express Specification.

11.3.3.1.49 Root Error Status Register. (ROOT_ERR_STATUS_OFF)

11.3.3.1.49.1 Offset

Register	Offset
ROOT_ERR_STATUS_OFF	130h

11.3.3.1.49.2 Function

Root Error Status Register. For a description of this standard PCIe register, see the PCI Express Specification.

11.3.3.1.49.3 Diagram

11.3.3.1.49.4 Fields

Field	Function
31-27 ADV_ERR_INT_MSG_NUM	Advanced Error Interrupt Message Number. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.
26-7 RSVDP_7	Reserved for future use.
6 FATAL_ERR_MSG_RX	One or more Fatal Error Messages Received. For a description of this standard PCIe register field, see the PCI Express Specification.
5 NON_FATAL_ERR_MSG_RX	One or more Non-Fatal Error Messages Received. For a description of this standard PCIe register field, see the PCI Express Specification.
4 FIRST_UNCORR_FATAL	First Uncorrectable Error is Fatal. For a description of this standard PCIe register field, see the PCI Express Specification.
3 MUL_ERR_FATAL_NON_FATAL_RX	Multiple Fatal or Non-Fatal Errors Received. For a description of this standard PCIe register field, see the PCI Express Specification.
2 ERR_FATAL_NON_FATAL_RX	Fatal or Non-Fatal Error Received. For a description of this standard PCIe register field, see the PCI Express Specification.
1 MUL_ERR_CORR_RX	Multiple Correctable Errors Received. For a description of this standard PCIe register field, see the PCI Express Specification.
0 ERR_CORR_RX	Correctable Error Received. For a description of this standard PCIe register field, see the PCI Express Specification.

11.3.3.1.50 Error Source Identification Register. (ERR_SRC_ID_OFF)**11.3.3.1.50.1 Offset**

Register	Offset
ERR_SRC_ID_OFF	134h

11.3.3.1.50.2 Function

Error Source Identification Register. For a description of this standard PCIe register, see the PCI Express Specification.

7-3 T_POWER_ON_VALUE	T Power On Value. For a description of this standard PCIe register field, see the PCI Express Specification.
2 RSVDP_2	Reserved for future use.
1-0 T_POWER_ON_SCALE	T Power On Scale. For a description of this standard PCIe register field, see the PCI Express Specification.

11.3.3.1.59 Ack Latency Timer and Replay Timer Register. (ACK_LATENCY_TIMER_OFF)

11.3.3.1.59.1 Offset

Register	Offset
ACK_LATENCY_TIMER_OFF	700h

11.3.3.1.59.2 Diagram

11.3.3.1.59.3 Fields

Field	Function
31-16 REPLAY_TIME_LIMIT	Replay Timer Limit. The replay timer expires when it reaches this limit. The controller initiates a replay upon reception of a NAK or when the replay timer expires. For more details, see "Transmit Replay". You can modify the effective timer limit with the TIMER_MOD_REPLAY_TIMER field of the TIMER_CTRL_MAX_FUNC_NUM_OFF register. After reset, the controller updates the default according to the Negotiated Link Width, Max_Payload_Size, and speed. The value is determined from Tables 3-4,

Table continues on the next page...

PCI Express (PCIe)

Field	Function
	3-5, and 3-6 of the PCIe 3.0 specification. If there is a change in the payload size or link speed, the controller will override any value that you have written to this register field, and reset the field back to the specification-defined value. It will not change the value in the TIMER_MOD_REPLAY_TIMER field of the TIMER_CTRL_MAX_FUNC_NUM_OFF register.
15-0 ROUND_TRIP_LATENCY_TIMER_LIMIT	Ack Latency Timer Limit. The Ack latency timer expires when it reaches this limit. For more details, see "Ack Scheduling". You can modify the effective timer limit with the TIMER_MOD_ACK_NAK field of the TIMER_CTRL_MAX_FUNC_NUM_OFF register. After reset, the controller updates the default according to the Negotiated Link Width, Max_Payload_Size, and speed. The value is determined from Tables 3-7, 3-8, and 3-9 of the PCIe 3.0 specification. The limit must reflect the round trip latency from requester to completer. If there is a change in the payload size or link width, the controller will override any value that you have written to this register field, and reset the field back to the specification-defined value. It will not change the value in the TIMER_MOD_ACK_NAK field of the TIMER_CTRL_MAX_FUNC_NUM_OFF register.

11.3.3.1.60 Vendor Specific DLLP Register. (VENDOR_SPEC_DLLP_OFF)

11.3.3.1.60.1 Offset

Register	Offset
VENDOR_SPEC_DLLP_OFF	704h

11.3.3.1.60.2 Diagram

11.3.3.1.60.3 Fields

Field	Function
31-0 VENDOR_SPEC_DLLP	Vendor Specific DLLP Register. Used to send a specific PCI Express DLLP. Your application writes the 8-bit DLLP Type and 24-bits of Payload data into this register, then sets the field VENDOR_SPECIFIC_DLLP_REQ of PORT_LINK_CTRL_OFF to send the DLLP. - [7:0] = Type - [31:8] = Payload (24 bits) The dllp type is in bits [7:0] while the remainder is the vendor defined payload. Note: This register field is sticky.

11.3.3.1.61 Port Force Link Register. (PORT_FORCE_OFF)

11.3.3.1.61.1 Offset

Register	Offset
PORT_FORCE_OFF	708h

11.3.3.1.61.2 Diagram

11.3.3.1.61.3 Fields

Field	Function
31-24 RSVDP_24	Reserved for future use.
23 DO_DESKEW_FOR_SRIS	Use the transitions from TS2 to Logical Idle Symbol, SKP OS to Logical Idle Symbol, and FTS Sequence to SKP OS to do deskew for SRIS instead of using received SKP OS if DO_DESKEW_FOR_SRIS is set to 1. Note: This register field is sticky.
22 RSVDP_22	Reserved for future use.

Table continues on the next page...

PCI Express (PCIe)

Field	Function
21-16 LINK_STATE	Forced LTSSM State. The LTSSM state that the controller is forced to when you set the FORCE_EN bit (Force Link). LTSSM state encoding is defined by the lts_state variable in workspace/src/Layer1/smlh_ltssm.v. Note: This register field is sticky.
15 FORCE_EN	Force Link. The controller supports a testing and debug capability to allow your software to force the LTSSM state machine into a specific state, and to force the controller to transmit a specific Link Command. Asserting this bit triggers the following actions: - Forces the LTSSM to the state specified by the Forced LTSSM State field. - Forces the controller to transmit the command specified by the Forced Link Command field. This is a self-clearing register field. Reading from this register field always returns a "0".
14-12 RSVDP_12	Reserved for future use.
11-8 FORCED_LTSSM	Forced Link Command. The link command that the controller is forced to transmit when you set FORCE_EN bit (Force Link). Link command encoding is defined by the ltssm_cmd variable in workspace/src/Layer1/smlh_ltssm.v. Note: This register field is sticky.
7-0 LINK_NUM	Link Number. Not used for endpoint. Not used for M-PCIe. Note: This register field is sticky.

11.3.3.1.62 Ack Frequency and L0-L1 ASPM Control Register. (ACK_F_AS PM_CTRL_OFF)

11.3.3.1.62.1 Offset

Register	Offset
ACK_F_AS PM_CTRL_OFF	70Ch

11.3.3.1.62.2 Diagram

11.3.3.1.62.3 Fields

Field	Function
31 RSVDP_31	Reserved for future use.
30 ENTER_ASPM	ASPM L1 Entry Control. - 1: Core enters ASPM L1 after a period in which it has been idle. - 0: Core enters ASPM L1 only after idle period during which both receive and transmit are in L0s. Note: This register field is sticky.
29-27 L1_ENTRANCE_LATENCY	L1 Entrance Latency. Value range is: - 000: 1 us - 001: 2 us - 010: 4 us - 011: 8 us - 100: 16 us - 101: 32 us - 110 or 111: 64 us Note: Programming this timer with a value greater than 32us has no effect unless extended sync is used, or all of the credits are infinite. Note: This register field is sticky.
26-24 LOS_ENTRANCE_LATENCY	L0s Entrance Latency. Values correspond to: - 000: 1 us - 001: 2 us - 010: 3 us - 011: 4 us - 100: 5 us - 101: 6 us - 110 or 111: 7 us This field is applicable to STALL while in L0 for M-PCIe. Note: This register field is sticky.
23-16 COMMON_CLK_N_FTS	Common Clock N_FTS. This is the N_FTS when common clock is used. The number of Fast Training Sequence ordered sets to be transmitted when transitioning from L0s to L0. The maximum number of FTS ordered-sets that a component can request is 255. The controller does not support a value of zero; a value of zero can cause the LTSSM to go into the recovery state when exiting from L0s. This field is reserved (fixed to '0') for M-PCIe. Note: The access attributes of this field are as follows: - Dbi: R
15-8 ACK_N_FTS	N_FTS. The number of Fast Training Sequence ordered sets to be transmitted when transitioning from L0s to L0. The maximum number of FTS ordered-sets that a component can request is 255. The controller does not support a value of zero; a value of zero can cause the LTSSM to go into the recovery state when exiting from L0s. This field is reserved (fixed to '0') for M-PCIe. Note: This register field is sticky.
7-0 ACK_FREQ	Ack Frequency. The controller accumulates the number of pending ACKs specified here (up to 255) before sending an ACK DLLP. - 0: Indicates that this Ack frequency control feature is turned off. The controller schedules a low-priority ACK DLLP for every TLP that it receives. - 1-255: Indicates that the

PCI Express (PCIe)

Field	Function
	controller will schedule a high-priority ACK after receiving this number of TLPs. It might schedule the ACK before receiving this number of TLPs, but never later. For a typical system, you do not have to modify the default setting. For more details, see "ACK/NAK Scheduling". Note: This register field is sticky.

11.3.3.1.63 Port Link Control Register. (PORT_LINK_CTRL_OFF)

11.3.3.1.63.1 Offset

25 CORRUPT_LCR C_ENABLE	CORRUPT_LCRC_ENABLE is an internally reserved field. Do not use. Note: This register field is sticky.
24 BEACON_ENA BLE	BEACON_ENABLE is an internally reserved field. Do not use. Note: This register field is sticky.
23-22 —	Reserved.
21-16 LINK_CAPABLE	Link Mode Enable. Sets the number of lanes in the link that you want to connect to the link partner. When you have unused lanes in your system, then you must change the value in this register to reflect the number of lanes. You must also change the value in the "Predetermined Number of Lanes" field of the "Link Width and Speed Change Control Register". For more information, see "How to Tie Off Unused Lanes". For information on upsizing and downsizing the link width, see "Link Establishment". - 000001: x1 - 000011: x2 - 000111: x4 - 001111: x8 - 011111: x16 - 111111: x32 (not supported) This field is reserved (fixed to '0') for M-PCIe. Note: This register field is sticky.
15-12 RSVDP_12	Reserved for future use.
11-8 LINK_RATE	LINK_RATE is an internally reserved field. Do not use. Note: This register field is sticky.
7 FAST_LINK_M ODE	Fast Link Mode. Sets all internal LTSSM millisecond timers to Fast Mode for speeding up simulation. Forces the LTSSM training (link initialization) to use shorter time-outs and to link up faster. The default scaling factor can be changed through the FAST_LINK_SCALING_FACTOR field in the TIMER_CTRL_MAX_FUNC_NUM_OFF register. If this bit is set to '1', tRRAPInitiatorResponse is set to 1.88 ms(60 ms/32). Note: This register field is sticky.
6 LINK_DISABLE	LINK_DISABLE is an internally reserved field. Do not use. Note: This register field is sticky.
5 DLL_LINK_EN	DLL Link Enable. Enables link initialization. When DLL Link Enable =0, the controller does not transmit InitFC DLLPs and does not establish a link. Note: This register field is sticky.
4 RSVDP_4	Reserved for future use.
3 RESET_ASSER T	Reset Assert. Triggers a recovery and forces the LTSSM to the hot reset state (downstream port only). Note: This register field is sticky.
2 LOOPBACK_EN ABLE	Loopback Enable. Turns on loopback. For more details, see "Loopback". For M-PCIe, to force the master to enter Digital Loopback mode, you must set this field to "1" during Configuration.start state(initial discovery/configuration). M-PCIe doesn't support loopback mode from L0 state - only from Configuration.start. Note: This register field is sticky.
1 SCRAMBLE_DI SABLE	Scramble Disable. Turns off data scrambling. Note: This register field is sticky.
0 VENDOR_SPE CIFIC_DLLP_R EQ	Vendor Specific DLLP Request. When software writes a '1' to this bit, the controller transmits the DLLP contained in the VENDOR_SPEC_DLLP field of VENDOR_SPEC_DLLP_OFF. Reading from this self-clearing register field always returns a '0'.

11.3.3.1.64 Lane Skew Register. (LANE_SKEW_OFF)

11.3.3.1.64.1 Offset

Register	Offset
LANE_SKEW_OFF	714h

11.3.3.1.64.2 Diagram

11.3.3.1.64.3 Fields

Field	Function
31 DISABLE_LANE_TO_LANE_DESKEW	Disable Lane-to-Lane Deskew. Causes the controller to disable the internal Lane-to-Lane deskew logic. Note: This register field is sticky.
30-27 IMPLEMENT_NUM_LANES	Implementation-specific Number of Lanes. Set the implementation-specific number of lanes. Allowed values are: - 4'b0000: 1 lane - 4'b0001: 2 lanes - 4'b0011: 4 lanes - 4'b0111: 8 lanes - 4'b1111: 16 lanes The number of lanes to be used when in Loopback Master. The number of lanes programmed must be equal to or less than the valid number of lanes set in LINK_CAPABLE field. You must configure this field before initiating Loopback by writing in the LOOPBACK_ENABLE field. The controller will transition from Loopback.Entry to Loopback.Active after receiving two consecutive TS1 Ordered Sets with the Loopback

Table continues on the next page...

PCI Express (PCIe)

Field	Function
	bit asserted on the implementation specific number of lanes configured in this field. Note: This register field is sticky.
26 GEN34_ELASTIC_BUFFER_MODE	Selects Elasticity Buffer operating mode in Gen3 or Gen4 rate: 0: Nominal Half Full Buffer mode 1: Nominal Empty Buffer Mode This register bit only affects Gen3 or Gen4 operating rate. For Gen1 or Gen2 operating rate the Elasticity Buffer operating mode is always the Nominal Half Full Buffer mode. Note: This register field is sticky.
25 ACK_NAK_DISABLE	Ack/Nak Disable. Prevents the controller from sending ACK and NAK DLLPs. Note: This register field is sticky.
24 FLOW_CTRL_DISABLE	Flow Control Disable. Prevents the controller from sending FC DLLPs. Note: This register field is sticky.
23-0 INSERT_LANE_SKEW	INSERT_LANE_SKEW is an internally reserved field. Do not use. Note: This register field is sticky.

11.3.3.1.65 Timer Control and Max Function Number Register. (TIMER_CTRL_MAX_FUNC_NUM_OFF)

11.3.3.1.65.1 Offset

Register	Offset
TIMER_CTRL_MAX_FUNC_NUM_OFF	718h

11.3.3.1.65.2 Diagram

11.3.3.1.65.3 Fields

Field	Function
31 RSVDP_31	Reserved for future use.
30-29 FAST_LINK_SCALING_FACTOR	Fast Link Timer Scaling Factor. Sets the scaling factor of LTSSM timer when FAST_LINK_MODE field in PORT_LINK_CTRL_OFF is set to '1'. - 0: Scaling Factor is 1024 (1ms is 1us) - 1: Scaling Factor is 256 (1ms is 4us) - 2: Scaling Factor is 64 (1ms is 16us) - 3: Scaling Factor is 16 (1ms is 64us). Not used for M-PCIe. Note: This register field is sticky.
28-24 UPDATE_FREQ_TIMER	UPDATE_FREQ_TIMER is an internally reserved field. Do not use. Note: This register field is sticky.
23-19 TIMER_MOD_ACK_NAK	Ack Latency Timer Modifier. Increases the timer value for the Ack latency timer in increments of 64 clock cycles. A value of "0" represents no modification to the timer value. For more details, see the ROUND_TRIP_LATENCY_TIME_LIMIT field of the ACK_LATENCY_TIMER_OFF register. Note: This register field is sticky.

Table continues on the next page...

Field	Function
18-14 TIMER_MOD_REPLAY_TIMER	Replay Timer Limit Modifier. Increases the time-out value for the replay timer in increments of 64 clock cycles at Gen1 or Gen2 speed, and in increments of 256 clock cycles at Gen3 speed. A value of "0" represents no modification to the timer limit. For more details, see the REPLAY_TIME_LIMIT field of the ACK_LATENCY_TIMER_OFF register. At Gen3 speed, the controller automatically changes the value of this field to DEFAULT_GEN3_REPLAY_ADJ. For M-PCIe, this field increases the time-out value for the replay timer in increments of 64 clock cycles at HS-Gear1, HS-Gear2, or HS-Gear3 speed. Note: This register field is sticky.
13-8 RSVDP_8	Reserved for future use.
7-0 MAX_FUNC_NUM	Maximum function number that can be used in a request. Configuration requests targeted at function numbers above this value are returned with UR (unsupported request). Note: This register field is sticky.

11.3.3.1.66 Symbol Timer Register and Filter Mask 1 Register. (SYMBOL_TIMER_FILTER_1_OFF)

11.3.3.1.66.1 Offset

Register	Offset
SYMBOL_TIMER_FILTER_1_OFF	71Ch

11.3.3.1.66.2 Function

Symbol Timer Register and Filter Mask 1 Register. The Filter Mask 1 Register modifies the RADM filtering and error handling rules. For more details, see the "Receive Filtering" section. In each case, '0' applies the associated filtering rule and '1' masks the associated filtering rule.

11.3.3.1.66.3 Diagram

11.3.3.1.66.4 Fields

Field	Function
31-16 MASK_RADM_1	Filter Mask 1. The Filter Mask 1 Register modifies the RADM filtering and error handling rules. For more details, see the "Receive Filtering" section. In each case, '0' applies the associated filtering rule and '1' masks the associated filtering rule. Note: This register field is sticky.
15 DISABLE_FC_WD_TIMER	Disable FC Watchdog Timer. Note: This register field is sticky.
14-11 EIDLE_TIMER	EIDLE_TIMER is an internally reserved field. Do not use. Note: This register field is sticky.
10-0 SKP_INT_VAL	SKP Interval Value. The number of symbol times to wait between transmitting SKP ordered sets. Note that the controller actually waits the number of symbol times in this register plus 1 between transmitting SKP ordered sets. Your application must program this register accordingly. For example, if 1536 were programmed into this register (in a 250 MHz controller), then the controller actually transmits SKP ordered sets once every 1537 symbol times. The value programmed to this register is actually clock ticks and not symbol times. In a 125 MHz controller, programming the value programmed to this register should be scaled down by a factor of 2 (because one clock tick = two symbol times in this case). Note: This value is not used at Gen3 speed; the skip interval is hardcoded to 370 blocks. Note: This register field is sticky.

11.3.3.1.67 Filter Mask 2 Register. (FILTER_MASK_2_OFF)

11.3.3.1.67.1 Offset

Register	Offset
FILTER_MASK_2_OFF	720h

11.3.3.1.67.2 Function

Filter Mask 2 Register. This register modifies the RADM filtering and error handling rules. For more details, see the "Receive Filtering" section. In each case, '0' applies the associated filtering rule and '1' masks the associated filtering rule.

11.3.3.1.67.3 Diagram**11.3.3.1.67.4 Fields**

Field	Function
31-0 MASK_RADM_2	Filter Mask 2. This field modifies the RADM filtering and error handling rules. For more details, see the "Receive Filtering" section. In each case, '0' applies the associated filtering rule and '1' masks the associated filtering rule. Note: This register field is sticky.

11.3.3.1.68 AMBA Multiple Outbound Decomposed NP SubRequests Control Register. (AMBA_MUL_OB_DECOMP_NP_SUB_REQ_CTRL_OFF)

11.3.3.1.68.1 Offset

Register	Offset
AMBA_MUL_OB_DECOMP_NP_SUB_REQ_CTRL_OFF	724h

11.3.3.1.68.2 Diagram

11.3.3.1.68.3 Fields

Field	Function
31-1 RSVDP_1	Reserved for future use.
0 OB_RD_SPLIT_BURST_EN	Enable AMBA Multiple Outbound Decomposed NP SubRequests. This bit when set to "0" disables the possibility of having multiple outstanding non-posted requests that were derived from decomposition of an outbound AMBA request. For more details, see "AXI Bridge Ordering" in the AXI chapter of the Databook. You should not clear this register unless your application master is requesting an amount of read data greater than Max_Read_Request_Size, and the remote device (or switch) is reordering completions that have different tags. Note: The access attributes of this field are as follows: - Dbi: R/W (sticky) Note: This register field is sticky.

Field	Function
31-20 RSVDP_20	Reserved for future use.
19-12 TX_CPL_HEADER_FC_CREDIT	Transmit Completion Header FC Credits. The Completion Header credits advertised by the receiver at the other end of the link, updated with each UpdateFC DLLP. Default value depends on the number of advertised credits for header and data [12'b0, xtlh_xadm_cplh_cdts, xtlh_xadm_cpId_cdts]; When the number of advertised completion credits (both header and data) are infinite, then the default would be [12'b0, 8'hFF, 12'hFFF].
11-0 TX_CPL_DATA_FC_CREDIT	Transmit Completion Data FC Credits. The Completion Data credits advertised by the receiver at the other end of the link, updated with each UpdateFC DLLP. Default value depends on the number of advertised credits for header and data [12'b0, xtlh_xadm_cplh_cdts, xtlh_xadm_cpId_cdts]; When the number of advertised completion credits (both header and data) are infinite, then the default would be [12'b0, 8'hFF, 12'hFFF].

11.3.3.1.74 Queue Status (QUEUE_STATUS_OFF)

11.3.3.1.74.1 Offset

Register	Offset
QUEUE_STATUS_OFF	73Ch

11.3.3.1.74.2 Diagram

11.3.3.1.74.3 Fields

Field	Function
31 TIMER_MOD_F LOW_CONTRO L_EN	FC Latency Timer Override Enable. When this bit is set, the value from the "FC Latency Timer Override Value" field in this register will override the FC latency timer value that the controller calculates according to the PCIe specification. Note: This register field is sticky.
30-29 RSVDP_29	Reserved for future use.

Table continues on the next page...

Field	Function
28-16 TIMER_MOD_F LOW_CONTROL	FC Latency Timer Override Value. When you set the "FC Latency Timer Override Enable" in this register, the value in this field will override the FC latency timer value that the controller calculates according to the PCIe specification. For more details, see "Flow Control". Note: This register field is sticky.
15 RX_SERIALIZA TION_Q_READ _ERR	Receive Serialization Read Error. Indicates the serialization queue has attempted to read an incorrectly formatted TLP.
14 RX_SERIALIZA TION_Q_WRIT E_ERR	Receive Serialization Queue Write Error. Indicates insufficient buffer space available to write to the serialization queue.
13 RX_SERIALIZA TION_Q_NON_ EMPTY	Receive Serialization Queue Not Empty. Indicates there is data in the serialization queue.
12-4 RSVDP_4	Reserved for future use.
3 RX_QUEUE_O VERFLOW	Receive Credit Queue Overflow. Indicates insufficient buffer space available to write to the P/NP/CPL credit queue.
2 RX_QUEUE_N ON_EMPTY	Receive Credit Queue Not Empty. Indicates there is data in one or more of the receive buffers.
1 TX_RETRY_BU FFER_NE	Transmit Retry Buffer Not Empty. Indicates that there is data in the transmit retry buffer.
0 RX_TLP_FC_C REDIT_NON_R ETURN	Received TLP FC Credits Not Returned. Indicates that the controller has received a TLP but has not yet sent an UpdateFC DLLP indicating that the credits for that TLP have been restored by the receiver at the other end of the link.

19-12 VC0_CPL_HEA DER_CREDIT	VC0 Completion Header Credits. The number of initial Completion header credits for VC0, used only in the segmented-buffer configuration. Note: The access attributes of this field are as follows: - Dbi: R (sticky) Note: This register field is sticky.
11-0 VC0_CPL_DAT A_CREDIT	VC0 Completion Data Credits. The number of initial Completion data credits for VC0, used only in the segmented-buffer configuration. Note: The access attributes of this field are as follows: - Dbi: R (sticky) Note: This register field is sticky.

11.3.3.1.80 Link Width and Speed Change Control Register. (GEN2_CTRL_OFF)

11.3.3.1.80.1 Offset

Register	Offset
GEN2_CTRL_OFF	80Ch

11.3.3.1.80.2 Diagram

11.3.3.1.80.3 Fields

Field	Function
31-22 RSVDP_22	Reserved for future use.
21 GEN1_EI_INFERENCE	Electrical Idle Inference Mode at Gen1 Rate. Programmable mode to determine inferred electrical idle (EI) in Recovery.Speed or Loopback.Active (as slave) state at Gen1 speed by looking for a "1" value on RxElecIdle instead of looking for a "0" on RxValid. If the PHY fails to deassert the RxValid signal in Recovery.Speed or Loopback.Active (because of corrupted EIOS for example), then EI cannot be inferred successfully in the controller by just detecting the condition RxValid=0. - 0: Use RxElecIdle signal to infer Electrical Idle - 1: Use RxValid signal to infer Electrical Idle Note: This register field is sticky.
20 SEL_DEEMPHASIS	Used to set the de-emphasis level for upstream ports. This bit selects the level of de-emphasis the link operates at. - 0: -6 dB - 1: -3.5 dB This field is reserved (fixed to '0') for M-PCIe. Note: The access attributes of this field are as follows: - Dbi: R/W (sticky) Note: This register field is sticky.
19 CONFIG_TX_COMP_RX	Config Tx Compliance Receive Bit. When set to 1, signals LTSSM to transmit TS ordered sets with the compliance receive bit assert (equal to "1"). This field is reserved (fixed to '0') for M-PCIe. Note: The access attributes of this field are as follows: - Dbi: R/W (sticky) Note: This register field is sticky.
18 CONFIG_PHY_TX_CHANGE	Config PHY Tx Swing. Controls the PHY transmitter voltage swing level. The controller drives the mac_phy_txswing output from this register bit field. - 0: Full Swing - 1: Low Swing This field is reserved (fixed to '0') for M-PCIe. Note: The access attributes of this field are as follows: - Dbi: R/W (sticky) Note: This register field is sticky.
17 DIRECT_SPEED_CHANGE	Directed Speed Change. Writing "1" to this field instructs the LTSSM to initiate a speed change to Gen2 or Gen3 after the link is initialized at Gen1 speed. When the speed change occurs, the controller will clear the contents of this field; and a read to this field by your software will return a "0". To manually initiate the speed change: - Write to LINK_CONTROL2_LINK_STATUS2_REG[PCIE_CAP_TARGET_LINK_SPEED] in the local device, deassert this field, and then assert this field. This field is reserved (fixed to '0') for M-PCIe. Note: The access attributes of this field are as follows: - Dbi: R/W
16 AUTO_LANE_FLIP_CTRL_EN	Enable Auto flipping of the lanes. This field is reserved (fixed to '0') for M-PCIe. Note: The access attributes of this field are as follows: - Dbi: R/W (sticky) Note: This register field is sticky.
15-13 PRE_DET_LANE	Predetermined Lane for Auto Flip. This field defines which physical lane is connected to logical Lane0 by the flip operation performed in Detect. Allowed values are: - 3'b000: Connect logical Lane0 to physical lane 0 - 3'b001: Connect logical Lane0 to physical lane 1 - 3'b010: Connect logical Lane0 to physical lane 3 - 3'b011: Connect logical Lane0 to physical lane 7 - 3'b100: Connect logical Lane0 to physical lane 15 This field is used to restrict the receiver detect procedure to a particular lane when the default detect and polling procedure performed on all lanes cannot be successful. A notable example of when it is useful to program this field to a value different from the default, is when a lane is asymmetrically broken, that is, it is detected in Detect LTSSM state but it cannot exit Electrical Idle in Polling LTSSM state. Note: This field is reserved (fixed to '0') for M-PCIe. Note: The access attributes of this field are as follows: - Dbi: R/W (sticky) Note: This register field is sticky.
12-8 NUM_OF_LANES	Predetermined Number of Lanes. Defines the number of lanes which are connected and not bad. Used to limit the effective link width to ignore "broken" or "unused" lanes that detect a receiver. Indicates the number of lanes to check for exit from Electrical Idle in Polling.Active and L2.Idle. It is possible that the LTSSM might detect a receiver on a bad or broken lane during the Detect Substate. However, it is also possible that such a lane might also fail to exit Electrical Idle and therefore prevent a valid link from being configured. This value is referred to as the "Predetermined Number of Lanes" in section 4.2.6.2.1 of the PCI Express Base 3.0 Specification, revision 1.0. Encoding is as follows: - 0x01: 1 lane - 0x02: 2 lanes - 0x03: 3 lanes - .. When you have unused lanes in your system, then you must change the value in this register to reflect the number of lanes. You must also change the value in the "Link Mode Enable" field of PORT_LINK_CTRL_OFF. The value in this register is normally the same as the encoded value in

Table continues on the next page...

Field	Function
	PORT_LINK_CTRL_OFF. If you find that one of your used lanes is bad then you must reduce the value in this register. For more information, see "How to Tie Off Unused Lanes." For information on upsizing and downsizing the link width, see "Link Establishment." This field is reserved (fixed to '0') for M-PCIe. Note: The access attributes of this field are as follows: - Dbi: R/W (sticky) Note: This register field is sticky.
7-0 FAST_TRAINING_SEQ	Sets the Number of Fast Training Sequences (N_FTS) that the controller advertises as its N_FTS during Gen2 or Gen3 link training. This value is used to inform the link partner about the PHY's ability to recover synchronization after a low power state. The number should be provided by the PHY vendor. Do not set N_FTS to zero; doing so can cause the LTSSM to go into the recovery state when exiting from L0s. This field is reserved (fixed to '0') for M-PCIe. Note: The access attributes of this field are as follows: - Dbi: R/W (sticky) Note: This register field is sticky.

11.3.3.1.81 PHY Status Register. (PHY_STATUS_OFF)

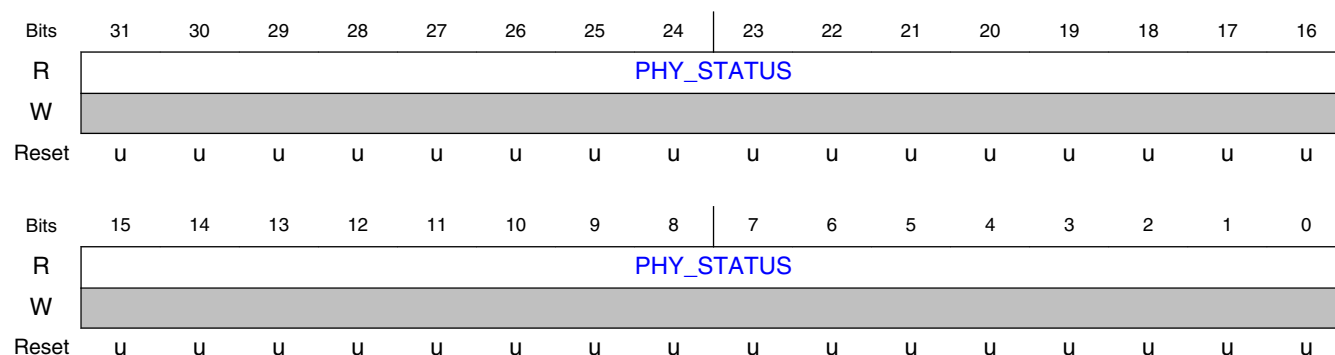

11.3.3.1.81.1 Offset

Register	Offset
PHY_STATUS_OFF	810h

11.3.3.1.81.2 Function

PHY Status Register. Memory mapped register from phy_cfg_status GPIO input pins.

11.3.3.1.81.3 Diagram

11.3.3.1.81.4 Fields

Field	Function
31-0 PHY_STATUS	PHY Status. Data received directly from the phy_cfg_status bus. This is a GPIO register reflecting the values on the static phy_cfg_status input signals. The usage is left completely to the user and does not in any way influence controller functionality. You can use it for any static sideband status signalling

PCI Express (PCIe)

Field	Function
	requirements that you have for your PHY. This field is reserved (fixed to '0') for M-PCIe. Note: This register field is sticky.

11.3.3.1.82 PHY Control Register. (PHY_CONTROL_OFF)

11.3.3.1.82.1 Offset

Register	Offset
PHY_CONTROL_OFF	814h

11.3.3.1.82.2 Function

PHY Control Register. Memory mapped register to cfg_phy_control GPIO output pins.

11.3.3.1.82.3 Diagram

11.3.3.1.82.4 Fields

Field	Function
31-0 PHY_CONTROL	PHY Control. Data sent directly to the cfg_phy_control bus. These is a GPIO register driving the values on the static cfg_phy_control output signals. The usage is left completely to the user and does not in any way influence controller functionality. You can use it for any static sideband control signalling requirements that you have for your PHY. This field is reserved (fixed to '0') for M-PCIe. Note: This register field is sticky.

11.3.3.1.83 Programmable Target Map Control Register. (TRGT_MAP_CTRL_L_OFF)

11.3.3.1.83.1 Offset

Register	Offset
TRGT_MAP_CTRL_OFF	81Ch

11.3.3.1.83.2 Diagram

11.3.3.1.83.3 Fields

Field	Function
31-21 TARGET_MAP_RESERVED_21_31	Reserved. Note: The access attributes of this field are as follows: - Dbi: R (sticky)
20-16 TARGET_MAP_INDEX	The number of the PF Function on which the Target Values are set. This register does not respect the Byte Enable setting. any write will affect all register bits.
15-13 TARGET_MAP_RESERVED_13_15	Reserved. Note: The access attributes of this field are as follows: - Dbi: R (sticky)
12-7 —	Reserved.
6 TARGET_MAP_ROM	Target Value for the ROM page of the PF Function selected by the index number. This register does not respect the Byte Enable setting. any write will affect all register bits.
5-0 TARGET_MAP_PF	Target Values for each BAR on the PF Function selected by the index number. This register does not respect the Byte Enable setting. any write will affect all register bits.

11.3.3.1.84 Integrated MSI Reception Module (iMRM) Address Register. (MSI_CTRL_ADDR_OFF)

11.3.3.1.84.1 Offset

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

11.3.3.1.84.3 Fields

Field	Function
31-0 MSI_CTRL_ADDR	Integrated MSI Reception Module Address. System specified address for MSI memory write transaction termination. Within the AXI Bridge, every received Memory Write request is examined to see if it targets the MSI Address that has been specified in this register; and also to see if it satisfies the definition of an MSI interrupt request. When these conditions are satisfied the Memory Write request is marked as an MSI request. Note: This register field is sticky.

11.3.3.1.85 Integrated MSI Reception Module Upper Address Register. (MSI_CTRL_UPPER_ADDR_OFF)

11.3.3.1.85.1 Offset

Register	Offset
MSI_CTRL_UPPER_ADDR_OFF	824h

11.3.3.1.85.2 Diagram

R	MSI_CTRL_UPPER_ADDR															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

11.3.3.1.85.3 Fields

Field	Function
31-0 MSI_CTRL_UPPER_ADDR	Integrated MSI Reception Module Upper Address. System specified upper address for MSI memory write transaction termination. Allows functions to support a 64-bit MSI address. Note: This register field is sticky.

11.3.3.1.86 Integrated MSI Reception Module Interrupt#i Enable Register. (MSI_CTRL_INT_0_EN_OFF)

11.3.3.1.86.1 Offset

Register	Offset
MSI_CTRL_INT_0_EN_OFF	828h

11.3.3.1.86.2 Diagram

11.3.3.1.86.3 Fields

Field	Function
31-0 MSI_CTRL_INT_0_EN	MSI Interrupt#i Enable. Specifies which interrupts are enabled. When an MSI is received from a disabled interrupt, no status bit gets set in MSI controller interrupt status register. Each bit corresponds to a single MSI Interrupt Vector. Note: This register field is sticky.

11.3.3.1.87 Integrated MSI Reception Module Interrupt#i Mask Register. (MSI_CTRL_INT_0_MASK_OFF)

11.3.3.1.87.1 Offset

Register	Offset
MSI_CTRL_INT_0_MASK_OFF	82Ch

11.3.3.1.87.2 Diagram

11.3.3.1.87.3 Fields

Field	Function
31-0 MSI_CTRL_INT_0_MASK	MSI Interrupt#i Mask. Allows enabled interrupts to be masked. When an MSI is received for a masked interrupt, the corresponding status bit gets set in the interrupt status register but the msi_ctrl_int output is not set HIGH. Each bit corresponds to a single MSI Interrupt Vector. Note: This register field is sticky.

11.3.3.1.88 Integrated MSI Reception Module Interrupt#i Status Register. (MSI_CTRL_INT_0_STATUS_OFF)

11.3.3.1.88.1 Offset

Register	Offset
MSI_CTRL_INT_0_STATUS_OFF	830h

11.3.3.1.88.2 Diagram

11.3.3.1.88.3 Fields

Field	Function
31-0 MSI_CTRL_INT_0_STATUS	MSI Interrupt#i Status. When an MSI is detected for EP#i, one bit in this register is set. The decoding of the data payload of the MSI Memory Write request determines which bit gets set. A status bit is cleared by writing a 1 to the bit. Each bit corresponds to a single MSI Interrupt Vector.

11.3.3.1.89 Integrated MSI Reception Module Interrupt#i Enable Register. (MSI_CTRL_INT_1_EN_OFF)

11.3.3.1.89.1 Offset

Register	Offset
MSI_CTRL_INT_1_EN_OFF	834h

11.3.3.1.89.2 Diagram

11.3.3.1.89.3 Fields

Field	Function
31-0 MSI_CTRL_INT_1_EN	MSI Interrupt#i Enable. Specifies which interrupts are enabled. When an MSI is received from a disabled interrupt, no status bit gets set in MSI controller interrupt status register. Each bit corresponds to a single MSI Interrupt Vector. Note: This register field is sticky.

11.3.3.1.90 Integrated MSI Reception Module Interrupt#i Mask Register. (MSI_CTRL_INT_1_MASK_OFF)

11.3.3.1.90.1 Offset

Register	Offset
MSI_CTRL_INT_1_MASK_OFF	838h

11.3.3.1.90.2 Diagram

11.3.3.1.90.3 Fields

Field	Function
31-0 MSI_CTRL_INT_1_MASK	MSI Interrupt#i Mask. Allows enabled interrupts to be masked. When an MSI is received for a masked interrupt, the corresponding status bit gets set in the interrupt status register but the msi_ctrl_int output is not set HIGH. Each bit corresponds to a single MSI Interrupt Vector. Note: This register field is sticky.

11.3.3.1.91 Integrated MSI Reception Module Interrupt#i Status Register. (MSI_CTRL_INT_1_STATUS_OFF)

31-0 MSI_GPIO_REG	MSI GPIO Register. The contents of this register drives the top-level GPIO msi_ctrl_io[31:0] Note: This register field is sticky.

11.3.3.1.111 RADM clock gating enable control register. (CLOCK_GATING_CTRL_OFF)

11.3.3.1.111.1 Offset

Register	Offset
CLOCK_GATING_CTRL_OFF	88Ch

11.3.3.1.111.2 Function

RADM clock gating enable control register. Using this register you can disable the RADM clock gating feature. The DWC_pcie_clk_rst.v modules uses the en_radm_clk_g output to gate core_clk and create the radm_clk_g clock input. The controller de-asserts the en_radm_clk_g output when there is no Rx traffic, Rx queues and pre/post-queue pipelines are empty, RADM completion LUT is empty, and there are no FLR actions pending. You must set the RADM_CLK_GATING_EN field to enable this functionality; otherwise the en_radm_clk_g output will always be set to '1'.

11.3.3.1.111.3 Diagram

11.3.3.1.111.4 Fields

Field	Function
31-1 RSVDP_1	Reserved for future use.
0 RADM_CLK_GATING_EN	Enable Radm clock gating feature. - 0: Disable - 1: Enable(default)

11.3.3.1.112 Order Rule Control Register. (ORDER_RULE_CTRL_OFF)

11.3.3.1.112.1 Offset

Register	Offset
ORDER_RULE_CTRL_OFF	8B4h

Register	Offset
PIPE_LOOPBACK_CONTROL_OFF	8B8h

11.3.3.1.113.2 Diagram

11.3.3.1.113.3 Fields

Field	Function
31 PIPE_LOOPBACK	PIPE Loopback Enable. Indicates RMMI Loopback if M-PCIe. Note: This register field is sticky.
30-27 RSVDP_27	Reserved for future use.
26-24 RXSTATUS_VALUE	RXSTATUS_VALUE is an internally reserved field. Do not use.
23-22 RSVDP_22	Reserved for future use.
21-16 RXSTATUS_LANE	RXSTATUS_LANE is an internally reserved field. Do not use. Note: This register field is sticky.
15-0 LPBK_RXVALID	LPBK_RXVALID is an internally reserved field. Do not use. Note: This register field is sticky.

11.3.3.1.114 DBI Read-Only Write Enable Register. (MISC_CONTROL_1_0 FF)

11.3.3.1.114.1 Offset

Register	Offset
MISC_CONTROL_1_0 FF	8BCh

11.3.3.1.114.2 Diagram

11.3.3.1.114.3 Fields

Field	Function
31-6 RSVDP_6	Reserved for future use.
5 ARI_DEVICE_NUMBER	When ARI is enabled, this field enables use of the device ID. Note: This register field is sticky.
4 —	Reserved.
3	Enables Simplified Replay Timer (Gen4). For more details, see "Transmit Replay" in the Controller Operations chapter of the Databook. Simplified Replay Timer Values are: - A value from 24,000 to 31,000

Table continues on the next page...

Field	Function
SIMPLIFIED_REPEAT_TIMER	Symbol Times when Extended Synch is 0b. - A value from 80,000 to 100,000 Symbol Times when Extended Synch is 1b. Must not be changed while link is in use. Note: This register field is sticky.
2 UR_CA_MASK_4_TRGT1	This field only applies to request TLPs (with UR filtering status) that you have chosen to forward to the application (when you set DEFAULT_TARGET in this register). - When you set this field to '1', the core suppresses error logging, Error Message generation, and CPL generation (for non-posted requests). Note: This register field is sticky.
1 DEFAULT_TARGET	Default target a received IO or MEM request with UR/CA/CRS is sent to by the controller. - 0: The controller drops all incoming I/O or MEM requests (after corresponding error reporting). A completion with UR status will be generated for non-posted requests. - 1: The controller forwards all incoming I/O or MEM requests with UR/CA/CRS status to your application. Note: This register field is sticky.
0 DBI_RO_WR_EN	Write to RO Registers Using DBI. When you set this field to "1", then some RO and HwInit bits are writable from the local application through the DBI. Note: This register field is sticky.

11.3.3.1.115 UpConfigure Multi-lane Control Register. (MULTI_LANE_CONTROL_OFF)

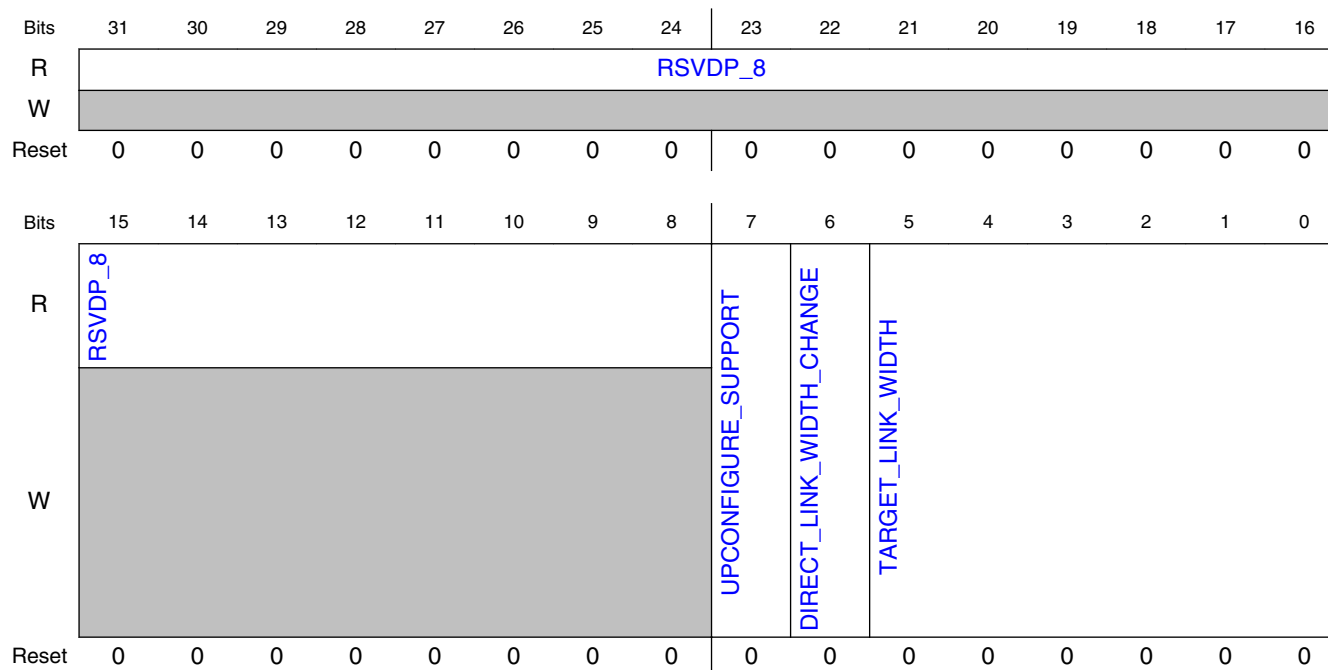

11.3.3.1.115.1 Offset

Register	Offset
MULTI_LANE_CONTROL_OFF	8C0h

11.3.3.1.115.2 Function

UpConfigure Multi-lane Control Register. Used when upsizing or downsizing the link width through Configuration state without bringing the link down. For more details, see the "Link Establishment" section in the "Controller Operations" chapter of the Databook.

11.3.3.1.115.3 Diagram

11.3.3.1.115.4 Fields

Field	Function
31-8 RSVDP_8	Reserved for future use.
7 UPCONFIGURE_SUPPORT	Upconfigure Support. The controller sends this value as the Link Upconfigure Capability in TS2 Ordered Sets in Configuration.Complete state. This field is reserved (fixed to '0') for M-PCIe. Note: This register field is sticky.
6 DIRECT_LINK_WIDTH_CHANGE	Directed Link Width Change. The controller always moves to Configuration state through Recovery state when this bit is set to '1'. - If the upconfigure_capable variable is '1' and the PCIE_CAP_HW_AUTO_WIDTH_DISABLE bit in LINK_CONTROL_LINK_STATUS_REG is '0', the controller starts upconfigure or autonomous width downsizing (to the TARGET_LINK_WIDTH value) in the Configuration state. - If TARGET_LINK_WIDTH value is 0x0, the controller does not start upconfigure or autonomous width downsizing in the Configuration state. The controller self-clears this field when the controller accepts this request. This field is reserved (fixed to '0') for M-PCIe.
5-0 TARGET_LINK_WIDTH	Target Link Width. Values correspond to: - 6'b000000: Core does not start upconfigure or autonomous width downsizing in the Configuration state. - 6'b000001: x1 - 6'b000010: x2 - 6'b000100: x4 - 6'b001000: x8 - 6'b010000: x16 - 6'b100000: x32 This field is reserved (fixed to '0') for M-PCIe.

11.3.3.1.116 PHY Interoperability Control Register. (PHY_INTEROP_CTRL_OFF)

11.3.3.1.116.1 Offset

Register	Offset
PHY_INTEROP_CTRL_OFF	8C4h

11.3.3.1.116.2 Function

PHY Interoperability Control Register. This register is reserved for internal use. You should not write to this register and change the default unless specifically instructed by Synopsys support.

11.3.3.1.116.3 Diagram

11.3.3.1.116.4 Fields

Field	Function
31-11 RSVDP_11	Reserved for future use.
10 L1_CLK_SEL	L1 Clock control bit. - 1: Controller does not request aux_clk switch and core_clk gating in L1. - 0: Controller requests aux_clk switch and core_clk gating in L1. Note: This register field is sticky.
9 L1_NOWAIT_P1	L1 entry control bit. - 1: Core does not wait for PHY to acknowledge transition to P1 before entering L1. - 0: Core waits for the PHY to acknowledge transition to P1 before entering L1. Note: The access attributes of this field are as follows: - Dbi: R/W (sticky) Note: This register field is sticky.

Table continues on the next page...

PCI Express (PCIe)

Field	Function
8 L1SUB_EXIT_MODE	L1 Exit Control Using phy_mac_pclckack_n. - 1: Core exits L1 without waiting for the PHY to assert phy_mac_pclckack_n. - 0: Core waits for the PHY to assert phy_mac_pclckack_n before exiting L1. Note: This register field is sticky.
7 RSVDP_7	Reserved for future use.
6-0 RXSTANDBY_CONTROL	Rxstandby Control. Bits 0..5 determine if the controller asserts the RxStandby signal (mac_phy_rxstandby) in the indicated condition. Bit 6 enables the controller to perform the RxStandby/RxStandbyStatus handshake. - [0]: Rx EIOS and subsequent TX-IDLE-MIN - [1]: Rate Change - [2]: Inactive lane for upconfigure/downconfigure - [3]: PowerDown=P1orP2 - [4]: RxL0s.Idle - [5]: EI Infer in L0 - [6]: Execute RxStandby/RxStandbyStatus Handshake This field is reserved (fixed to '0') for M-PCIe. Note: This register field is sticky.

11.3.3.1.117 TRGT_CPL_LUT Delete Entry Control register. (TRGT_CPL_LUT_DELETE_ENTRY_OFF)

11.3.3.1.117.1 Offset

Register	Offset
TRGT_CPL_LUT_DELETE_ENTRY_OFF	8C8h

11.3.3.1.117.2 Function

TRGT_CPL_LUT Delete Entry Control register. Using this register you can delete one entry in the target completion LUT. You should only use this register when you know that your application will never send the completion because of an FLR or any other reason. Note:: The target completion LUT (and associated target completion timeout event) is watching for completions (from your application on XALI0/1/2 or AXI master read channel) corresponding to previously received non-posted requests from the PCIe wire.

11.3.3.1.117.3 Diagram

11.3.3.1.117.4 Fields

Field	Function
31 DELETE_EN	This is a one-shot bit. A '1' write to this bit triggers the deletion of the target completion LUT entry that is specified in the LOOK_UP_ID field. This is a self-clearing register field. Reading from this register field always returns a '0'.
30-0 LOOK_UP_ID	This number selects one entry to delete of the TRGT_CPL_LUT.

11.3.3.1.118 Link Reset Request Flush Control Register. (LINK_FLUSH_CONTROL_OFF)

11.3.3.1.118.1 Offset

Register	Offset
LINK_FLUSH_CONTROL_OFF	8CCh

11.3.3.1.118.2 Diagram

11.3.3.1.118.3 Fields

Field	Function
31-24 RSVD_I_8	This is an internally reserved field. Do not use. Note: This register field is sticky.
23-1 RSVDP_1	Reserved for future use.
0 AUTO_FLUSH_EN	Enables automatic flushing of pending requests before sending the reset request to the application logic to reset the PCIe controller and the AXI Bridge. The flushing process is initiated if any of the following events occur: - Hot reset request. A downstream port (DSP) can "hot reset" an upstream port (USP) by sending two consecutive TS1 ordered sets with the hot reset bit asserted. - Warm (Soft) reset request. Generated when exiting from D3 to D0 and <code>cfg_pm_no_soft_rst=0</code> . - Link down reset request. A high to low transition on <code>smlh_req_rst_not</code> indicates the link has gone down and the controller is requesting a reset. If you disable automatic flushing, your application is responsible for resetting the PCIe controller and the AXI Bridge. For more details see "Warm and Hot Resets" section in the Architecture chapter of the Databook. Note: This register field is sticky.

11.3.3.1.119 AXI Bridge Slave Error Response Register. (AMBA_ERROR_RESPONSE_DEFAULT_OFF)

11.3.3.1.119.1 Offset

Register	Offset
AMBA_ERROR_RESPONSE_DEFAULT_OFF	8D0h

11.3.3.1.119.2 Diagram

11.3.3.1.119.3 Fields

Field	Function
31-16 RSVDP_16	Reserved for future use.
15-10 AMBA_ERROR_RESPONSE_MAP	AXI Slave Response Error Map. Allows you to selectively map the errors received from the PCIe completion (for non-posted requests) to the AXI slave responses, slv_resp or slv_bresp. The recommended setting is SLVERR. CRS is always mapped to OKAY. - [0] -- 0: UR (unsupported request) -> DECERR -- 1: UR (unsupported request) -> SLVERR - [1] -- 0: CRS (configuration retry status) -> DECERR -- 1: CRS (configuration retry status) -> SLVERR - [2] -- 0: CA (completer abort) -> DECERR -- 1: CA (completer abort) -> SLVERR - [3]: Reserved - [4]: Reserved - [5]: -- 0: Completion Timeout -> DECERR -- 1: Completion Timeout -> SLVERR The AXI bridge internally drops (processes internally but not passed to your application) a completion that has been marked by the Rx filter as UC or MLF, and does not pass its status directly down to the slave interface. It waits for a timeout and then signals "Completion Timeout" to the slave interface. The controller sets the AXI slave read databus to 0xFFFF for all error responses. Note: This register field is sticky.
9-5 RSVDP_5	Reserved for future use.
4-3 AMBA_ERROR_RESPONSE_CR	CRS Slave Error Response Mapping. Determines the AXI slave response for CRS completions. For more details see "Error Handling" in the AXI chapter of the Databook. AHB: - always returns OKAY AXI: - 00: OKAY - 01: OKAY with all FFFF_FFFF data for all CRS completions - 10: OKAY with FFFF_0001 data for CRS completions to vendor ID read requests, OKAY with FFFF_FFFF data for all other CRS completions - 11: SLVERR/DECERR (the AXI_ERROR_RESPONSE_MAP field determines the PCIe-to-AXI Slave error response mapping) Note: This register field is sticky.

Table continues on the next page...

Field	Function
2 AMBA_ERROR_RESPONSE_VENDORID	Vendor ID Non-existent Slave Error Response Mapping. Determines the AXI slave response for errors on reads to non-existent Vendor ID register. For more details see "Error Handling" in the AXI chapter of the Databook. AHB: - 0: OKAY (with FFFF data). The controller ignores the setting in the bit when bit 0 of this register is '0'. - 1: ERROR AXI: - 0: OKAY (with FFFF data). - 1: SLVERR/DECERR (the AXI_ERROR_RESPONSE_MAP field determines the PCIe-to-AXI Slave error response mapping) Note: This register field is sticky.
1 RSVDP_1	Reserved for future use.
0 AMBA_ERROR_RESPONSE_GLOBAL	Global Slave Error Response Mapping. Determines the AXI slave response for all error scenarios on non-posted requests. For more details see "Error Handling" in the AXI chapter of the Databook. AHB: - 0: OKAY (with FFFF data for non-posted requests) and ignore the setting in bit [2] of this register. - 1: ERROR for normal link (data) accesses and look at bit [2] for other scenarios. AXI: - 0: OKAY (with FFFF data for non-posted requests) - 1: SLVERR/DECERR (the AXI_ERROR_RESPONSE_MAP field determines the PCIe-to-AXI Slave error response mapping) The error response mapping is not applicable to Non-existent Vendor ID register reads. Note: This register field is sticky.

11.3.3.1.120 Link Down AXI Bridge Slave Timeout Register. (AMBA_LINK_TIMEOUT_OFF)

11.3.3.1.120.1 Offset

Register	Offset
AMBA_LINK_TIMEOUT_OFF	8D4h

11.3.3.1.120.2 Function

Link Down AXI Bridge Slave Timeout Register. If your application AXI master issues outbound requests to the AXI bridge slave interface before the PCIe link is operational, the controller starts a "flush" timer. The timeout value of the timer is set by this register. The timer will timeout and then flush the bridge TX request queues after this amount of time. The timer counts when there are pending outbound AXI slave interface (or DMA) requests and the PCIe TX link is not transmitting any of these requests. For more details, see the "AXI Bridge Initialization, Clocking and Reset" section in the AXI chapter of the Databook.

11.3.3.1.120.3 Diagram

11.3.3.1.120.4 Fields

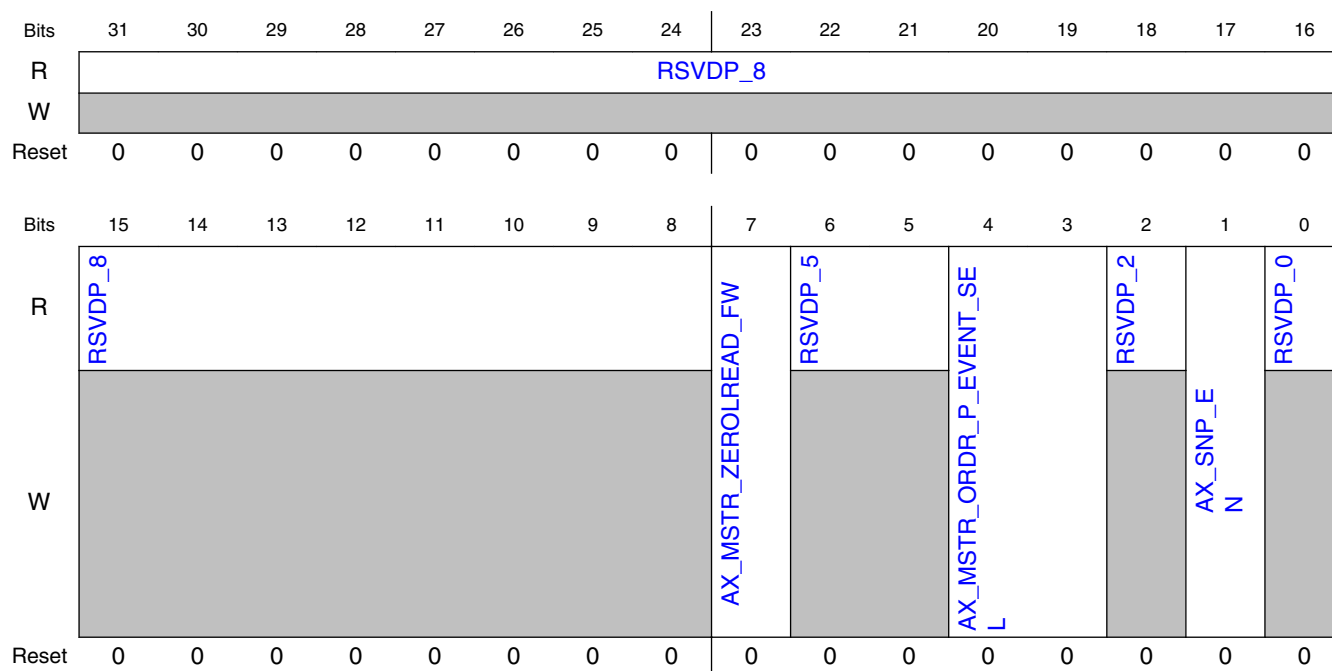

Field	Function
31-9 RSVDP_9	Reserved for future use.
8 LINK_TIMEOUT_ENABLE_DEFAULT	Disable Flush. You can disable the flush feature by setting this field to "1". Note: This register field is sticky.
7-0 LINK_TIMEOUT_PERIOD_DEFAULT	Timeout Value (ms). The timer will timeout and then flush the bridge TX request queues after this amount of time. The timer counts when there are pending outbound AXI slave interface requests and the PCIe TX link is not transmitting any of these requests. The timer is clocked by core_clk. For an M-PCIe configuration: - Time unit of this field is 4 ms. - Margin of error for RateA clock is < 1%. - Margin of error for RateB clock is between 16% and 17%. Note: This register field is sticky.

11.3.3.1.121 AMBA Ordering Control. (AMBA_ORDERING_CTRL_OFF)

11.3.3.1.121.1 Offset

Register	Offset
AMBA_ORDERING_CTL_OFF	8D8h

11.3.3.1.121.2 Diagram

11.3.3.1.121.3 Fields

Field	Function
31-8 RSVDP_8	Reserved for future use.
7 AX_MSTR_ZEROLREAD_FW	AXI Master Zero Length Read Forward to the application. The DW PCIe controller AXI bridge is able to terminate in order with the Posted transactions the zero length read, implementing the PCIe express flush semantics of the Posted transactions. - 0x0: The zero length Read is terminated at the DW PCIe AXI bridge master - 0x1: The zero length Read is forward to the application.
6-5 RSVDP_5	Reserved for future use.
4-3 AX_MSTR_ORDR_P_EVENT_SELECTOR	AXI Master Posted Ordering Event Selector. This field selects how the master interface determines when a P write is completed when enforcing the PCIe ordering rule, "NP must not pass P" at the AXI Master Interface. The AXI protocol does not support ordering between channels. Therefore, NP reads can pass P on your AXI bus fabric. This can result in an ordering violation when the read overtakes a P that is going to the same address. Therefore, the bridge master does not issue any NP requests until all outstanding P writes reach their destination. It does this by waiting for the all of the write responses on

Table continues on the next page...

Field	Function
	the B channel. This can affect the performance of the master read channel. For scenarios where the interconnect serializes the AXI master "AW", "W" and "AR" channels, you can increase the performance by reducing the need to wait until the complete Posted transaction has effectively reached the application slave. - 00: B'last event: wait for the all of the write responses on the B channel thereby ensuring that the complete Posted transaction has effectively reached the application slave (default). - 01: AW'last event: wait until the complete Posted transaction has left the AXI address channel at the bridge master. - 10: W'last event: wait until the complete Posted transaction has left the AXI data channel at the bridge master. - 11: Reserved Note 2: This setting will not affect: - MSI interrupt catcher and P data ordering. This is always driven by the B'last event. - DMA read engine TLP ordering. This is always driven by the B'last event. - NP write transactions which are always serialized with P write transactions.
2 RSVDP_2	Reserved for future use.
1 AX_SNP_EN	AXI Serialize Non-Posted Requests Enable. This field enables the AXI Bridge to serialize same ID Non-Posted Read/Write Requests on the wire. Serialization implies one outstanding same ID NP Read or Write on the wire and used to avoid AXI RAR and WAW hazards at the remote link partner. For more details, see the "Optional Serialization of AXI Slave Non-posted Requests" section in the AXI chapter of the Databook.
0 RSVDP_0	Reserved for future use.

11.3.3.1.122 ACE Cache Coherency Control Register 1 (COHERENCY_CONTROL_1_OFF)

11.3.3.1.122.1 Offset

Register	Offset
COHERENCY_CONTROL_1_OFF	8E0h

Field	Function
—	
14-11 CFG_MSTR_AWCACHE_MODE	Master Write CACHE Signal Behavior. Defines how the individual bits in mstr_awcache are controlled: - 0: set automatically by the AXI master - 1: set by the value of the corresponding bit of the CFG_MSTR_AWCACHE_VALUE field Note: for message requests the value of mstr_awcache is always "0000" regardless of the value of this bit Note: This register field is sticky.
10-7 —	Reserved.
6-3 CFG_MSTR_ARCACHE_MODE	Master Read CACHE Signal Behavior. Defines how the individual bits in mstr_arcache are controlled: - 0: set automatically by the AXI master - 1: set by the value of the corresponding bit of the CFG_MSTR_ARCACHE_VALUE field Note: This register field is sticky.
2-0 —	Reserved.

11.3.3.1.125 Lower 20 bits of the programmable AXI address where Messages coming from wire are mapped to. (AXI_MSTR_MSG_ADDR_LOW_OFF)

11.3.3.1.125.1 Offset

Register	Offset
AXI_MSTR_MSG_ADDR_LOW_OFF	8F0h

11.3.3.1.125.2 Function

Lower 20 bits of the programmable AXI address where Messages coming from wire are mapped to. Bits [11:0] of the register are tied to zero for the address to be 4k-aligned. In previous releases, the third and fourth DWORDs of a message (Msg/MsgD) TLP header were delivered though the AXI master address bus (mstr_awaddr). These DWORDS are now supplied through the mstr_awmisc_info_hdr_34dw[63:0] output; and the value on mstr_awaddr is driven to the value you have programmed into the AXI_MSTR_MSG_ADDR_LOW_OFF and AXI_MSTR_MSG_ADDR_HIGH_OFF registers.

11.3.3.1.125.3 Diagram

11.3.3.1.125.4 Fields

Field	Function
31-12 CFG_AXIMSTR_MSG_ADDR_LOW	Lower 20 bits of the programmable AXI address for Messages. Note: This register field is sticky.
11-0 CFG_AXIMSTR_MSG_ADDR_LOW_RESERVED	Reserved for future use. Note: This register field is sticky.

11.3.3.1.126 Upper 32 bits of the programmable AXI address where Messages coming from wire are mapped to. (AXI_MSTR_MSG_ADDR_HIGH_OFF)

11.3.3.1.129.3 Fields

Field	Function
31-10 RSVDP_10	Reserved for future use.
9-0 AUX_CLK_FREQ	The aux_clk frequency in MHz. This value is used to provide a 1 us reference for counting time during low-power states with aux_clk when the PHY has removed the pipe_clk. Frequencies lower than 1 MHz are possible but with a loss of accuracy in the time counted. If the actual frequency (f) of aux_clk does not exactly match the programmed frequency (f_prog), then there is an error in the time counted by the controller that can be expressed in percentage as: $err\% = (f_prog/f - 1) * 100$. For example if f=2.5 MHz and f_prog=3 MHz, then $err\% = (3/2.5 - 1) * 100 = 20\%$, meaning that the time counted by the controller on aux_clk will be 20% greater than the time in us programmed in the corresponding time register (for example T_POWER_ON). Note: This register field is sticky.

11.3.3.1.130 L1 Substates Timing Register. (L1_SUBSTATES_OFF)

11.3.3.1.130.1 Offset

Register	Offset
L1_SUBSTATES_OFF	B44h

11.3.3.1.130.3 Fields

Field	Function
31-8 RSVDP_8	Reserved for future use.
7-6 L1SUB_T_PCLKACK	Max delay (in 1us units) between a MAC request to remove the clock on mac_phy_pclkreq_n and a PHY response on phy_mac_pclckack_n. If the PHY does not respond within this time the request is aborted. Range is 0..3 Note: This register field is sticky.
5-2 L1SUB_T_L1_2	Duration (in 1us units) of L1.2. Range is 0.15. Note: The timeout value can vary by 50%. Note: This register field is sticky.
1-0 L1SUB_T_POWER_OFF	Duration (in 1us units) of L1.2.Entry. Range is 0.3. Note: The timeout value can vary by 50%. Note: This register field is sticky.

11.3.3.1.131 iATU Region Control 1 Register. (IATU_REGION_CTRL_1_OFF_OUTBOUND_0)

11.3.3.1.131.1 Offset

Register	Offset
IATU_REGION_CTRL_1_OFF_OUTBOUND_0	8000_0000h

11.3.3.1.131.2 Diagram

11.3.3.1.131.3 Fields

Field	Function
31-23 —	Reserved.
22-20 CTRL_1_FUNC_NUM	Function Number. - When the address of an outbound TLP is matched to this region and the FUNC_BYPASS field in the "iATU Control 2 Register" is '0', then the function number used in generating the function part of the requester ID (RID) field of the TLP is taken from this 5-bit register. When you are using the AXI Bridge, then this field is swapped before AXI decomposition occurs so that the correct "Max_Read_Request_Size" and "Max_Payload_Size" values are used. Note: This register field is sticky.
19-14 —	Reserved.
13 INCREASE_REGION_SIZE	Increase the maximum ATU Region size. When set, the size is determined by the Maximum Size of iATU Region. When clear, the maximum ATU Region size is 4 GB (default). Note: This register field is sticky.
12-11 —	Reserved.
10-9 ATTR	When the address of an outbound TLP is matched to this region, then the ATTR field of the TLP is changed to the value in this register. Note: This register field is sticky.

Table continues on the next page...

Field	Function
8 TD	When the address of an outbound TLP is matched to this region, then the TD field of the TLP is changed to the value in this register. Note: This register field is sticky.
7-5 TC	When the address of an outbound TLP is matched to this region, then the TC field of the TLP is changed to the value in this register. Note: This register field is sticky.
4-0 TYPE	When the address of an outbound TLP is matched to this region, then the TYPE field of the TLP is changed to the value in this register. Note: This register field is sticky.

11.3.3.1.132 iATU Region Control 2 Register. (IATU_REGION_CTRL_2_OFF_OUTBOUND_0)

11.3.3.1.132.1 Offset

Register	Offset
IATU_REGION_CTRL_2_OFF_OUTBOUND_0	8000_0004h

11.3.3.1.132.2 Diagram

11.3.3.1.132.3 Fields

Field	Function
31 REGION_EN	Region Enable. This bit must be set to '1' for address translation to take place. Note: This register field is sticky.
30 —	Reserved.
29 INVERT_MODE	Invert Mode. When set the address matching region is inverted. Therefore, an address match occurs when the untranslated address is in the region outside the defined range (Base Address to Limit Address). Note: This register field is sticky.
28 CFG_SHIFT_M ODE	CFG Shift Mode. The iATU uses bits [27:12] of the untranslated address (on the XALI0/1/2 interface or AXI slave interface address) to form the BDF number of the outgoing CFG TLP. This supports the Enhanced Configuration Address Mapping (ECAM) mechanism (Section 7.2.2 of the PCI Express Base 3.1 Specification, revision 1.0) by allowing all outgoing I/O and MEM TLPs (that have been translated to CFG) to be mapped from memory space into any 256 MB region of the PCIe configuration space. Note: This register field is sticky.
27 DMA_BYPASS	DMA Bypass Mode. Allows request TLPs which are initiated by the DMA controller to pass through the iATU untranslated. Note: This field is reserved for the SW product. You must set it to '0'. Note: This register field is sticky.
26-24 —	Reserved.
23 HEADER_SUBS TITUTE_EN	Header Substitute Enable. When enabled and region address is matched, the iATU fully substitutes bytes 8-11 (for 3 DWORD header) or bytes 12-15 (for 4 DWORD header) of the outbound TLP header with the contents of the LWR_TARGET_RW field in IATU_LWR_TARGET_ADDR_OFF_OUTBOUND_i. - 1: LWR_TARGET_RW in the iATU_LWR_TARGET_ADDR_OFF_OUTBOUND_i register is used to fill bytes 8-to-11 (for 3 DWORD header) or bytes 12-to-15 (for 4 DWORD header) of the translated TLP header. - 0: LWR_TARGET_RW in the iATU_LWR_TARGET_ADDR_OFF_OUTBOUND_i register forms the new address of the translated region. Note: This register field is sticky.
22 INHIBIT_PAYLO AD	Inhibit TLP Payload Data for TLP's in Matched Region; assign iATU region to be TLP without data. When enabled and region address is matched, the iATU marks all TLPs as having no payload data by forcing the TLP header Fmt[1] bit =0, regardless of the application inputs such as slv_wstrb. - 1: Fmt[1] =0 so that only TLP type without data is sent. For example, a Msg instead of MsgD will be sent. - 0: Fmt[1] =0/1 so that TLPs with or without data can be sent. Note: This register field is sticky.
21 —	Reserved.
20 SNP	Serialize Non-Posted Requests. In this mode, when the AXI Bridge is populated, same AXI ID Non-Posted Read/Write Requests are transmitted on the wire if there are no other same ID Non-Posted Requests outstanding. Note: This register field is sticky.
19 FUNC_BYPASS	Function Number Translation Bypass. In this mode, the function number of the translated TLP is taken from your application transmit interface and not from the CTRL_1_FUNC_NUM field of the "iATU Control 1 Register" or the VF_NUMBER field of the "iATU Control 3 Register." Note: This register field is sticky.
18-17 —	Reserved.
16 TAG_SUBSTIT UTE_EN	TAG Substitute Enable. When enabled and region address is matched, the iATU substitutes the TAG field of the outbound TLP header with the contents of the TAG field in this register. The expected usage scenario is translation from AXI MWr to Vendor Defined Msg/MsgD. Note: This register field is sticky.
15-8 TAG	TAG. The substituted TAG field (byte 6) in the outgoing TLP header when TAG_SUBSTITUTE_EN is set. Note: This register field is sticky.

Table continues on the next page...

Field	Function
7-0 MSG_CODE	MSG TLPs (Message Code). When the address of an outbound TLP is matched to this region, and the translated TLP TYPE field is Msg or MsgD; then the message field of the TLP is changed to the value in this register. Memory TLPs: (ST;Steering Tag). When the ST field of an outbound TLP is matched to this region, and the translated TLP TYPE field targets memory space; then the ST field of the TLP is changed to the value in this register. Note: This register field is sticky.

11.3.3.1.133 iATU Lower Base Address Register. (IATU_LWR_BASE_ADDRESS_OFFSET_OUTBOUND_0)

11.3.3.1.133.1 Offset

Register	Offset
IATU_LWR_BASE_ADDRESS_OFFSET_OUTBOUND_0	8000_0008h

11.3.3.1.133.2 Function

iATU Lower Base Address Register. The Minimum Size of iATU Region (Value Range: 4 kB, 8 kB, 16 kB, 32 kB, 64 kB defaults to 64 kB) specifies the minimum size of an address translation region. For example, if set to 64 kB; the lower 16 bits of the Base, Limit and Target registers are zero and all address regions are aligned on 64 kB boundaries. More precisely, the lower $\log_2(\text{Minimum Size of iATU Region})$ bits are zero.

11.3.3.1.133.3 Diagram

11.3.3.1.133.4 Fields

Field	Function
31-16 LWR_BASE_R W	Forms bits [31:n] of the start address of the address region to be translated. n is log2(Minimum Size of iATU Region) Note: This register field is sticky.
15-0 LWR_BASE_H W	Forms bits [n-1:0] of the start address of the address region to be translated. The start address must be aligned to the Minimum Size of iATU Region kB boundary, so these bits are always 0. A write to this location is ignored by the PCIe controller. n is log2(Minimum Size of iATU Region)

11.3.3.1.134 iATU Upper Base Address Register. (IATU_UPPER_BASE_ADDR_OFF_OUTBOUND_0)**11.3.3.1.134.1 Offset**

Register	Offset
IATU_UPPER_BASE_ADDR_OFF_OUTBOUND_0	8000_000Ch

11.3.3.1.134.2 Diagram**11.3.3.1.134.3 Fields**

Field	Function
31-0 UPPER_BASE_RW	Forms bits [63:32] of the start (and end) address of the address region to be translated. In systems with a 32-bit address space, this register is not used and therefore writing to this register has no effect. Note: This register field is sticky.

11.3.3.1.135 iATU Limit Address Register. (IATU_LIMIT_ADDR_OFF_OUTBOUND_0)

11.3.3.1.135.1 Offset

Register	Offset
IATU_LIMIT_ADDR_OFF_OUTBOUND_0	8000_0010h

11.3.3.1.135.2 Diagram

11.3.3.1.138.1 Offset

Register	Offset
IATU_REGION_CTRL_1_OFF_INBOUND_0	8000_0100h

11.3.3.1.138.2 Diagram

11.3.3.1.138.3 Fields

Field	Function
31-23 —	Reserved.
22-20 CTRL_1_FUNC_NUM	Function Number. - MEM-I/O: When the Address and BAR matching logic in the controller indicate that a MEM-I/O transaction matches a BAR in the function corresponding to this value, then address translation proceeds. This check is only performed if the "Function Number Match Enable" bit of the "iATU Control 2 Register" is set. - CFG0/CFG1: When the destination function number as specified in the routing ID of the TLP header matches the function, then address translation proceeds. This check is only performed if the "Function Number Match Enable" bit of the "iATU Control 2 Register" is set. Note: This register field is sticky.
19-14 —	Reserved.
13 INCREASE_REGION_SIZE	Increase the maximum ATU Region size. When set, the size is determined by the Maximum Size of iATU Region. When clear, the maximum ATU Region size is 4 GB (default). Note: This register field is sticky.
12-11 —	Reserved.
10-9 ATTR	When the ATTR field of an inbound TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "ATTR Match Enable" bit of the "iATU Control 2 Register" is set. Note: This register field is sticky.

Table continues on the next page...

Field	Function
8 TD	When the TD field of an inbound TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "TD Match Enable" bit of the "iATU Control 2 Register" is set. Note: This register field is sticky.
7-5 TC	When the TC field of an inbound TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "TC Match Enable" bit of the "iATU Control 2 Register" is set. Note: This register field is sticky.
4-0 TYPE	When the TYPE field of an inbound TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). Note: This register field is sticky.

11.3.3.1.139 iATU Region Control 2 Register. (IATU_REGION_CTRL_2_OFF_INBOUND_0)

11.3.3.1.139.1 Offset

Register	Offset
IATU_REGION_CTRL_2_OFF_INBOUND_0	8000_0104h

11.3.3.1.139.2 Diagram

11.3.3.1.139.3 Fields

Field	Function
31 REGION_EN	Region Enable. This bit must be set to '1' for address translation to take place. Note: This register field is sticky.
30 MATCH_MODE	Match Mode. Determines Inbound matching mode for TLPs. The mode depends on the type of TLP that is received as follows: For MEM-I/O TLPs, this field is interpreted as follows: - 0: Address Match Mode. The iATU operates using addresses as in the outbound direction. The Region Base and Limit Registers must be setup. - 1: BAR Match Mode. BAR matching is used. The "BAR Number" field is relevant. Not used for RC. For CFG0 TLPs, this field is interpreted as follows: - 0: Routing ID Match Mode. The iATU interprets the Routing ID (Bytes 8 to 11 of TLP header) as an address. This corresponds to the upper 16 bits of the address in MEM-I/O transactions. The Routing ID of the TLP must be within the base and limit of the iATU region for matching to proceed. - 1: Accept Mode. The iATU accepts all CFG0 transactions as address matches. The routing ID in the CFG0 TLP is ignored. This is useful as all received CFG0 TLPs should be processed regardless of the Bus number. For MSG/MSGD TLPs, this field is interpreted as follows: - 0: Address Match Mode. The iATU treats the third dword and fourth dword of the inbound MSG/MSGD TLP as an address and it is matched against the Region Base and Limit Registers. - 1: Vendor ID Match Mode. This mode is relevant for ID-routed Vendor Defined Messages. The iATU ignores the Routing ID (Bus, Device, Function) in bits [31:16] of the third dword of the TLP header, but matches

Table continues on the next page...

Field	Function
	against the Vendor ID in bits [15:0] of the third dword of the TLP header. Bits [15:0] of the Region Upper Base register should be programmed with the required Vendor ID. The lower Base and Limit Register should be programmed to translate TLPs based on vendor specific information in the fourth dword of the TLP header. - If SINGLE_ADDRESS_LOCATION_TRANSLATE_EN = 1 AND MSG_TYPE_MATCH_MODE = 1, then Match Mode is ignored. Note: This register field is sticky.
29 INVERT_MODE	Invert Mode. When set the address matching region is inverted. Therefore, an address match occurs when the untranslated address is in the region outside the defined range (Base Address to Limit Address). Note: This register field is sticky.
28 CFG_SHIFT_MODE	CFG Shift Mode. This is useful for CFG transactions where the PCIe configuration mechanism maps bits [27:12] of the address to the bus/device and function number. This allows a CFG configuration space to be located in any 256MB window of your application memory space using a 28-bit effective address. Shifts bits [31:16] of the untranslated address to form bits [27:12] of the translated address. Note: This register field is sticky.
27 FUZZY_TYPE_MATCH_CODE	Fuzzy Type Match Mode. When enabled, the iATU relaxes the matching of the TLP TYPE field against the expected TYPE field so that - CfgRd0 and CfgRd1 TLPs are seen as identical. Similarly with CfgWr0 and CfgWr1. - MWr, MRd and MRdLk TLPs are seen as identical - The Routing field of Msg/MsgD TLPs is ignored - FetchAdd, Swap and CAS are seen as identical. For example, CFG0 in the TYPE field in the "iATU Control 1 Register" matches against an inbound CfgRd0, CfgRd1, CfgWr0 or CfgWr1 TLP. Note: This register field is sticky.
26 —	Reserved.
25-24 RESPONSE_CODE	Response Code. Defines the type of response to give for accesses matching this region. This overrides the normal RADM filter response. Note that this feature is not available for any region where Single Address Location Translate is enabled. - 00 - Normal RADM filter response is used. - 01 - Unsupported request (UR) - 10 - Completer abort (CA) - 11 - Not used / undefined / reserved. Note: This register field is sticky.
23 SINGLE_ADDR_LOC_TRANSLATE_EN	Single Address Location Translate Enable. When enabled, Rx TLPs can be translated to a single address location as determined by the target address register of the iATU region. The main usage scenario is translation of Messages (such as Vendor Defined or ATS Messages) to MWr TLPs when the AXI bridge is enabled. Note: This register field is sticky.
22 —	Reserved.
21 MSG_CODE_MATCH_EN	Message Code Match Enable (Msg TLPS). Ensures that a successful message Code TLP field comparison match (see Message Code field of the "iATU Control 2 Register") occurs (in MSG transactions) for address translation to proceed. ST Match Enable (Mem TLPS). Ensures that a successful ST TLP field comparison match (see ST field of the "iATU Control 2 Register") occurs (in MEM transactions) for address translation to proceed. Note: This register field is sticky.
20 —	Reserved.
19 FUNC_NUM_MATCH_EN	Function Number Match Enable. Ensures that a successful Function Number TLP field comparison match (see Function Number field of the "iATU Control 1 Register") occurs (in MEM-I/O and CFG0/CFG1 transactions) for address translation to proceed. Note: This register field is sticky.
18-17 —	Reserved.
16 ATTR_MATCH_EN	ATTR Match Enable. Ensures that a successful ATTR TLP field comparison match (see ATTR field of the "iATU Control 1 Register") occurs for address translation to proceed. Note: This register field is sticky.

Table continues on the next page...

Field	Function
15 TD_MATCH_EN	TD Match Enable. Ensures that a successful TD TLP field comparison match (see TD field of the "iATU Control 1 Register") occurs for address translation to proceed. Note: This register field is sticky.
14 TC_MATCH_EN	TC Match Enable. Ensures that a successful TC TLP field comparison match (see TC field of the "iATU Control 1 Register") occurs for address translation to proceed. Note: This register field is sticky.
13 MSG_TYPE_MATCH_MODE	Message Type Match Mode. When enabled, and if single address location translate enable is set, then inbound TLPs of type MSG/MSGd which match the type field of the iatu_region_ctrl_1_OFF_inbound register (=>TYPE[4:3]=2'b10) will be translated. Message type match mode overrides any value of MATCH_MODE field in this register. Usage scenarios for this are translation of VDM or ATS messages when AXI bridge is configured on client interface. Note: This register field is sticky.
12-11 —	Reserved.
10-8 BAR_NUM	BAR Number. When the BAR number of an inbound MEM or IO TLP " that is matched by the normal internal BAR address matching mechanism " is the same as this field, address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "Match Mode" bit of the "iATU Control 2 Register" is set. - 000b - BAR0 - 001b - BAR1 - 010b - BAR2 - 011b - BAR3 - 100b - BAR4 - 101b - BAR5 - 110b - ROM - 111b - reserved - IO translation would require either 00100b or 00101b in the inbound TLP TYPE; the BAR Number set in the range 000b - 101b and that BAR configured as an IO BAR. Note: This register field is sticky.
7-0 MSG_CODE	MSG TLPs: (Message Code). When the TYPE field of an inbound Msg/MsgD TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "Message Code Match Enable" bit of the "iATU Control 2 Register" is set. Memory TLPs: (ST;Steering Tag). When the ST field of an inbound TLP is matched to this value, then address translation proceeds. This check is only performed if the "ST Match Enable" bit of the "iATU Control2 Register" is set. The setting is independent of the setting of the TH field. Note: This register field is sticky.

11.3.3.1.140 iATU Lower Base Address Register. (IATU_LWR_BASE_ADDR_OFF_INBOUND_0)

11.3.3.1.140.1 Offset

Register	Offset
IATU_LWR_BASE_ADDR_OFF_INBOUND_0	8000_0108h

11.3.3.1.140.2 Function

iATU Lower Base Address Register. The Minimum Size of iATU Region (Value Range: 4 kB, 8 kB, 16 kB, 32 kB, 64 kB defaults to 64 kB) specifies the minimum size of an address translation region. For example, if set to 64 kB; the lower 16 bits of the Base, Limit and Target registers are zero and all address regions are aligned on 64 kB boundaries. More precisely, the lower log2(Minimum Size of iATU Region) bits are zero.

11.3.3.1.140.3 Diagram

11.3.3.1.140.4 Fields

Field	Function
31-16 LWR_BASE_R W	Forms bits [31:n] of the start address of the address region to be translated. n is log2(Minimum Size of iATU Region) Note: This register field is sticky.
15-0 LWR_BASE_H W	Forms bits [n-1:0] of the start address of the address region to be translated. The start address must be aligned to the Minimum Size of iATU Region kB boundary, so these bits are always 0. A write to this location is ignored by the PCIe controller. n is log2(Minimum Size of iATU Region)

11.3.3.1.141 iATU Upper Base Address Register. (IATU_UPPER_BASE_ADDR_OFF_INBOUND_0)

11.3.3.1.141.1 Offset

Register	Offset
IATU_UPPER_BASE_ADDR_OFF_INBOUND_0	8000_010Ch

11.3.3.1.141.2 Diagram

11.3.3.1.141.3 Fields

Field	Function
31-0 UPPER_BASE_ RW	Forms bits [63:32] of the start (and end) address of the address region to be translated. Note: This register field is sticky.

11.3.3.1.142 iATU Limit Address Register. (IATU_LIMIT_ADDR_OFF_INBOUND_0)

11.3.3.1.142.1 Offset

Register	Offset
IATU_LIMIT_ADDR_OFF_INBOUND_0	8000_0110h

11.3.3.1.142.2 Diagram

11.3.3.1.142.3 Fields

Field	Function
31-16 LIMIT_ADDR_R W	Forms upper bits of the end address of the address region to be translated. The end address must be aligned to the Minimum Size of iATU Region kB boundary, so these bits are always 0. A write to this location is ignored by the PCIe controller. Note: This register field is sticky.
15-0 LIMIT_ADDR_H W	Forms lower bits of the end address of the address region to be translated. The end address must be aligned to the Minimum Size of iATU Region kB boundary, so these bits are always 0. A write to this location is ignored by the PCIe controller.

11.3.3.1.143 iATU Lower Target Address Register. (IATU_LWR_TARGET_ADDR_OFF_INBOUND_0)

11.3.3.1.143.1 Offset

11.3.3.1.143.3 Fields

Field	Function
31-16 LWR_TARGET_RW	Forms MSB's of the Lower Target part of the new address of the translated region. These bits are always '0'. - Field size depends on log2(Minimum Size of iATU Region) in address match mode. - Field size depends on log2(BAR_MASK+1) in BAR match mode. Note: This register field is sticky.

Table continues on the next page...

PCI Express (PCIe)

Field	Function
15-0 LWR_TARGET_HW	Forms the LSB's of the Lower Target part of the new address of the translated region. The start address must be aligned to the Minimum Size of iATU Region kB boundary (in address match mode); and to the Bar size boundary (in BAR match mode) so that these bits are always '0'. If the BAR is smaller than the iATU region size, then the iATU target address must align to the iATU region size; otherwise it must align to the BAR size. A write to this location is ignored by the PCIe controller. - Field size depends on log2(Minimum Size of iATU Region) in address match mode. - Field size depends on log2(BAR_MASK +1) in BAR match mode.

11.3.3.1.144 iATU Region Control 1 Register. (IATU_REGION_CTRL_1_OFF_OUTBOUND_1)

11.3.3.1.144.1 Offset

Register	Offset
IATU_REGION_CTRL_1_OFF_OUTBOUND_1	8000_0200h

11.3.3.1.144.2 Diagram

11.3.3.1.144.3 Fields

Field	Function
31-23 —	Reserved.
22-20 CTRL_1_FUNC_NUM	Function Number. - When the address of an outbound TLP is matched to this region and the FUNC_BYPASS field in the "iATU Control 2 Register" is '0', then the function number used in generating the function part of the requester ID (RID) field of the TLP is taken from this 5-bit register. When you are using the AXI Bridge, then this field is swapped before AXI decomposition occurs so that the correct "Max_Read_Request_Size" and "Max_Payload_Size" values are used. Note: This register field is sticky.
19-14 —	Reserved.
13 INCREASE_REGION_SIZE	Increase the maximum ATU Region size. When set, the size is determined by the Maximum Size of iATU Region. When clear, the maximum ATU Region size is 4 GB (default). Note: This register field is sticky.
12-11 —	Reserved.
10-9 ATTR	When the address of an outbound TLP is matched to this region, then the ATTR field of the TLP is changed to the value in this register. Note: This register field is sticky.
8 TD	When the address of an outbound TLP is matched to this region, then the TD field of the TLP is changed to the value in this register. Note: This register field is sticky.
7-5 TC	When the address of an outbound TLP is matched to this region, then the TC field of the TLP is changed to the value in this register. Note: This register field is sticky.
4-0 TYPE	When the address of an outbound TLP is matched to this region, then the TYPE field of the TLP is changed to the value in this register. Note: This register field is sticky.

11.3.3.1.145 iATU Region Control 2 Register. (IATU_REGION_CTRL_2_OFF_OUTBOUND_1)

11.3.3.1.145.1 Offset

Register	Offset
IATU_REGION_CTRL_2_OFF_OUTBOUND_1	8000_0204h

11.3.3.1.145.2 Diagram

11.3.3.1.145.3 Fields

Field	Function
31 REGION_EN	Region Enable. This bit must be set to '1' for address translation to take place. Note: This register field is sticky.
30 —	Reserved.
29 INVERT_MODE	Invert Mode. When set the address matching region is inverted. Therefore, an address match occurs when the untranslated address is in the region outside the defined range (Base Address to Limit Address). Note: This register field is sticky.
28 CFG_SHIFT_MODE	CFG Shift Mode. The iATU uses bits [27:12] of the untranslated address (on the XALI0/1/2 interface or AXI slave interface address) to form the BDF number of the outgoing CFG TLP. This supports the Enhanced Configuration Address Mapping (ECAM) mechanism (Section 7.2.2 of the PCI Express Base 3.1 Specification, revision 1.0) by allowing all outgoing I/O and MEM TLPs (that have been translated to CFG) to be mapped from memory space into any 256 MB region of the PCIe configuration space. Note: This register field is sticky.
27 DMA_BYPASS	DMA Bypass Mode. Allows request TLPs which are initiated by the DMA controller to pass through the iATU untranslated. Note: This field is reserved for the SW product. You must set it to '0'. Note: This register field is sticky.
26-24 —	Reserved.
23 HEADER_SUBSTITUTE_EN	Header Substitute Enable. When enabled and region address is matched, the iATU fully substitutes bytes 8-11 (for 3 DWORD header) or bytes 12-15 (for 4 DWORD header) of the outbound TLP header with the contents of the LWR_TARGET_RW field in IATU_LWR_TARGET_ADDR_OFF_OUTBOUND_i. - 1: LWR_TARGET_RW in the iATU_LWR_TARGET_ADDR_OFF_OUTBOUND_i register is used to fill bytes 8-to-11 (for 3 DWORD header) or bytes 12-to-15 (for 4 DWORD header) of the translated TLP header. - 0: LWR_TARGET_RW in the iATU_LWR_TARGET_ADDR_OFF_OUTBOUND_i register forms the new address of the translated region. Note: This register field is sticky.

Table continues on the next page...

Field	Function
22 INHIBIT_PAYLOAD_AD	Inhibit TLP Payload Data for TLP's in Matched Region; assign iATU region to be TLP without data. When enabled and region address is matched, the iATU marks all TLPs as having no payload data by forcing the TLP header Fmt[1] bit =0, regardless of the application inputs such as slv_wstrb. - 1: Fmt[1] =0 so that only TLP type without data is sent. For example, a Msg instead of MsgD will be sent. - 0: Fmt[1] =0/1 so that TLPs with or without data can be sent. Note: This register field is sticky.
21 —	Reserved.
20 SNP	Serialize Non-Posted Requests. In this mode, when the AXI Bridge is populated, same AXI ID Non-Posted Read/Write Requests are transmitted on the wire if there are no other same ID Non-Posted Requests outstanding. Note: This register field is sticky.
19 FUNC_BYPASS	Function Number Translation Bypass. In this mode, the function number of the translated TLP is taken from your application transmit interface and not from the CTRL_1_FUNC_NUM field of the "iATU Control 1 Register" or the VF_NUMBER field of the "iATU Control 3 Register." Note: This register field is sticky.
18-17 —	Reserved.
16 TAG_SUBSTITUTE_EN	TAG Substitute Enable. When enabled and region address is matched, the iATU substitutes the TAG field of the outbound TLP header with the contents of the TAG field in this register. The expected usage scenario is translation from AXI MWr to Vendor Defined Msg/MsgD. Note: This register field is sticky.
15-8 TAG	TAG. The substituted TAG field (byte 6) in the outgoing TLP header when TAG_SUBSTITUTE_EN is set. Note: This register field is sticky.
7-0 MSG_CODE	MSG TLPs (Message Code). When the address of an outbound TLP is matched to this region, and the translated TLP TYPE field is Msg or MsgD; then the message field of the TLP is changed to the value in this register. Memory TLPs: (ST;Steering Tag). When the ST field of an outbound TLP is matched to this region, and the translated TLP TYPE field targets memory space; then the ST field of the TLP is changed to the value in this register. Note: This register field is sticky.

11.3.3.1.146 iATU Lower Base Address Register. (IATU_LWR_BASE_ADDR_OFF_OUTBOUND_1)

11.3.3.1.146.1 Offset

Register	Offset
IATU_LWR_BASE_ADDR_OFF_OUTBOUND_1	8000_0208h

11.3.3.1.146.2 Function

iATU Lower Base Address Register. The Minimum Size of iATU Region (Value Range: 4 kB, 8 kB, 16 kB, 32 kB, 64 kB defaults to 64 kB) specifies the minimum size of an address translation region. For example, if set to 64 kB; the lower 16 bits of the Base, Limit and Target registers are zero and all address regions are aligned on 64 kB boundaries. More precisely, the lower $\log_2(\text{Minimum Size of iATU Region})$ bits are zero.

11.3.3.1.146.3 Diagram

11.3.3.1.146.4 Fields

Field	Function
31-16 LWR_BASE_R W	Forms bits [31:n] of the start address of the address region to be translated. n is log2(Minimum Size of iATU Region) Note: This register field is sticky.
15-0 LWR_BASE_H W	Forms bits [n-1:0] of the start address of the address region to be translated. The start address must be aligned to the Minimum Size of iATU Region kB boundary, so these bits are always 0. A write to this location is ignored by the PCIe controller. n is log2(Minimum Size of iATU Region)

11.3.3.1.147 iATU Upper Base Address Register. (IATU_UPPER_BASE_ADDR_OFF_OUTBOUND_1)

11.3.3.1.147.1 Offset

Register	Offset
IATU_UPPER_BASE_ADDR_OFF_OUTBOUND_1	8000_020Ch

11.3.3.1.148.3 Fields

Field	Function
31-16 LIMIT_ADDR_R W	Forms upper bits of the end address of the address region to be translated. The end address must be aligned to the Minimum Size of iATU Region kB boundary, so these bits are always 0. A write to this location is ignored by the PCIe controller. Note: This register field is sticky.
15-0 LIMIT_ADDR_H W	Forms lower bits of the end address of the address region to be translated. The end address must be aligned to the Minimum Size of iATU Region kB boundary, so these bits are always 0. A write to this location is ignored by the PCIe controller.

11.3.3.1.149 iATU Lower Target Address Register. (IATU_LWR_TARGET_ADDR_OFF_OUTBOUND_1)

11.3.3.1.149.1 Offset

Register	Offset
IATU_LWR_TARGET_ADDR_OFF_OUTBOUND_1	8000_0214h

11.3.3.1.149.2 Diagram

11.3.3.1.149.3 Fields

Field	Function
31-0 LWR_TARGET_RW_OUTBOUND	When HEADER_SUBSTITUTE_EN in IATU_REGION_CTRL_2_OFF_OUTBOUND_ is '0' (normal operation): - LWR_TARGET_RW[31:n] forms MSB's of the Lower Target part of the new address of the translated region; - LWR_TARGET_RW[n-1:0] are not used. (The start address must be aligned to the Minimum Size of iATU Region kB boundary, so the lower bits of the start address of the new address of the translated region (bits n-1:0) are always '0'). - n is log2(Minimum Size of iATU Region). When

Field	Function
	HEADER_SUBSTITUTE_EN in IATU_REGION_CTRL_2_OFF_OUTBOUND_i is '1': - LWR_TARGET_RW[31:0] forms bytes 8-11 (for 3 dword header) or bytes 12-15 (for 4 dword header) of the outbound TLP header. Usage scenarios include the transmission of Vendor Defined Messages where the controller determines the content of bytes 12 to 15 of the TLP header. Note: This register field is sticky.

11.3.3.1.150 iATU Upper Target Address Register. (IATU_UPPER_TARGET_ADDR_OFF_OUTBOUND_1)

11.3.3.1.150.1 Offset

11.3.3.1.151.2 Diagram

11.3.3.1.151.3 Fields

Field	Function
31-23 —	Reserved.
22-20 CTRL_1_FUNC_NUM	Function Number. - MEM-I/O: When the Address and BAR matching logic in the controller indicate that a MEM-I/O transaction matches a BAR in the function corresponding to this value, then address translation proceeds. This check is only performed if the "Function Number Match Enable" bit of the "iATU Control 2 Register" is set. - CFG0/CFG1: When the destination function number as specified in the routing ID of the TLP header matches the function, then address translation proceeds. This check is only performed if the

Table continues on the next page...

Field	Function
	"Function Number Match Enable" bit of the "iATU Control 2 Register" is set. Note: This register field is sticky.
19-14 —	Reserved.
13 INCREASE_REGION_SIZE	Increase the maximum ATU Region size. When set, the size is determined by the Maximum Size of iATU Region. When clear, the maximum ATU Region size is 4 GB (default). Note: This register field is sticky.
12-11 —	Reserved.
10-9 ATTR	When the ATTR field of an inbound TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "ATTR Match Enable" bit of the "iATU Control 2 Register" is set. Note: This register field is sticky.
8 TD	When the TD field of an inbound TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "TD Match Enable" bit of the "iATU Control 2 Register" is set. Note: This register field is sticky.
7-5 TC	When the TC field of an inbound TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "TC Match Enable" bit of the "iATU Control 2 Register" is set. Note: This register field is sticky.
4-0 TYPE	When the TYPE field of an inbound TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). Note: This register field is sticky.

11.3.3.1.152 iATU Region Control 2 Register. (IATU_REGION_CTRL_2_OFFSET_INBOUND_1)

11.3.3.1.152.1 Offset

Register	Offset
IATU_REGION_CTRL_2_OFFSET_INBOUND_1	8000_0304h

11.3.3.1.152.2 Diagram

11.3.3.1.152.3 Fields

Field	Function
31 REGION_EN	Region Enable. This bit must be set to '1' for address translation to take place. Note: This register field is sticky.
30 MATCH_MODE	Match Mode. Determines Inbound matching mode for TLPs. The mode depends on the type of TLP that is received as follows: For MEM-I/O TLPs, this field is interpreted as follows: - 0: Address Match Mode. The iATU operates using addresses as in the outbound direction. The Region Base and Limit Registers must be setup. - 1: BAR Match Mode. BAR matching is used. The "BAR Number" field is relevant. Not used for RC. For CFG0 TLPs, this field is interpreted as follows: - 0: Routing ID Match Mode. The iATU interprets the Routing ID (Bytes 8 to 11 of TLP header) as an address. This corresponds to the upper 16 bits of the address in MEM-I/O transactions. The Routing ID of the TLP must be within the base and limit of the iATU region for matching to proceed. - 1: Accept Mode. The iATU accepts all CFG0 transactions as address matches. The routing ID in the CFG0 TLP is ignored. This is useful as all received CFG0 TLPs should be processed regardless of the Bus number. For MSG/MSGD TLPs, this field is interpreted as follows: - 0: Address Match Mode. The iATU treats the third dword and fourth dword of the inbound MSG/MSGD TLP as an address and it is matched against the Region Base and Limit Registers. - 1: Vendor ID Match Mode. This mode is relevant for ID-routed Vendor Defined Messages. The iATU ignores the Routing ID (Bus, Device, Function) in bits [31:16] of the third dword of the TLP header, but matches

Table continues on the next page...

Field	Function
	against the Vendor ID in bits [15:0] of the third dword of the TLP header. Bits [15:0] of the Region Upper Base register should be programmed with the required Vendor ID. The lower Base and Limit Register should be programmed to translate TLPs based on vendor specific information in the fourth dword of the TLP header. - If SINGLE_ADDRESS_LOCATION_TRANSLATE_EN = 1 AND MSG_TYPE_MATCH_MODE = 1, then Match Mode is ignored. Note: This register field is sticky.
29 INVERT_MODE	Invert Mode. When set the address matching region is inverted. Therefore, an address match occurs when the untranslated address is in the region outside the defined range (Base Address to Limit Address). Note: This register field is sticky.
28 CFG_SHIFT_MODE	CFG Shift Mode. This is useful for CFG transactions where the PCIe configuration mechanism maps bits [27:12] of the address to the bus/device and function number. This allows a CFG configuration space to be located in any 256MB window of your application memory space using a 28-bit effective address. Shifts bits [31:16] of the untranslated address to form bits [27:12] of the translated address. Note: This register field is sticky.
27 FUZZY_TYPE_MATCH_CODE	Fuzzy Type Match Mode. When enabled, the iATU relaxes the matching of the TLP TYPE field against the expected TYPE field so that - CfgRd0 and CfgRd1 TLPs are seen as identical. Similarly with CfgWr0 and CfgWr1. - MWr, MRd and MRdLk TLPs are seen as identical - The Routing field of Msg/MsgD TLPs is ignored - FetchAdd, Swap and CAS are seen as identical. For example, CFG0 in the TYPE field in the "iATU Control 1 Register" matches against an inbound CfgRd0, CfgRd1, CfgWr0 or CfgWr1 TLP. Note: This register field is sticky.
26 —	Reserved.
25-24 RESPONSE_CODE	Response Code. Defines the type of response to give for accesses matching this region. This overrides the normal RADM filter response. Note that this feature is not available for any region where Single Address Location Translate is enabled. - 00 - Normal RADM filter response is used. - 01 - Unsupported request (UR) - 10 - Completer abort (CA) - 11 - Not used / undefined / reserved. Note: This register field is sticky.
23 SINGLE_ADDR_LOC_TRANSLATE_EN	Single Address Location Translate Enable. When enabled, Rx TLPs can be translated to a single address location as determined by the target address register of the iATU region. The main usage scenario is translation of Messages (such as Vendor Defined or ATS Messages) to MWr TLPs when the AXI bridge is enabled. Note: This register field is sticky.
22 —	Reserved.
21 MSG_CODE_MATCH_EN	Message Code Match Enable (Msg TLPS). Ensures that a successful message Code TLP field comparison match (see Message Code field of the "iATU Control 2 Register") occurs (in MSG transactions) for address translation to proceed. ST Match Enable (Mem TLPS). Ensures that a successful ST TLP field comparison match (see ST field of the "iATU Control 2 Register") occurs (in MEM transactions) for address translation to proceed. Note: This register field is sticky.
20 —	Reserved.
19 FUNC_NUM_MATCH_EN	Function Number Match Enable. Ensures that a successful Function Number TLP field comparison match (see Function Number field of the "iATU Control 1 Register") occurs (in MEM-I/O and CFG0/CFG1 transactions) for address translation to proceed. Note: This register field is sticky.
18-17 —	Reserved.
16 ATTR_MATCH_EN	ATTR Match Enable. Ensures that a successful ATTR TLP field comparison match (see ATTR field of the "iATU Control 1 Register") occurs for address translation to proceed. Note: This register field is sticky.

Table continues on the next page...

Field	Function
15 TD_MATCH_EN	TD Match Enable. Ensures that a successful TD TLP field comparison match (see TD field of the "iATU Control 1 Register") occurs for address translation to proceed. Note: This register field is sticky.
14 TC_MATCH_EN	TC Match Enable. Ensures that a successful TC TLP field comparison match (see TC field of the "iATU Control 1 Register") occurs for address translation to proceed. Note: This register field is sticky.
13 MSG_TYPE_MATCH_MODE	Message Type Match Mode. When enabled, and if single address location translate enable is set, then inbound TLPs of type MSG/MSGd which match the type field of the iatu_region_ctrl_1_OFF_inbound register (=>TYPE[4:3]=2'b10) will be translated. Message type match mode overrides any value of MATCH_MODE field in this register. Usage scenarios for this are translation of VDM or ATS messages when AXI bridge is configured on client interface. Note: This register field is sticky.
12-11 —	Reserved.
10-8 BAR_NUM	BAR Number. When the BAR number of an inbound MEM or IO TLP " that is matched by the normal internal BAR address matching mechanism " is the same as this field, address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "Match Mode" bit of the "iATU Control 2 Register" is set. - 000b - BAR0 - 001b - BAR1 - 010b - BAR2 - 011b - BAR3 - 100b - BAR4 - 101b - BAR5 - 110b - ROM - 111b - reserved - IO translation would require either 00100b or 00101b in the inbound TLP TYPE; the BAR Number set in the range 000b - 101b and that BAR configured as an IO BAR. Note: This register field is sticky.
7-0 MSG_CODE	MSG TLPs: (Message Code). When the TYPE field of an inbound Msg/MsgD TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "Message Code Match Enable" bit of the "iATU Control 2 Register" is set. Memory TLPs: (ST;Steering Tag). When the ST field of an inbound TLP is matched to this value, then address translation proceeds. This check is only performed if the "ST Match Enable" bit of the "iATU Control2 Register" is set. The setting is independent of the setting of the TH field. Note: This register field is sticky.

11.3.3.1.153 iATU Lower Base Address Register. (IATU_LWR_BASE_ADDR_OFF_INBOUND_1)

11.3.3.1.153.1 Offset

Register	Offset
IATU_LWR_BASE_ADDR_OFF_INBOUND_1	8000_0308h

11.3.3.1.153.2 Function

iATU Lower Base Address Register. The Minimum Size of iATU Region (Value Range: 4 kB, 8 kB, 16 kB, 32 kB, 64 kB defaults to 64 kB) specifies the minimum size of an address translation region. For example, if set to 64 kB; the lower 16 bits of the Base, Limit and Target registers are zero and all address regions are aligned on 64 kB boundaries. More precisely, the lower log2(Minimum Size of iATU Region) bits are zero.

11.3.3.1.153.3 Diagram

11.3.3.1.153.4 Fields

Field	Function
31-16 LWR_BASE_R W	Forms bits [31:n] of the start address of the address region to be translated. n is log2(Minimum Size of iATU Region) Note: This register field is sticky.
15-0 LWR_BASE_H W	Forms bits [n-1:0] of the start address of the address region to be translated. The start address must be aligned to the Minimum Size of iATU Region kB boundary, so these bits are always 0. A write to this location is ignored by the PCIe controller. n is log2(Minimum Size of iATU Region)

11.3.3.1.154 iATU Upper Base Address Register. (IATU_UPPER_BASE_ADDR_OFF_INBOUND_1)

11.3.3.1.154.1 Offset

Register	Offset
IATU_UPPER_BASE_ADDR_OFF_INBOUND_1	8000_030Ch

11.3.3.1.156.3 Fields

Field	Function
31-16 LWR_TARGET_RW	Forms MSB's of the Lower Target part of the new address of the translated region. These bits are always '0'. - Field size depends on log2(Minimum Size of iATU Region) in address match mode. - Field size depends on log2(BAR_MASK+1) in BAR match mode. Note: This register field is sticky.

Table continues on the next page...

PCI Express (PCIe)

Field	Function
15-0 LWR_TARGET_HW	Forms the LSB's of the Lower Target part of the new address of the translated region. The start address must be aligned to the Minimum Size of iATU Region kB boundary (in address match mode); and to the Bar size boundary (in BAR match mode) so that these bits are always '0'. If the BAR is smaller than the iATU region size, then the iATU target address must align to the iATU region size; otherwise it must align to the BAR size. A write to this location is ignored by the PCIe controller. - Field size depends on log2(Minimum Size of iATU Region) in address match mode. - Field size depends on log2(BAR_MASK +1) in BAR match mode.

11.3.3.1.157 iATU Region Control 1 Register. (IATU_REGION_CTRL_1_OFF_OUTBOUND_2)

Register	Offset
IATU_REGION_CTRL_1_OFF_OUTBOUND_2	8000_0400h

11.3.3.1.157.2 Diagram

11.3.3.1.157.3 Fields

Field	Function
31-23 —	Reserved.
22-20 CTRL_1_FUNC_NUM	Function Number. - When the address of an outbound TLP is matched to this region and the FUNC_BYPASS field in the "iATU Control 2 Register" is '0', then the function number used in generating the function part of the requester ID (RID) field of the TLP is taken from this 5-bit register. When you are using the AXI Bridge, then this field is swapped before AXI decomposition occurs so that the correct "Max_Read_Request_Size" and "Max_Payload_Size" values are used. Note: This register field is sticky.
19-14 —	Reserved.
13 INCREASE_REGION_SIZE	Increase the maximum ATU Region size. When set, the size is determined by the Maximum Size of iATU Region. When clear, the maximum ATU Region size is 4 GB (default). Note: This register field is sticky.
12-11 —	Reserved.
10-9 ATTR	When the address of an outbound TLP is matched to this region, then the ATTR field of the TLP is changed to the value in this register. Note: This register field is sticky.
8 TD	When the address of an outbound TLP is matched to this region, then the TD field of the TLP is changed to the value in this register. Note: This register field is sticky.
7-5 TC	When the address of an outbound TLP is matched to this region, then the TC field of the TLP is changed to the value in this register. Note: This register field is sticky.
4-0 TYPE	When the address of an outbound TLP is matched to this region, then the TYPE field of the TLP is changed to the value in this register. Note: This register field is sticky.

11.3.3.1.158 iATU Region Control 2 Register. (IATU_REGION_CTRL_2_OFF_OUTBOUND_2)

11.3.3.1.158.1 Offset

Register	Offset
IATU_REGION_CTRL_2_OFF_OUTBOUND_2	8000_0404h

11.3.3.1.158.2 Diagram

11.3.3.1.158.3 Fields

Field	Function
31 REGION_EN	Region Enable. This bit must be set to '1' for address translation to take place. Note: This register field is sticky.
30 —	Reserved.
29 INVERT_MODE	Invert Mode. When set the address matching region is inverted. Therefore, an address match occurs when the untranslated address is in the region outside the defined range (Base Address to Limit Address). Note: This register field is sticky.
28 CFG_SHIFT_MODE	CFG Shift Mode. The iATU uses bits [27:12] of the untranslated address (on the XALI0/1/2 interface or AXI slave interface address) to form the BDF number of the outgoing CFG TLP. This supports the Enhanced Configuration Address Mapping (ECAM) mechanism (Section 7.2.2 of the PCI Express Base 3.1 Specification, revision 1.0) by allowing all outgoing I/O and MEM TLPs (that have been translated to CFG) to be mapped from memory space into any 256 MB region of the PCIe configuration space. Note: This register field is sticky.
27 DMA_BYPASS	DMA Bypass Mode. Allows request TLPs which are initiated by the DMA controller to pass through the iATU untranslated. Note: This field is reserved for the SW product. You must set it to '0'. Note: This register field is sticky.
26-24 —	Reserved.
23 HEADER_SUBSTITUTE_EN	Header Substitute Enable. When enabled and region address is matched, the iATU fully substitutes bytes 8-11 (for 3 DWORD header) or bytes 12-15 (for 4 DWORD header) of the outbound TLP header with the contents of the LWR_TARGET_RW field in IATU_LWR_TARGET_ADDR_OFF_OUTBOUND_i. - 1: LWR_TARGET_RW in the iATU_LWR_TARGET_ADDR_OFF_OUTBOUND_i register is used to fill bytes 8-to-11 (for 3 DWORD header) or bytes 12-to-15 (for 4 DWORD header) of the translated TLP header. - 0: LWR_TARGET_RW in the iATU_LWR_TARGET_ADDR_OFF_OUTBOUND_i register forms the new address of the translated region. Note: This register field is sticky.

Table continues on the next page...

Field	Function
22 INHIBIT_PAYLOAD_AD	Inhibit TLP Payload Data for TLP's in Matched Region; assign iATU region to be TLP without data. When enabled and region address is matched, the iATU marks all TLPs as having no payload data by forcing the TLP header Fmt[1] bit =0, regardless of the application inputs such as slv_wstrb. - 1: Fmt[1] =0 so that only TLP type without data is sent. For example, a Msg instead of MsgD will be sent. - 0: Fmt[1] =0/1 so that TLPs with or without data can be sent. Note: This register field is sticky.
21 —	Reserved.
20 SNP	Serialize Non-Posted Requests. In this mode, when the AXI Bridge is populated, same AXI ID Non-Posted Read/Write Requests are transmitted on the wire if there are no other same ID Non-Posted Requests outstanding. Note: This register field is sticky.
19 FUNC_BYPASS	Function Number Translation Bypass. In this mode, the function number of the translated TLP is taken from your application transmit interface and not from the CTRL_1_FUNC_NUM field of the "iATU Control 1 Register" or the VF_NUMBER field of the "iATU Control 3 Register." Note: This register field is sticky.
18-17 —	Reserved.
16 TAG_SUBSTITUTE_EN	TAG Substitute Enable. When enabled and region address is matched, the iATU substitutes the TAG field of the outbound TLP header with the contents of the TAG field in this register. The expected usage scenario is translation from AXI MWr to Vendor Defined Msg/MsgD. Note: This register field is sticky.
15-8 TAG	TAG. The substituted TAG field (byte 6) in the outgoing TLP header when TAG_SUBSTITUTE_EN is set. Note: This register field is sticky.
7-0 MSG_CODE	MSG TLPs (Message Code). When the address of an outbound TLP is matched to this region, and the translated TLP TYPE field is Msg or MsgD; then the message field of the TLP is changed to the value in this register. Memory TLPs: (ST;Steering Tag). When the ST field of an outbound TLP is matched to this region, and the translated TLP TYPE field targets memory space; then the ST field of the TLP is changed to the value in this register. Note: This register field is sticky.

11.3.3.1.159 iATU Lower Base Address Register. (IATU_LWR_BASE_ADDR_OFF_OUTBOUND_2)

11.3.3.1.159.1 Offset

Register	Offset
IATU_LWR_BASE_ADDR_OFF_OUTBOUND_2	8000_0408h

11.3.3.1.159.2 Function

iATU Lower Base Address Register. The Minimum Size of iATU Region (Value Range: 4 kB, 8 kB, 16 kB, 32 kB, 64 kB defaults to 64 kB) specifies the minimum size of an address translation region. For example, if set to 64 kB; the lower 16 bits of the Base, Limit and Target registers are zero and all address regions are aligned on 64 kB boundaries. More precisely, the lower $\log_2(\text{Minimum Size of iATU Region})$ bits are zero.

11.3.3.1.159.3 Diagram

11.3.3.1.159.4 Fields

Field	Function
31-16 LWR_BASE_R W	Forms bits [31:n] of the start address of the address region to be translated. n is log2(Minimum Size of iATU Region) Note: This register field is sticky.
15-0 LWR_BASE_H W	Forms bits [n-1:0] of the start address of the address region to be translated. The start address must be aligned to the Minimum Size of iATU Region kB boundary, so these bits are always 0. A write to this location is ignored by the PCIe controller. n is log2(Minimum Size of iATU Region)

11.3.3.1.160 iATU Upper Base Address Register. (IATU_UPPER_BASE_ADDR_OFF_OUTBOUND_2)

11.3.3.1.160.1 Offset

Register	Offset
IATU_UPPER_BASE_ADDR_OFF_OUTBOUND_2	8000_040Ch

11.3.3.1.160.2 Diagram

11.3.3.1.160.3 Fields

Field	Function
31-0 UPPER_BASE_ RW	Forms bits [63:32] of the start (and end) address of the address region to be translated. In systems with a 32-bit address space, this register is not used and therefore writing to this register has no effect. Note: This register field is sticky.

11.3.3.1.161 iATU Limit Address Register. (IATU_LIMIT_ADDR_OFF_OUTBOUND_2)

11.3.3.1.161.1 Offset

Register	Offset
IATU_LIMIT_ADDR_OFF_OUTBOUND_2	8000_0410h

11.3.3.1.164.3 Fields

Field	Function
31-23 —	Reserved.
22-20 CTRL_1_FUNC_NUM	Function Number. - MEM-I/O: When the Address and BAR matching logic in the controller indicate that a MEM-I/O transaction matches a BAR in the function corresponding to this value, then address translation proceeds. This check is only performed if the "Function Number Match Enable" bit of the "iATU Control 2 Register" is set. - CFG0/CFG1: When the destination function number as specified in the routing ID of the TLP header matches the function, then address translation proceeds. This check is only performed if the

Table continues on the next page...

Field	Function
	"Function Number Match Enable" bit of the "iATU Control 2 Register" is set. Note: This register field is sticky.
19-14 —	Reserved.
13 INCREASE_REGION_SIZE	Increase the maximum ATU Region size. When set, the size is determined by the Maximum Size of iATU Region. When clear, the maximum ATU Region size is 4 GB (default). Note: This register field is sticky.
12-11 —	Reserved.
10-9 ATTR	When the ATTR field of an inbound TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "ATTR Match Enable" bit of the "iATU Control 2 Register" is set. Note: This register field is sticky.
8 TD	When the TD field of an inbound TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "TD Match Enable" bit of the "iATU Control 2 Register" is set. Note: This register field is sticky.
7-5 TC	When the TC field of an inbound TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "TC Match Enable" bit of the "iATU Control 2 Register" is set. Note: This register field is sticky.
4-0 TYPE	When the TYPE field of an inbound TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). Note: This register field is sticky.

11.3.3.1.165 iATU Region Control 2 Register. (IATU_REGION_CTRL_2_OFFSET_INBOUND_2)

11.3.3.1.165.1 Offset

Register	Offset
IATU_REGION_CTRL_2_OFFSET_INBOUND_2	8000_0504h

11.3.3.1.165.2 Diagram

11.3.3.1.165.3 Fields

Field	Function
31 REGION_EN	Region Enable. This bit must be set to '1' for address translation to take place. Note: This register field is sticky.
30 MATCH_MODE	Match Mode. Determines Inbound matching mode for TLPs. The mode depends on the type of TLP that is received as follows: For MEM-I/O TLPs, this field is interpreted as follows: - 0: Address Match Mode. The iATU operates using addresses as in the outbound direction. The Region Base and Limit Registers must be setup. - 1: BAR Match Mode. BAR matching is used. The "BAR Number" field is relevant. Not used for RC. For CFG0 TLPs, this field is interpreted as follows: - 0: Routing ID Match Mode. The iATU interprets the Routing ID (Bytes 8 to 11 of TLP header) as an address. This corresponds to the upper 16 bits of the address in MEM-I/O transactions. The Routing ID of the TLP must be within the base and limit of the iATU region for matching to proceed. - 1: Accept Mode. The iATU accepts all CFG0 transactions as address matches. The routing ID in the CFG0 TLP is ignored. This is useful as all received CFG0 TLPs should be processed regardless of the Bus number. For MSG/MSGD TLPs, this field is interpreted as follows: - 0: Address Match Mode. The iATU treats the third dword and fourth dword of the inbound MSG/MSGD TLP as an address and it is matched against the Region Base and Limit Registers. - 1: Vendor ID Match Mode. This mode is relevant for ID-routed Vendor Defined Messages. The iATU ignores the Routing ID (Bus, Device, Function) in bits [31:16] of the third dword of the TLP header, but matches

Table continues on the next page...

Field	Function
	against the Vendor ID in bits [15:0] of the third dword of the TLP header. Bits [15:0] of the Region Upper Base register should be programmed with the required Vendor ID. The lower Base and Limit Register should be programmed to translate TLPs based on vendor specific information in the fourth dword of the TLP header. - If SINGLE_ADDRESS_LOCATION_TRANSLATE_EN = 1 AND MSG_TYPE_MATCH_MODE = 1, then Match Mode is ignored. Note: This register field is sticky.
29 INVERT_MODE	Invert Mode. When set the address matching region is inverted. Therefore, an address match occurs when the untranslated address is in the region outside the defined range (Base Address to Limit Address). Note: This register field is sticky.
28 CFG_SHIFT_MODE	CFG Shift Mode. This is useful for CFG transactions where the PCIe configuration mechanism maps bits [27:12] of the address to the bus/device and function number. This allows a CFG configuration space to be located in any 256MB window of your application memory space using a 28-bit effective address. Shifts bits [31:16] of the untranslated address to form bits [27:12] of the translated address. Note: This register field is sticky.
27 FUZZY_TYPE_MATCH_CODE	Fuzzy Type Match Mode. When enabled, the iATU relaxes the matching of the TLP TYPE field against the expected TYPE field so that - CfgRd0 and CfgRd1 TLPs are seen as identical. Similarly with CfgWr0 and CfgWr1. - MWr, MRd and MRdLk TLPs are seen as identical - The Routing field of Msg/MsgD TLPs is ignored - FetchAdd, Swap and CAS are seen as identical. For example, CFG0 in the TYPE field in the "iATU Control 1 Register" matches against an inbound CfgRd0, CfgRd1, CfgWr0 or CfgWr1 TLP. Note: This register field is sticky.
26 —	Reserved.
25-24 RESPONSE_CODE	Response Code. Defines the type of response to give for accesses matching this region. This overrides the normal RADM filter response. Note that this feature is not available for any region where Single Address Location Translate is enabled. - 00 - Normal RADM filter response is used. - 01 - Unsupported request (UR) - 10 - Completer abort (CA) - 11 - Not used / undefined / reserved. Note: This register field is sticky.
23 SINGLE_ADDR_LOC_TRANSLATE_EN	Single Address Location Translate Enable. When enabled, Rx TLPs can be translated to a single address location as determined by the target address register of the iATU region. The main usage scenario is translation of Messages (such as Vendor Defined or ATS Messages) to MWr TLPs when the AXI bridge is enabled. Note: This register field is sticky.
22 —	Reserved.
21 MSG_CODE_MATCH_EN	Message Code Match Enable (Msg TLPS). Ensures that a successful message Code TLP field comparison match (see Message Code field of the "iATU Control 2 Register") occurs (in MSG transactions) for address translation to proceed. ST Match Enable (Mem TLPS). Ensures that a successful ST TLP field comparison match (see ST field of the "iATU Control 2 Register") occurs (in MEM transactions) for address translation to proceed. Note: This register field is sticky.
20 —	Reserved.
19 FUNC_NUM_MATCH_EN	Function Number Match Enable. Ensures that a successful Function Number TLP field comparison match (see Function Number field of the "iATU Control 1 Register") occurs (in MEM-I/O and CFG0/CFG1 transactions) for address translation to proceed. Note: This register field is sticky.
18-17 —	Reserved.
16 ATTR_MATCH_EN	ATTR Match Enable. Ensures that a successful ATTR TLP field comparison match (see ATTR field of the "iATU Control 1 Register") occurs for address translation to proceed. Note: This register field is sticky.

Table continues on the next page...

Field	Function
15 TD_MATCH_EN	TD Match Enable. Ensures that a successful TD TLP field comparison match (see TD field of the "iATU Control 1 Register") occurs for address translation to proceed. Note: This register field is sticky.
14 TC_MATCH_EN	TC Match Enable. Ensures that a successful TC TLP field comparison match (see TC field of the "iATU Control 1 Register") occurs for address translation to proceed. Note: This register field is sticky.
13 MSG_TYPE_MATCH_MODE	Message Type Match Mode. When enabled, and if single address location translate enable is set, then inbound TLPs of type MSG/MSGd which match the type field of the iatu_region_ctrl_1_OFF_inbound register (=>TYPE[4:3]=2'b10) will be translated. Message type match mode overrides any value of MATCH_MODE field in this register. Usage scenarios for this are translation of VDM or ATS messages when AXI bridge is configured on client interface. Note: This register field is sticky.
12-11 —	Reserved.
10-8 BAR_NUM	BAR Number. When the BAR number of an inbound MEM or IO TLP " that is matched by the normal internal BAR address matching mechanism " is the same as this field, address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "Match Mode" bit of the "iATU Control 2 Register" is set. - 000b - BAR0 - 001b - BAR1 - 010b - BAR2 - 011b - BAR3 - 100b - BAR4 - 101b - BAR5 - 110b - ROM - 111b - reserved - IO translation would require either 00100b or 00101b in the inbound TLP TYPE; the BAR Number set in the range 000b - 101b and that BAR configured as an IO BAR. Note: This register field is sticky.
7-0 MSG_CODE	MSG TLPs: (Message Code). When the TYPE field of an inbound Msg/MsgD TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "Message Code Match Enable" bit of the "iATU Control 2 Register" is set. Memory TLPs: (ST;Steering Tag). When the ST field of an inbound TLP is matched to this value, then address translation proceeds. This check is only performed if the "ST Match Enable" bit of the "iATU Control2 Register" is set. The setting is independent of the setting of the TH field. Note: This register field is sticky.

11.3.3.1.166 iATU Lower Base Address Register. (IATU_LWR_BASE_ADDR_OFF_INBOUND_2)

11.3.3.1.166.1 Offset

Register	Offset
IATU_LWR_BASE_ADDR_OFF_INBOUND_2	8000_0508h

11.3.3.1.166.2 Function

iATU Lower Base Address Register. The Minimum Size of iATU Region (Value Range: 4 kB, 8 kB, 16 kB, 32 kB, 64 kB defaults to 64 kB) specifies the minimum size of an address translation region. For example, if set to 64 kB; the lower 16 bits of the Base, Limit and Target registers are zero and all address regions are aligned on 64 kB boundaries. More precisely, the lower log2(Minimum Size of iATU Region) bits are zero.

11.3.3.1.166.3 Diagram

11.3.3.1.166.4 Fields

Field	Function
31-16 LWR_BASE_R W	Forms bits [31:n] of the start address of the address region to be translated. n is log2(Minimum Size of iATU Region) Note: This register field is sticky.
15-0 LWR_BASE_H W	Forms bits [n-1:0] of the start address of the address region to be translated. The start address must be aligned to the Minimum Size of iATU Region kB boundary, so these bits are always 0. A write to this location is ignored by the PCIe controller. n is log2(Minimum Size of iATU Region)

11.3.3.1.167 iATU Upper Base Address Register. (IATU_UPPER_BASE_ADDR_OFF_INBOUND_2)

11.3.3.1.169.3 Fields

Field	Function
31-16 LWR_TARGET_RW	Forms MSB's of the Lower Target part of the new address of the translated region. These bits are always '0'. - Field size depends on log2(Minimum Size of iATU Region) in address match mode. - Field size depends on log2(BAR_MASK+1) in BAR match mode. Note: This register field is sticky.

Table continues on the next page...

PCI Express (PCIe)

Field	Function
15-0 LWR_TARGET_HW	Forms the LSB's of the Lower Target part of the new address of the translated region. The start address must be aligned to the Minimum Size of iATU Region kB boundary (in address match mode); and to the Bar size boundary (in BAR match mode) so that these bits are always '0'. If the BAR is smaller than the iATU region size, then the iATU target address must align to the iATU region size; otherwise it must align to the BAR size. A write to this location is ignored by the PCIe controller. - Field size depends on log2(Minimum Size of iATU Region) in address match mode. - Field size depends on log2(BAR_MASK +1) in BAR match mode.

IATU_REGION_CTRL_1_OFF_OUTBOUND_3	8000_0600h

11.3.3.1.170.2 Diagram

11.3.3.1.170.3 Fields

Field	Function
31-23 —	Reserved.
22-20 CTRL_1_FUNC_NUM	Function Number. - When the address of an outbound TLP is matched to this region and the FUNC_BYPASS field in the "iATU Control 2 Register" is '0', then the function number used in generating the function part of the requester ID (RID) field of the TLP is taken from this 5-bit register. When you are using the AXI Bridge, then this field is swapped before AXI decomposition occurs so that the correct "Max_Read_Request_Size" and "Max_Payload_Size" values are used. Note: This register field is sticky.
19-14 —	Reserved.
13 INCREASE_REGION_SIZE	Increase the maximum ATU Region size. When set, the size is determined by the Maximum Size of iATU Region. When clear, the maximum ATU Region size is 4 GB (default). Note: This register field is sticky.
12-11 —	Reserved.
10-9 ATTR	When the address of an outbound TLP is matched to this region, then the ATTR field of the TLP is changed to the value in this register. Note: This register field is sticky.
8 TD	When the address of an outbound TLP is matched to this region, then the TD field of the TLP is changed to the value in this register. Note: This register field is sticky.
7-5 TC	When the address of an outbound TLP is matched to this region, then the TC field of the TLP is changed to the value in this register. Note: This register field is sticky.
4-0 TYPE	When the address of an outbound TLP is matched to this region, then the TYPE field of the TLP is changed to the value in this register. Note: This register field is sticky.

11.3.3.1.171 iATU Region Control 2 Register. (IATU_REGION_CTRL_2_OFF_OUTBOUND_3)

11.3.3.1.171.1 Offset

Register	Offset
IATU_REGION_CTRL_2_OFF_OUTBOUND_3	8000_0604h

11.3.3.1.171.2 Diagram

11.3.3.1.171.3 Fields

Field	Function
31 REGION_EN	Region Enable. This bit must be set to '1' for address translation to take place. Note: This register field is sticky.
30 —	Reserved.
29 INVERT_MODE	Invert Mode. When set the address matching region is inverted. Therefore, an address match occurs when the untranslated address is in the region outside the defined range (Base Address to Limit Address). Note: This register field is sticky.
28 CFG_SHIFT_MODE	CFG Shift Mode. The iATU uses bits [27:12] of the untranslated address (on the XALI0/1/2 interface or AXI slave interface address) to form the BDF number of the outgoing CFG TLP. This supports the Enhanced Configuration Address Mapping (ECAM) mechanism (Section 7.2.2 of the PCI Express Base 3.1 Specification, revision 1.0) by allowing all outgoing I/O and MEM TLPs (that have been translated to CFG) to be mapped from memory space into any 256 MB region of the PCIe configuration space. Note: This register field is sticky.
27 DMA_BYPASS	DMA Bypass Mode. Allows request TLPs which are initiated by the DMA controller to pass through the iATU untranslated. Note: This field is reserved for the SW product. You must set it to '0'. Note: This register field is sticky.
26-24 —	Reserved.
23 HEADER_SUBSTITUTE_EN	Header Substitute Enable. When enabled and region address is matched, the iATU fully substitutes bytes 8-11 (for 3 DWORD header) or bytes 12-15 (for 4 DWORD header) of the outbound TLP header with the contents of the LWR_TARGET_RW field in IATU_LWR_TARGET_ADDR_OFF_OUTBOUND_i. - 1: LWR_TARGET_RW in the iATU_LWR_TARGET_ADDR_OFF_OUTBOUND_i register is used to fill bytes 8-to-11 (for 3 DWORD header) or bytes 12-to-15 (for 4 DWORD header) of the translated TLP header. - 0: LWR_TARGET_RW in the iATU_LWR_TARGET_ADDR_OFF_OUTBOUND_i register forms the new address of the translated region. Note: This register field is sticky.

Table continues on the next page...

Field	Function
22 INHIBIT_PAYLOAD_AD	Inhibit TLP Payload Data for TLP's in Matched Region; assign iATU region to be TLP without data. When enabled and region address is matched, the iATU marks all TLPs as having no payload data by forcing the TLP header Fmt[1] bit =0, regardless of the application inputs such as slv_wstrb. - 1: Fmt[1] =0 so that only TLP type without data is sent. For example, a Msg instead of MsgD will be sent. - 0: Fmt[1] =0/1 so that TLPs with or without data can be sent. Note: This register field is sticky.
21 —	Reserved.
20 SNP	Serialize Non-Posted Requests. In this mode, when the AXI Bridge is populated, same AXI ID Non-Posted Read/Write Requests are transmitted on the wire if there are no other same ID Non-Posted Requests outstanding. Note: This register field is sticky.
19 FUNC_BYPASS	Function Number Translation Bypass. In this mode, the function number of the translated TLP is taken from your application transmit interface and not from the CTRL_1_FUNC_NUM field of the "iATU Control 1 Register" or the VF_NUMBER field of the "iATU Control 3 Register." Note: This register field is sticky.
18-17 —	Reserved.
16 TAG_SUBSTITUTE_EN	TAG Substitute Enable. When enabled and region address is matched, the iATU substitutes the TAG field of the outbound TLP header with the contents of the TAG field in this register. The expected usage scenario is translation from AXI MWr to Vendor Defined Msg/MsgD. Note: This register field is sticky.
15-8 TAG	TAG. The substituted TAG field (byte 6) in the outgoing TLP header when TAG_SUBSTITUTE_EN is set. Note: This register field is sticky.
7-0 MSG_CODE	MSG TLPs (Message Code). When the address of an outbound TLP is matched to this region, and the translated TLP TYPE field is Msg or MsgD; then the message field of the TLP is changed to the value in this register. Memory TLPs: (ST;Steering Tag). When the ST field of an outbound TLP is matched to this region, and the translated TLP TYPE field targets memory space; then the ST field of the TLP is changed to the value in this register. Note: This register field is sticky.

11.3.3.1.172 iATU Lower Base Address Register. (IATU_LWR_BASE_ADDR_OFF_OUTBOUND_3)

11.3.3.1.172.1 Offset

Register	Offset
IATU_LWR_BASE_ADDR_OFF_OUTBOUND_3	8000_0608h

11.3.3.1.172.2 Function

iATU Lower Base Address Register. The Minimum Size of iATU Region (Value Range: 4 kB, 8 kB, 16 kB, 32 kB, 64 kB defaults to 64 kB) specifies the minimum size of an address translation region. For example, if set to 64 kB; the lower 16 bits of the Base, Limit and Target registers are zero and all address regions are aligned on 64 kB boundaries. More precisely, the lower $\log_2(\text{Minimum Size of iATU Region})$ bits are zero.

11.3.3.1.172.3 Diagram

11.3.3.1.172.4 Fields

Field	Function
31-16 LWR_BASE_R W	Forms bits [31:n] of the start address of the address region to be translated. n is log2(Minimum Size of iATU Region) Note: This register field is sticky.
15-0 LWR_BASE_H W	Forms bits [n-1:0] of the start address of the address region to be translated. The start address must be aligned to the Minimum Size of iATU Region kB boundary, so these bits are always 0. A write to this location is ignored by the PCIe controller. n is log2(Minimum Size of iATU Region)

11.3.3.1.173 iATU Upper Base Address Register. (IATU_UPPER_BASE_ADDR_OFF_OUTBOUND_3)

11.3.3.1.173.1 Offset

Register	Offset
IATU_UPPER_BASE_ADDR_OFF_OUTBOUND_3	8000_060Ch

11.3.3.1.177.3 Fields

Field	Function
31-23 —	Reserved.
22-20 CTRL_1_FUNC_NUM	Function Number. - MEM-I/O: When the Address and BAR matching logic in the controller indicate that a MEM-I/O transaction matches a BAR in the function corresponding to this value, then address translation proceeds. This check is only performed if the "Function Number Match Enable" bit of the "iATU Control 2 Register" is set. - CFG0/CFG1: When the destination function number as specified in the routing ID of the TLP header matches the function, then address translation proceeds. This check is only performed if the

Table continues on the next page...

Field	Function
	"Function Number Match Enable" bit of the "iATU Control 2 Register" is set. Note: This register field is sticky.
19-14 —	Reserved.
13 INCREASE_REGION_SIZE	Increase the maximum ATU Region size. When set, the size is determined by the Maximum Size of iATU Region. When clear, the maximum ATU Region size is 4 GB (default). Note: This register field is sticky.
12-11 —	Reserved.
10-9 ATTR	When the ATTR field of an inbound TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "ATTR Match Enable" bit of the "iATU Control 2 Register" is set. Note: This register field is sticky.
8 TD	When the TD field of an inbound TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "TD Match Enable" bit of the "iATU Control 2 Register" is set. Note: This register field is sticky.
7-5 TC	When the TC field of an inbound TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "TC Match Enable" bit of the "iATU Control 2 Register" is set. Note: This register field is sticky.
4-0 TYPE	When the TYPE field of an inbound TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). Note: This register field is sticky.

11.3.3.1.178 iATU Region Control 2 Register. (IATU_REGION_CTRL_2_OFF_INBOUND_3)

11.3.3.1.178.1 Offset

Register	Offset
IATU_REGION_CTRL_2_OFF_INBOUND_3	8000_0704h

11.3.3.1.178.2 Diagram

11.3.3.1.178.3 Fields

Field	Function
31 REGION_EN	Region Enable. This bit must be set to '1' for address translation to take place. Note: This register field is sticky.
30 MATCH_MODE	Match Mode. Determines Inbound matching mode for TLPs. The mode depends on the type of TLP that is received as follows: For MEM-I/O TLPs, this field is interpreted as follows: - 0: Address Match Mode. The iATU operates using addresses as in the outbound direction. The Region Base and Limit Registers must be setup. - 1: BAR Match Mode. BAR matching is used. The "BAR Number" field is relevant. Not used for RC. For CFG0 TLPs, this field is interpreted as follows: - 0: Routing ID Match Mode. The iATU interprets the Routing ID (Bytes 8 to 11 of TLP header) as an address. This corresponds to the upper 16 bits of the address in MEM-I/O transactions. The Routing ID of the TLP must be within the base and limit of the iATU region for matching to proceed. - 1: Accept Mode. The iATU accepts all CFG0 transactions as address matches. The routing ID in the CFG0 TLP is ignored. This is useful as all received CFG0 TLPs should be processed regardless of the Bus number. For MSG/MSGD TLPs, this field is interpreted as follows: - 0: Address Match Mode. The iATU treats the third dword and fourth dword of the inbound MSG/MSGD TLP as an address and it is matched against the Region Base and Limit Registers. - 1: Vendor ID Match Mode. This mode is relevant for ID-routed Vendor Defined Messages. The iATU ignores the Routing ID (Bus, Device, Function) in bits [31:16] of the third dword of the TLP header, but matches

Table continues on the next page...

Field	Function
	against the Vendor ID in bits [15:0] of the third dword of the TLP header. Bits [15:0] of the Region Upper Base register should be programmed with the required Vendor ID. The lower Base and Limit Register should be programmed to translate TLPs based on vendor specific information in the fourth dword of the TLP header. - If SINGLE_ADDRESS_LOCATION_TRANSLATE_EN = 1 AND MSG_TYPE_MATCH_MODE = 1, then Match Mode is ignored. Note: This register field is sticky.
29 INVERT_MODE	Invert Mode. When set the address matching region is inverted. Therefore, an address match occurs when the untranslated address is in the region outside the defined range (Base Address to Limit Address). Note: This register field is sticky.
28 CFG_SHIFT_MODE	CFG Shift Mode. This is useful for CFG transactions where the PCIe configuration mechanism maps bits [27:12] of the address to the bus/device and function number. This allows a CFG configuration space to be located in any 256MB window of your application memory space using a 28-bit effective address. Shifts bits [31:16] of the untranslated address to form bits [27:12] of the translated address. Note: This register field is sticky.
27 FUZZY_TYPE_MATCH_CODE	Fuzzy Type Match Mode. When enabled, the iATU relaxes the matching of the TLP TYPE field against the expected TYPE field so that - CfgRd0 and CfgRd1 TLPs are seen as identical. Similarly with CfgWr0 and CfgWr1. - MWr, MRd and MRdLk TLPs are seen as identical - The Routing field of Msg/MsgD TLPs is ignored - FetchAdd, Swap and CAS are seen as identical. For example, CFG0 in the TYPE field in the "iATU Control 1 Register" matches against an inbound CfgRd0, CfgRd1, CfgWr0 or CfgWr1 TLP. Note: This register field is sticky.
26 —	Reserved.
25-24 RESPONSE_CODE	Response Code. Defines the type of response to give for accesses matching this region. This overrides the normal RADM filter response. Note that this feature is not available for any region where Single Address Location Translate is enabled. - 00 - Normal RADM filter response is used. - 01 - Unsupported request (UR) - 10 - Completer abort (CA) - 11 - Not used / undefined / reserved. Note: This register field is sticky.
23 SINGLE_ADDR_LOC_TRANSLATE_EN	Single Address Location Translate Enable. When enabled, Rx TLPs can be translated to a single address location as determined by the target address register of the iATU region. The main usage scenario is translation of Messages (such as Vendor Defined or ATS Messages) to MWr TLPs when the AXI bridge is enabled. Note: This register field is sticky.
22 —	Reserved.
21 MSG_CODE_MATCH_EN	Message Code Match Enable (Msg TLPS). Ensures that a successful message Code TLP field comparison match (see Message Code field of the "iATU Control 2 Register") occurs (in MSG transactions) for address translation to proceed. ST Match Enable (Mem TLPS). Ensures that a successful ST TLP field comparison match (see ST field of the "iATU Control 2 Register") occurs (in MEM transactions) for address translation to proceed. Note: This register field is sticky.
20 —	Reserved.
19 FUNC_NUM_MATCH_EN	Function Number Match Enable. Ensures that a successful Function Number TLP field comparison match (see Function Number field of the "iATU Control 1 Register") occurs (in MEM-I/O and CFG0/CFG1 transactions) for address translation to proceed. Note: This register field is sticky.
18-17 —	Reserved.
16 ATTR_MATCH_EN	ATTR Match Enable. Ensures that a successful ATTR TLP field comparison match (see ATTR field of the "iATU Control 1 Register") occurs for address translation to proceed. Note: This register field is sticky.

Table continues on the next page...

Field	Function
15 TD_MATCH_EN	TD Match Enable. Ensures that a successful TD TLP field comparison match (see TD field of the "iATU Control 1 Register") occurs for address translation to proceed. Note: This register field is sticky.
14 TC_MATCH_EN	TC Match Enable. Ensures that a successful TC TLP field comparison match (see TC field of the "iATU Control 1 Register") occurs for address translation to proceed. Note: This register field is sticky.
13 MSG_TYPE_MATCH_MODE	Message Type Match Mode. When enabled, and if single address location translate enable is set, then inbound TLPs of type MSG/MSGd which match the type field of the iatu_region_ctrl_1_OFF_inbound register (=>TYPE[4:3]=2'b10) will be translated. Message type match mode overrides any value of MATCH_MODE field in this register. Usage scenarios for this are translation of VDM or ATS messages when AXI bridge is configured on client interface. Note: This register field is sticky.
12-11 —	Reserved.
10-8 BAR_NUM	BAR Number. When the BAR number of an inbound MEM or IO TLP " that is matched by the normal internal BAR address matching mechanism " is the same as this field, address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "Match Mode" bit of the "iATU Control 2 Register" is set. - 000b - BAR0 - 001b - BAR1 - 010b - BAR2 - 011b - BAR3 - 100b - BAR4 - 101b - BAR5 - 110b - ROM - 111b - reserved - IO translation would require either 00100b or 00101b in the inbound TLP TYPE; the BAR Number set in the range 000b - 101b and that BAR configured as an IO BAR. Note: This register field is sticky.
7-0 MSG_CODE	MSG TLPs: (Message Code). When the TYPE field of an inbound Msg/MsgD TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "Message Code Match Enable" bit of the "iATU Control 2 Register" is set. Memory TLPs: (ST;Steering Tag). When the ST field of an inbound TLP is matched to this value, then address translation proceeds. This check is only performed if the "ST Match Enable" bit of the "iATU Control2 Register" is set. The setting is independent of the setting of the TH field. Note: This register field is sticky.

11.3.3.1.179 iATU Lower Base Address Register. (IATU_LWR_BASE_ADDR_OFF_INBOUND_3)

11.3.3.1.179.1 Offset

Register	Offset
IATU_LWR_BASE_ADDR_OFF_INBOUND_3	8000_0708h

11.3.3.1.179.2 Function

iATU Lower Base Address Register. The Minimum Size of iATU Region (Value Range: 4 kB, 8 kB, 16 kB, 32 kB, 64 kB defaults to 64 kB) specifies the minimum size of an address translation region. For example, if set to 64 kB; the lower 16 bits of the Base, Limit and Target registers are zero and all address regions are aligned on 64 kB boundaries. More precisely, the lower log2(Minimum Size of iATU Region) bits are zero.

11.3.3.1.179.3 Diagram

11.3.3.1.179.4 Fields

Field	Function
31-16 LWR_BASE_R W	Forms bits [31:n] of the start address of the address region to be translated. n is log2(Minimum Size of iATU Region) Note: This register field is sticky.
15-0 LWR_BASE_H W	Forms bits [n-1:0] of the start address of the address region to be translated. The start address must be aligned to the Minimum Size of iATU Region kB boundary, so these bits are always 0. A write to this location is ignored by the PCIe controller. n is log2(Minimum Size of iATU Region)

11.3.3.1.180 iATU Upper Base Address Register. (IATU_UPPER_BASE_ADDR_OFF_INBOUND_3)

11.3.3.1.180.3 Fields

Field	Function
31-0 UPPER_BASE_ RW	Forms bits [63:32] of the start (and end) address of the address region to be translated. Note: This register field is sticky.

11.3.3.1.181 iATU Limit Address Register. (IATU_LIMIT_ADDR_OFF_INBOUND_3)

11.3.3.1.181.1 Offset

Register	Offset
IATU_LIMIT_ADDR_OFF_INBOUND_3	8000_0710h

11.3.3.1.181.2 Diagram

11.3.3.1.181.3 Fields

Field	Function
31-16 LIMIT_ADDR_R W	Forms upper bits of the end address of the address region to be translated. The end address must be aligned to the Minimum Size of iATU Region kB boundary, so these bits are always 0. A write to this location is ignored by the PCIe controller. Note: This register field is sticky.
15-0 LIMIT_ADDR_H W	Forms lower bits of the end address of the address region to be translated. The end address must be aligned to the Minimum Size of iATU Region kB boundary, so these bits are always 0. A write to this location is ignored by the PCIe controller.

11.3.3.1.182 iATU Lower Target Address Register. (IATU_LWR_TARGET_ADDR_OFF_INBOUND_3)

11.3.3.1.182.1 Offset

Register	Offset
IATU_LWR_TARGET_ADDR_OFF_INBOUND_3	8000_0714h

11.3.3.1.182.3 Fields

Field	Function
31-16 LWR_TARGET_R W	Forms MSB's of the Lower Target part of the new address of the translated region. These bits are always '0'. - Field size depends on log2(Minimum Size of iATU Region) in address match mode. - Field size depends on log2(BAR_MASK+1) in BAR match mode. Note: This register field is sticky.

Table continues on the next page...

Field	Function
15-0 LWR_TARGET_HW	Forms the LSB's of the Lower Target part of the new address of the translated region. The start address must be aligned to the Minimum Size of iATU Region kB boundary (in address match mode); and to the Bar size boundary (in BAR match mode) so that these bits are always '0'. If the BAR is smaller than the iATU region size, then the iATU target address must align to the iATU region size; otherwise it must align to the BAR size. A write to this location is ignored by the PCIe controller. - Field size depends on log2(Minimum Size of iATU Region) in address match mode. - Field size depends on log2(BAR_MASK +1) in BAR match mode.

11.3.3.1.183.1 Offset

Register	Offset
DMA_CTRL_DATA_ARB_PRIOR_OFF	8008_0000h

11.3.3.1.183.2 Function

DMA Arbitration Scheme for TRGT1 Interface. This register is used to control traffic priorities among various sources that are delivered to your application through TRGT1 where 0x0 represents the highest priority. - Non-DMA Rx Requests - DMA Write Channel MRd Requests (DMA data requests and LL element/descriptor access) - DMA Read Channel MRd Requests (LL element/descriptor access) - DMA Read Channel MWr Requests Concurrent traffic from channels with same priority are sorted according to Round-Robin arbitration rules. The arbitration priority defaults to Non-DMA requests (highest), Write Channel MRd, Read Channel MRd, Read Channel MWr.

Field	Function
31-24 RSVDP_24	Reserved for future use.
23-16 —	Reserved.
15-1 RSVDP_1	Reserved for future use.
0 DMA_WRITE_ENGINE	<p>DMA Write Engine Enable. - 1: Enable - 0: Disable (Soft Reset) For normal operation, you must initially set this bit to "1", before any other software setup actions. You do not need to toggle or rewrite to this bit during normal operation. You should set this bit to "0" when you want to "Soft Reset" the DMA controller write logic. There are three possible reasons for resetting the DMA controller write logic: - The "Abort Interrupt Status" bit is set (in the "DMA Write Interrupt Status Register" (DMA_WRITE_INT_STATUS_OFF), and any of the bits in the "DMA Write Error Status Register" (DMA_WRITE_ERR_STATUS_OFF) are set. Resetting the DMA controller write logic re-initializes the control logic, ensuring that the next DMA write transfer is executed successfully. - You have executed the procedure outlined in "Stop Bit", after which, the "Abort Interrupt Status" bit is set and the Channel Status field (CS) of the DMA write "DMA Channel Control 1 Register " (DMA_CH_CONTROL1_OFF_WRCH_0) is set to "Stopped." Resetting the DMA controller write logic re-initializes the control logic ensuring that the next DMA write transfer is executed successfully. - During software development, when you incorrectly program the DMA write engine. To "Soft Reset" the DMA controller write logic, you must: - De-assert the DMA write engine enable bit. - Wait for the DMA to complete any in-progress TLP transfer, by waiting until a read on the DMA write engine enable bit returns a "0". - Assert the DMA write engine enable bit. This "Soft Reset" does not clear the DMA configuration registers. The DMA write transfer does not start until you write to the "DMA Write Doorbell Register" (DMA_WRITE_DOORBELL_OFF). Note: The access attributes of this field are as follows: - Dbi: R/W</p>

11.3.3.1.186 DMA Write Doorbell Register. (DMA_WRITE_DOORBELL_OFF)**11.3.3.1.186.1 Offset**

Register	Offset
DMA_WRITE_DOORBELL_OFF	8008_0010h

11.3.3.1.186.2 Diagram

11.3.3.1.186.3 Fields

Field	Function
31 WR_STOP	Stop. Set in conjunction with the Doorbell Number field. The DMA write channel stops issuing requests, sets the channel status to "Stopped", and asserts the "Abort" interrupt if it is enabled. Before setting the Stop bit, you must read the channel Status field (CS) of the "DMA Channel Control 1 Register" (DMA_CH_CONTROL1_OFF_WRCH_0) to ensure that the write channel is "Running" (transferring data). For more information, see "Stopping the DMA Transfer (Software Stop)." Note: The access attributes of this field are as follows: - Dbi: R/W
30-3 RSVDP_3	Reserved for future use.
2-0 WR_DOORBELL_NUM	Doorbell Number. You must write the channel number to this register to start the DMA write transfer for that channel. The DMA detects a write to this register field even if the value of this field does not change. You do not need to toggle or write any other value to this register to start a new transfer. The range of this field is 0x0 to 0x7, and 0x0 corresponds to channel 0. Also note that a write to this field triggers the controller to exit L1 substates. Note: The access attributes of this field are as follows: - Dbi: R/W

11.3.3.1.187 DMA Write Engine Channel Arbitration Weight Low Register. (DMA_WRITE_CHANNEL_ARB_WEIGHT_LOW_OFF)

11.3.3.1.187.1 Offset

Register	Offset
DMA_WRITE_CHANNE L_ARB_WEIGHT_LOW_ OFF	8008_0018h

11.3.3.1.187.2 Function

DMA Write Engine Channel Arbitration Weight Low Register. The 5-bit channel weight (for write channels 0-3) specifies the maximum number of TLP requests that the DMA can issue for that channel before it must return to the arbitration routine. When the channel weight count is reached or DMA channel request transfer size reaches zero, the WWR arbiter selects the next channel to be processed. Your software must initialize this register before ringing the doorbell. For more details, see "Multichannel Arbitration". Value range is (0-0x1F) corresponding to (1-32) transaction requests.

11.3.3.1.196.3 Fields

Field	Function
31-24 RSVDP_24	Reserved for future use.
23-16 LINKLIST_ELEMENT_FETCH_ERR_DETECT	Linked List Element Fetch Error Detected. The DMA write channel has received an error response from the AXI bus (or TRGT1 interface when the AXI Bridge is not used) while reading a linked list element from local memory. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. - Enabling: For details, see "Interrupts and Error Handling". - Masking: The DMA write interrupt Mask register has no effect on this register. - Clearing: You must write a 1'b1 to the corresponding channel bit in the Abort interrupt field of the "DMA Write Interrupt Clear Register" (DMA_WRITE_INT_CLEAR_OFF) to clear this error bit.
15-8 RSVDP_8	Reserved for future use.
7-0 APP_READ_ERR_DETECT	Application Read Error Detected. The DMA write channel has received an error response from the AXI bus (or TRGT1 interface when the AXI Bridge is not used) while reading data from it. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. - Enabling: For details, see "Interrupts and Error Handling". - Masking: The DMA write interrupt Mask register has no effect on this register. - Clearing: You must write a 1'b1 to the corresponding channel bit in the Abort interrupt field of the "DMA Write Interrupt Clear Register" (DMA_WRITE_INT_CLEAR_OFF) to clear this error bit.

11.3.3.1.204.3 Fields

Field	Function
31-16 WR_CHANNEL_7_DATA	The DMA uses this field to generate the data field for the Done or Abort IMWr TLPs it generates for write channel 7. Note: The access attributes of this field are as follows: - Dbi: R/W
15-0 WR_CHANNEL_6_DATA	The DMA uses this field to generate the data field for the Done or Abort IMWr TLPs it generates for write channel 6. Note: The access attributes of this field are as follows: - Dbi: R/W

11.3.3.1.205 DMA Write Linked List Error Enable Register. (DMA_WRITE_LINKED_LIST_ERR_EN_OFF)

11.3.3.1.205.1 Offset

Register	Offset
DMA_WRITE_LINKED_LIST_ERR_EN_OFF	8008_0090h

11.3.3.1.205.2 Function

DMA Write Linked List Error Enable Register. The LIE and RIE bits in the LL element enable the channel "done" interrupts (local and remote). The LLLAIE and LLRAIE bits enable the channel "abort" interrupts (local and remote).

11.3.3.1.205.3 Diagram

11.3.3.1.205.4 Fields

Field	Function
31-24 RSVDP_24	Reserved for future use.
23-17 —	Reserved.
16 WR_CHANNEL_LLLAIE	Write Channel LL Local Abort Interrupt Enable (LLLAIE). You enable the write channel local abort interrupt through this bit. The LIE and RIE bits in the LL element enable the write channel done interrupts. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. Used in linked list mode only. For more details, see "Interrupt Handling". Note: The access attributes of this field are as follows: - Dbi: R/W
15-8	Reserved for future use.

Table continues on the next page...

PCI Express (PCIe)

Field	Function
RSVDP_8	
7-1 —	Reserved.
0 WR_CHANNEL_LLRAIE	Write Channel LL Remote Abort Interrupt Enable (LLRAIE). You enable the write channel remote abort interrupt through this bit. The LIE and RIE bits in the LL element enable the write channel done interrupts. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. Used in linked list mode only. For more details, see "Interrupt Handling". Note: The access attributes of this field are as follows: - Dbi: R/W

11.3.3.1.206 DMA Read Interrupt Status Register. (DMA_READ_INT_STATUS_OFF)

11.3.3.1.206.1 Offset

Register	Offset
DMA_READ_INT_STATUS_OFF	8008_00A0h

11.3.3.1.206.2 Diagram

11.3.3.1.206.3 Fields

Field	Function
31-24 RSVDP_24	Reserved for future use.
23-16 RD_ABORT_INT_STATUS	Abort Interrupt Status. The DMA read channel has detected an error, or you manually stopped the transfer as described in "Stopping the DMA Transfer (Software Stop)". Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. You can read the "DMA Read Error Status Low Register" (DMA_READ_ERR_STATUS_LOW_OFF) and "DMA Read Error Status High Register"

Table continues on the next page...

Field	Function
	(DMA_READ_ERR_STATUS_HIGH_OFF) to determine the source of the error. - Enabling: For details, see "Interrupts and Error Handling". - Masking: The DMA read interrupt Mask register has no effect on this register. - Clearing: You must write a 1'b1 to the corresponding channel bit in the DMA read interrupt Clear register to clear this interrupt bit. Note: You can write to this register to emulate interrupt generation, during software or hardware testing. A write to the address triggers an interrupt, but the DMA does not set the Done or Abort bits in this register. Note: The access attributes of this field are as follows: - Dbi: R/W
15-8 RSVDP_8	Reserved for future use.
7-0 RD_DONE_INT_STATUS	Done Interrupt Status. The DMA read channel has successfully completed the DMA read transfer. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. - Enabling: For details, see "Interrupts and Error Handling". - Masking: The DMA read interrupt Mask register has no effect on this register. - Clearing: You must write a 1'b1 to the corresponding channel bit in the DMA read interrupt Clear register to clear this interrupt bit. Note: You can write to this register to emulate interrupt generation, during software or hardware testing. A write to the address triggers an interrupt, but the DMA does not set the Done or Abort bits in this register. Note: The access attributes of this field are as follows: - Dbi: R/W

11.3.3.1.207 DMA Read Interrupt Mask Register. (DMA_READ_INT_MASK_OFF)

11.3.3.1.207.3 Fields

Field	Function
31-24 RSVDP_24	Reserved for future use.
23-17 —	Reserved.
16 RD_ABORT_INT_MASK	Abort Interrupt Mask. Prevents the Abort interrupt status field in the DMA read interrupt status register from asserting the edma_int output. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. Note: The access attributes of this field are as follows: - Dbi: R/W
15-8 RSVDP_8	Reserved for future use.
7-1 —	Reserved.
0 RD_DONE_INT_MASK	Done Interrupt Mask. Prevents the Done interrupt status field in the DMA read interrupt status register from asserting the edma_int output. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. Note: The access attributes of this field are as follows: - Dbi: R/W

11.3.3.1.208 DMA Read Interrupt Clear Register. (DMA_READ_INT_CLEAR_OFF)

Field	Function
31-24 RSVDP_24	Reserved for future use.
23-16 LINK_LIST_ELEMENT_FETCH_ERR_DETECT	Linked List Element Fetch Error Detected. - The DMA read channel has received an error response from the AXI bus while reading a linked list element from local memory. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. - Enabling: For details, see "Interrupts and Error Handling". - Masking: The DMA read interrupt Mask register has no effect on this register. - Clearing: You must write a 1'b1 to the corresponding channel bit in the Abort interrupt field of the "DMA Read Interrupt Clear Register" (DMA_READ_INT_CLEAR_OFF) to clear this error bit. Note, this clears all bits in this register, and also the DMA Read Error Status High register (DMA_READ_ERR_STATUS_HIGH_OFF).

Table continues on the next page...

Field	Function
15-8 RSVDP_8	Reserved for future use.
7-0 APP_WR_ERR_DETECT	Application Write Error Detected. The DMA read channel has received an error response from the AXI bus (or TRGT1 interface when the AXI Bridge is not used) while writing data to it. This error is fatal. You must restart the transfer from the beginning, as the channel context is corrupted, and the transfer is not rolled back. For more details, see "Linked List Mode". Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. - Enabling: For details, see "Interrupts and Error Handling". - Masking: The DMA read interrupt Mask register has no effect on this register. - Clearing: You must write a 1'b1 to the corresponding channel bit in the Abort interrupt field of the "DMA Read Interrupt Clear Register" (DMA_READ_INT_CLEAR_OFF) to clear this error bit. Note, this clears all bits in this register, and also the DMA Read Error Status High register (DMA_READ_ERR_STATUS_HIGH_OFF).

11.3.3.1.210.3 Fields

Field	Function
31-24 DATA_POISONING	Data Poisoning. The DMA read channel has detected data poisoning in the completion from the remote device (in response to the MRd request). The DMA read channel will drop the completion and then be halted. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. - Enabling: For details, see "Interrupts and Error Handling". - Masking: The DMA read interrupt Mask register has no effect on this register. - Clearing: You must write a 1'b1 to the corresponding channel bit in the Abort interrupt field

Table continues on the next page...

Field	Function
	of the "DMA Read Interrupt Clear Register" (DMA_READ_INT_CLEAR_OFF) to clear this error bit. Note, this also clears the other error bits for the same channel in this register and in the DMA Read Error Status Low register.
23-16 CPL_TIMEOUT	Completion Time Out. The DMA read channel has timed-out while waiting for the remote device to respond to the MRd request, or a malformed CplD has been received. For more details, see "Linked List Mode". Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. - Enabling: For details, see "Interrupts and Error Handling". - Masking: The DMA read interrupt Mask register has no effect on this register. - Clearing: You must write a 1'b1 to the corresponding channel bit in the Abort interrupt field of the "DMA Read Interrupt Clear Register" (DMA_READ_INT_CLEAR_OFF) to clear this error bit. Note, this also clears the other error bits for the same channel in this register and in the DMA Read Error Status Low register.
15-8 CPL_ABORT	Completer Abort. The DMA read channel has received a PCIe completer abort completion status from the remote device in response to the MRd request. For more details, see "Linked List Mode". Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. - Enabling: For details, see "Interrupts and Error Handling". - Masking: The DMA read interrupt Mask register has no effect on this register. - Clearing: You must write a 1'b1 to the corresponding channel bit in the Abort interrupt field of the "DMA Read Interrupt Clear Register" (DMA_READ_INT_CLEAR_OFF) to clear this error bit. Note, this also clears the other error bits for the same channel in this register and in the DMA Read Error Status Low register.
7-0 UNSUPPORTED_REQ	Unsupported Request. The DMA read channel has received a PCIe unsupported request completion status from the remote device in response to the MRd request. For more details, see "Linked List Mode". Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. - Enabling: For details, see "Interrupts and Error Handling". - Masking: The DMA read interrupt Mask register has no effect on this register. - Clearing: You must write a 1'b1 to the corresponding channel bit in the Abort interrupt field of the "DMA Read Interrupt Clear Register" (DMA_READ_INT_CLEAR_OFF) to clear this error bit. Note, this also clears the other error bits for the same channel in this register and in the DMA Read Error Status Low register.

11.3.3.1.220.3 Fields

Field	Function
31-30 DMA_AT	Address Translation TLP Header Bit (AT) The DMA uses this TLP header field when generating MRd/MWr (not IMWr) TLPs. Note: The access attributes of this field are as follows: - Dbi: R/W
29-27 DMA_TC	Traffic Class TLP Header Bit (TC) The DMA uses this TLP header field when generating MRd/MWr (not IMWr) TLPs. Note: The access attributes of this field are as follows: - Dbi: R/W
26 DMA_RESERVED5	Reserved. Note: The access attributes of this field are as follows: - Dbi: R/W
25 DMA_RO	Relaxed Ordering TLP Header Bit (RO) The DMA uses this TLP header field when generating MRd/MWr (not IMWr) TLPs. Note: The access attributes of this field are as follows: - Dbi: R/W
24 DMA_NS_SRC	Source No Snoop TLP Header Bit (DMA_NS_SRC). The DMA uses this TLP header field when generating MRd (SAR addressing space) (not IMWr) TLPs. Note: The access attributes of this field are as follows: - Dbi: R/W
23 DMA_NS_DST	Destination No Snoop TLP Header Bit (DMA_NS_DST). The DMA uses this TLP header field when generating MWr (DAR addressing space) (not IMWr) TLPs. Note: The access attributes of this field are as follows: - Dbi: R/W
22-17 DMA_RESERVED2	Reserved. Note: The access attributes of this field are as follows: - Dbi: R/W
16-12	Function Number (FN). The controller uses this field when generating the requester ID for the MRd/MWr DMA TLP. When you have enabled SR-IOV, then this field is ignored if you have set the VFE field in the

Table continues on the next page...

Field	Function
DMA_FUNC_NUM	"DMA Write Channel Control 2 Register" (DMA_CH_CONTROL2_OFF_WRCH_0). Note: The access attributes of this field are as follows: - Dbi: R/W
11-10 DMA_RESERVED1	Reserved. Note: The access attributes of this field are as follows: - Dbi: R/W
9 LLE	Linked List Enable (LLE). - 0: Disable linked list operation - 1: Enable linked list operation Note: The access attributes of this field are as follows: - Dbi: R/W
8 CCS	Consumer Cycle State (CCS). Used in linked list mode only. It is used to synchronize the producer (software) and the consumer (DMA). For more details, see "PCS-CCS-CB-TCB Producer-Consumer Synchronization". You must initialize this bit. The DMA updates this bit during linked list operation. Note: The access attributes of this field are as follows: - Dbi: R/W
7 DMA_RESERVED0	Reserved. Note: The access attributes of this field are as follows: - Dbi: R/W
6-5 CS	Channel Status (CS). The channel status bits identify the current operational state of the DMA channel. The operation state encoding for each DMA channel is as follows: - 00: Reserved - 01: Running. This channel is active and transferring data. - 10: Halted. An error condition has been detected, and the DMA has stopped this channel. - 11: Stopped. The DMA has transferred all data for this channel, or you have prematurely stopped this channel by writing to the Stop field of the "DMA Write Doorbell Register" (DMA_WRITE_DOORBELL_OFF) or "DMA Read Doorbell Register" (DMA_READ_DOORBELL_OFF).
4 RIE	Remote Interrupt Enable (RIE). You must set this bit to enable the generation of the Done or Abort Remote interrupts. For more details, see "Interrupts and Error Handling". In LL mode, the DMA overwrites this with the RIE of the LL element. The RIE bit in a LL element only enables the Done interrupt. In non-LL mode, the RIE bit enables the Done and Abort interrupts. This field is not defined in a link LL element. Note: The access attributes of this field are as follows: - Dbi: R/W
3 LIE	Local Interrupt Enable (LIE). You must set this bit to enable the generation of the Done or Abort Local interrupts. For more details, see "Interrupts and Error Handling". In LL mode, the DMA overwrites this with the LIE of the LL element. The LIE bit in a LL element only enables the Done interrupt. In non-LL mode, the LIE bit enables the Done and Abort interrupts. This field is not defined in a link LL element. Note: The access attributes of this field are as follows: - Dbi: R/W
2 LLP	Load Link Pointer (LLP). Used in linked list mode only. Indicates that this linked list element is a link element, and its LL element pointer dwords are pointing to the next (non-contiguous) element. The DMA loads this field with the LLP of the linked list element. Note: The access attributes of this field are as follows: - Dbi: R/W
1 TCB	Toggle Cycle Bit (TCB). Indicates to the DMA to toggle its interpretation of the CB. Used in linked list mode only. It is used to synchronize the producer (software) and the consumer (DMA). For more details, see "PCS-CCS-CB-TCB Producer-Consumer Synchronization". The DMA loads this field with the TCB of the linked list element. this field is not defined in a data LL element. Note: The access attributes of this field are as follows: - Dbi: R/W
0 CB	Cycle Bit (CB). Used in linked list mode only. It is used to synchronize the producer (software) and the consumer (DMA). For more details, see "PCS-CCS-CB-TCB Producer-Consumer Synchronization". The DMA loads this field with the CB of the linked list element. Note: The access attributes of this field are as follows: - Dbi: R/W

11.3.3.1.221 DMA Write Transfer Size Register. (DMA_TRANSFER_SIZE_OFF_WRCH_0)

11.3.3.1.221.1 Offset

Register	Offset
DMA_TRANSFER_SIZE_OFF_WRCH_0	8008_0208h

11.3.3.1.221.2 Diagram

11.3.3.1.221.3 Fields

Field	Function
31-0 DMA_TRANSFER_SIZE	DMA Transfer Size. You program this register with the size of the DMA transfer. The maximum DMA transfer size is 4Gbytes. The minimum transfer size is one byte (0x1). This field is automatically decremented by the DMA as the DMA write channel transfer progresses. This field indicates the number bytes remaining to be transferred. When all bytes are successfully transferred the current transfer size is zero. In LL mode, the DMA overwrites this register with the corresponding dword of the LL element. You can read this register to monitor the transfer progress, however in some scenarios this register is updated after a delay. For example, when less than 3 channels are doorbelled, this register is updated only after a descriptor finishes(linked list mode), or the transfer ends (non-linked list mode). Note: The access attributes of this field are as follows: - Dbi: R/W

11.3.3.1.222 DMA Write SAR Low Register. (DMA_SAR_LOW_OFF_WRCH_0)

11.3.3.1.222.1 Offset

Register	Offset
DMA_SAR_LOW_OFF_WRCH_0	8008_020Ch

11.3.3.1.222.2 Diagram**11.3.3.1.222.3 Fields**

Field	Function
31-0 SRC_ADDR_REG_LOW	Source Address Register (Lower 32 bits). Indicates the next address to be read from. The DMA increments the SAR as the DMA transfer progresses. In LL mode, the DMA overwrites this with the corresponding dword of the LL element. - DMA Read: The SAR is the address of the remote memory. - DMA Write: The SAR is the address of the local memory. Note: The access attributes of this field are as follows: - Dbi: R/W

11.3.3.1.223 DMA Write SAR High Register. (DMA_SAR_HIGH_OFF_WRC H_0)**11.3.3.1.223.1 Offset**

Register	Offset
DMA_SAR_HIGH_OFF_WRCH_0	8008_0210h

11.3.3.1.228.3 Fields

Field	Function
31-30 DMA_AT	Address Translation TLP Header Bit (AT) The DMA uses this TLP header field when generating MRd/MWr (not IMWr) TLPs. Note: The access attributes of this field are as follows: - Dbi: R/W
29-27 DMA_TC	Traffic Class TLP Header Bit (TC) The DMA uses this TLP header field when generating MRd/MWr (not IMWr) TLPs. Note: The access attributes of this field are as follows: - Dbi: R/W
26 DMA_RESERV ED5	Reserved. Note: The access attributes of this field are as follows: - Dbi: R/W
25 DMA_RO	Relaxed Ordering TLP Header Bit (RO) The DMA uses this TLP header field when generating MRd/MWr (not IMWr) TLPs. Note: The access attributes of this field are as follows: - Dbi: R/W
24 DMA_NS_SRC	Source No Snoop TLP Header Bit (DMA_NS_SRC). The DMA uses this TLP header field when generating MRd (SAR addressing space) (not IMWr) TLPs. Note: The access attributes of this field are as follows: - Dbi: R/W
23 DMA_NS_DST	Destination No Snoop TLP Header Bit (DMA_NS_DST). The DMA uses this TLP header field when generating MWr (DAR addressing space) (not IMWr) TLPs. Note: The access attributes of this field are as follows: - Dbi: R/W
22-17 DMA_RESERV ED2	Reserved. Note: The access attributes of this field are as follows: - Dbi: R/W
16-12 DMA_FUNC_N UM	Function Number (FN). The controller uses this field when generating the requester ID for the MRd/MWr DMA TLP. When you have enabled SR-IOV, then this field is ignored if you have set the VFE field in the "DMA Read Channel Control 2 Register" (DMA_CH_CONTROL2_OFF_RDCH_0). Note: The access attributes of this field are as follows: - Dbi: R/W
11-10 DMA_RESERV ED1	Reserved. Note: The access attributes of this field are as follows: - Dbi: R/W
9 LLE	Linked List Enable (LLE). - 0: Disable linked list operation - 1: Enable linked list operation Note: The access attributes of this field are as follows: - Dbi: R/W
8 CCS	Consumer Cycle State (CCS). Used in linked list mode only. It is used to synchronize the producer (software) and the consumer (DMA). For more details, see "PCS-CCS-CB-TCB Producer-Consumer Synchronization". You must initialize this bit. The DMA updates this bit during linked list operation. Note: The access attributes of this field are as follows: - Dbi: R/W
7 DMA_RESERV ED0	Reserved. Note: The access attributes of this field are as follows: - Dbi: R/W
6-5 CS	Channel Status (CS). The channel status bits identify the current operational state of the DMA channel. The operation state encoding for each DMA channel is as follows: - 00: Reserved - 01: Running. This channel is active and transferring data. - 10: Halted. An error condition has been detected, and the DMA has stopped this channel. - 11: Stopped. The DMA has transferred all data for this channel, or you have prematurely stopped this channel by writing to the Stop field of the "DMA Read Doorbell Register" (DMA_WRITE_DOORBELL_OFF) or "DMA Read Doorbell Register" (DMA_READ_DOORBELL_OFF).
4 RIE	Remote Interrupt Enable (RIE). You must set this bit to enable the generation of the Done or Abort Remote interrupts. For more details, see "Interrupts and Error Handling". In LL mode, the DMA overwrites this with the RIE of the LL element. The RIE bit in a LL element only enables the Done interrupt. In non-LL mode, the RIE bit enables the Done and Abort interrupts. This field is not defined in a link LL element. Note: The access attributes of this field are as follows: - Dbi: R/W

Table continues on the next page...

Field	Function
3 LIE	Local Interrupt Enable (LIE). You must set this bit to enable the generation of the Done or Abort Local interrupts. For more details, see "Interrupts and Error Handling". In LL mode, the DMA overwrites this with the LIE of the LL element. The LIE bit in a LL element only enables the Done interrupt. In non-LL mode, the LIE bit enables the Done and Abort interrupts. This field is not defined in a link LL element. Note: The access attributes of this field are as follows: - Dbi: R/W
2 LLP	Load Link Pointer (LLP). Used in linked list mode only. Indicates that this linked list element is a link element, and its LL element pointer dwords are pointing to the next (non-contiguous) element. The DMA loads this field with the LLP of the linked list element. Note: The access attributes of this field are as follows: - Dbi: R/W
1 TCB	Toggle Cycle Bit (TCB). Indicates to the DMA to toggle its interpretation of the CB. Used in linked list mode only. It is used to synchronize the producer (software) and the consumer (DMA). For more details, see "PCS-CCS-CB-TCB Producer-Consumer Synchronization". The DMA loads this field with the TCB of the linked list element. this field is not defined in a data LL element. Note: The access attributes of this field are as follows: - Dbi: R/W
0 CB	Cycle Bit (CB). Used in linked list mode only. It is used to synchronize the producer (software) and the consumer (DMA). For more details, see "PCS-CCS-CB-TCB Producer-Consumer Synchronization". The DMA loads this field with the CB of the linked list element. Note: The access attributes of this field are as follows: - Dbi: R/W

11.4 PCI Express PHY (PCle_PHY)

11.4.1 Overview

The PCIe Gen4 PHY IP core is used for PCI-Express (PCIe) applications. The transceiver in the core performs these functions:

- Serializes the 8b/10b encoded data for transmission for Gen1 and Gen2 operation, and 128b/130b encoded data for Gen3 and Gen4
- De-serializes the received code groups

When transmitting the data, the transceiver performs these functions:

- Accepts four 10-bit 8b/10b encoded transmit characters or four 8-bit 128b/130b encoded data
- Attaches and serializes the data to the TXP/TXN differential outputs to a maximum value of 16.0 Gb/s

When receiving the data, the transceiver performs these functions:

- Samples the received serial data on the RXP/RXN differential inputs
- Deserializes it into four 10-bit(or 8b-bit) received characters

PCIe Gen4 PHY core has on-chip PLL circuitry for synthesis of the baud-rate transmitting clocks, and extraction of the retimed clocks from the received serial stream.

11.4.1.1 Features

The supported features in a Samsung PCIe Gen4 PHY IP core are:

- PCI Express Base Specification 4.0 compliance
- 2.5Gb/s, 5.0Gb/s, 8.0Gb/s and 16Gb/s Serializer/Deserializer
- PHY Interface for the PCI Express Architecture, Version 4.2 compliance
- Receiver Detection
- Spread Spectrum Clocking in Transmitter and Receiver
- Separate Refclk Independent SSC (SRIS) Architecture
- Continuous-Time Linear Equalizer and 5-tap adaptive Decision-Feedback Equalizer

11.4.1.2 Block Diagram

The figure below illustrates the block diagram of a 4-lane PCIe Gen4 PHY.

Figure 11-60. Block Diagram of PCIe Gen4 PH

The PCIe Gen4 PHY comprises of one Common, four lanes of transceiver, one external reference clock in/output buffer, and PMA digital.

11.4.2 Functional Description

The PCIe Gen4 PHY comprises of a PMA analog and PMA digital. The PMA consists of:

- One CMN block
- Four lane blocks including a full-duplex transceiver,
- One external reference clock input/output (bidirectional) buffer.

In the transmitter side, the PMA Analog executes these actions:

- PMA Analog receives parallel data from PMA digital.
- The TX driver characteristics, such as amplitude and 3-tap FIR filter, are both presettable and user- controllable.

In the receiver side, the PMA executes these actions:

- Distortion on received signal due to channel loss is compensated by Continuous Time Linear Equalizer (CTLE) and Decision Feedback Equalizer (DFE).
- Clock and Data Recovery (CDR) generates frequency- and phase-aligned clock and equalized signal is deserialized to parallel data which is delivered to the PHY digital.

11.4.2.1 Common (CMN)

The CMN consists of a band-gap reference (BGR), bias generator, PLL, and RX RCAL. Detailed information on each block is described in the following sections

11.4.2.1.1 BGR and bias generator

The BGR circuit generates high-accuracy reference voltage across PVT variation.

A bias generator makes two kinds of current, external- and internal-resistor (RMRES)-referred current, and these currents are distributed to each block in CMN and lanes. The external resistor-referred (REXT) current is generated using an 8.2K Ω resistor which is connected between the rext pad and ground outside the chip. On the other hand, the internal resistor-referred current is generated using internally integrated replica resistor to compensate resistance error across PVT variation.

11.4.2.1.2 Phase Locked Loop (PLL)

The PLL in the CMN synthesizes high-speed clock, which is used for TX serializer and RX CDR lock, from a reference clock. The reference clock can be selected from two clock sources; internal SoC reference clock and external differential reference clock.

In the PCIe Gen4 PHY, the high frequency clock from PLL is used in the serialization of TX data and CDR lock acquisition and maintenance. The following are the main features of the PLL:

- Supports wide-range LC VCO from 8GHz to 10GHz
- Supports pre-defined and programmable divider setting for each PCIe specification
- Supports spread spectrum clocking (SSC) with sigma-delta modulated fractional divider.
- Supports Automatic Frequency Calibrated (AFC) oscillator setting for the desired frequency of operation
- Supports programmable charge pump current and loop filter resistance allowing for wide range of programmable loop bandwidth and peaking

The PLL is based on a second-order system in dual-path (integral and proportional) structure.

There is a controllable third pole with an additional ripple suppression capacitor in the loop filter.

In initial phase, the frequency of the VCO is roughly calibrated by AFC function. During AFC, the loop is disconnected and control voltage of the VCO is tied to DC voltage. The VCO frequency is measured by a digital counter for every AFC code and an AFC logic stops when the measured digital number reaches a target number. After the AFC is completed, the loop is closed again and tries to lock frequency and phase.

The PLL has two gain paths, proportional and integral paths, to control the frequency and phase of VCO clock. Each path is driven by proportional or integral charge pump. The bandwidth of the PLL is mainly affected by proportional path gain, especially by the current of proportional charge-pump, the resistance in loop filter and the VCO gain.

11.4.2.1.3 RX resistance calibration (RCAL)

In order to meet the return-loss specification across the PVT variation, the resistance of termination circuit is automatically calibrated by a programmed logic sequence, which is called resistance calibration (RCAL)

Unlike TX RCAL, RX RCAL is implemented in the CMN and the RX in each lane shares the calibration code.

The PCIe Gen4 PHY performs RX RCAL at the start of power-up sequence in default. Although the result of RX RCAL is commonly used in each lane, the RX RTERM in each lane can be tuned with offset value.

11.4.2.2 Transmitter

The main features of the TX are provided below:

- Supports high voltage swing with auxiliary current-mode driver.
- Supports 3-tap FIR filter with resolution of 1/48.
- Supports 10 FIR presets (P0 to P9)
- Supports automatic TX termination resistance calibration.
- Supports electrical idle mode with either fast or low-power common-mode keep.
- Supports receiver detection.

11.4.2.2.1 Serializer

The serializer accepts 20-bit or 32-bit data from the PMA digital via 40-bit bus which is synchronized to TX byte clock (TBC). The serializer has 40-bit data input port in order to support bit-duplication (This is not used in normal operation). The parallel data is

converted to serial according to input bit-width and TBC frequency for each specification as shown in the following table. Note that the LSB in the input parallel data is transmitted first and the MSB the last.

Table 11-95. TX serializer input bit width and frequency

Protocol	Input bit width	TBC frequency
Gen1	40	62.5MHz
Gen2	40	125MHz
Gen3	32	250MHz
Gen4	32	500MHz

In order to support 3-tap FIR filtering in TX driver, the serializer gives not only the present bit but also both 1-bit preceding and 1-bit delayed bits to the pre-driver.

11.4.3 Memory Map and register definition

This section includes the PCIE_PHY module memory map and descriptions of the registers.

11.4.3.1 PCIe PHY register descriptions

11.4.3.1.1 PCIE_PHY Memory map

11.5 Ethernet MAC (ENET)

11.5.1 Introduction

The MAC-NET core, in conjunction with a 10/100/1000-Mbit/s MAC, implements layer 3 network acceleration functions. These functions are designed to accelerate the processing of various common networking protocols, such as IP, TCP, UDP, and ICMP, providing wire speed services to client applications.

11.5.2 Overview

The core implements a triple-speed 10/100/1000-Mbit/s Ethernet MAC compliant with the IEEE802.3-2002 standard. The MAC layer provides compatibility with half- or full-duplex 10/100-Mbit/s and full-duplex gigabit Ethernet LANs.

The MAC operation is fully programmable and can be used in Network Interface Card (NIC), bridging, or switching applications. The core implements the remote network monitoring (RMON) counters according to IETF RFC 2819.

The core also implements a hardware acceleration block to optimize the performance of network controllers providing TCP/IP, UDP, and ICMP protocol services. The acceleration block performs critical functions in hardware, which are typically implemented with large software overhead.

The core implements programmable embedded FIFOs that can provide buffering on the receive path for lossless flow control.

Advanced power management features are available with magic packet detection and programmable power-down modes.

A unified DMA (uDMA), internal to the ENET module, optimizes data transfer between the ENET core and the SoC, and supports an enhanced buffer descriptor programming model to support IEEE 1588 functionality.

The programmable Ethernet MAC with IEEE 1588 integrates a standard IEEE 802.3 Ethernet MAC with a time-stamping module. The IEEE 1588 standard provides accurate clock synchronization for distributed control nodes for industrial automation applications.

11.5.2.1 Features

The MAC-NET core includes the following features.

11.5.2.1.1 Ethernet MAC features

- Implements the full 802.3 specification with preamble/SFD generation, frame padding generation, CRC generation and checking
- Supports zero-length preamble
- Dynamically configurable to support 10/100-Mbit/s and gigabit operation
- Supports 10/100 Mbit/s full-duplex and configurable half-duplex operation
- Supports gigabit full-duplex operation
- Compliant with the AMD magic packet detection with interrupt for node remote power management
- Seamless interface to commercial ethernet PHY devices via one of the following:
 - a 4-bit Media Independent Interface (MII) operating at 2.5/25 MHz.
 - a 4-bit non-standard MII-Lite (MII without the CRS and COL signals) operating at 2.5/25 MHz.
 - a 2-bit Reduced MII (RMII) operating at 50 MHz.
 - a (double data rate) 4-bit Reduced GMII (RGMII) operating at 125 MHz.
- Simple 64-Bit FIFO user-application interface
- CRC-32 checking at full speed with optional forwarding of the frame check sequence (FCS) field to the client
- CRC-32 generation and append on transmit or forwarding of user application provided FCS selectable on a per-frame basis
- In full-duplex mode:
 - Implements automated pause frame (802.3 x31A) generation and termination, providing flow control without user application intervention
 - Pause quanta used to form pause frames — dynamically programmable
 - Pause frame generation additionally controllable by user application offering flexible traffic flow control
 - Optional forwarding of received pause frames to the user application
 - Implements standard flow-control mechanism
- In half-duplex mode: provides full collision support, including jamming, backoff, and automatic retransmission
- Supports VLAN-tagged frames according to IEEE 802.1Q
- Programmable MAC address: Insertion on transmit; discards frames with mismatching destination address on receive (except broadcast and pause frames)
- Programmable promiscuous mode support to omit MAC destination address checking on receive
- Multicast and unicast address filtering on receive based on 64-entry hash table, reducing higher layer processing load

- Programmable frame maximum length providing support for any standard or proprietary frame length
- Statistics indicators for frame traffic and errors (alignment, CRC, length) and pause frames providing for IEEE 802.3 basic and mandatory management information database (MIB) package and remote network monitoring (RFC 2819)
- Simple handshake user application FIFO interface with fully programmable depth and threshold levels
- Provides separate status word for each received frame on the user interface providing information such as frame length, frame type, VLAN tag, and error information
- Multiple internal loopback options
- MDIO master interface for PHY device configuration and management supports two programmable MDIO base addresses, and standard (IEEE 802.3 Clause 22) and extended (Clause 45) MDIO frame formats
- Supports legacy FEC buffer descriptors
- Interrupt coalescing reduces the number of interrupts generated by the MAC, reducing CPU loading
- Traffic-shaping bandwidth distribution supports credit-based and round-robin-based policies. Either policy can be combined with time-based shaping.
- AVB (Audio Video Bridging, IEEE 802.1Qav) features:
 - Credit-based bandwidth distribution policy can be combined with time-based shaping
 - AVB endpoint talker and listener support
 - Support for arbitration between different priority traffic (for example, AVB class A, AVB class B, and non-AVB)

11.5.2.1.2 IP protocol performance optimization features

- Operates on TCP/IP and UDP/IP and ICMP/IP protocol data or IP header only
- Enables wire-speed processing
- Supports IPv4 and IPv6
- Transparent passing of frames of other types and protocols
- Supports VLAN tagged frames according to IEEE 802.1q with transparent forwarding of VLAN tag and control field
- Automatic IP-header and payload (protocol specific) checksum calculation and verification on receive
- Automatic IP-header and payload (protocol specific) checksum generation and automatic insertion on transmit configurable on a per-frame basis
- Supports IP and TCP, UDP, ICMP data for checksum generation and checking

- Supports full header options for IPv4 and TCP protocol headers
- Provides IPv6 support to datagrams with base header only — datagrams with extension headers are passed transparently unmodified/unchecked
- Provides statistics information for received IP and protocol errors
- Configurable automatic discard of erroneous frames
- Configurable automatic host-to-network (RX) and network-to-host (TX) byte order conversion for IP and TCP/UDP/ICMP headers within the frame
- Configurable padding remove for short IP datagrams on receive
- Configurable Ethernet payload alignment to allow for 32-bit word-aligned header and payload processing
- Programmable store-and-forward operation with clock and rate decoupling FIFOs

11.5.2.1.3 IEEE 1588 features

- Supports all IEEE 1588 frames.
- Allows reference clock to be chosen independently of network speed.
- Software-programmable precise time-stamping of ingress and egress frames
- Timer monitoring capabilities for system calibration and timing accuracy management
- Precise time-stamping of external events with programmable interrupt generation
- Programmable event and interrupt generation for external system control
- Supports hardware- and software-controllable timer synchronization.
- Provides a 4-channel IEEE 1588 timer. Each channel supports input capture and output compare using the 1588 counter.

11.5.2.2 Block diagram

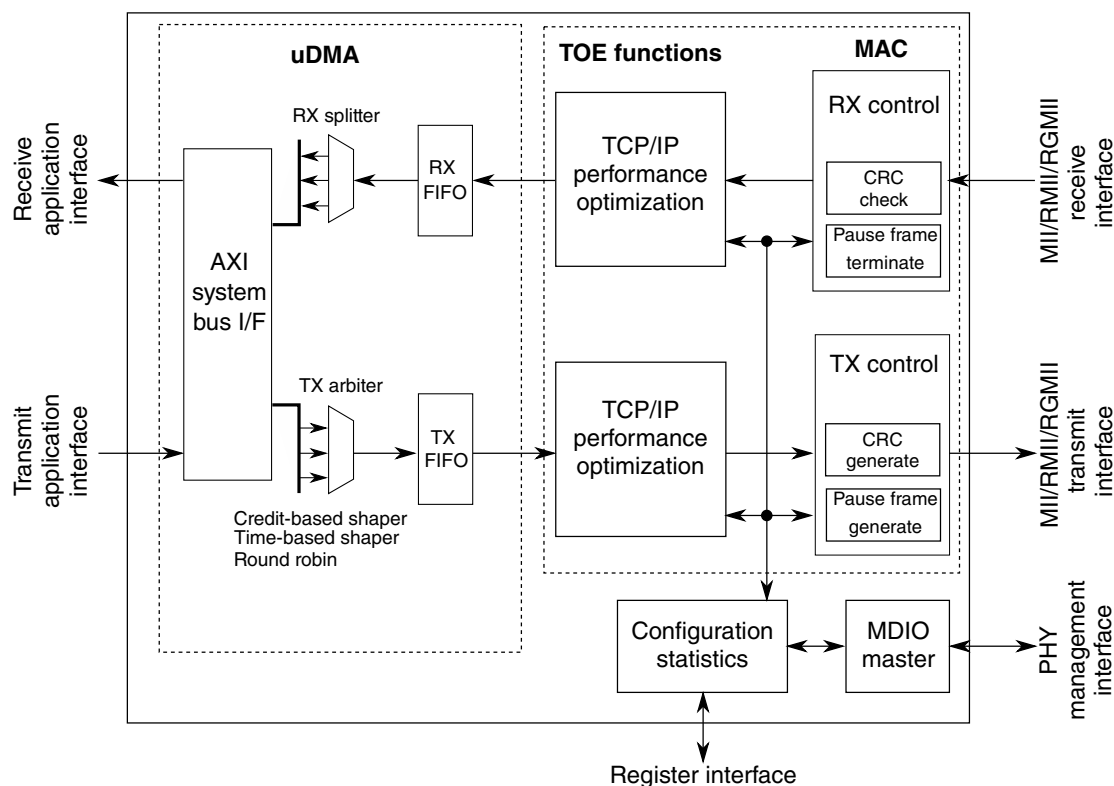

Figure 11-61. Ethernet MAC-NET core block diagram

11.5.3 External Signals

The table found here describes the external signals of ENET.

11.5.4 Clocks

The table found here describes the clock sources for ENET.

11.5.5 Memory map/register definition

ENET registers must be read or written with 32-bit accesses. Non-32 bit accesses will terminate with an error.

Reserved bits should be written with 0 and ignored on read. Unused registers read zero and a write has no effect.

This table shows Ethernet registers organization.

Table 11-96. Register map summary

Offset Address	Section	Description
0x0000 – 0x01FF	Configuration	Core control and status registers
0x0200 – 0x03FF	Statistics counters	MIB and Remote Network Monitoring (RFC 2819) registers
0x0400 – 0x0430	1588 control	1588 adjustable timer (TSM) and 1588 frame control
0x0600 – 0x07FC	Capture/Compare block	Registers for the Capture/Compare block

11.5.5.1 Interrupt Event Register (ENET_EIR)

When an event occurs that sets a bit in EIR, an interrupt occurs if the corresponding bit in the interrupt mask register (EIMR) is also set. Writing a 1 to an EIR bit clears it; writing 0 has no effect. This register is cleared upon hardware reset.

NOTE

TxBD[INT] and RxBD[INT] must be set to 1 to allow setting the corresponding EIR register flags in enhanced mode, ENET_ECR[EN1588] = 1. Legacy mode does not require these flags to be enabled.

Address: 30BE_0000h base + 4h offset = 30BE_0004h

ENET_EIR field descriptions

Field	Description
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 BABR	Babbling Receive Error Indicates a frame was received with length in excess of RCR[MAX_FL] bytes.
29 BABT	Babbling Transmit Error Indicates the transmitted frame length exceeds RCR[MAX_FL] bytes. Usually this condition is caused when a frame that is too long is placed into the transmit data buffer(s). Truncation does not occur.
28 GRA	Graceful Stop Complete This interrupt is asserted after the transmitter is put into a pause state after completion of the frame currently being transmitted. See Graceful Transmit Stop (GTS) for conditions that lead to graceful stop.

Table continues on the next page...

ENET_EIR field descriptions (continued)

Field	Description
	NOTE: The GRA interrupt is asserted only when the TX transitions into the stopped state. If this bit is cleared by writing 1 and the TX is still stopped, the bit is not set again.
27 TXF	Transmit Frame Interrupt Indicates a frame has been transmitted and the last corresponding buffer descriptor has been updated.
26 TXB	Transmit Buffer Interrupt Indicates a transmit buffer descriptor has been updated.
25 RXF	Receive Frame Interrupt Indicates a frame has been received and the last corresponding buffer descriptor has been updated.
24 RXB	Receive Buffer Interrupt Indicates a receive buffer descriptor is not the last in the frame has been updated.
23 MII	MII Interrupt. Indicates that the MII has completed the data transfer requested.
22 EBERR	Ethernet Bus Error Indicates a system bus error occurred when a uDMA transaction is underway. When this bit is set, ECR[ETHEREN] is cleared, halting frame processing by the MAC. When this occurs, software must ensure proper actions, possibly resetting the system, to resume normal operation.
21 LC	Late Collision Indicates a collision occurred beyond the collision window (slot time) in half-duplex mode. The frame truncates with a bad CRC and the remainder of the frame is discarded.
20 RL	Collision Retry Limit Indicates a collision occurred on each of 16 successive attempts to transmit the frame. The frame is discarded without being transmitted and transmission of the next frame commences. This error can only occur in half-duplex mode.
19 UN	Transmit FIFO Underrun Indicates the transmit FIFO became empty before the complete frame was transmitted. NOTE: In situations where the device has various masters generating high traffic, a FIFO underrun can occur on the transmit FIFO. To avoid transmit FIFO underrun, store and forward can be enabled in ENET_TFWR[STRFWD]. See STRFWD . Also, a higher priority can be set for ENET traffic using available means on the central bus fabric connecting the ENET module.
18 PLR	Payload Receive Error Indicates a frame was received with a payload length error. See Frame Length/Type Verification: Payload Length Check for more information.
17 WAKEUP	Node Wakeup Request Indication Read-only status bit to indicate that a magic packet has been detected. Will act only if ECR[MAGICEN] is set.
16 TS_AVAIL	Transmit Timestamp Available Indicates that the timestamp of the last transmitted timing frame is available in the ATSTMP register.
15 TS_TIMER	Timestamp Timer

Table continues on the next page...

ENET_EIR field descriptions (continued)

Field	Description
	The adjustable timer reached the period event. A period event interrupt can be generated if ATCR[PEREN] is set and the timer wraps according to the periodic setting in the ATPER register. Set the timer period value before setting ATCR[PEREN].
14 RXFLUSH_2	RX DMA Ring 2 flush indication. This ring's RX frame has been flushed due to either RDAR2[RDAR] or RxBD[E] being clear and only if QOS[RXFLUSH_2] is enabled.
13 RXFLUSH_1	RX DMA Ring 1 flush indication. This ring's RX frame has been flushed due to either RDAR1[RDAR] or RxBD[E] being clear and only if QOS[RXFLUSH_1] is enabled.
12 RXFLUSH_0	RX DMA Ring 0 flush indication. . This ring's RX frame has been flushed due to either RDAR[RDAR] or RxBD[E] being clear and only if QOS[RXFLUSH_0] is enabled.
11–9 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
8 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
7 TXF2	Transmit frame interrupt, class 2 This bit indicates that a frame has been transmitted and the last corresponding buffer descriptor has been updated (ring/class 2).
6 TXB2	Transmit buffer interrupt, class 2 This field indicates that a transmit buffer descriptor has been updated (ring/class 2).
5 RXF2	Receive frame interrupt, class 2 This field indicates that a frame has been received and the last corresponding buffer descriptor has been updated (ring/class 2).
4 RXB2	Receive buffer interrupt, class 2 This field indicates that a receive buffer descriptor, that not the last in the frame, has been updated (ring/class 2).
3 TXF1	Transmit frame interrupt, class 1 This bit indicates that a frame has been transmitted and the last corresponding buffer descriptor has been updated (ring/class 1).
2 TXB1	Transmit buffer interrupt, class 1 This field indicates that a transmit buffer descriptor has been updated (ring/class 1).
1 RXF1	Receive frame interrupt, class 1 This field indicates that a frame has been received and the last corresponding buffer descriptor has been updated (ring/class 1).
0 RXB1	Receive buffer interrupt, class 1 This field indicates that a receive buffer descriptor, that not the last in the frame, has been updated (ring/class 1).

11.5.5.2 Interrupt Mask Register (ENET_EIMR)

EIMR controls which interrupt events are allowed to generate actual interrupts. A hardware reset clears this register. If the corresponding bits in the EIR and EIMR registers are set, an interrupt is generated. The interrupt signal remains asserted until a 1 is written to the EIR field (write 1 to clear) or a 0 is written to the EIMR field.

Address: 30BE_0000h base + 8h offset = 30BE_0008h

Field	Description
	corresponding EIR LC field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
20 RL	RL Interrupt Mask Corresponds to interrupt source EIR[RL] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR RL field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
19 UN	UN Interrupt Mask Corresponds to interrupt source EIR[UN] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR UN field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
18 PLR	PLR Interrupt Mask Corresponds to interrupt source EIR[PLR] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR PLR field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
17 WAKEUP	WAKEUP Interrupt Mask Corresponds to interrupt source EIR[WAKEUP] register and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR WAKEUP field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
16 TS_AVAIL	TS_AVAIL Interrupt Mask Corresponds to interrupt source EIR[TS_AVAIL] register and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR TS_AVAIL field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
15 TS_TIMER	TS_TIMER Interrupt Mask Corresponds to interrupt source EIR[TS_TIMER] register and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR TS_TIMER field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
14 RXFLUSH_2	Corresponds to interrupt source EIR[RXFLUSH_2] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. EIR[RXFLUSH_2] reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
13 RXFLUSH_1	Corresponds to interrupt source EIR[RXFLUSH_1] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. EIR[RXFLUSH_1] reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
12 RXFLUSH_0	Corresponds to interrupt source EIR[RXFLUSH_0] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. EIR[RXFLUSH_0] reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
11–9 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.

Table continues on the next page...

ENET_EIMR field descriptions (continued)

Field	Description
8 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
7 TXF2	Transmit frame interrupt, class 2 Corresponds to interrupt source EIR[TXF2] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. EIR[TXF2] reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
6 TXB2	Transmit buffer interrupt, class 2 Corresponds to interrupt source EIR[TXB2] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. EIR[TXB2] reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
5 RXF2	Receive frame interrupt, class 2 Corresponds to interrupt source EIR[RXF2] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. EIR[RXF2] reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
4 RXB2	Receive buffer interrupt, class 2 Corresponds to interrupt source EIR[RXB2] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. EIR[RXB2] reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
3 TXF1	Transmit frame interrupt, class 1 Corresponds to interrupt source EIR[TXF1] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. EIR[TXF1] reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
2 TXB1	Transmit buffer interrupt, class 1 Corresponds to interrupt source EIR[TXB1] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. EIR[TXB1] reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
1 RXF1	Receive frame interrupt, class 1 Corresponds to interrupt source EIR[RXF1] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. EIR[RXF1] reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
0 RXB1	Receive buffer interrupt, class 1 Corresponds to interrupt source EIR[RXB1] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. EIR[RXB1] reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.

11.5.5.3 Receive Descriptor Active Register - Ring 0 (ENET_RDAR)

RDAR is a command register, written by the user, to indicate that the receive descriptor ring 0 has been updated, that is, that the driver produced empty receive buffers with the empty bit set.

Address: 30BE_0000h base + 10h offset = 30BE_0010h

ENET_RDAR field descriptions

Field	Description
31–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 RDAR	Receive Descriptor Active Always set to 1 when this register is written, regardless of the value written. This field is cleared by the MAC device when no additional empty descriptors remain in the receive ring. It is also cleared when ECR[ETHEREN] transitions from set to cleared or when ECR[RESET] is set.
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

11.5.5.4 Transmit Descriptor Active Register - Ring 0 (ENET_TDAR)

The TDAR is a command register that the user writes to indicate that the transmit descriptor ring 0 has been updated, that is, that transmit buffers have been produced by the driver with the ready bit set in the buffer descriptor.

The TDAR register is cleared at reset, when ECR[ETHEREN] transitions from set to cleared, or when ECR[RESET] is set.

Address: 30BE_0000h base + 14h offset = 30BE_0014h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

ENET_ECR field descriptions (continued)

Field	Description
	<p>Enables/disables the Ethernet MAC. When the MAC is disabled, the buffer descriptors for an aborted transmit frame are not updated. The uDMA, buffer descriptor, and FIFO control logic are reset, including the buffer descriptor and FIFO pointers.</p> <p>Hardware clears this field under the following conditions:</p> <ul style="list-style-type: none"> • RESET is set by software • An error condition causes the EBERR field to set. <p>NOTE:</p> <ul style="list-style-type: none"> • ETHEREN must be set at the very last step during ENET configuration/setup/initialization, only <i>after</i> all other ENET-related registers have been configured. • If ETHEREN is cleared to 0 by software then next time ETHEREN is set, the EIR interrupts must cleared to 0 due to previous pending interrupts. <p>0 Reception immediately stops and transmission stops after a bad CRC is appended to any currently transmitted frame.</p> <p>1 MAC is enabled, and reception and transmission are possible.</p>
0 RESET	<p>Ethernet MAC Reset</p> <p>When this field is set, it clears the ETHEREN field.</p>

11.5.5.6 MII Management Frame Register (ENET_MMFR)

Writing to MMFR triggers a management frame transaction to the PHY device unless MSCR is programmed to zero.

If MSCR is changed from zero to non-zero during a write to MMFR, an MII frame is generated with the data previously written to the MMFR. This allows MMFR and MSCR to be programmed in either order if MSCR is currently zero.

If the MMFR register is written while frame generation is in progress, the frame contents are altered. Software must use the EIR[MII] interrupt indication to avoid writing to the MMFR register while frame generation is in progress.

Address: 30BE_0000h base + 40h offset = 30BE_0040h

22–18 RA	Register Address See Table 11-135 (Clause 22) or Table 11-137 (Clause 45) for correct value.
17–16 TA	Turn Around This field must be programmed to 10 to generate a valid MII management frame.
DATA	Management Frame Data This is the field for data to be written to or read from the PHY register.

11.5.5.7 MII Speed Control Register (ENET_MSCR)

MSCR provides control of the MII clock (MDC pin) frequency and allows a preamble drop on the MII management frame.

The MII_SPEED field must be programmed with a value to provide an MDC frequency of less than or equal to 2.5 MHz to be compliant with the IEEE 802.3 MII specification. The MII_SPEED must be set to a non-zero value to source a read or write management frame. After the management frame is complete, the MSCR register may optionally be cleared to turn off MDC. The MDC signal generated has a 50% duty cycle except when MII_SPEED changes during operation. This change takes effect following a rising or falling edge of MDC.

For example, if the internal module clock (that is, peripheral bus clock) is 25 MHz, programming MII_SPEED to 0x4 results in an MDC as given in the following equation:

$$\text{MII clock frequency} = 25 \text{ MHz} / ((4 + 1) \times 2) = 2.5 \text{ MHz}$$

The following table shows the optimum values for MII_SPEED as a function of IPS bus clock frequency.

Table 11-97. Programming Examples for MSCR

Internal module clock frequency	MSCR [MII_SPEED]	MDC frequency
25 MHz	0x4	2.50 MHz
33 MHz	0x6	2.36 MHz
40 MHz	0x7	2.50 MHz
50 MHz	0x9	2.50 MHz
66 MHz	0xD	2.36 MHz

Ethernet MAC (ENET)

Address: 30BE_0000h base + 44h offset = 30BE_0044h

ENET_MSCR field descriptions

Field	Description
31–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10–8 HOLDTIME	Hold time On MDIO Output IEEE802.3 clause 22 defines a minimum of 10 ns for the hold time on the MDIO output. Depending on the host bus frequency, the setting may need to be increased. 000 1 internal module clock cycle 001 2 internal module clock cycles 010 3 internal module clock cycles 111 8 internal module clock cycles
7 DIS_PRE	Disable Preamble Enables/disables prepending a preamble to the MII management frame. The MII standard allows the preamble to be dropped if the attached PHY devices do not require it. 0 Preamble enabled. 1 Preamble (32 ones) is not prepended to the MII management frame.
6–1 MII_SPEED	MII Speed Controls the frequency of the MII management interface clock (MDC) relative to the internal module clock. A value of 0 in this field turns off MDC and leaves it in low voltage state. Any non-zero value results in the MDC frequency of: $1/((\text{MII_SPEED} + 1) \times 2)$ of the internal module clock frequency
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

11.5.5.8 MIB Control Register (ENET_MIBC)

MIBC is a read/write register controlling and observing the state of the MIB block. Access this register to disable the MIB block operation or clear the MIB counters. The MIB_DIS field resets to 1.

Address: 30BE_0000h base + 64h offset = 30BE_0064h

ENET_MIBC field descriptions

Field	Description
31 MIB_DIS	Disable MIB Logic If this control field is set, 0 MIB logic is enabled. 1 MIB logic is disabled. The MIB logic halts and does not update any MIB counters.

Table continues on the next page...

ENET_MIBC field descriptions (continued)

Field	Description
30 MIB_IDLE	MIB Idle 0 The MIB block is updating MIB counters. 1 The MIB block is not currently updating any MIB counters.
29 MIB_CLEAR	MIB Clear NOTE: This field is not self-clearing. To clear the MIB counters set and then clear this field. 0 See note above. 1 All statistics counters are reset to 0.
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

11.5.5.9 Receive Control Register (ENET_RCR)

Address: 30BE_0000h base + 84h offset = 30BE_0084h

ENET_RCR field descriptions

Field	Description
31 GRS	Graceful Receive Stopped Read-only status indicating that the MAC receive datapath is stopped.
30 NLC	Payload Length Check Disable Enables/disables a payload length check. 0 The payload length check is disabled. 1 The core checks the frame's payload length with the frame length/type field. Errors are indicated in the EIR[PLR] field.
29–16 MAX_FL	Maximum Frame Length Resets to decimal 1518. Length is measured starting at DA and includes the CRC at the end of the frame. Transmit frames longer than MAX_FL cause the BABT interrupt to occur. Receive frames longer than MAX_FL cause the BABR interrupt to occur and set the LG field in the end of frame receive buffer descriptor. The recommended default value to be programmed is 1518 or 1522 if VLAN tags are supported.
15 CFEN	MAC Control Frame Enable Enables/disables the MAC control frame. 0 MAC control frames with any opcode other than 0x0001 (pause frame) are accepted and forwarded to the client interface. 1 MAC control frames with any opcode other than 0x0001 (pause frame) are silently discarded.
14 CRCFWD	Terminate/Forward Received CRC Specifies whether the CRC field of received frames is transmitted or stripped. NOTE: If padding function is enabled (PADEN = 1), CRCFWD is ignored and the CRC field is checked and always terminated and removed. 0 The CRC field of received frames is transmitted to the user application. 1 The CRC field is stripped from the frame.
13 PAUFWD	Terminate/Forward Pause Frames Specifies whether pause frames are terminated or forwarded. 0 Pause frames are terminated and discarded in the MAC. 1 Pause frames are forwarded to the user application.
12 PADEN	Enable Frame Padding Remove On Receive Specifies whether the MAC removes padding from received frames. 0 No padding is removed on receive by the MAC. 1 Padding is removed from received frames.
11–10 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
9 RMII_10T	Enables 10-Mbit/s mode of the RMII or RGMII . 0 100-Mbit/s operation. 1 10-Mbit/s operation.

Table continues on the next page...

ENET_RCR field descriptions (continued)

Field	Description
8 RMII_MODE	<p>RMII Mode Enable</p> <p>Specifies whether the MAC is configured for MII mode or RMII operation , when ECR[SPEED] is cleared .</p> <p>NOTE: Do not set both RCR[RGMIEN] and RCR[RMII_MODE].</p> <p>0 MAC configured for MII mode. 1 MAC configured for RMII operation.</p>
7 Reserved	<p>This field is reserved.</p> <p>This write-only field is reserved. It must always be written with the value 0.</p>
6 RGMII_EN	<p>RGMII Mode Enable</p> <p>NOTE: Do not set both RCR[RGMIEN] and RCR[RMII_MODE].</p> <p>0 MAC configured for non-RGMII operation 1 MAC configured for RGMII operation. If ECR[SPEED] is set, the MAC is in RGMII 1000-Mbit/s mode. If ECR[SPEED] is cleared, the MAC is in RGMII 10/100-Mbit/s mode.</p>
5 FCE	<p>Flow Control Enable</p> <p>If set, the receiver detects PAUSE frames. Upon PAUSE frame detection, the transmitter stops transmitting data frames for a given duration.</p>
4 BC_REJ	<p>Broadcast Frame Reject</p> <p>If set, frames with destination address (DA) equal to 0xFFFF_FFFF_FFFF are rejected unless the PROM field is set. If BC_REJ and PROM are set, frames with broadcast DA are accepted and the MISS (M) is set in the receive buffer descriptor.</p>
3 PROM	<p>Promiscuous Mode</p> <p>All frames are accepted regardless of address matching.</p> <p>0 Disabled. 1 Enabled.</p>
2 MII_MODE	<p>Media Independent Interface Mode</p> <p>This field must always be set.</p> <p>0 Reserved. 1 MII or RMII mode, as indicated by the RMII_MODE field.</p>
1 DRT	<p>Disable Receive On Transmit</p> <p>0 Receive path operates independently of transmit (i.e., full-duplex mode). Can also be used to monitor transmit activity in half-duplex mode. 1 Disable reception of frames while transmitting. (Normally used for half-duplex mode.)</p>
0 LOOP	<p>Internal Loopback</p> <p>This is an MII internal loopback, therefore MII_MODE must be written to 1 and RMII_MODE must be written to 0.</p> <p>0 Loopback disabled. 1 Transmitted frames are looped back internal to the device and transmit MII output signals are not asserted. DRT must be cleared.</p>

11.5.5.10 Transmit Control Register (ENET_TCR)

TCR is read/write and configures the transmit block. This register is cleared at system reset. FDEN can only be modified when ECR[ETHEREN] is cleared.

Address: 30BE_0000h base + C4h offset = 30BE_00C4h

ENET_TCR field descriptions

Field	Description
31–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10 Reserved	This field is reserved. This field is read/write and must be set to 0.
9 CRCFWD	Forward Frame From Application With CRC

Table continues on the next page...

ENET_TCR field descriptions (continued)

Field	Description
	<p>0 TxBD[TC] controls whether the frame has a CRC from the application.</p> <p>1 The transmitter does not append any CRC to transmitted frames, as it is expecting a frame with CRC from the application.</p>
8 ADDINS	<p>Set MAC Address On Transmit</p> <p>0 The source MAC address is not modified by the MAC.</p> <p>1 The MAC overwrites the source MAC address with the programmed MAC address according to ADDSEL.</p>
7–5 ADDSEL	<p>Source MAC Address Select On Transmit</p> <p>If ADDINS is set, indicates the MAC address that overwrites the source MAC address.</p> <p>000 Node MAC address programmed on PADDR1/2 registers.</p> <p>100 Reserved.</p> <p>101 Reserved.</p> <p>110 Reserved.</p>
4 RFC_PAUSE	<p>Receive Frame Control Pause</p> <p>This status field is set when a full-duplex flow control pause frame is received and the transmitter pauses for the duration defined in this pause frame. This field automatically clears when the pause duration is complete.</p>
3 TFC_PAUSE	<p>Transmit Frame Control Pause</p> <p>Pauses frame transmission. When this field is set, EIR[GRA] is set. With transmission of data frames stopped, the MAC transmits a MAC control PAUSE frame. Next, the MAC clears TFC_PAUSE and resumes transmitting data frames. If the transmitter pauses due to user assertion of GTS or reception of a PAUSE frame, the MAC may continue transmitting a MAC control PAUSE frame.</p> <p>0 No PAUSE frame transmitted.</p> <p>1 The MAC stops transmission of data frames after the current transmission is complete.</p>
2 FDEN	<p>Full-Duplex Enable</p> <p>If this field is set, frames transmit independent of carrier sense and collision inputs. Only modify this bit when ECR[ETHEREN] is cleared.</p>
1 Reserved	<p>This field is reserved.</p> <p>This write-only field is reserved. It must always be written with the value 0.</p>
0 GTS	<p>Graceful Transmit Stop</p> <p>When this field is set, MAC stops transmission after any frame currently transmitted is complete and EIR[GRA] is set. If frame transmission is not currently underway, the GRA interrupt is asserted immediately. After transmission finishes, clear GTS to restart. The next frame in the transmit FIFO is then transmitted. If an early collision occurs during transmission when GTS is set, transmission stops after the collision. The frame is transmitted again after GTS is cleared. There may be old frames in the transmit FIFO that transmit when GTS is reasserted. To avoid this, clear ECR[ETHEREN] following the GRA interrupt.</p>

11.5.5.11 Physical Address Lower Register (ENET_PALR)

PALR contains the lower 32 bits (bytes 0, 1, 2, 3) of the 48-bit address used in the address recognition process to compare with the destination address (DA) field of receive frames with an individual DA. In addition, this register is used in bytes 0 through 3 of the six-byte source address field when transmitting PAUSE frames.

Address: 30BE_0000h base + E4h offset = 30BE_00E4h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

ENET_PALR field descriptions

Field	Description
PADDR1	Pause Address Bytes 0 (bits 31:24), 1 (bits 23:16), 2 (bits 15:8), and 3 (bits 7:0) of the 6-byte individual address are used for exact match and the source address field in PAUSE frames.

11.5.5.12 Physical Address Upper Register (ENET_PAUR)

PAUR contains the upper 16 bits (bytes 4 and 5) of the 48-bit address used in the address recognition process to compare with the destination address (DA) field of receive frames with an individual DA. In addition, this register is used in bytes 4 and 5 of the six-byte source address field when transmitting PAUSE frames. Bits 15:0 of PAUR contain a constant type field (0x8808) for transmission of PAUSE frames.

Address: 30BE_0000h base + E8h offset = 30BE_00E8h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

ENET_PAUR field descriptions

Field	Description
31–16 PADDR2	Bytes 4 (bits 31:24) and 5 (bits 23:16) of the 6-byte individual address used for exact match, and the source address field in PAUSE frames.
TYPE	Type Field In PAUSE Frames These fields have a constant value of 0x8808.

11.5.5.13 Opcode/Pause Duration Register (ENET_OPD)

OPD is read/write accessible. This register contains the 16-bit opcode and 16-bit pause duration fields used in transmission of a PAUSE frame. The opcode field is a constant value, 0x0001. When another node detects a PAUSE frame, that node pauses transmission for the duration specified in the pause duration field. The lower 16 bits of this register are not reset and you must initialize it.

Address: 30BE_0000h base + ECh offset = 30BE_00ECh

ENET_OPD field descriptions

Field	Description
31–16 OPCODE	Opcode Field In PAUSE Frames These fields have a constant value of 0x0001.
PAUSE_DUR	Pause Duration Pause duration field used in PAUSE frames.

11.5.5.14 Transmit Interrupt Coalescing Register (ENET_TXICn)

See [Interrupt coalescence](#) for more information.

Address: 30BE_0000h base + F0h offset + (4d × i), where i=0d to 2d

ENET_TXICn field descriptions

Field	Description
31 ICEN	Interrupt Coalescing Enable

Table continues on the next page...

ENET_TXICn field descriptions (continued)

Field	Description
	0 Disable Interrupt coalescing. 1 Enable Interrupt coalescing.
30 ICCS	Interrupt Coalescing Timer Clock Source Select 0 Use MII/GMII TX clocks. 1 Use ENET system clock.
29–28 Reserved	This field must be set to 0. This field is reserved.
27–20 ICFT	Interrupt coalescing frame count threshold This value determines the number of frames needed to be transmitted for raising an interrupt. Frame counter restarts after reaching this threshold value or after the expiring of the coalescing timer. Must be greater than zero to avoid unpredictable behavior.
19–16 Reserved	This field must be set to 0. This field is reserved.
ICTT	Interrupt coalescing timer threshold Interrupt coalescing timer threshold in units of 64 clock periods. This value determines the maximum amount of time after transmitting a frame before raising an interrupt. The threshold timer is disabled after expiring or number of frame transmission defined by ICFT and starts again upon transmission of the next first frame. Must be greater than zero to avoid unpredictable behavior.

11.5.5.15 Receive Interrupt Coalescing Register (ENET_RXICn)

See [Interrupt coalescence](#) for more information.

Address: 30BE_0000h base + 100h offset + (4d × i), where i=0d to 2d

ENET_RXICn field descriptions (continued)

Field	Description
30 ICCS	Interrupt Coalescing Timer Clock Source Select 0 Use MII/GMII TX clocks. 1 Use ENET system clock.
29–28 Reserved	This field must be set to 0. This field is reserved.
27–20 ICFT	Interrupt coalescing frame count threshold This value determines the number of frames needed to be received for raising an interrupt. Frame counter restarts after reaching this threshold value or after the expiring of the coalescing timer. Must be greater than zero to avoid unpredictable behavior.
19–16 Reserved	This field must be set to 0. This field is reserved.
ICTT	Interrupt coalescing timer threshold Interrupt coalescing timer threshold in units of 64 clock periods. This value determines the maximum amount of time after receiving a frame before raising an interrupt. The threshold timer is disabled after expiring or number of frame reception defined by ICFT and starts again upon reception of the next first frame. Must be greater than zero to avoid unpredictable behavior.

11.5.5.16 Descriptor Individual Upper Address Register (ENET_IAUR)

IAUR contains the upper 32 bits of the 64-bit individual address hash table. The address recognition process uses this table to check for a possible match with the destination address (DA) field of receive frames with an individual DA. This register is not reset and you must initialize it.

Address: 30BE_0000h base + 118h offset = 30BE_0118h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Field	Description
GADDR1	Contains the upper 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a multicast address. Bit 31 of GADDR1 contains hash index bit 63. Bit 0 of GADDR1 contains hash index bit 32.

11.5.5.19 Descriptor Group Lower Address Register (ENET_GALR)

GALR contains the lower 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a multicast address. You must initialize this register.

Address: 30BE_0000h base + 124h offset = 30BE_0124h

ENET_GALR field descriptions

Field	Description
GADDR2	Contains the lower 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a multicast address. Bit 31 of GADDR2 contains hash index bit 31. Bit 0 of GADDR2 contains hash index bit 0.

11.5.5.20 Transmit FIFO Watermark Register (ENET_TFWR)

If TFWR[STRFWD] is cleared, TFWR[TFWR] controls the amount of data required in the transmit FIFO before transmission of a frame can begin. This allows you to minimize transmit latency (TFWR = 00 or 01) or allow for larger bus access latency (TFWR = 11) due to contention for the system bus. Setting the watermark to a high value minimizes the risk of transmit FIFO underrun due to contention for the system bus. The byte counts associated with the TFWR field may need to be modified to match a given system requirement, for example, worst-case bus access latency by the transmit data uDMA channel.

When the FIFO level reaches the value the TFWR field and when the STR_FWD is set to ‘0’, the MAC transmit control logic starts frame transmission even before the end-of-frame is available in the FIFO (cut-through operation).

If a complete frame has a size smaller than the threshold programmed with TFWR, the MAC also transmits the Frame to the line.

To enable store and forward on the Transmit path, set STR_FWD to ‘1’. In this case, the MAC starts to transmit data only when a complete frame is stored in the Transmit FIFO.

Address: 30BE_0000h base + 144h offset = 30BE_0144h

ENET_TFWR field descriptions

Field	Description
31–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 STRFWD	Store And Forward Enable 0 Reset. The transmission start threshold is programmed in TFWR[TFWR]. 1 Enabled.
7–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
TFWR	Transmit FIFO Write If TFWR[STRFWD] is cleared, this field indicates the number of bytes, in steps of 64 bytes, written to the transmit FIFO before transmission of a frame begins. NOTE: If a frame with less than the threshold is written, it is still sent independently of this threshold setting. The threshold is relevant only if the frame is larger than the threshold given. 000000 64 bytes written. 000001 64 bytes written. 000010 128 bytes written. 000011 192 bytes written. 111111 4032 bytes written.

11.5.5.21 Receive Descriptor Ring 1 Start Register (ENET_RDSR1)

RDSR1 points to the beginning of circular receive buffer descriptor queue 1 in external memory. This pointer must be 64-bit aligned (bits 2–0 must be zero); however, for optimal performance the pointer should be 512-bit aligned, that is, evenly divisible by 64.

NOTE

This register must be initialized prior to operation.

11.5.5.23 Maximum Receive Buffer Size Register - Ring 1 (ENET_MRBR1)

MRBR1 is a user-programmable register that dictates the maximum size of all ring-1 receive buffers. This value should take into consideration that the receive CRC is always written into the last receive buffer.

- To allow one maximum size frame per buffer, MRBR1 must be set to RCR[MAX_FL] or larger.
- R_BUF_SIZE is concatenated with the four least-significant bits of this register and are used as the maximum receive buffer size.
- To properly align the buffer, MRBR1 must be evenly divisible by 64. To ensure this, set the lower two bits of R_BUF_SIZE to zero. The lower four bits are already set to zero by the device.
- To minimize bus usage (descriptor fetches), set MRBR1 greater than or equal to 256 bytes.

NOTE

This register must be initialized before operation.

Address: 30BE_0000h base + 168h offset = 30BE_0168h

ENET_RSFL field descriptions

Field	Description
31–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
RX_SECTION_FULL	Value Of Receive FIFO Section Full Threshold Value, in 64-bit words, of the receive FIFO section full threshold. Clear this field to enable store and forward on the RX FIFO. When programming a value greater than 0 (cut-through operation), it must be greater than RAEM[RX_ALMOST_EMPTY]. When the FIFO level reaches the value in this field, data is available in the Receive FIFO (cut-through operation).

11.5.5.31 Receive FIFO Section Empty Threshold (ENET_RSEM)

Address: 30BE_0000h base + 194h offset = 30BE_0194h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0											STAT_SECTION_EMPTY				0				RX_SECTION_EMPTY												
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ENET_RSEM field descriptions

Field	Description
31–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–16 STAT_SECTION_EMPTY	RX Status FIFO Section Empty Threshold Defines number of frames in the receive FIFO, independent of its size, that can be accepted. If the limit is reached, reception will continue normally, however a pause frame will be triggered to indicate a possible congestion to the remote device to avoid FIFO overflow. A value of 0 disables automatic pause frame generation
15–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
RX_SECTION_EMPTY	Value Of The Receive FIFO Section Empty Threshold Value, in 64-bit words, of the receive FIFO section empty threshold. When the FIFO has reached this level, a pause frame will be issued. A value of 0 disables automatic pause frame generation. When the FIFO level goes below the value programmed in this field, an XON pause frame is issued to indicate the FIFO congestion is cleared to the remote Ethernet client. NOTE: The section-empty threshold indications from both FIFOs are OR'ed to cause XOFF pause frame generation.

11.5.5.32 Receive FIFO Almost Empty Threshold (ENET_RAEM)

Address: 30BE_0000h base + 198h offset = 30BE_0198h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

ENET_RAEM field descriptions

Field	Description
31–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

ENET_RAEM field descriptions (continued)

Field	Description
RX_ALMOST_EMPTY	Value Of The Receive FIFO Almost Empty Threshold Value, in 64-bit words, of the receive FIFO almost empty threshold. When the FIFO level reaches the value programmed in this field and the end-of-frame has not been received for the frame yet, the core receive read control stops FIFO read (and subsequently stops transferring data to the MAC client application). It continues to deliver the frame, if again more data than the threshold or the end-of-frame is available in the FIFO. A minimum value of 4 should be set.

11.5.5.33 Receive FIFO Almost Full Threshold (ENET_RAFL)

Address: 30BE_0000h base + 19Ch offset = 30BE_019Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																RX_ALMOST_FULL															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0

ENET_RAFL field descriptions

Field	Description
31–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
RX_ALMOST_FULL	Value Of The Receive FIFO Almost Full Threshold Value, in 64-bit words, of the receive FIFO almost full threshold. When the FIFO level comes close to the maximum, so that there is no more space for at least RX_ALMOST_FULL number of words, the MAC stops writing data in the FIFO and truncates the received frame to avoid FIFO overflow. The corresponding error status will be set when the frame is delivered to the application. A minimum value of 4 should be set.

11.5.5.34 Transmit FIFO Section Empty Threshold (ENET_TSEM)

Address: 30BE_0000h base + 1A0h offset = 30BE_01A0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

ENET_TSEM field descriptions

Field	Description
31–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
TX_SECTION_EMPTY	Value Of The Transmit FIFO Section Empty Threshold

Table continues on the next page...

ENET_TSEM field descriptions (continued)

Field	Description
	Value, in 64-bit words, of the transmit FIFO section empty threshold. See Transmit FIFO for more information.

11.5.5.35 Transmit FIFO Almost Empty Threshold (ENET_TAEM)

Address: 30BE_0000h base + 1A4h offset = 30BE_01A4h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R																																
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0

ENET_TAEM field descriptions

Field	Description
31–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
TX_ALMOST_EMPTY	Value of Transmit FIFO Almost Empty Threshold Value, in 64-bit words, of the transmit FIFO almost empty threshold. When the FIFO level reaches the value programmed in this field, and no end-of-frame is available for the frame, the MAC transmit logic, to avoid FIFO underflow, stops reading the FIFO and transmits a frame with an MII error indication. See Transmit FIFO for more information. A minimum value of 4 should be set.

11.5.5.36 Transmit FIFO Almost Full Threshold (ENET_TAFL)

Address: 30BE_0000h base + 1A8h offset = 30BE_01A8h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																TX_ALMOST_FULL															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0

ENET_TAFL field descriptions

Field	Description
31–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
TX_ALMOST_FULL	Value Of The Transmit FIFO Almost Full Threshold Value, in 64-bit words, of the transmit FIFO almost full threshold. A minimum value of six is required . A recommended value of at least 8 should be set allowing a latency of two clock cycles to the application. If more latency is required the value can be increased as necessary (latency = TAFL - 5).

Table continues on the next page...

ENET_TAFL field descriptions (continued)

Field	Description
	When the FIFO level comes close to the maximum, so that there is no more space for at least TX_ALMOST_FULL number of words, the pin ff_tx_rdy is deasserted. If the application does not react on this signal, the FIFO write control logic, to avoid FIFO overflow, truncates the current frame and sets the error status. As a result, the frame will be transmitted with an GMII/MII error indication. See Transmit FIFO for more information.
	NOTE: A FIFO overflow is a fatal error and requires a global reset on the transmit datapath or at least deassertion of ETHEREN.

11.5.5.37 Transmit Inter-Packet Gap (ENET_TIPG)

Address: 30BE_0000h base + 1ACh offset = 30BE_01ACh

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

ENET_FTRL field descriptions

Field	Description
31–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
TRUNC_FL	Frame Truncation Length

Table continues on the next page...

ENET_FTRL field descriptions (continued)

Field	Description
	Indicates the value a receive frame is truncated, if it is greater than this value. Must be greater than or equal to RCR[MAX_FL].
	NOTE: Truncation happens at TRUNC_FL. However, when truncation occurs, the application (FIFO) may receive less data, guaranteeing that it never receives more than the set limit.

11.5.5.39 Transmit Accelerator Function Configuration (ENET_TACC)

TACC controls accelerator actions when sending frames. The register can be changed before or after each frame, but it must remain unmodified during frame writes into the transmit FIFO.

The TFWR[STRFWD] field must be set to use the checksum feature.

Address: 30BE_0000h base + 1C0h offset = 30BE_01C0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

ENET_TACC field descriptions

Field	Description
31–5 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
4 PROCHK	Enables insertion of protocol checksum. 0 Checksum not inserted. 1 If an IP frame with a known protocol is transmitted, the checksum is inserted automatically into the frame. The checksum field must be cleared. The other frames are not modified.
3 IPCHK	Enables insertion of IP header checksum. 0 Checksum is not inserted. 1 If an IP frame is transmitted, the checksum is inserted automatically. The IP header checksum field must be cleared. If a non-IP frame is transmitted the frame is not modified.

Table continues on the next page...

ENET_TACC field descriptions (continued)

Field	Description
2–1 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
0 SHIFT16	TX FIFO Shift-16 0 Disabled. 1 Indicates to the transmit data FIFO that the written frames contain two additional octets before the frame data. This means the actual frame begins at bit 16 of the first word written into the FIFO. This function allows putting the frame payload on a 32-bit boundary in memory, as the 14-byte Ethernet header is extended to a 16-byte header.

11.5.5.40 Receive Accelerator Function Configuration (ENET_RACC)

Address: 30BE_0000h base + 1C4h offset = 30BE_01C4h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ENET_RACC field descriptions

Field	Description
31–8 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
7 SHIFT16	RX FIFO Shift-16 When this field is set, the actual frame data starts at bit 16 of the first word read from the RX FIFO aligning the Ethernet payload on a 32-bit boundary. NOTE: This function only affects the FIFO storage and has no influence on the statistics, which use the actual length of the frame received. 0 Disabled. 1 Instructs the MAC to write two additional bytes in front of each frame received into the RX FIFO.
6 LINEDIS	Enable Discard Of Frames With MAC Layer Errors 0 Frames with errors are not discarded. 1 Any frame received with a CRC, length, or PHY error is automatically discarded and not forwarded to the user application interface.

Table continues on the next page...

ENET_RACC field descriptions (continued)

Field	Description
5–3 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
2 PRODIS	Enable Discard Of Frames With Wrong Protocol Checksum 0 Frames with wrong checksum are not discarded. 1 If a TCP/IP, UDP/IP, or ICMP/IP frame is received that has a wrong TCP, UDP, or ICMP checksum, the frame is discarded. Discarding is only available when the RX FIFO operates in store and forward mode (RSFL cleared).
1 IPDIS	Enable Discard Of Frames With Wrong IPv4 Header Checksum 0 Frames with wrong IPv4 header checksum are not discarded. 1 If an IPv4 frame is received with a mismatching header checksum, the frame is discarded. IPv6 has no header checksum and is not affected by this setting. Discarding is only available when the RX FIFO operates in store and forward mode (RSFL cleared).
0 PADREM	Enable Padding Removal For Short IP Frames 0 Padding not removed. 1 Any bytes following the IP payload section of the frame are removed from the frame.

11.5.5.41 Receive Classification Match Register for Class n (ENET_RCMRn)

This match register allows specifying up to four priorities, which are tested (OR'ed) simultaneously. The match detection uses the extracted VLAN field according to the rules for VLAN detection configured through the ECR register. If both match registers, RCMR1 and RCMR2, report a match at the same time, only the class 1 match is indicated as the final result.

Address: 30BE_0000h base + 1C8h offset + (4d × i), where i=0d to 1d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															MATCHEN
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	CMP3			0	CMP2			0	CMP1			0	CMP0		
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ENET_RCMRn field descriptions

Field	Description
31–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 MATCHEN	Match Enable NOTE: A comparison is done only on incoming VLAN frames. If no VLAN frame is received no match will occur. If both match registers have overlapping compare values and hence can match both on the same frame, only class 1 will be indicated and the class 2 match is ignored. 0 Disabled (default): no compares will occur and the classification indicator for this class will never assert. 1 The register contents are valid and a comparison with all compare values is done when a VLAN frame is received.
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14–12 CMP3	Compare 3 Fourth value to compare against. If unused it must be set to the same value as CMP0.
11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10–8 CMP2	Compare 2 Third value to compare against. If unused it must be set to the same value as CMP0.
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–4 CMP1	Compare 1 Second value to compare against. If unused it must be set to the same value as CMP0.
3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
CMP0	Compare 0 A three-bit value that will be compared with the frame's VLAN priority field (if a VLAN frame is received). All four compare values, CMP0..3, will be used in parallel. If any of the values match, a match for the class is reported (if MATCHEN is 1). NOTE: To implement a single priority match, all four compare values must be set to the same value.

11.5.5.42 DMA Class Based Configuration (ENET_DMAnCFG)

The DMA class based configuration registers are used to configure the DMA controller interface to support the additional class 1 (buffer descriptor ring 1) and class 2 (buffer descriptor ring 2) traffic and define configuration options such as bandwidth allocation as needed.

NOTE

The registers are cleared when ECR[ETHEREN] becomes 0.

Address: 30BE_0000h base + 1D8h offset + (4d × i), where i=0d to 1d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0								Reserved							
W															CALC_NOIPG	DMA_CLASS_EN

ENET_DMAnCFG field descriptions

Field	Description
31–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23–18 Reserved	This field is reserved. NOTE: Write only zeroes to this field.
17 CALC_NOIPG	Calculate no IPG Disable inclusion of IPG bytes for bandwidth calculations. 0 The traffic shaper function should consider 12 octets of IPG in addition to the frame data transferred for a frame when doing bandwidth calculations. This is the default. 1 Addition of 12 bytes for the IPG should be omitted when calculating the bandwidth (for traffic shaping, when writing a frame into the transmit FIFO, the shaper will usually consider 12 bytes of IPG for every frame as part of the bandwidth allocated by the frame. This addition can be suppressed, meaning short frames will become more bandwidth than large frames due to the relation of data to IPG overhead).
16 DMA_CLASS_EN	DMA class enable 0 The DMA controller's channel for the class is not used. NOTE: Disabling the DMA controller of a class also requires disabling the class match comparator for the class (see registers RCMRn). When class 1 and class 2 queues are disabled then their frames will be placed in queue 0. 1 Enable the DMA controller to support the corresponding descriptor ring for this class of traffic.
IDLE_SLOPE	Idle slope 16-bit value to define the per class idle slope setting used by the credit based shaper defining allocated bandwidth for the class. This value is used to calculate the BW (bandwidth) fraction, given by the equation, BW fraction = 1/(1+512/IDLE_SLOPE). Idle slope is restricted to certain values. For values less than 128, idle slope = 2 ⁿ , where n = 0, 1, 2, ...6. For values equal to or greater than 128, idle slope = 128×m, where m = 1, 2, 3, ...12.

Table continues on the next page...

ENET_DMAnCFG field descriptions (continued)

Field	Description
	<p>Example 1. BW fraction = $0.20 = 1/(1+(512/128))$; therefore idleslope = 128.</p> <p>Example 2. BW fraction = $0.33 = 1/(1+(512/256))$; therefore idleslope = 256.</p> <p>Example 3. BW fraction = $0.75 = 1/(1+(512/1536))$; therefore idleslope = 1536.</p> <p>NOTE: For AVB applications, the BW fraction of class 1 and class 2 combined must not exceed .75.</p>

11.5.5.43 Receive Descriptor Active Register - Ring 1 (ENET_RDAR1)

RDAR1 is a command register, written by the user, to indicate that the receive descriptor ring 1 has been updated, that is, that the driver produced empty receive buffers with the empty bit set.

Address: 30BE_0000h base + 1E0h offset = 30BE_01E0h

ENET_TDAR2 field descriptions

Field	Description
31–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 TDAR	Transmit Descriptor Active Always set to 1 when this register is written, regardless of the value written. This bit is cleared by the MAC device when no additional ready descriptors remain in the transmit ring. Also cleared when ECR[ETHEREN] transitions from set to cleared or when ECR[RESET] is set.
Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

11.5.5.47 QOS Scheme (ENET_QOS)

This register sets the QOS scheme.

NOTE

When both class 1 and class 2 are disabled, RX flushing for these rings must also be disabled.

Ethernet MAC (ENET)

Address: 30BE_0000h base + 1F0h offset = 30BE_01F0h

ENET_QOS field descriptions

Field	Description
31–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5 RX_FLUSH2	RX Flush Ring 2 Enable or disable RX Flush for ring 2. See Receive flushing . 0 Disable 1 Enable
4 RX_FLUSH1	RX Flush Ring 1 Enable or disable RX Flush for ring 1. See Receive flushing . 0 Disable 1 Enable
3 RX_FLUSH0	RX Flush Ring 0 Enable or disable RX Flush for ring 0. See Receive flushing . 0 Disable 1 Enable
TX_SCHEME	TX scheme configuration Configuration information for DMA to select transmitter queue selection/arbitration scheme. 000 Credit-based scheme 001 Round-robin scheme 010-111 Reserved

11.5.5.48 Reserved Statistic Register (ENET_RMON_T_DROP)

Address: 30BE_0000h base + 200h offset = 30BE_0200h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

ENET_IEEE_R_OCTETS_OK field descriptions

Field	Description
COUNT	Number of octets for frames received without error NOTE: Counts total octets (includes header and FCS fields). Does not increment for the broadcast frames when broadcast reject is enabled and promiscuous mode is disabled within the receive control register (RCR).

11.5.5.102 Adjustable Timer Control Register (ENET_ATCR)

ATCR command fields can trigger the corresponding events directly. It is not necessary to preserve any of the configuration fields when a command field is set in the register, that is, no read-modify-write is required.

NOTE

The CAPTURE and RESTART fields and bits 12 and 10 must be 0 in order to write to the other fields in this register.

Address: 30BE_0000h base + 400h offset = 30BE_0400h

ENET_ATCR field descriptions

Field	Description
31–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 SLAVE	Enable Timer Slave Mode 0 The timer is active and all configuration fields in this register are relevant. 1 The internal timer is disabled and the externally provided timer value is used. All other fields, except CAPTURE, in this register have no effect. CAPTURE can still be used to capture the current timer value.

Table continues on the next page...

ENET_ATCR field descriptions (continued)

Field	Description
12 Reserved	This field is reserved. Always write 0 to this field.
11 CAPTURE	<p>Capture Timer Value</p> <p>When this field is set, all other fields are ignored during a write. This field automatically clears to 0 after the command completes.</p> <p>NOTE: To ensure that the correct time value is read from the ATVR register, a minimum amount of time must elapse from issuing this command to reading the ATVR register. This minimum time is defined by the greater of either six register clock cycles or six 1588/timestamp clock cycles.</p> <p>0 No effect. 1 The current time is captured and can be read from the ATVR register.</p>
10 Reserved	This field is reserved. Always write 0 to this field.
9 RESTART	<p>Reset Timer</p> <p>Resets the timer to zero. This has no effect on the counter enable. If the counter is enabled when this field is set, the timer is reset to zero and starts counting from there. When set, all other fields are ignored during a write. This field automatically clears to 0 after the command completes. RESTART should be used when the timer is enabled.</p> <p>NOTE: The Reset Timer command requires at least 6 clock cycles of either the register clock or the 1588/timestamp clock, whichever is greater, to complete.</p>
8 Reserved	This field is reserved.
7 PINPER	<p>Enables event signal output assertion on period event.</p> <p>NOTE: Not all devices contain the event signal output. See the chip configuration details.</p> <p>0 Disable. 1 Enable.</p>
6 Reserved	This field is reserved.
5 Reserved	<p>This field is reserved.</p> <p>NOTE: This field must be written always with one.</p>
4 PEREN	<p>Enable Periodical Event</p> <p>0 Disable. 1 A period event interrupt can be generated (EIR[TS_TIMER]) and the event signal output is asserted when the timer wraps around according to the periodic setting ATPER. The timer period value must be set before setting this bit.</p> <p>NOTE: Not all devices contain the event signal output. See the chip configuration details.</p>
3 OFFRST	<p>Reset Timer On Offset Event</p> <p>0 The timer is not affected and no action occurs, besides clearing OFFEN, when the offset is reached. 1 If OFFEN is set, the timer resets to zero when the offset setting is reached. The offset event does not cause a timer interrupt.</p>
2 OFFEN	Enable One-Shot Offset Event

Table continues on the next page...

ENET_ATCR field descriptions (continued)

Field	Description
0	Disable.
1	The timer can be reset to zero when the given offset time is reached (offset event). The field is cleared when the offset event is reached, so no further event occurs until the field is set again. The timer offset value must be set before setting this field.
1 Reserved	This field is reserved.
0 EN	Enable Timer
0	The timer stops at the current value.
1	The timer starts incrementing.

ENET_ATPER field descriptions

Field	Description
PERIOD	Value for generating periodic events. Each instance the timer reaches this value, the period event occurs and the timer restarts. If the increment value in ATINC is given in true nanoseconds, this value is also given in true nanoseconds. The value should be initialized to 1,000,000,000 (1×10^9) to represent a timer wrap around of one second. The increment value set in ATINC should be set to the true nanoseconds of the period of clock ts_clk, hence implementing a true 1 second counter. NOTE: The value of PERIOD has the following constraint: $2^{32} - \text{ENET_ATINC}[\text{INC_COR}] - 3 \times \text{ENET_ATINC}[\text{INC}] \geq \text{PERIOD} > 0$.

11.5.5.106 Timer Correction Register (ENET_ATCOR)

Address: 30BE_0000h base + 410h offset = 30BE_0410h

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

ENET_TCCR_n field descriptions

Field	Description
TCC	<p>Timer Capture Compare</p> <p>This register is double buffered between the module clock and 1588 clock domains.</p> <p>When configured for compare, the 1588 clock domain updates with the value in the module clock domain whenever the Timer Channel is first enabled and on each subsequent compare. Write to this register with the first compare value before enabling the Timer Channel. When the Timer Channel is enabled, write the second compare value either immediately, or at least before the first compare occurs. After each compare, write the next compare value before the previous compare occurs and before clearing the Timer Flag.</p> <p>The compare occurs one 1588 clock cycle after the IEEE 1588 Counter increments past the compare value in the 1588 clock domain. If the compare value is less than the value of the 1588 Counter when the Timer Channel is first enabled, then the compare does not occur until following the next overflow of the 1588 Counter. If the compare value is greater than the IEEE 1588 Counter when the 1588 Counter overflows, or the compare value is less than the value of the IEEE 1588 Counter after the overflow, then the compare occurs one 1588 clock cycle following the overflow.</p> <p>When configured for capture, the value of the IEEE 1588 Counter is captured into the 1588 clock domain and then updated into the module clock domain, provided the Timer Flag is clear. Always read the capture value before clearing the Timer Flag.</p>

11.5.6 Functional description

This section provides a complete functional description of the MAC-NET core.

11.5.6.1 Ethernet MAC frame formats

The IEEE 802.3 standard defines the Ethernet frame format as follows:

- Minimum length of 64 bytes
- Maximum length of 1518 bytes excluding the preamble and the start frame delimiter (SFD) bytes

An Ethernet frame consists of the following fields:

- Seven bytes preamble
- Start frame delimiter (SFD)
- Two address fields
- Length or type field
- Data field
- Frame check sequence (CRC value)
- Extension field is defined only for Gigabit Ethernet half-duplex implementations and is not supported by the MAC core

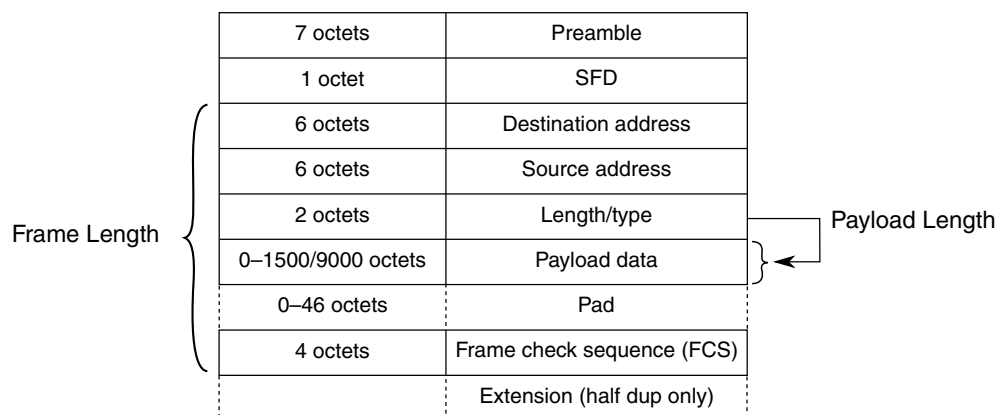

Figure 11-62. MAC frame format overview

Optionally, MAC frames can be VLAN-tagged with an additional four-byte field inserted between the MAC source address and the type/length field. VLAN tagging is defined by the IEEE P802.1q specification. VLAN-tagged frames have a maximum length of 1522 bytes, excluding the preamble and the SFD bytes.

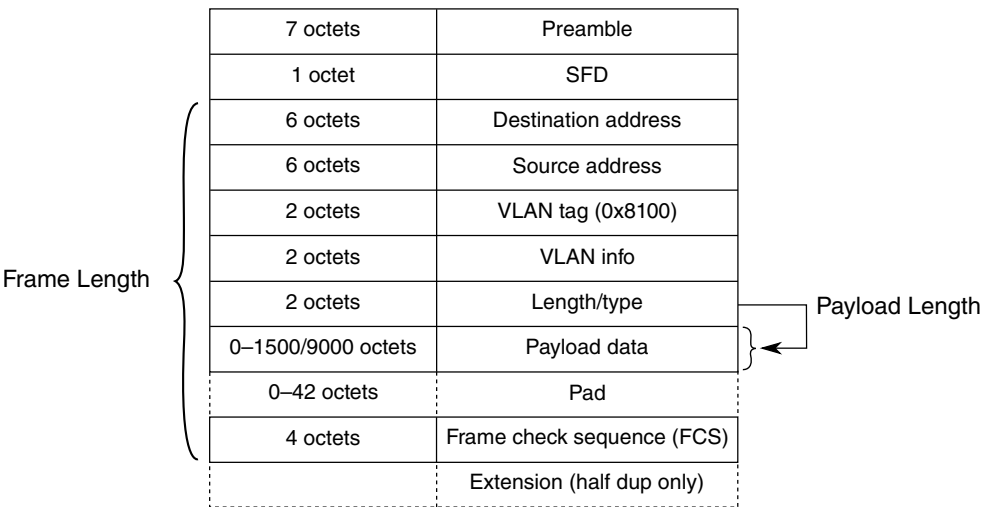

Figure 11-63. VLAN-tagged MAC frame format overview

Table 11-98. MAC frame definition

Term	Description
Frame length	Defines the length, in octets, of the complete frame without preamble and SFD. A frame has a valid length if it contains at least 64 octets and does not exceed the programmed maximum length.
Payload length	<div>The length/type field indicates the length of the frame's payload section. The most significant byte is sent/received first.<ul style="list-style-type: none">If the length/type field is set to a value less than 46, the payload is padded so that the minimum frame length requirement (64 bytes) is met. For VLAN-tagged frames, a value less than 42 indicates a padded frame.If the length/type field is set to a value larger than the programmed frame maximum length (e.g. 1518) it is interpreted as a type field.</div>
Destination and source address	48-bit MAC addresses. The least significant byte is sent/received first and the first two least significant bits of the MAC address distinguish MAC frames, as detailed in MAC address check .

Note

Although the IEEE specification defines a maximum frame length, the MAC core provides the flexibility to program any value for the frame maximum length.

11.5.6.1.1 Pause Frames

The receiving device generates a pause frame to indicate a congestion to the emitting device, which should stop sending data.

Pause frames are indicated by the length/type set to 0x8808. The two first bytes of a pause frame following the type, defines a 16-bit opcode field set to 0x0001 always. A 16-bit pause quanta is defined in the frame payload bytes 2 (P1) and 3 (P2) as defined in the following table. The P1 pause quanta byte is the most significant.

Table 11-99. Pause Frame Format (Values in Hex)

1	2	3	4	5	6	7	8	9	10	11	12	13	14
55	55	55	55	55	55	55	D5	01	80	C2	00	00	01
Preamble							SFD	Multicast Destination Address					
15	16	17	18	19	20	21	22	23	24	25	26	27 –68	
00	00	00	00	00	00	88	08	00	01	hi	lo	00	
Source Address						Type		Opcode		P1	P2	pad (42)	
69	70	71	72										
26	6B	AE	0A										
CRC-32													

There is no payload length field found within a pause frame and a pause frame is always padded with 42 bytes (0x00).

If a pause frame with a pause value greater than zero (XOFF condition) is received, the MAC stops transmitting data as soon the current frame transfer is completed. The MAC stops transmitting data for the value defined in pause quanta. One pause quanta fraction refers to 512 bit times.

If a pause frame with a pause value of zero (XON condition) is received, the transmitter is allowed to send data immediately (see [Full-duplex flow control operation](#) for details).

11.5.6.1.2 Magic packets

A magic packet is a unicast, multicast, or broadcast packet, which carries a defined sequence in the payload section.

Magic packets are received and inspected only under specific conditions as described in [Magic packet detection](#).

The defined sequence to decode a magic packet is formed with a synchronization stream which consists of six consecutive 0xFF bytes, and is followed by sequence of sixteen consecutive unicast MAC addresses of the node to be awakened.

This sequence can be located anywhere in the magic packet payload. The magic packet is formed with a standard Ethernet header, optional padding, and CRC.

11.5.6.2 IP and higher layers frame format

The following sections use the term datagram to describe the protocol specific data unit that is found within the payload section of its container entity.

For example, an IP datagram specifies the payload section of an Ethernet frame. A TCP datagram specifies the payload section within an IP datagram.

11.5.6.2.1 Ethernet types

IP datagrams are carried in the payload section of an Ethernet frame. The Ethernet frame type/length field discriminates several datagram types.

The following table lists the types of interest:

Table 11-100. Ethernet type value examples

Type	Description
0x8100	VLAN-tagged frame. The actual type is found 4 octets later in the frame.
0x0800	IPv4
0x0806	ARP
0x86DD	IPv6

11.5.6.2.2 IPv4 datagram format

The following figure shows the IP Version 4 (IPv4) header, which is located at the beginning of an IP datagram. It is organized in 32-bit words. The first byte sent/received is the leftmost byte of the first word (in other words, version/IHL field).

The IP header can contain further options, which are always padded if necessary to guarantee the payload following the header is aligned to a 32-bit boundary.

The IP header is immediately followed by the payload, which can contain further protocol headers (for example, TCP or UDP, as indicated by the protocol field value). The complete IP datagram is transported in the payload section of an Ethernet frame.

Table 11-101. IPv4 header format

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0				
Version				IHL				TOS								Length																			
Fragment ID																Flags				Fragment offset															
TTL								Protocol								Header checksum																			
Source address																																			
Destination address																																			
Options																																			

Table 11-102. IPv4 header fields

Field name	Description
Version	4-bit IP version information. 0x4 for IPv4 frames.
IHL	4-bit Internet header length information. Determines number of 32-bit words found within the IP header. If no options are present, the default value is 0x5.
TOS	Type of service/DiffServ field.
Length	Total length of the datagram in bytes, including all octets of header and payload.
Fragment ID, flags, fragment offset	Fields used for IP fragmentation.
TTL	Time-to-live. In effect, is decremented at each router arrival. If zero, datagram must be discarded.
Protocol	Identifier of protocol that follows in the datagram.
Header checksum	Checksum of IP header. For computational purposes, this field's value is zero.
Source address	Source IP address.
Destination address	Destination IP address.

11.5.6.2.3 IPv6 datagram format

The following figure shows the IP version 6 (IPv6) header, which is located at the beginning of an IP datagram. It is organized in 32-bit words and has a fixed length of ten words (40 bytes). The next header field identifies the type of the header that follows the IPv6 header. It is defined similar to the protocol identifier within IPv4, with new definitions for identifying extension headers. These headers can be inserted between the IPv6 header and the protocol header, which will shift the protocol header accordingly. The accelerator currently only supports IPv6 without extension headers (in other words, the next header specifies TCP, UDP, or IMCP).

The first byte sent/received is the leftmost byte of the first word (in other words, version/traffic class fields).

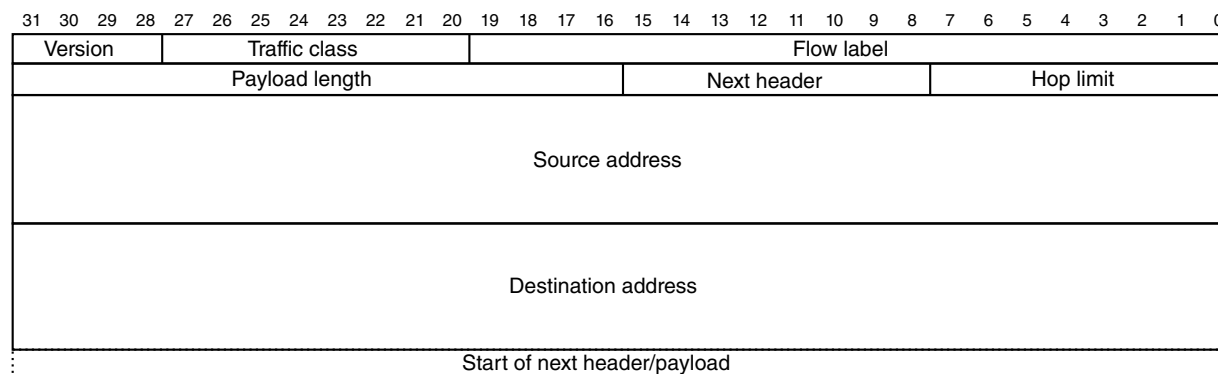

**Figure 11-64. IPv6 header format**

Table 11-103. IPv6 header fields

Field name	Description
Version	4-bit IP version information. 0x6 for all IPv6 frames.
Traffic class	8-bit field defining the traffic class.
Flow label	20-bit flow label identifying frames of the same flow.
Payload length	16-bit length of the datagram payload in bytes. It includes all octets following the IPv6 header.
Next header	Identifies the header that follows the IPv6 header. This can be the protocol header or any IPv6 defined extension header.
Hop limit	Hop counter, decremented by one by each station that forwards the frame. If hop limit is 0 the frame must be discarded.
Source address	128-bit IPv6 source address.
Destination address	128-bit IPv6 destination address.

11.5.6.2.4 Internet Control Message Protocol (ICMP) datagram format

An internet control message protocol (ICMP) is found following the IP header, if the protocol identifier is 1. The ICMP datagram has a four-octet header followed by additional message data.

Table 11-104. ICMP header format

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Type								Code								Checksum															
ICMP message data																															

Table 11-105. IP header fields

Field name	Description
Type	8-bit type information
Code	8-bit code that is related to the message type
Checksum	16-bit one's complement checksum over the complete ICMP datagram

11.5.6.2.5 User Datagram Protocol (UDP) datagram format

A user datagram protocol header is found after the IP header, when the protocol identifier is 17.

The payload of the datagram is after the UDP header. The header byte order follows the conventions given for the IP header above.

Table 11-106. UDP header format

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Length																Checksum															

Table 11-107. UDP header fields

Field name	Description
Source port	Source application port
Destination port	Destination application port
Length	Length of user data which immediately follows the header, including the UDP header (that is, minimum value is 8)
Checksum	Checksum over the complete datagram and some IP header information

11.5.6.2.6 TCP datagram format

A TCP header is found following the IP header, when the protocol identifier has a value of 6.

The TCP payload immediately follows the TCP header.

Table 11-108. TCP header format

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 11-109. TCP header fields

Field name	Description
Source port	Source application port
Destination port	Destination application port
Sequence number	Transmit sequence number
Ack. number	Receive sequence number
Offset	Data offset, which is number of 32-bit words within TCP header — if no options selected, defaults to value of 5
Flags	URG, ACK, PSH, RST, SYN, FIN flags

Table continues on the next page...

Table 11-109. TCP header fields (continued)

Field name	Description
Window	TCP receive window size information
Checksum	Checksum over the complete datagram (TCP header and data) and IP header information
Options	Additional 32-bit words for protocol options

11.5.6.3 IEEE 1588 message formats

The following sections describe the IEEE 1588 message formats.

11.5.6.3.1 Transport encapsulation

The precision time protocol (PTP) datagrams are encapsulated in Ethernet frames using the UDP/IP transport mechanism, or optionally, with the newer 1588v2 directly in Ethernet frames (layer 2).

Typically, multicast addresses are used to allow efficient distribution of the synchronization messages.

11.5.6.3.1.1 UDP/IP

The 1588 messages (v1 and v2) can be transported using UDP/IP multicast messages.

[Table 11-110](#) shows IP multicast groups defined for PTP. The table also shows their respective MAC layer multicast address mapping according to RFC 1112 (last three octets of IP follow the fixed value of 01-00-5E).

Table 11-110. UDP/IP multicast domains

Name	IP Address	MAC Address mapping
DefaultPTPdomain	224.0.1.129	01-00-5E-00-01-81
AlternatePTPdomain1	224.0.1.130	01-00-5E-00-01-82
AlternatePTPdomain2	224.0.1.131	01-00-5E-00-01-83
AlternatePTPdomain3	224.0.1.132	01-00-5E-00-01-84

Table 11-111. UDP port numbers

Message type	UDP port	Note
Event	319	Used for SYNC and DELAY_REQUEST messages
General	320	All other messages (for example, follow-up, delay-response)

11.5.6.3.1.2 Native Ethernet (PTPv2)

In addition to using UDP/IP frames, IEEE 1588v2 defines a native Ethernet frame format that uses ethertype = 0x88F7. The payload of the Ethernet frame immediately contains the PTP datagram, starting with the PTPv2 header.

Besides others, version 2 adds a peer delay mechanism to allow delay measurements between individual point-to-point links along a path over multiple nodes. The following multicast domains are also defined in PTPv2.

Table 11-112. PTPv2 multicast domains

Name	MAC address
Normal messages	01-1B-19-00-00-00
Peer delay messages	01-80-C2-00-00-0E

11.5.6.3.2 PTP header

All PTP frames contain a common header that determines the protocol version and the type of message, which defines the remaining content of the message.

All multi-octet fields are transmitted in big-endian order (the most significant byte is transmitted/received first).

The last four bits of versionPTP are at the same position (second byte) for PTPv1 and PTPv2 headers. This allows accurate identification by inspecting the first two bytes of the message.

11.5.6.3.2.1 PTPv1 header

Table 11-113. Common PTPv1 message header

Offset	Octets	Bits							
		7	6	5	4	3	2	1	0
0	2	versionPTP = 0x0001							
2	2	versionNetwork							
4	16	subdomain							
20	1	messageType							
21	1	sourceCommunicationTechnology							
22	6	sourceUuid							
28	2	sourcePortId							
30	2	sequenceId							

Table continues on the next page...

Table 11-113. Common PTPv1 message header (continued)

Offset	Octets	Bits							
		7	6	5	4	3	2	1	0
32	1	control							
33	1	0x00							
34	2	flags							
36	4	reserved							

The type of message is encoded in the messageType and control fields as shown in [Table 11-114](#):

Table 11-114. PTPv1 message type identification

messageType	control	Message Name	Message
0x01	0x0	SYNC	Event message
0x01	0x1	DELAY_REQ	Event message
0x02	0x2	FOLLOW_UP	General message
0x02	0x3	DELAY_RESP	General message
0x02	0x4	MANAGEMENT	General message
other	other	—	Reserved

The field sequenceId is used to non-ambiguously identify a message.

11.5.6.3.2.2 PTPv2 header

Table 11-115. Common PTPv2 message header

Offset	Octets	Bits							
		7	6	5	4	3	2	1	0
0	1	transportSpecific				messageId			
1	1	reserved				versionPTP = 0x2			
2	2	messageLength							
4	1	domainNumber							
5	1	reserved							
6	2	flags							
8	8	correctionField							
16	4	reserved							
20	10	sourcePortIdentity							
30	2	sequenceId							
32	1	control							
33	1	logMeanMessageInterval							

The type of message is encoded in the field `messageId` as follows:

Table 11-116. PTPv2 message type identification

messageId	Message name	Message
0x0	SYNC	Event message
0x1	DELAY_REQ	Event message
0x2	PATH_DELAY_REQ	Event message
0x3	PATH_DELAY_RESP	Event message
0x4–0x7	—	Reserved
0x8	FOLLOW_UP	General message
0x9	DELAY_RESP	General message
0xa	PATH_DELAY_FOLLOW_UP	General message
0xb	ANNOUNCE	General message
0xc	SIGNALING	General message
0xd	MANAGEMENT	General message

The PTPv2 flags field contains further details on the type of message, especially if one-step or two-step implementations are used. The one- or two-step implementation is controlled by the `TWO_STEP` bit in the first octet of the flags field as shown below. Reserved bits are cleared.

Table 11-117. PTPv2 message flags field definitions

Bit	Name	Description
0	ALTERNATE_MASTER	See IEEE 1588 Clause 17.4
1	TWO_STEP	1 Two-step clock 0 One-step clock
2	UNICAST	1 Transport layer address uses a unicast destination address 0 Multicast is used
3	—	Reserved
4	—	Reserved
5	Profile specific	
6	Profile specific	
7	—	Reserved

11.5.6.4 MAC receive

The MAC receive engine performs the following tasks:

- Check frame framing

- Remove frame preamble and frame SFD field
- Discard frame based on frame destination address field
- Terminate pause frames
- Check frame length
- Remove payload padding if it exists
- Calculate and verify CRC-32
- Write received frames in the core receive FIFO

If the MAC is programmed to operate in half-duplex mode, it will also check if the frame is received with a collision.

Figure 11-65. MAC receive flow

11.5.6.4.1 Collision detection in half-duplex mode

If the packet is received with a collision detected during reception of the first 64 bytes, the packet is discarded (if frame size was less than ~14 octets) or transmitted to the user application with an error and RxBD[CE] set.

11.5.6.4.2 Preamble processing

The IEEE 802.3 standard allows a maximum size of 56 bits (seven bytes) for the preamble, while the MAC core allows any preamble length, including zero length preamble.

The MAC core checks for the start frame delimiter (SFD) byte. If the next byte of the preamble, which is different from 0x55, is not 0xD5, the frame is discarded.

Although the IEEE specification dictates that the inner-packet gap should be at least 96 bits, the MAC core is designed to accept frames separated by only 64 10/100-Mbit/s operation (MII) bits.

The MAC core removes the preamble and SFD bytes.

11.5.6.4.3 MAC address check

The destination address bit 0 differentiates between multicast and unicast addresses.

- If bit 0 is 0, the MAC address is an individual (unicast) address.
- If bit 0 is 1, the MAC address defines a group (multicast) address.
- If all 48 bits of the MAC address are set, it indicates a broadcast address.

11.5.6.4.3.1 Unicast address check

If a unicast address is received, the destination MAC address is compared to the node MAC address programmed by the host in the PADDR1/2 registers.

If the destination address matches any of the programmed MAC addresses, the frame is accepted.

If Promiscuous mode is enabled ($\text{RCR}[\text{PROM}] = 1$) no address checking is performed and all unicast frames are accepted.

11.5.6.4.3.2 Multicast and unicast address resolution

The hash table algorithm used in the group and individual hash filtering operates as follows.

- The 48-bit destination address is mapped into one of 64 bits, represented by 64 bits in $\text{ENET}_n\text{_GAUR/GALR}$ (group address hash match) or $\text{ENET}_n\text{_IAUR/IALR}$ (individual address hash match).

- This mapping is performed by passing the 48-bit address through the on-chip 32-bit CRC generator and selecting the six most significant bits of the CRC-encoded result to generate a number between 0 and 63.
- The msb of the CRC result selects ENET n _GAUR (msb = 1) or ENET n _GALR (msb = 0).
- The five lsbs of the hash result select the bit within the selected register.
- If the CRC generator selects a bit set in the hash table, the frame is accepted; else, it is rejected.

For example, if eight group addresses are stored in the hash table and random group addresses are received, the hash table prevents roughly 56/64 (or 87.5%) of the group address frames from reaching memory. Those that do reach memory must be further filtered by the processor to determine if they truly contain one of the eight desired addresses.

The effectiveness of the hash table declines as the number of addresses increases.

The user must initialize the hash table registers. Use this CRC32 polynomial to compute the hash:

- $FCS(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x^1 + 1$

If Promiscuous mode is enabled (ENET n _RCR[PROM] = 1) all unicast and multicast frames are accepted regardless of ENET n _GAUR/GALR and ENET n _IAUR/IALR settings.

11.5.6.4.3.3 Broadcast address reject

All broadcast frames are accepted if BC_REJ is cleared or ENET n _RCR[PROM] is set. If PROM is cleared when ENET n _RCR[BC_REJ] is set, all broadcast frames are rejected.

Table 11-118. Broadcast address reject programming

PROM	BC_REJ	Broadcast frames
0	0	Accepted
0	1	Rejected
1	0	Accepted
1	1	Accepted

11.5.6.4.3.4 Miss-bit implementation

For higher layer filtering purposes, RxBD[M] indicates an address miss when the MAC operates in promiscuous mode and accepts a frame that would otherwise be rejected.

If a group/individual hash or exact match does not occur and Promiscuous mode is enabled (RCR[PROM] = 1), the frame is accepted and the M bit is set in the buffer descriptor; otherwise, the frame is rejected.

This means the status bit is set in any of the following conditions during Promiscuous mode:

- A broadcast frame is received when BC_REJ is set
- A unicast is received that does not match either:
 - Node address (PALR[PADDR1] and PAUR[PADDR2])
 - Hash table for unicast (IAUR[IADDR1] and IALR[IADDR2])
- A multicast is received that does not match the GAUR[GADDR1] and GALR[GADDR2] hash table entries

11.5.6.4.4 Frame length/type verification: payload length check

If the length/type is less than 0x600 and NLC is set, the MAC checks the payload length and reports any error in the frame status word and interrupt bit PLR.

If the length/type is greater than or equal to 0x600, the MAC interprets the field as a type and no payload length check is performed.

The length check is performed on VLAN and stacked VLAN frames. If a padded frame is received, no length check can be performed due to the extended frame payload because padded frames can never have a payload length error.

11.5.6.4.5 Frame length/type verification: frame length check

When the receive frame length exceeds MAX_FL bytes, the BABR interrupt is generated and the RxBD[LG] bit is set.

The frame is not truncated unless the frame length exceeds the value programmed in ENET n _FTRL[TRUNC_FL]. If the frame is truncated, RxBD[TR] is set. In addition, a truncated frame always has the CRC error indication set (RxBD[CR]).

11.5.6.4.6 VLAN frames processing

VLAN frames have a length/type field set to 0x8100 immediately followed by a 16-Bit VLAN control information field.

VLAN-tagged frames are received as normal frames because the VLAN tag is not interpreted by the MAC function, and are pushed complete with the VLAN tag to the user application. If the length/type field of the VLAN-tagged frame, which is found four octets later in the frame, is less than 42, the padding is removed. In addition, the frame status word (RxB_{NO}) indicates that the current frame is VLAN tagged.

11.5.6.4.7 Pause frame termination

The receive engine terminates pause frames and does not transfer them to the receive FIFO. The quanta is extracted and sent to the MAC transmit path via a small internal clock rate decoupling asynchronous FIFO.

The quanta is written only if a correct CRC and frame length are detected by the control state machine. If not, the quanta is discarded and the MAC transmit path is not paused.

Good pause frames are ignored if ENET_n_RCR[FCE] is cleared and are forwarded to the client interface when ENET_n_RCR[PAUFWD] is set.

11.5.6.4.8 CRC check

The CRC-32 field is checked and forwarded to the core FIFO interface if ENET_n_RCR[CRCFWD] is cleared and ENET_n_RCR[PADEN] is cleared. When CRCFWD is set (regardless of PADEN), the CRC-32 field is checked and terminated (not transmitted to the FIFO).

The CRC polynomial, as specified in the 802.3 standard, is:

$$\bullet \text{ FCS}(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x^1 + 1$$

The 32 bits of the CRC value are placed in the frame check sequence (FCS) field with the x^{31} term as right-most bit of the first octet. The CRC bits are thus received in the following order: $x^{31}, x^{30}, \dots, x^1, x^0$.

If a CRC error is detected, the frame is marked invalid and RxB_{CR} is set.

11.5.6.4.9 Frame padding removal

When a frame is received with a payload length field set to less than 46 (42 for VLAN-tagged frames and 38 for frames with stacked VLANs), the zero padding can be removed before the frame is written into the data FIFO depending on the setting of `ENETn_RCR[PADEN]`.

Note

If a frame is received with excess padding (in other words, the length field is set as mentioned above, but the frame has more than 64 octets) and padding removal is enabled, then the padding is removed as normal and no error is reported if the frame is otherwise correct (for example: good CRC, less than maximum length, and no other error).

11.5.6.4.10 Frame classification (AVB)

To support protocols such as Audio Video Bridging (AVB, IEEE 802.1Qav), normal traffic is separated from time-sensitive traffic immediately at the application interface to allow storing them in different queues for further processing. For every frame received, a classification based on VLAN priority can be performed. When a frame is received, and it contains a VLAN tag, the priority is compared against the values set in the classification match registers (see [Receive Classification Match Register for Class n \(ENET_RCMRn\)](#)) and the following figure.

Figure 11-66. AVB frame classification

11.5.6.4.11 Receive flushing

RX flushing prevents frames in the RX FIFO from being blocked. Blocking can occur if the frame at the head of the RX FIFO cannot be forwarded because the ring it is associated with cannot accept it. This situation occurs when either the ring's `RxBD[EMPTY]` is not set or `ENET_RDARn` is not set. When RX flushing is enabled, via [QOS Scheme \(ENET_QOS\)](#), the blocking frame will be flushed (discarded).

11.5.6.5 MAC transmit

Frame transmission starts when the transmit FIFO holds enough data.

After a transfer starts, the MAC transmit function performs the following tasks:

- Generates preamble and SFD field before frame transmission
- Generates XOFF pause frames if the receive FIFO reports a congestion or if ENET n _TCR[TFC_PAUSE] is set with ENET n _OPD[PAUSE_DUR] set to a non-zero value
- Generates XON pause frames if the receive FIFO congestion condition is cleared or if TFC_PAUSE is set with PAUSE_DUR cleared
- Suspends Ethernet frame transfer (XOFF) if a non-zero pause quanta is received from the MAC receive path
- Adds padding to the frame if required
- Calculates and appends CRC-32 to the transmitted frame
- Sends the frame with correct inter-packet gap (IPG) (deferring)

When the MAC is configured to operate in half-duplex mode, the following additional tasks are performed:

- Collision detection
- Frame retransmit after back-off timer expires

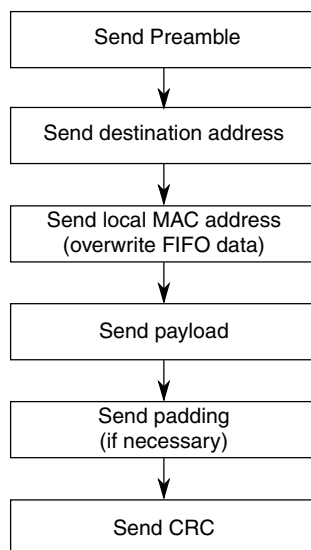

Figure 11-67. Frame transmit overview

11.5.6.5.1 Frame payload padding

The IEEE specification defines a minimum frame length of 64 bytes.

If the frame sent to the MAC from the user application has a size smaller than 60 bytes, the MAC automatically adds padding bytes (0x00) to comply with the Ethernet minimum frame length specification. Transmit padding is always performed and cannot be disabled.

If the MAC is not allowed to append a CRC ($\text{TxBD}[\text{TC}] = 1$), the user application is responsible for providing frames with a minimum length of 64 octets.

11.5.6.5.2 MAC address insertion

On each frame received from the core transmit FIFO interface, the source MAC address is either:

- Replaced by the address programmed in the PADDR1/2 fields ($\text{ENETn_TCR}[\text{ADDINS}] = 1$)
- Transparently forwarded to the Ethernet line ($\text{ENETn_TCR}[\text{ADDINS}] = 0$)

11.5.6.5.3 CRC-32 generation

The CRC-32 field is optionally generated and appended at the end of a frame.

The CRC polynomial, as specified in the 802.3 standard, is:

- $\text{FCS}(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x^1 + 1$

The 32 bits of the CRC value are placed in the FCS field so that the x^{31} term is the right-most bit of the first octet. The CRC bits are thus transmitted in the following order: x^{31} , x^{30}, \dots, x^1, x^0 .

11.5.6.5.4 Inter-packet gap (IPG)

In full-duplex mode, after frame transmission and before transmission of a new frame, an IPG (programmed in ENETn_TIPG) is maintained. The minimum IPG can be programmed between 8 and 26 byte-times (64 and 208 bit-times).

In half-duplex mode, the core constantly monitors the line. Actual transmission of the data onto the network occurs only if it has been idle for a 96-bit time period, and any back-off time requirements have been satisfied. In accordance with the standard, the core begins to measure the IPG from CRS/GMII_CRS de-assertion.

11.5.6.5.5 Collision detection and handling — half-duplex operation only

A collision occurs on a half-duplex network when concurrent transmissions from two or more nodes take place. During transmission, the core monitors the line condition and detects a collision when the PHY device asserts COL.

When the core detects a collision while transmitting, it stops transmission of the data and transmits a 32-bit jam pattern. If the collision is detected during the preamble or the SFD transmission, the jam pattern is transmitted after completing the SFD, which results in a minimum 96-bit fragment. The jam pattern is a fixed pattern that is not compared to the actual frame CRC, and has a very low probability (0.532) of having a jam pattern identical to the CRC.

If a collision occurs before transmission of 64 bytes (including preamble and SFD), the MAC core waits for the backoff period and retransmits the packet data (stored in a 64-byte re-transmit buffer) that has already been sent on the line. The backoff period is generated from a pseudo-random process (truncated binary exponential backoff).

If a collision occurs after transmission of 64 bytes (including preamble and SFD), the MAC discards the remainder of the frame, optionally sets the LC interrupt bit, and sets TxBD[LCE].

Figure 11-68. Packet re-transmit overview

The backoff time is represented by an integer multiple of slot times. One slot is equal to a 512-bit time period. The number of the delay slot times, before the n^{th} re-transmission attempt, is chosen as a uniformly-distributed random integer in the range:

- $0 < r < 2^k$
- $k = \min(n, N)$; where n is the number of retransmissions and $N = 10$

For example, after the first collision, the backoff period is 0 or 1 slot time. If a collision occurs on the first retransmission, the backoff period is 0, 1, 2, or 3, and so on.

The maximum backoff time (in 512-bit time slots) is limited by $N = 10$ as specified in the IEEE 802.3 standard.

If a collision occurs after 16 consecutive retransmissions, the core reports an excessive collision condition (ENET n _EIR[RL] interrupt field and TxBD[EE]) and discards the current packet from the FIFO.

In networks violating the standard requirements, a collision may occur after transmission of the first 64 bytes. In this case, the core stops the current packet transmission and discards the rest of the packet from the transmit FIFO. The core resumes transmission with the next packet available in the core transmit FIFO.

warning

Ethernet PHYs that support the SQE Test, or "heartbeat," feature must disable this feature. When this feature is enabled, the PHY asserts the collision signal after a frame is transmitted to indicate to the ENET that the PHY's collision logic is working. This may cause data corruption in the next frame from the ENET. This corrupted frame contains up to 21 zero bytes which start somewhere within the MAC destination address field. The ENET, however, will still generate a good FCS (CRC-32) but with corrupted data.

11.5.6.5.6 Rate limiting / traffic shaping support

The MAC-NET supports two methods to optimize frame traffic for either time-sensitive AVB frames (Class A and Class B) or best-effort non-AVB frames:

- Round-robin scheme
- Credit-based traffic shaping

To ensure that sufficient bandwidth is allocated for the AVB frames, the credit-based shaper must be used. Either method can be combined with a time-based shaper to ensure that a frame is always transmitted in its correct time slot.

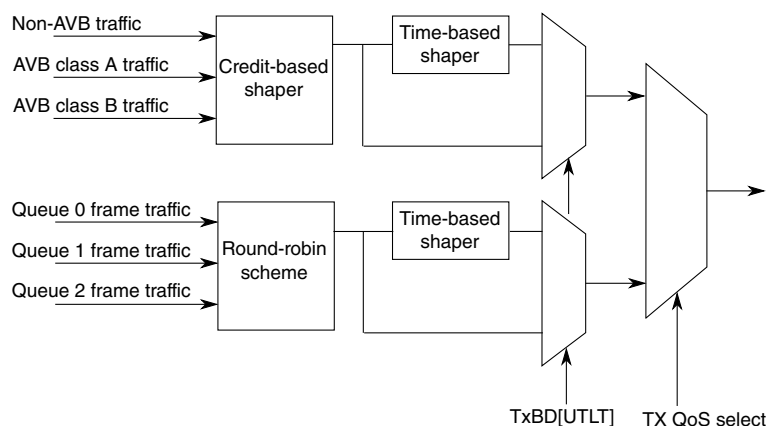

Figure 11-69. Transmit arbitration schemes

11.5.6.5.6.1 Round-robin policy

In the round-robin QoS scheme, each queue is given an equal opportunity to transmit one frame. For example, if queue n has a frame to transmit, the queue transmits its frame. After queue n has transmitted its frame, or if queue n does not have a frame to transmit, queue $n+1$ is then allowed to transmit its frame, and so on.

11.5.6.5.6.2 Credit-based shaper

The AVB credit based shaper acts independently, per class, to control the bandwidth distribution between normal traffic and time-sensitive traffic with respect to the total link bandwidth available. As per the IEEE 802.1Q, the maximum bandwidth distribution that can be allocated for the time-sensitive frames is 75%. The following example uses 70% for AVB frames and 30% for non-AVB frames:

Table 11-119. Bandwidth allocation example

AVB Class A	50%
AVB Class B	20%
non-AVB frames	30%
Total	100%

See [DMA Class Based Configuration \(ENET_DMA \$n\$ CFG\)](#) for information on how to allocate bandwidth. The following figure shows how frame traffic is controlled within the MAC-NET core.

11.5.6.5.6.3 Time-based shaper

The time-based shaper enables the user to specify when a frame can be transmitted. It is always used in combination with either the round-robin scheme or the credit-based shaper. Use of the time-based shaper can ensure that frames are always transmitted in the correct time slot.

11.5.6.5.6.3.1 Time-based shaper example

Time-based shaping involves the following procedure:

1. Read the current value of the timer. See [Timer Value Register \(ENET_ATVR\)](#) and [Adjustable Timer Control Register \(ENET_ATCR\)](#).
2. Calculate the frame launch time and write this value to the TLT field of the frame's TxBD. See [Enhanced transmit buffer descriptor](#).
3. Instruct the ENET to use the TLT by setting TxBD[UTLT].

The frame will be fetched and transmitted only if TxBD[TLT] is less than the current value of the timer. In other words, the timer must be past, that is, be greater than, the transmit launch time before the frame will be fetched and transmitted.

The transmit launch time must be not be greater than the current value of ENET_ATVR + (0.5 × ENET_ATPER). This means the application can not prepare frames with launch times beyond ENET_ATVR + (0.5 × ENET_ATPER). Because ENET_ATVR wraps, calculate TLT using the equation

$$(ENET_ATVR + (0.5 \times ENET_ATPER)) \bmod ENET_ATPER$$

For example, if ENET_ATPER is set to the recommended value of 1,000,000,000 ns (one second), then the user must not prepare future frames with launch times greater than (500,000,000 + ENET_ATVR).

As a specific example, if the current value of ENET_ATVR is 100,000, then you can prepare the following frames:

1. Frame 1 TxBD[TLT] = 100,000ns + 125,000ns
2. Frame 2 TxBD[TLT] = 100,000ns + 250,000ns
3. And so on

11.5.6.6 Full-duplex flow control operation

Three conditions are handled by the core's flow control engine:

- Remote device congestion — The remote device connected to the same Ethernet segment as the core reports congestion and requests that the core stop sending data.

- Core FIFO congestion — When the core's receive FIFO reaches a user-programmable threshold (RX section empty), the core sends a pause frame back to the remote device requesting the data transfer to stop.
- Local device congestion — Any device connected to the core can request (typically, via the host processor) the remote device to stop transmitting data.

11.5.6.6.1 Remote device congestion

When the MAC transmit control gets a valid pause quanta from the receive path and if `ENETn_RCR[FCE]` is set, the MAC transmit logic:

- Completes the transfer of the current frame.
- Stops sending data for the amount of time specified by the pause quanta in 512 bit time increments.
- Sets `ENETn_TCR[RFC_PAUSE]`.

Frame transfer resumes when the time specified by the quanta expires and if no new quanta value is received, or if a new pause frame with a quanta value set to 0x0000 is received. The MAC also resets `RFC_PAUSE` to zero.

If `ENETn_RCR[FCE]` cleared, the MAC ignores received pause frames.

Optionally and independent of `ENETn_RCR[FCE]`, pause frames are forwarded to the client interface if `PAUFWD` is set.

11.5.6.6.2 Local device/FIFO congestion

The MAC transmit engine generates pause frames when the local receive FIFO is not able to receive more than a pre-defined number of words (FIFO programmable threshold) or when pause frame generation is requested by the local host processor.

- To generate a pause frame, the host processor sets `ENETn_TCR[TFC_PAUSE]`. A single pause frame is generated when the current frame transfer is completed and `TFC_PAUSE` is automatically cleared. Optionally, an interrupt is generated.

- An XOFF pause frame is generated when the receive FIFO asserts its section empty flag (internal). An XOFF pause frame is generated automatically, when the current frame transfer completes.
- An XON pause frame is generated when the receive FIFO deasserts its section empty flag (internal). An XON pause frame is generated automatically, when the current frame transfer completes.

When an XOFF pause frame is generated, the pause quanta (payload byte P1 and P2) is filled with the value programmed in `ENETn_OPD[PAUSE_DUR]`.

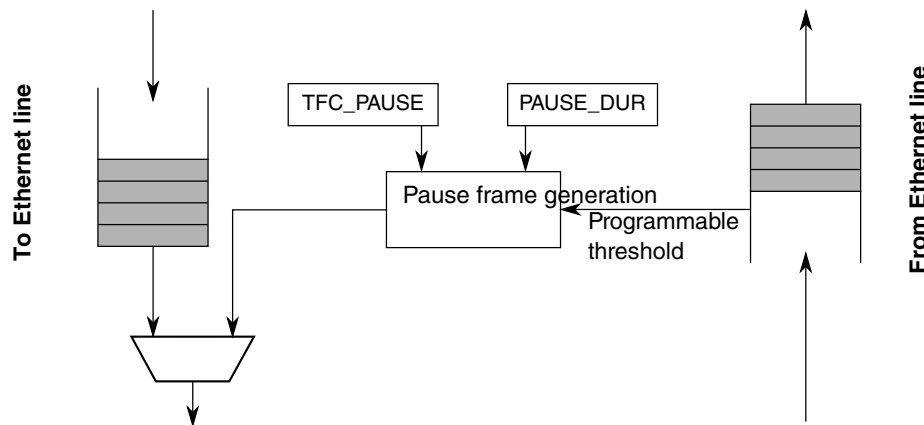

Figure 11-70. Pause frame generation overview

Note

Although the flow control mechanism should prevent any FIFO overflow on the MAC core receive path, the core receive FIFO is protected. When an overflow is detected on the receive FIFO, the current frame is truncated with an error indication set in the frame status word. The frame should subsequently be discarded by the user application.

11.5.6.7 Magic packet detection

Magic packet detection wakes a node that is put in power-down mode by the node management agent. Magic packet detection is supported only if the MAC is configured in sleep mode.

11.5.6.7.1 Sleep mode

To put the MAC in Sleep mode, set `ENETn_ECR[SLEEP]`. At the same time `ENETn_ECR[MAGICEN]` should also be set to enable magic packet detection.

In addition, if ENET is enabled, write 1 to ENET n _ECR[SLEEP] before entering into low power mode.

When the MAC is in Sleep mode:

- The transmit logic is disabled.
- The FIFO receive/transmit functions are disabled.
- The receive logic is kept in Normal mode, but it ignores all traffic from the line except magic packets. They are detected so that a remote agent can wake the node.

11.5.6.7.2 Magic packet detection

The core is designed to detect magic packets (see [Magic packets](#)) with the destination address set to:

- Any multicast address
- The broadcast address
- The unicast address programmed in PADDR1/2

When a magic packet is detected, EIR[WAKEUP] is set and none of the statistic registers are incremented.

11.5.6.7.3 Wakeup

When a magic packet is detected, indicated by ENET n _EIR[WAKEUP], ENET n _ECR[SLEEP] should be cleared to resume normal operation of the MAC. Clearing the SLEEP bit automatically masks ENET n _ECR[MAGICEN], disabling magic packet detection.

11.5.6.8 IP accelerator functions

The following sections describe the IP accelerator functions.

11.5.6.8.1 Checksum calculation

The IP and ICMP, TCP, UDP checksums are calculated with one's complement arithmetic summing up 16-bit values.

- For ICMP, the checksum is calculated over the complete ICMP datagram, in other words without IP header.
- For TCP and UDP, the checksums contain the header and data sections and values from the IP header, which can be seen as a pseudo-header that is not actually present in the data stream.

Table 11-120. IPv4 pseudo-header for checksum calculation

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Source address																															
Destination address																															
Zero								Protocol								TCP/UDP length															

Table 11-121. IPv6 pseudo-header for checksum calculation

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0				
Source address																																			
Destination address																																			
TCP/UDP length																																			
Zero																								Next header											

The TCP/UDP length value is the length of the TCP or UDP datagram, which is equal to the payload of an IP datagram. It is derived by subtracting the IP header length from the complete IP datagram length that is given in the IP header (IPv4), or directly taken from the IP header (IPv6). The protocol field is the corresponding value from the IP header. The Zero fields are all zeroes.

For IPv6, the complete 128-bit addresses are considered. The next header value identifies the upper layer protocol as either TCP or UDP. It may differ from the next header value of the IPv6 header if extension headers are inserted before the protocol header.

The checksum calculation uses 16-bit words in network byte order: The first byte sent/received is the MSB, and the second byte sent/received is the LSB of the 16-bit value to add to the checksum. If the frame ends on an odd number of bytes, a zero byte is appended for checksum calculation only, and is not actually transmitted.

11.5.6.8.2 Additional padding processing

According to IEEE 802.3, any Ethernet frame must have a minimum length of 64 octets.

The MAC usually removes padding on receive when a frame with length information is received. Because IP frames have a type value instead of length, the MAC does not remove padding for short IP frames, as it is not aware of the frame contents.

The IP accelerator function can be configured to remove the Ethernet padding bytes that might follow the IP datagram.

On transmit, the MAC automatically adds padding as necessary to fill any frame to a 64-byte length.

11.5.6.8.3 32-bit Ethernet payload alignment

The data FIFOs allow inserting two additional arbitrary bytes in front of a frame. This extends the 14-byte Ethernet header to a 16-byte header, which leads to alignment of the Ethernet payload, following the Ethernet header, on a 32-bit boundary.

This function can be enabled for transmit and receive independently with the corresponding SHIFT16 bits in the ENETn_TACC and ENETn_RACC registers.

When enabled, the valid frame data is arranged as shown in [Table 11-122](#).

Table 11-122. 64-bit interface data structure with SHIFT16 enabled

63 56	55 48	47 40	39 32	31 24	23 16	15 8	7 0
Byte 5	Byte 4	Byte 3	Byte 2	Byte 1	Byte 0	Any value	Any value
Byte 13	Byte 12	Byte 11	Byte 10	Byte 9	Byte 8	Byte 7	Byte 6
...							

11.5.6.8.3.1 Receive processing

When ENETn_RACC[SHIFT16] is set, each frame is received with two additional bytes in front of the frame.

The user application must ignore these first two bytes and find the first byte of the frame in bits 23–16 of the first word from the RX FIFO.

Note

SHIFT16 must be set during initialization and kept set during the complete operation, because it influences the FIFO write behavior.

11.5.6.8.3.2 Transmit processing

When ENETn_TACC[SHIFT16] is set, the first two bytes of the first word written (bits 15–0) are discarded immediately by the FIFO write logic.

The SHIFT16 bit can be enabled/disabled for each frame individually if required, but can be changed only between frames.

11.5.6.8.4 Received frame discard

Because the receive FIFO must be operated in store and forward mode (ENETn_RSFL cleared), received frames can be discarded based on the following errors:

- The MAC function receives the frame with an error:
 - The frame has an invalid payload length
 - Frame length is greater than MAX_FL
 - Frame received with a CRC-32 error
 - Frame truncated due to receive FIFO overflow
 - Frame is corrupted as PHY signaled an error (RX_ERR asserted during reception)
- An IP frame is detected and the IP header checksum is wrong
- An IP frame with a valid IP header and a valid IP header checksum is detected, the protocol is known but the protocol-specific checksum is wrong

If one of the errors occurs and the IP accelerator function is configured to discard frames (ENETn_RACC), the frame is automatically discarded. Statistics are maintained normally and are not affected by this discard function.

11.5.6.8.5 IPv4 fragments

When an IPv4 IP fragment frame is received, only the IP header is inspected and its checksum verified. 32-bit alignment operates the same way on fragments as it does on normal IP frames, as specified above.

The IP fragment frame payload is not inspected for any protocol headers. As such, a protocol header would only exist in the very first fragment. To assist in protocol-specific checksum verification, the one's-complement sum is calculated on the IP payload (all bytes following the IP header) and provided with the frame status word.

The frame fragment status field (RxBD[FRAG]) is set to indicate a fragment reception, and the one's-complement sum of the IP payload is available in RxBD[Payload checksum].

Note

After all fragments have been received and reassembled, the application software can take advantage of the payload checksum delivered with the frame's status word to calculate the protocol-specific checksum of the datagram.

For example, if a TCP payload is delivered by multiple IP fragments, the application software can calculate the pseudo-header checksum value from the first fragment, and add the payload checksums delivered with the status for all fragments to verify the TCP datagram checksum.

11.5.6.8.6 IPv6 support

The following sections describe the IPv6 support.

11.5.6.8.6.1 Receive processing

An Ethernet frame of type 0x86DD identifies an IP Version 6 frame (IPv6) frame. If an IPv6 frame is received, the first IP header is inspected (first ten words), which is available in every IPv6 frame.

If the receive SHIFT16 function is enabled, the IP header is aligned on a 32-bit boundary allowing more efficient processing (see [32-bit Ethernet payload alignment](#)).

For TCP and UDP datagrams, the pseudo-header checksum calculation is performed and verified.

To assist in protocol-specific checksum verification, the one's-complement sum is always calculated on the IP payload (all bytes following the IP header) and provided with the frame status word. For example, if extension headers were present, their sums can be subtracted in software from the checksum to isolate the TCP/UDP datagram checksum, if required.

11.5.6.8.6.2 Transmit processing

For IPv6 transmission, the SHIFT16 function is supported to process 32-bit aligned datagrams.

IPv6 has no IP header checksum; therefore, the IP checksum insertion configuration is ignored.

The protocol checksum is inserted only if the next header of the IP header is a known protocol (TCP, UDP, or ICMP). If a known protocol is detected, the checksum over all bytes following the IP header is calculated and inserted in the correct position.

The pseudo-header checksum calculation is performed for TCP and UDP datagrams accordingly.

11.5.6.9 Resets and stop controls

The following sections describe the resets and stop controls.

11.5.6.9.1 Hardware reset

To reset the Ethernet module, set `ENETn_ECR[RESET]`.

11.5.6.9.2 Soft reset

When `ENETn_ECR[ETHER_EN]` is cleared during operation, the following occurs:

- uDMA, buffer descriptor, and FIFO control logic are reset, including the buffer descriptor and FIFO pointers.
- A currently ongoing transmit is terminated by asserting GMII/TXER to the PHY.
- A currently ongoing transmit FIFO write from the application is terminated by stopping the write to the FIFO, and all further data from the application is ignored. All subsequent writes are ignored until re-enabled.
- A currently ongoing receive FIFO read is terminated. The RxBD has arbitrary values in this case.

11.5.6.9.3 Hardware freeze

When the processor enters debug mode and `ECR[DBGEN]` is set, the MAC enters a freeze state where it stops all transmit and receive activities gracefully.

The following happens when the MAC enters hardware freeze:

- A currently ongoing receive transaction on the receive application interface is completed as normal. No further frames are read from the FIFO.
- A currently ongoing transmit transaction on the transmit application interface is completed as normal (in other words, until writing end-of-packet (EOP)).

- A currently ongoing frame receive is completed normally, after which no further frames are accepted from the MII/GMII.
- A currently ongoing frame transmit is completed normally, after which no further frames are transmitted.

11.5.6.9.4 Graceful stop

During a graceful stop, any currently ongoing transactions are completed normally and no further frames are accepted. The MAC can resume from a graceful stop without the need for a reset (for example, clearing ETHER_EN is not required).

The following conditions lead to a graceful stop of the MAC transmit or receive datapaths.

11.5.6.9.4.1 Graceful transmit stop (GTS)

When gracefully stopped, the MAC is no longer reading frame data from the transmit FIFO and has completed any ongoing transmission.

In any of the following conditions, the transmit datapath stops after an ongoing frame transmission has been completed normally.

- ENET n _TCR[GTS] is set by software.
- ENET n _TCR[TFC_PAUSE] is set by software requesting a pause frame transmission. The status (and register bit) is cleared after the pause frame has been sent.
- A pause frame was received stopping the transmitter. The stopped situation is terminated when the pause timer expires or a pause frame with zero quanta is received.
- MAC is placed in Sleep mode by software or the processor entering Stop mode (see [Sleep mode](#)).
- The MAC is in Hardware Freeze mode.

When the transmitter has reached its stopped state, the following events occur:

- The GRA interrupt is asserted, when transitioned into stopped.
- In Hardware Freeze mode, the GRA interrupt does not wait for the application write completion and asserts when the transmit state machine (in other words, line side of TX FIFO) reaches its stopped state.

11.5.6.9.4.2 Graceful receive stop (GRS)

When gracefully stopped, the MAC is no longer writing frames into the receive FIFO.

The receive datapath stops after any ongoing frame reception has been completed normally, if any of the following conditions occur:

- MAC is placed in Sleep mode either by the software or the processor is in Stop mode). The MAC continues to receive frames and search for magic packets if enabled (see [Magic packet detection](#)). However, no frames are written into the receive FIFO, and therefore are not forwarded to the application.
- The MAC is in Hardware Freeze mode. The MAC does not accept any frames from the MII/GMII.

When the receive datapath is stopped, the following events occur:

- If the RX is in the stopped state, RCR[GRS] is set
- The GRA interrupt is asserted when the transmitter and receiver are stopped
- Any ongoing receive transaction to the application (RX FIFO read) continues normally until the frame end of package (EOP) is reached. After this, the following occurs:
 - When Sleep mode is active, all further frames are discarded, flushing the RX FIFO
 - In Hardware Freeze mode, no further frames are delivered to the application and they stay in the receive FIFO.

Note

The assertion of GRS does not wait for an ongoing FIFO read transaction on the application side of the FIFO (FIFO read).

11.5.6.9.4.3 Graceful stop interrupt (GRA)

The graceful stopped interrupt (GRA) is asserted for the following conditions:

- In Sleep mode, the interrupt asserts only after both TX and RX datapaths are stopped.
- In Hardware Freeze mode, the interrupt asserts only after both TX and RX datapaths are stopped.
- The MAC transmit datapath is stopped for any other condition (GTS, TFC_PAUSE, pause received).

The GRA interrupt is triggered only once when the stopped state is entered. If the interrupt is cleared while the stop condition persists, no further interrupt is triggered.

11.5.6.10 IEEE 1588 functions

To allow for IEEE 1588 or similar time synchronization protocol implementations, the MAC is combined with a time-stamping module to support precise time-stamping of incoming and outgoing frames. Set `ENETn_ECR[EN1588]` to enable 1588 support.

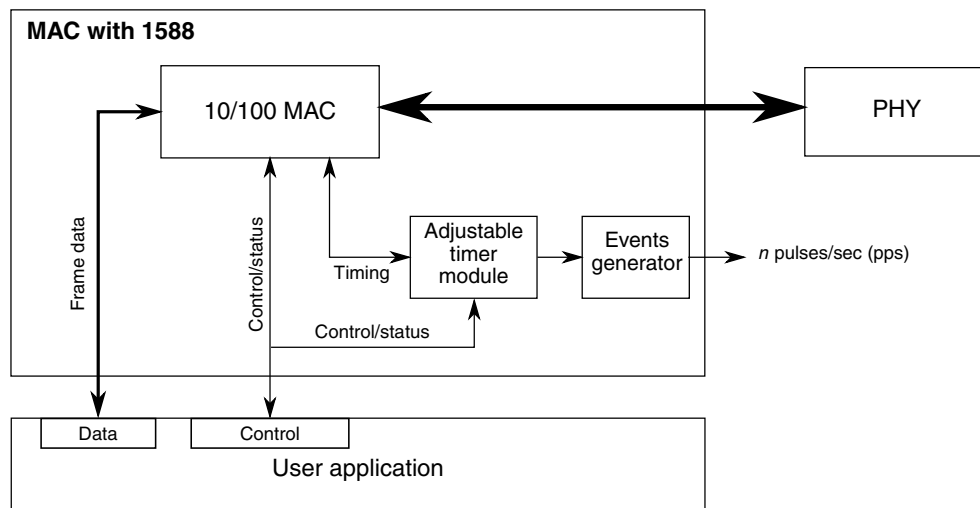

Figure 11-71. IEEE 1588 functions overview

11.5.6.10.1 Adjustable timer module

The adjustable timer module (TSM) implements the free-running counter (FRC), which generates the timestamps. The FRC operates with the time-stamping clock, which can be set to any value depending on your system requirements.

Through dedicated correction logic, the timer can be adjusted to allow synchronization to a remote master and provide a synchronized timing reference to the local system. The timer can be configured to cause an interrupt after a fixed time period, to allow synchronization of software timers or perform other synchronized system functions.

The timer is typically used to implement a period of one second; hence, its value ranges from 0 to $(1 \times 10^9) - 1$. The period event can trigger an interrupt, and software can maintain the seconds and hours time values as necessary.

11.5.6.10.1.1 Adjustable timer implementation

The adjustable timer consists of a programmable counter/accumulator and a correction counter. The periods of both counters and their increment rates are freely configurable, allowing very fine tuning of the timer.

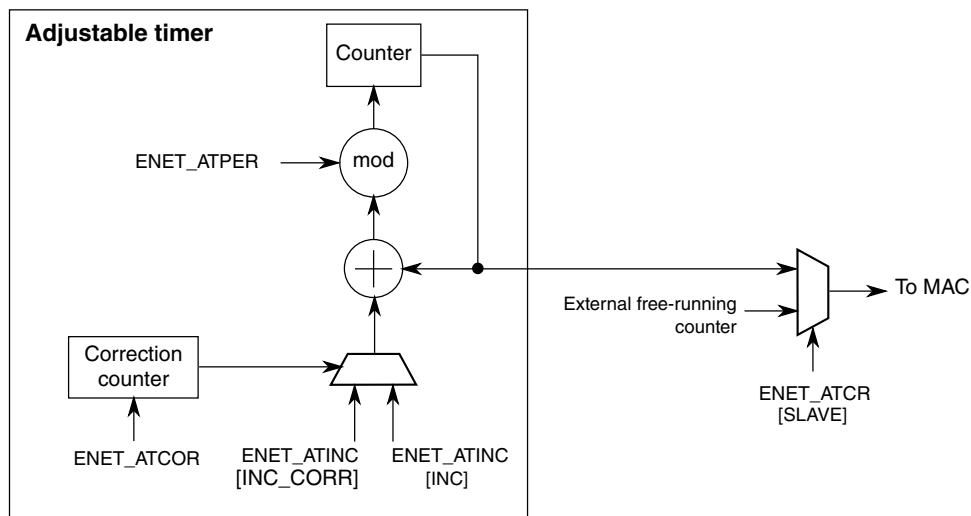

Figure 11-72. Adjustable timer implementation detail

The counter produces the current time. During each time-stamping clock cycle, a constant value is added to the current time as programmed in ENET_n_ATINC . The value depends on the chosen time-stamping clock frequency. For example, if it operates at 125 MHz, setting the increment to eight represents 8 ns.

The period, configured in ENET_n_ATPER , defines the modulo when the counter wraps. In a typical implementation, the period is set to 1×10^9 so that the counter wraps every second, and hence all timestamps represent the absolute nanoseconds within the one second period. When the period is reached, the counter wraps to start again respecting the period modulo. This means it does not necessarily start from zero, but instead the counter is loaded with the value $(\text{Current} + \text{Inc} - (1 \times 10^9))$, assuming the period is set to 1×10^9 .

The correction counter operates fully independently, and increments by one with each time-stamping clock cycle. When it reaches the value configured in `ENET n _ATCOR`, it restarts and instructs the timer once to increment by the correction value, instead of the normal value.

The normal and correction increments are configured in `ENET n _ATINC`. To speed up the timer, set the correction increment more than the normal increment value. To slow down the timer, set the correction increment less than the normal increment value.

The correction counter only defines the distance of the corrective actions, not the amount. This allows very fine corrections and low jitter (in the range of 1 ns) independent of the chosen clock frequency.

By enabling slave mode (`ENET n _ATCR[SLAVE] = 1`), the timer is ignored and the current time is externally provided from one of the external modules. See the Chip Configuration details for which clock source is used. This is useful if multiple modules within the system must operate from a single timer. When slave mode is enabled, you still must set `ENET n _ATINC[INC]` to the value of the master, since it is used for internal comparisons.

11.5.6.10.2 Transmit timestamping

Only 1588 event frames need to be time-stamped on transmit. The client application (for example, the MAC driver) should detect 1588 event frames and set `TxBD[TS]` together with the frame.

If `TxBD[TS]` is set, the MAC records the timestamp for the frame in `ENET n _ATSTMP`. `ENET n _EIR[TS_AVAIL]` is set to indicate that a new timestamp is available.

Software implements a handshaking procedure by setting `TxBD[TS]` when it transmits the frame for which a timestamp is needed, and then waits for `ENET n _EIR[TS_AVAIL]` to determine when the timestamp is available. The timestamp is then read from `ENET n _ATSTMP`. This is done for all event frames. Other frames do not use `TxBD[TS]` and, therefore, do not interfere with the timestamp capture.

11.5.6.10.3 Receive timestamping

When a frame is received, the MAC latches the value of the timer when the frame's start of frame delimiter (SFD) field is detected, and provides the captured timestamp on `RxBD[1588 timestamp]`. This is done for all received frames.

11.5.6.10.4 Time synchronization

The adjustable timer module is available to synchronize the local clock of a node to a remote master. It implements a free running 32-bit counter, and also contains an additional correction counter.

The correction counter increases or decreases the rate of the free running counter, enabling very fine granular changes of the timer for synchronization, yet adding only very low jitter when performing corrections.

The application software implements, in a slave scenario, the required control algorithm, setting the correction to compensate for local oscillator drifts and locking the timer to the remote master clock on the network.

The timer and all timestamp-related information should be configured to show the true nanoseconds value of a second (in other words, the timer is configured to have a period of one second). Hence, the values range from 0 to $(1 \times 10^9) - 1$. In this application, the seconds counter is implemented in software using an interrupt function that is executed when the nanoseconds counter wraps at 1×10^9 .

11.5.6.10.5 Input Capture and Output Compare

The Input Capture Output Compare block can be used to provide precise hardware timing for input and output events.

11.5.6.10.5.1 Input capture

The $TCCR_n$ capture registers latch the time value when the corresponding external event occurs. An event can be a rising-, falling-, or either-edge of one of the 1588_TMR $_n$ signals. An event will cause the corresponding TCSR $_n$ [TF] timer flag to be set, indicating that an input capture has occurred. If the corresponding interrupt is enabled with the TCSR $_n$ [TIE] field, an interrupt can be generated.

11.5.6.10.5.2 Output compare

The $TCCR_n$ compare registers are loaded with the time at which the corresponding event should occur. When the ENET free-running counter value matches the output compare reference value in the $TCCR_n$ register, the corresponding flag, TCSR $_n$ [TF], is set, indicating that an output compare has occurred. The corresponding interrupt, if enabled by TCSR $_n$ [TIE], will be generated. The corresponding 1588_TMR $_n$ output signal will be asserted according to TCSR $_n$ [TMODE].

NOTE

If TCSR n [TMODE] is set to 10X1b or 1010b then the timer output pin toggle-on-overflow will occur only when PINPER, PEREN, and EN bits of the ATCR register are one.

11.5.6.10.5.3 DMA requests

A DMA request can be enabled by setting TCSR n [TDRE]. The corresponding DMA request is generated when the TCSR n [TF] timer flag is set. When the DMA has completed, the corresponding TCSR n [TF] flag is cleared.

11.5.6.11 FIFO thresholds

The core FIFO thresholds are fully programmable to dynamically change the FIFO operation.

For example, store and forward transfer can be enabled by a simple change in the FIFO threshold registers.

The thresholds are defined in 64-bit words.

The receive and transmit FIFOs both have a depth of 1024 words.

11.5.6.11.1 Receive FIFO

Four programmable thresholds are available, which can be set to any value to control the core operation as follows.

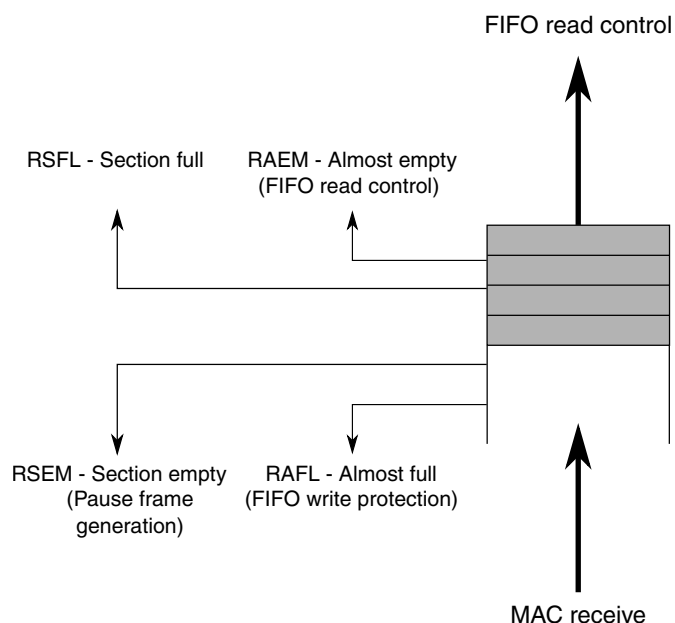

Table 11-123. Receive FIFO thresholds definition

Register	Description
ENET n _RSFL [RX_SECTION_F ULL]	<p>When the FIFO level reaches the ENETn_RSFL value, the MAC status signal is asserted to indicate that data is available in the receive FIFO (cut-through operation). Once asserted, if the FIFO empties below the threshold set with ENETn_RAEM and if the end-of-frame is not yet stored in the FIFO, the status signal is deasserted again.</p> <p>If a frame has a size smaller than the threshold (in other words, an end-of-frame is available for the frame), the status is also asserted.</p> <p>To enable store and forward on the receive path, clear ENETn_RSFL. The MAC status signal is asserted only when a complete frame is stored in the receive FIFO.</p> <p>When programming a non-zero value to ENETn_RSFL (cut-through operation) it should be greater than ENETn_RAEM.</p>
ENET n _RAEM [RX_ALMOST_E MPTY]	<p>When the FIFO level reaches the ENETn_RAEM value, and the end-of-frame has not been received, the core receive read control stops the FIFO read (and subsequently stops transferring data to the MAC client application).</p>

Table continues on the next page...

Table 11-123. Receive FIFO thresholds definition (continued)

Register	Description
	It continues to deliver the frame, if again more data than the threshold or the end-of-frame is available in the FIFO. Set ENETn_RAEM to a minimum of six.
ENETn_RAFL [RX_ALMOST_FULL]	When the FIFO level approaches the maximum and there is no more space remaining for at least ENETn_RAFL number of words, the MAC control logic stops writing data in the FIFO and truncates the receive frame to avoid FIFO overflow. The corresponding error status is set when the frame is delivered to the application. Set ENETn_RAFL to a minimum of 4.
ENETn_RSEM [RX_SECTION_EMPTY]	When the FIFO level reaches the ENETn_RSEM value, an indication is sent to the MAC transmit logic, which generates an XOFF pause frame. This indicates FIFO congestion to the remote Ethernet client. When the FIFO level goes below the value programmed in ENETn_RSEM, an indication is sent to the MAC transmit logic, which generates an XON pause frame. This indicates the FIFO congestion is cleared to the remote Ethernet client. Clearing ENETn_RSEM disables any pause frame generation.

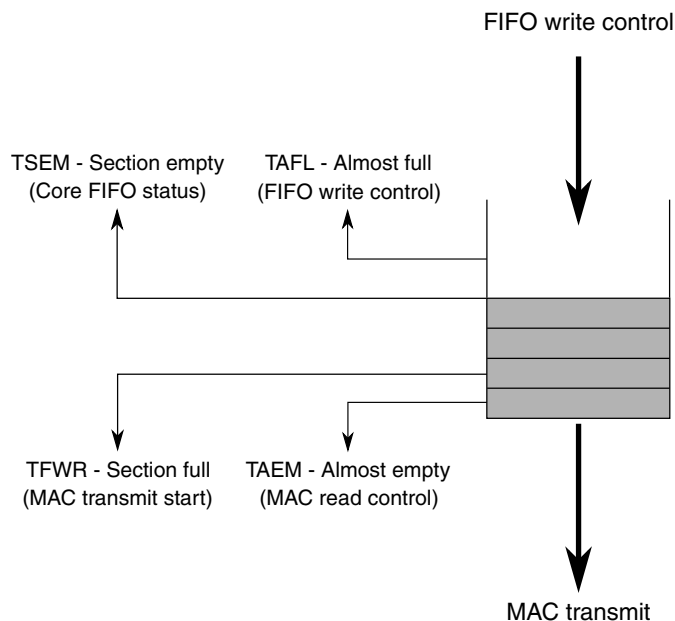

**Figure 11-73. Receive FIFO overview**

11.5.6.11.2 Transmit FIFO

Four programmable thresholds are available which control the core operation as described below.

Table 11-124. Transmit FIFO thresholds definition

Register	Description
ENET n _TAEM [TX_ALMOST_EMPTY]	When the FIFO level reaches the ENET n _TAEM value and no end-of-frame is available for the frame, the MAC transmit logic avoids a FIFO underflow by stopping FIFO reads and transmitting the Ethernet frame with an MII error indication. Set ENET n _TAEM to a minimum of 4.
ENET n _TAFL [TX_ALMOST_FULL]	When the FIFO level approaches the maximum, so that there is no more space for at least ENET n _TAFL number of words, the MAC deasserts its control signal to the application. If the application does not react on this signal, the FIFO write control logic avoids FIFO overflow by truncating the current frame and setting the error status. As a result, the frame is transmitted with an GMII/MII error indication. Set ENET n _TAFL to a minimum of 4. Larger values allow more latency for the application to react on the MAC control signal deassertion, before the frame is truncated. A typical setting is 8, which offers 3–4 clock cycles of latency to the application to react on the MAC control signal deassertion.
ENET n _TSEM [TX_SECTION_EMPTY]	When the FIFO level reaches the ENET n _TSEM value, a MAC status signal is deasserted to indicate that the transmit FIFO is getting full. This gives the ENET module an indication to slow or stop its write transaction to avoid a buffer overflow. This is a pure indication function to the application. It has no effect within the MAC. When ENET n _TSEM is 0, the signal is never deasserted.
ENET n _TFWR	When the FIFO level reaches the ENET n _TFWR value and when STRFWD is cleared, the MAC transmit control logic starts frame transmission before the end-of-frame is available in the FIFO (cut-through operation). If a complete frame has a size smaller than the ENET n _TFWR threshold, the MAC also transmits the frame to the line. To enable store and forward on the transmit path, set STRFWD. In this case, the MAC starts to transmit data only when a complete frame is stored in the transmit FIFO.

**Figure 11-74. Transmit FIFO overview**

11.5.6.12 Loopback options

The core implements external and internal loopback options, which are controlled by the ENET n _RCR register fields found here.

The core implements external and internal loopback options, which are controlled by the following ENET n _RCR register fields:

Table 11-125. Loopback options

Register field	Description
LOOP	Internal MII loopback. The MAC transmit is returned to the MAC receive. No data is transmitted to the external interfaces. In MII internal loopback, MII_TXCLK and MII_RXCLK must be provided with a clock signal (2.5 MHz for 10 Mbit/s, and 25 MHz for 100 Mbit/s))

Figure 11-75. Loopback options

11.5.6.13 Legacy buffer descriptors

To support the Ethernet controller on previous chips, legacy FEC buffer descriptors are available. To enable legacy support, write 0 to ENET n _ECR[1588EN].

NOTE

- Legacy buffer descriptors are used in single-ring mode, that is, when DMA n CFG[DMA_CLASS_EN] are zero. In multi-ring mode, legacy TxBDs are used only with the round-robin scheme.
- The legacy buffer descriptor tables show the byte order for big-endian chips. **DBSWP** must be set to 0 after reset to enable big-endian mode.

11.5.6.13.1 Legacy receive buffer descriptor

The following table shows the legacy FEC receive buffer descriptor. [Table 11-129](#) contains the descriptions for each field.

Table 11-126. Legacy FEC receive buffer descriptor (RxBD)

	Byte 0								Byte 1							
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Offset + 0	E	RO1	W	RO2	L	—	—	M	BC	MC	LG	NO	—	CR	OV	TR
Offset + 2	Data length															
Offset + 4	Rx data buffer pointer — high halfword															
Offset + 6	Rx data buffer pointer — low halfword															

11.5.6.13.2 Legacy transmit buffer descriptor

The following table shows the legacy FEC transmit buffer descriptor. [Table 11-131](#) contains the descriptions for each field.

Table 11-127. Legacy FEC transmit buffer descriptor (TxBD)

	Byte 0								Byte 1							
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Offset + 4	Tx Data Buffer Pointer — high halfword															
Offset + 6	Tx Data Buffer Pointer — low halfword															

1. This field is not supported by the uDMA.

11.5.6.14 Enhanced buffer descriptors

This section provides a description of the enhanced operation of the driver/uDMA via the buffer descriptors.

It is followed by a detailed description of the receive and transmit descriptor fields. To enable the enhanced features, set `ENETn_ECR[1588EN]`.

NOTE

The enhanced buffer descriptor tables show the byte order for big-endian chips. [DBSWP](#) must be set to 0 after reset to enable big-endian mode.

11.5.6.14.1 Enhanced receive buffer descriptor

The following table shows the enhanced uDMA receive buffer descriptor. [Table 11-129](#) contains the descriptions for each field.

Table 11-128. Enhanced uDMA receive buffer descriptor (RxBd)

	Byte 0								Byte 1							
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 11-129. Receive buffer descriptor field definitions

Word	Field	Description
Offset + 0	15	Empty. Written by the MAC (= 0) and user (= 1).
	E	0 The data buffer associated with this BD is filled with received data, or data reception has aborted due to an error condition. The status and length fields have been updated as required. 1 The data buffer associated with this BD is empty, or reception is currently in progress.
Offset + 0	14 RO1	Receive software ownership. This field is reserved for use by software. This read/write field is not modified by hardware, nor does its value affect hardware.
Offset + 0	13 W	Wrap. Written by user. 0 The next buffer descriptor is found in the consecutive location. 1 The next buffer descriptor is found at the location defined in ENET _n _RDSR.
Offset + 0	12 RO2	Receive software ownership. This field is reserved for use by software. This read/write field is not modified by hardware, nor does its value affect hardware.
Offset + 0	11	Last in frame. Written by the uDMA.
	L	0 The buffer is not the last in a frame.

Table continues on the next page...

Table 11-129. Receive buffer descriptor field definitions (continued)

Word	Field	Description
		1 The buffer is the last in a frame.
Offset + 0	10–9	Reserved, must be cleared.
Offset + 0	8 M	Miss. Written by the MAC. This field is set by the MAC for frames accepted in promiscuous mode, but flagged as a miss by the internal address recognition. Therefore, while in promiscuous mode, you can use this field to quickly determine whether the frame was destined to this station. This field is valid only if the L and PROM fields are set to 1. 0 The frame was received because of an address recognition hit. 1 The frame was received because of promiscuous mode. The information needed for this field comes from the promiscuous_miss(ff_rx_err_stat[26]) sideband signal.
Offset + 0	7 BC	Set if the DA is broadcast (FFFF_FFFF_FFFF).
Offset + 0	6 MC	Set if the DA is multicast and not BC.
Offset + 0	5 LG	Receive frame length violation. Written by the MAC. A frame length greater than RCR[MAX_FL] was recognized. This field is valid only if the L field is set. The receive data is not altered in any way unless the length exceeds TRUNC_FL bytes.
Offset + 0	4 NO	Receive non-octet aligned frame. Written by the MAC. A frame that contained a number of bits not divisible by 8 was received, and the CRC check that occurred at the preceding byte boundary generated an error or a PHY error occurred. This field is valid only if the L field is set. If this field is set, the CR field is not set.
Offset + 0	3	Reserved, must be cleared.
Offset + 0	2 CR	Receive CRC or frame error. Written by the MAC. This frame contains a PHY or CRC error and is an integral number of octets in length. This field is valid only if the L field is set.
Offset + 0	1 OV	Overflow. Written by the MAC. A receive FIFO overrun occurred during frame reception. If this field is set, the other status fields, M, LG, NO, and CR, lose their normal meaning and are zero. This field is valid only if the L field is set.
Offset + 0	0 TR	Set if the receive frame is truncated (frame length >TRUNC_FL). If the TR field is set, the frame must be discarded and the other error fields must be ignored because they may be incorrect.
Offset + 2	15–0 Data Length	Data length. Written by the MAC. Data length is the number of octets written by the MAC into this BD's data buffer if L is cleared (the value is equal to EMRBR), or the length of the frame including CRC if L is set. It is written by the MAC once as the BD is closed.
Offset + 4	15–0 Data buffer pointer high	Receive data buffer pointer, high halfword ¹
Offset + 6	15–0 Data buffer pointer low	Receive data buffer pointer, low halfword
Offset + 8	15 ME	MAC error. This field is written by the uDMA. This field means that the frame stored in the system memory was received with an error (typically, a receive FIFO overflow). This field is only valid when the L field is set.
Offset + 8	14–11	Reserved, must be cleared.

Table continues on the next page...

Table 11-129. Receive buffer descriptor field definitions (continued)

Word	Field	Description
Offset + 8	10 PE	PHY Error. This field is written by the uDMA. Set to "1" when the frame was received with an Error character on the PHY interface. The frame is invalid. This field is valid only when the L field is set.
Offset + 8	9 CE	Collision. This field is written by the uDMA. Set when the frame was received with a collision detected during reception. The frame is invalid and sent to the user application. This field is valid only when the L field is set.
Offset + 8	8 UC	Unicast. This field is written by the uDMA, and means that the frame is unicast. This field is valid regardless of whether the L field is set.
Offset + 8	7 INT	Generate RXB/RXF interrupt. This field is set by the user to indicate that the uDMA is to generate an interrupt on the <i>dma_int_rxb / dma_int_rxfevent</i> .
Offset + 8	6–0	Reserved, must be cleared.
Offset + A	15–13 VPCP	VLAN priority code point. This field is written by the uDMA to indicate the frame priority level. Valid values are from 0 (best effort) to 7 (highest). This value can be used to prioritize different classes of traffic (e.g., voice, video, data). This field is only valid if the L field is set.
Offset + A	12–6	Reserved, must be cleared.
Offset + A	5 ICE	IP header checksum error. This is an accelerator option. This field is written by the uDMA. Set when either a non-IP frame is received or the IP header checksum was invalid. An IP frame with less than 3 bytes of payload is considered to be an invalid IP frame. This field is only valid if the L field is set.
Offset + A	4 PCR	Protocol checksum error. This is an accelerator option. This field is written by the uDMA. Set when the checksum of the protocol is invalid or an unknown protocol is found and checksumming could not be performed. This field is only valid if the L field is set.
Offset + A	3	Reserved, must be cleared.
Offset + A	2 VLAN	VLAN. This is an accelerator option. This field is written by the uDMA. It means that the frame has a VLAN tag. This field is valid only if the L field is set.
Offset + A	1 IPV6	IPV6 Frame. This field is written by the uDMA. This field indicates that the frame has an IPv6 frame type. If this field is not set it means that an IPv4 or other protocol frame was received. This field is valid only if the L field is set.
Offset + A	0 FRAG	IPv4 Fragment. This is an accelerator option. This field is written by the uDMA. It indicates that the frame is an IPv4 fragment frame. This field is only valid when the L field is set.
Offset + C	15–11 Header length	Header length. This is an accelerator option. This field is written by the uDMA. This field is the sum of 32-bit words found within the IP and its following protocol headers. If an IP datagram with an unknown protocol is found, then the value is the length of the IP header. If no IP frame or an erroneous IP header is found, the value is 0. The following values are minimum values if no header options exist in the respective headers: <ul style="list-style-type: none"> • ICMP/IP: 6 (5 IP header, 1 ICMP header) • UDP/IP: 7 (5 IP header, 2 UDP header) • TCP/IP: 10 (5 IP header, 5 TCP header) This field is only valid if the L field is set.
Offset + C	10–8	Reserved, must be cleared.
Offset + C	7–0 Protocol type	Protocol type. This is an accelerator option. The 8-bit protocol field found within the IP header of the frame. It is valid only when ICE is cleared. This field is valid only when the L field is set.

Table continues on the next page...

Table 11-129. Receive buffer descriptor field definitions (continued)

Word	Field	Description
Offset + E	15–0 Payload checksum	Internet payload checksum. This is an accelerator option. It is the one's complement sum of the payload section of the IP frame. The sum is calculated over all data following the IP header until the end of the IP payload. This field is valid only when the L field is set.
Offset + 10	15 BDU	Last buffer descriptor update done. Indicates that the last BD data has been updated by uDMA. This field is written by the user (=0) and uDMA (=1).
Offset + 10	14–0	Reserved, must be cleared.
Offset + 12	15–0	Reserved, must be cleared.
Offset + 14	15–0	This value is written by the uDMA. It is only valid if the L field is set.
Offset + 16	1588 timestamp	
Offset + 18 – Offset + 1E	15–0	Reserved, must be cleared.

1. The receive buffer pointer, containing the address of the associated data buffer, must always be evenly divisible by 64. The buffer must reside in memory external to the MAC. The Ethernet controller never modifies this value.

11.5.6.14.2 Enhanced transmit buffer descriptor

Table 11-130. Enhanced transmit buffer descriptor (TxBD)

Offset + 1E	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 11-131. Enhanced transmit buffer descriptor field definitions

Word	Field	Description
Offset + 0	15 R	Ready. Written by the MAC and user. 0 The data buffer associated with this BD is not ready for transmission. You are free to manipulate this BD or its associated data buffer. The MAC clears this field after the buffer has been transmitted or after an error condition is encountered. 1 The data buffer, prepared for transmission by you, has not been transmitted or currently transmits. You may write no fields of this BD after this field is set.
Offset + 0	14 TO1	Transmit software ownership. This field is reserved for software use. This read/write field is not modified by hardware and its value does not affect hardware.
Offset + 0	13 W	Wrap. Written by user. 0 The next buffer descriptor is found in the consecutive location 1 The next buffer descriptor is found at the location defined in ETDSR.
Offset + 0	12 TO2	Transmit software ownership. This field is reserved for use by software. This read/write field is not modified by hardware and its value does not affect hardware.
Offset + 0	11 L	Last in frame. Written by user. 0 The buffer is not the last in the transmit frame 1 The buffer is the last in the transmit frame
Offset + 0	10 TC	Transmit CRC. Written by user, and valid only when L is set. 0 End transmission immediately after the last data byte 1 Transmit the CRC sequence after the last data byte This field is valid only when the L field is set.
Offset + 0	9 ABC	Append bad CRC. Note: This field is not supported by the uDMA and is ignored.
Offset + 0	8–0	Reserved, must be cleared.
Offset + 2	15–0 Data Length	Data length, written by user. Data length is the number of octets the MAC should transmit from this BD's data buffer. It is never modified by the MAC.
Offset + 4	15–0 Data buffer pointer high	Tx data buffer pointer, high halfword. The buffer must reside in memory external to the MAC. This value is never modified by the Ethernet controller. NOTE: For optimal performance, make the transmit buffer pointer evenly divisible by 64.
Offset + 6	15–0 Data buffer pointer low	Tx data buffer pointer, low halfword
Offset + 8	15	Reserved, must be cleared.
Offset + 8	14 INT	Generate interrupt flags. This field is written by the user. This field is valid regardless of the L field and must be the same for all EBD for a given frame. The uDMA does not update this value.
Offset + 8	13 TS	Timestamp. This field is written by the user. This indicates that the uDMA is to generate a timestamp frame to the MAC. This field is valid regardless of the L field and must be the same for all EBD for the given frame. The uDMA does not update this value.

Table continues on the next page...

Table 11-131. Enhanced transmit buffer descriptor field definitions (continued)

Word	Field	Description
Offset + 8	12 PINS	Insert protocol specific checksum. This field is written by the user. If set, the MAC's IP accelerator calculates the protocol checksum and overwrites the corresponding checksum field with the calculated value. The checksum field must be cleared by the application generating the frame. The uDMA does not update this value. This field is valid regardless of the L field and must be the same for all EBD for a given frame.
Offset + 8	11 IINS	Insert IP header checksum. This field is written by the user. If set, the MAC's IP accelerator calculates the IP header checksum and overwrites the corresponding header field with the calculated value. The checksum field must be cleared by the application generating the frame. The uDMA does not update this value. This field is valid regardless of the L field and must be the same for all EBD for a given frame.
Offset + 8	10-9	Reserved, must be cleared.
Offset + 8	8 UTLT	Use transmit launch time. If set to 1, TLT high and low values are used to determine if the frame can be transmitted. This field must only be set in the <i>first</i> BD of a frame. TLT is always used in combination with either the round-robin scheme or the credit-based shaper. TLT can be used with single a BD queue. However, at least one DMA class, DMA _n CFG[DMA_CLASS_EN] must be enabled. For example, to use TLT with only queue 0, enable one of the DMA _n CFG[DMA_CLASS_EN] fields and clear both TDAR1 and TDAR2. Although this enables multi-queue, only the single queue 0 is used.
Offset + 8	7-4 FTYPE	Type of frame to be transmitted. If a credit-based scheme is used, this field must match the BD ring queue. 0x0 – Non-AVB. Corresponds to ENET_TDSR. 0x1 – AVB Class A. Corresponds to ENET_TDSR1. 0x2 – AVB Class B. Corresponds to ENET_TDSR2. All other values are reserved.
Offset + 8	3-0	Reserved, must be cleared.
Offset + A	15 TXE	Transmit error occurred. This field is written by the uDMA. This field indicates that there was a transmit error of some sort reported with the frame. Effectively this field is an OR of the other error fields including UE, EE, FE, LCE, OE, and TSE. This field is valid only when the L field is set.
Offset + A	14	Reserved, must be cleared.
Offset + A	13 UE	Underflow error. This field is written by the uDMA. This field indicates that the MAC reported an underflow error on transmit. This field is valid only when the L field is set.
Offset + A	12 EE	Excess Collision error. This field is written by the uDMA. This field indicates that the MAC reported an excess collision error on transmit. This field is valid only when the L field is set.
Offset + A	11 FE	Frame with error. This field is written by the uDMA. This field indicates that the MAC reported that the uDMA reported an error when providing the packet. This field is valid only when the L field is set.
Offset + A	10 LCE	Late collision error. This field is written by the uDMA. This field indicates that the MAC reported that there was a Late Collision on transmit. This field is valid only when the L field is set.

Table continues on the next page...

Table 11-131. Enhanced transmit buffer descriptor field definitions (continued)

Word	Field	Description
Offset + A	9 OE	Overflow error. This field is written by the uDMA. This field indicates that the MAC reported that there was a FIFO overflow condition on transmit. This field is only valid when the L field is set.
Offset + A	8 TSE	Timestamp error. This field is written by the uDMA. This field indicates that the MAC reported a different frame type than a timestamp frame. This field is valid only when the L field is set.
Offset + A	7–0	Reserved, must be cleared.
Offset + C	15–0 TLT high	Transmit launch time high. Specifies when frame can be transmitted.
Offset + E	15–0 TLT low	Transmit launch time low. Specifies when frame can be transmitted.
Offset + 10	15 BDU	Last buffer descriptor update done. Indicates that the last BD data has been updated by uDMA. This field is written by the user (=0) and uDMA (=1).
Offset + 10	14–0	Reserved, must be cleared.
Offset + 12	15–0	Reserved, must be cleared.
Offset + 14	15–0 1588 timestamp	This value is written by the uDMA. It is valid only when the L field is set.
Offset + 16		
Offset + 18–Offset + 1E	15–0	Reserved, must be cleared.

11.5.6.15 Client FIFO application interface

The FIFO interface is completely asynchronous from the Ethernet line, and the transmit and receive interface can operate at a different clock rate.

All transfers to/from the user application are handled independently of the core operation, and the core provides a simple interface to user applications based on a two-signal handshake.

11.5.6.15.1 Data structure description

The data structure defined in the following tables for the FIFO interface must be respected to ensure proper data transmission on the Ethernet line. Byte 0 is sent to and received from the line first.

Table 11-132. FIFO interface data structure

	63	56 55	48 47	40 39	32 31	24 23	16 15	8 7	0
Word 0	Byte 7	Byte 6	Byte 5	Byte 4	Byte 3	Byte 2	Byte 1	Byte 0	
Word 1	Byte 15	Byte 14	Byte 13	Byte 12	Byte 11	Byte 10	Byte 9	Byte 8	
...	...								

The size of a frame on the FIFO interface may not be a modulo of 64-bit.

The user application may not care about the Ethernet frame formats in full detail. It needs to provide and receive an Ethernet frame with the following structure:

- Ethernet MAC destination address
- Ethernet MAC source address
- Optional 802.1q VLAN tag (VLAN type and info field)
- Ethernet length/type field
- Payload

Frames on the FIFO interface do not contain preamble and SFD fields, which are inserted and discarded by the MAC on transmit and receive, respectively.

- On receive, CRC and frame padding can be stripped or passed through transparently.
- On transmit, padding and CRC can be provided by the user application, or appended automatically by the MAC independently for each frame. No size restrictions apply.

Note

On transmit, if `ENETn_TCR[ADDINS]` is set, bytes 6–11 of each frame can be set to any value, since the MAC overwrites the bytes with the MAC address programmed in the `ENETn_PAUR` and `ENETn_PALR` registers.

Table 11-133. FIFO interface frame format

Byte number	Field
0–5	Destination MAC address
6–11	Source MAC address
12–13	Length/type field
14–N	Payload data

VLAN-tagged frames are supported on both transmit and receive, and implement additional information (VLAN type and info).

Table 11-134. FIFO interface VLAN frame format

Byte number	Field
0–5	Destination MAC address
6–11	Source MAC address

Table continues on the next page...

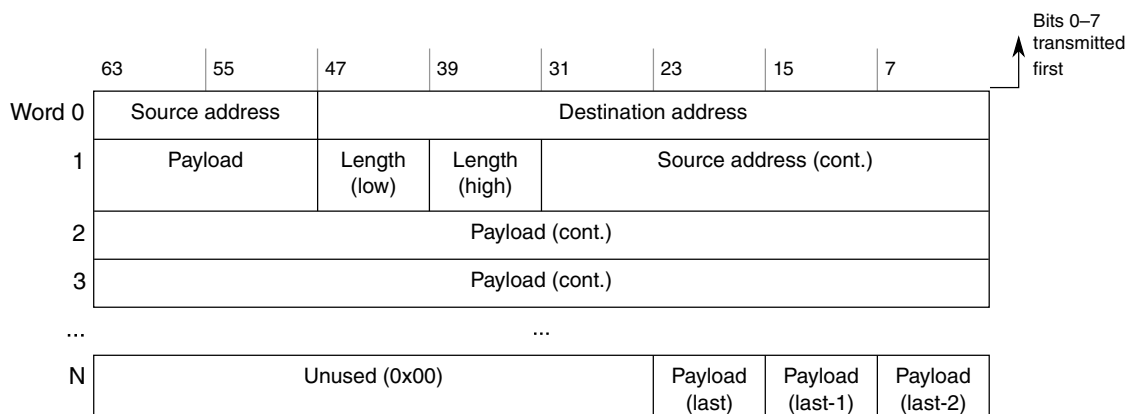

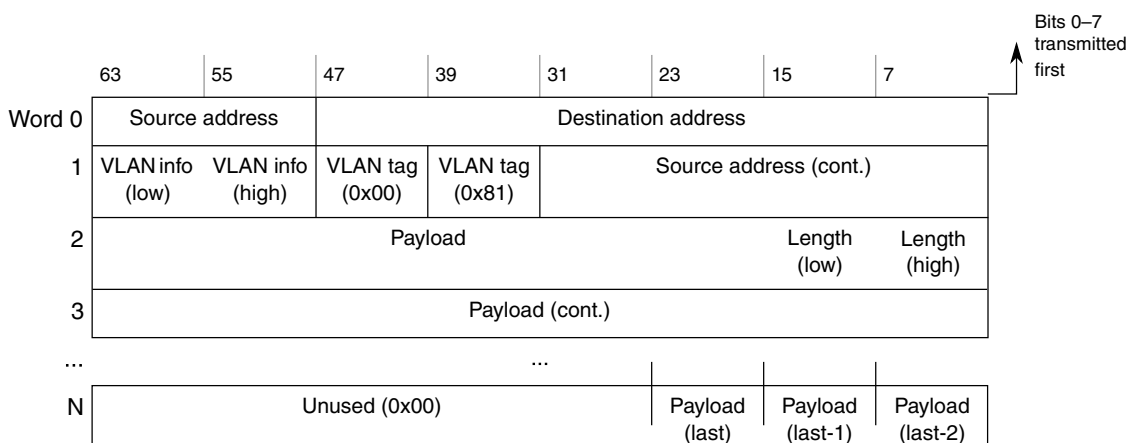

Table 11-134. FIFO interface VLAN frame format (continued)

Byte number	Field
12–15	VLAN tag and info
16–17	Length/type field
18–N	Payload data

Note

The standard defines that the LSB of the MAC address is sent/received first, while for all the other header fields — in other words, length/type, VLAN tag, VLAN info, and pause quanta — the MSB is sent/received first.

11.5.6.15.2 Data structure examples

**Figure 11-76. Normal Ethernet frame 64-bit mapping example****Figure 11-77. VLAN-tagged frame 64-bit mapping example**

If CRC forwarding is enabled (CRCFWD = 0), the last four valid octets of the frame contain the FCS field. The non-significant bytes of the last word can have any value.

11.5.6.15.3 Frame status

A MAC layer status word and an accelerator status word is available in the receive buffer descriptor.

See [Enhanced buffer descriptors](#) for details.

The status is available with each frame with the last data of the frame.

If the frame status contains a MAC layer error (for example, CRC or length error), RxBD[ME] is also set with the last data of the frame.

11.5.6.16 FIFO protection

The following sections describe the FIFO protection mechanisms.

11.5.6.16.1 Transmit FIFO underflow

During a frame transfer, when the transmit FIFO reaches the almost empty threshold with no end-of-frame indication stored in the FIFO, the MAC logic:

- Stops reading data from the FIFO
- Asserts the MII error signal (MII_TXER) (1 in [Figure 11-78](#)) to indicate that the fragment already transferred is not valid
- Deasserts the MII transmit enable signal (MII_TXEN) to terminate the frame transfer (2)

After an underflow, when the application completes the frame transfer (3), the MAC transmit logic discards any new data available in the FIFO until the end of packet is reached (4) and sets the enhanced TxBD[UE] field.

The MAC starts to transfer data on the MII interface when the application sends a new frame with a start of frame indication (5).

Figure 11-78. Transmit FIFO underflow protection

11.5.6.16.2 Transmit FIFO overflow

On the transmit path, when the FIFO reaches the programmable almost full threshold, the internal MAC ready signal is deasserted. The application should stop sending new data.

However, if the application keeps sending data, the transmit FIFO overflows, corrupting contents that were previously stored. The core logic sets the enhanced TxBD[OE] field for the next frame transmitted to indicate this overflow occurrence.

Note

Overflow is a fatal error and must be addressed by resetting the core or clearing ENET n _ECR[ETHER_EN], to clear the FIFOs and prepare for normal operation again.

11.5.6.16.3 Receive FIFO overflow

During a frame reception, if the client application is not able to receive data (1), the MAC receive control truncates the incoming frame when the FIFO reaches the programmable almost-full threshold to avoid an overflow.

The frame is subsequently received on the FIFO interface with an error indication (enhanced RxBD[ME] field set together with receive end-of-packet) (2) with the truncation error status field set (3).

Figure 11-79. Receive FIFO overflow protection

11.5.6.17 PHY management interface

The MDIO interface is a two-wire management interface. The MDIO management interface implements a standardized method to access the PHY device management registers.

The core implements a master MDIO interface, which can be connected to up to 32 PHY devices.

11.5.6.17.1 MDIO clause 22 frame format

The core MDIO master controller communicates with the slave (PHY device) using frames that are defined in the following table.

A complete frame has a length of 64 bits made up of an optional 32-bit preamble, 14-bit command, 2-bit bus direction change, and 16-bit data. Each bit is transferred on the rising edge of the MDIO clock (MDC signal). The MDIO data signal is tri-stated between frames.

The core PHY management interface supports the standard MDIO specification (IEEE 802.3 Clause 22).

Table 11-135. MDIO clause 22 frame structure

ST	OP	PHYADR	REGADR	TA	DATA
----	----	--------	--------	----	------

Table 11-136. MDIO frame field descriptions

Field	Description
ST (2 bits)	Start indication field, programmed with ENET n _MMFR[ST] and equal to 01 for Standard MDIO (Clause 22).
OP (2 bits)	Opcode defines type of operation. Programmed with ENET n _MMFR[OP]. 01 Write operation 10 Read operation
PHYADR (5 bits)	Five-bit PHY device address, programmed with ENET n _MMFR[PA]. Up to 32 devices can be addressed.
REGADR (5 bits)	Five-bit register address, programmed with ENET n _MMFR[RA]. Each PHY can implement up to 32 registers.
TA (2 bits)	Turnaround time, programmed with ENET n _MMFR[TA]. Two bit-times are reserved for read operations to switch the data bus from write to read. The PHY device presents its register contents in the data phase and drives the bus from the second bit of the turnaround phase.
Data (16 bits)	Data, set by ENET n _MMFR[DATA]. Written to or read from the PHY

11.5.6.17.2 MDIO clause 45 frame format

The extended MDIO frame structure defined in IEEE 802.3 Clause 45 introduces indirect addressing. First, a write transaction to an address register is done, followed by a write or read transaction which will put the 16-bit data in the register or retrieve the register contents respectively. A preamble of 32 bits of logical ones is sent prior to every transaction. The MDIO data signal is tri-stated between frames.

The extended MDIO defines four transactions, which are determined by the two-bit opcode field.

Table 11-137. MDIO clause 45 frame structure

ST	OP	PRTAD	DEVAD	TA	ADDR/DATA
----	----	-------	-------	----	-----------

All bits are transmitted from left to right (Preamble bits first) and all fields have their Most-Significant bit sent first (leftmost in above table). The complete frame has a length of 64 bits (32-bit preamble, 14-bit command, 2-bit bus direction change, 16-bit data). Each bit is transferred with the rising edge of the MDIO clock (MDC).

The fields and transactions are summarized in the following tables.

Table 11-138. MDIO clause 45 frame field descriptions

Field	Description
ST	Start indication. Indicates the end of the preamble and start of the frame. This value is 00 for extended MDIO (Clause 45) frames.
OP	Opcode defines if a read or write operation is performed and is programmed with ENETn_MMFR[OP]. See Table 11-139 for more information. 00 Address write 01 Write operation 10 Read inc. operation 11 Read operation
PRTAD	The port address specifies a MDIO port. Each Port can have up to 32 devices which each can have a separate set of registers.
DEVAD	Device address. Up to 32 devices can be addressed (within a port).
TA	Turnaround time, programmed with ENETn_MMFR[TA]. Two bit-times are reserved for read operations to switch the data bus from write to read. The PHY device presents its register contents in the data phase and drives the bus from the second bit of the turnaround phase.
ADDR/DATA	16-bit address (for address write) or data, set by ENETn_MMFR[DATA], written to or read from the PHY.

Table 11-139. MDIO Clause 45 Transactions

Transaction Type	Description
Address	A write transaction to the internal address register of the device/port. The data section of the frame contains the value to be stored in the device's internal address "pointer" register for further transactions.
Write	Data write to a register. The 16 bit data will be written to the register identified by the device-internal address.
Read	Data is read from the register identified by the device-internal address.
Read inc.	Read with address postincrement. The register identified by the device-internal address is read. After this, the device-internal address is incremented. If the address register is all '1' (0xFFFF) no increment is done (i.e. increment does not wrap around).

11.5.6.17.3 MDIO clock generation

The MDC clock is generated from the internal bus clock (i.e., IPS bus clock) divided by the value programmed in ENETn_MSCR[MII_SPEED].

11.5.6.17.4 MDIO operation

To perform an MDIO access, set the MDIO command register (ENET n _MMFR) according to the description provided in MII Management Frame Register (ENET n _MMFR).

To check when the programmed access completes, read the ENET n _EIR[MII] field.

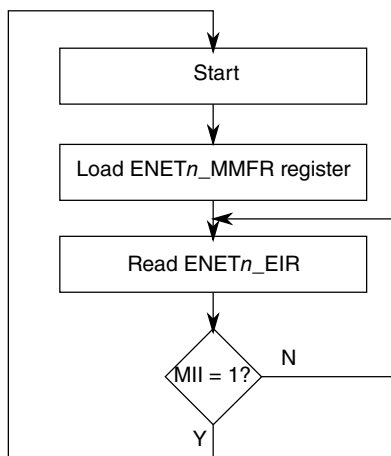

Figure 11-80. MDIO access overview

11.5.6.18 Ethernet interfaces

The following Ethernet interfaces are implemented:

- Fast Ethernet MII (Media Independent Interface)
- RMII 10/100 using interface converters/gaskets
- RGMII 10/100/1000 by way of interface converters/gaskets

The following table shows how to configure ENET registers to select each interface.

Mode	ECR[SPEED]	RCR[RMII_10T]	RCR[RMII_MODE]	RCR[RGMII_EN]
MII - 10 Mbit/s	0	—	0	0
MII - 100 Mbit/s	0	—	0	0
RMII - 10 Mbit/s	0	1	1	0
RMII - 100 Mbit/s	0	0	1	0
RGMII - 10 Mbit/s	0	1	0	1
RGMII - 100 Mbit/s	0	0	0	1
RGMII - 1000 Mbit/s	1	—	0	1

11.5.6.18.1 RMII interface

In RMII receive mode, for normal reception following assertion of CRS_DV, RXD[1:0] is 00 until the receiver determines that the receive event has a proper start-of-stream delimiter (SSD).

The preamble appears (RXD[1:0]=01) and the MACs begin capturing data following detection of SFD.

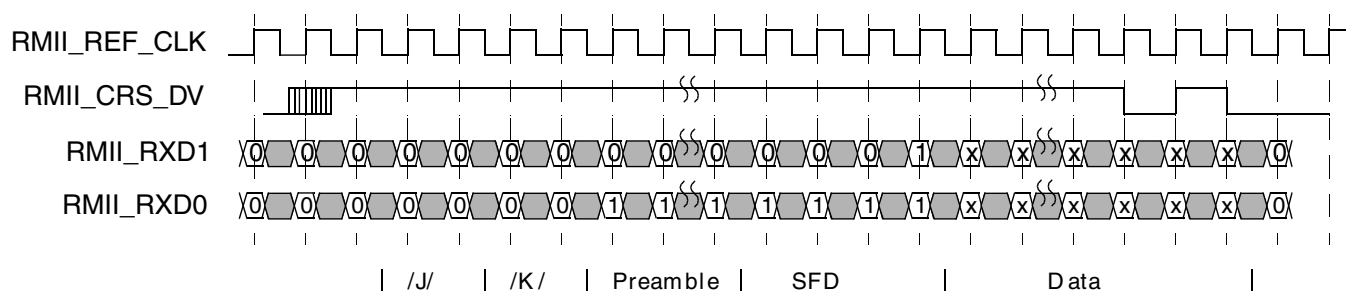

Figure 11-81. RMII receive operation

If a false carrier is detected (bad SSD), then RXD[1:0] is 10 until the end of the receive event. This is a unique pattern since a false carrier can only occur at the beginning of a packet where the preamble is decoded (RXD[1:0] = 01).

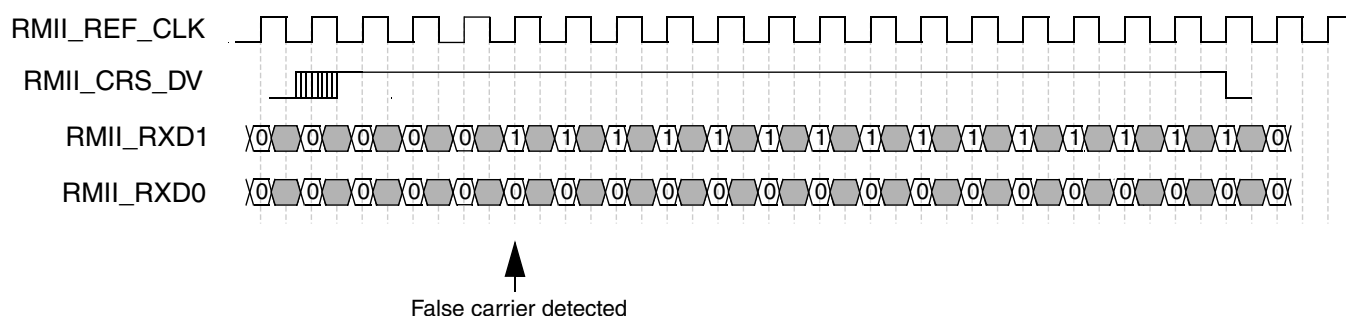

Figure 11-82. RMII receive operation with false carrier

In RMII transmit mode, TXD[1:0] provides valid data for each REF_CLK period while TXEN is asserted.

Figure 11-83. RMII transmit operation

11.5.6.18.2 RGMII interface

In RGMII modes, the data and control information is multiplexed by taking advantage of both edges of the reference clocks.

The data signals contain the lower four data bits on the rising edge and the upper four bits on the falling edge. The control signals are multiplexed into a single clock cycle using the same technique.

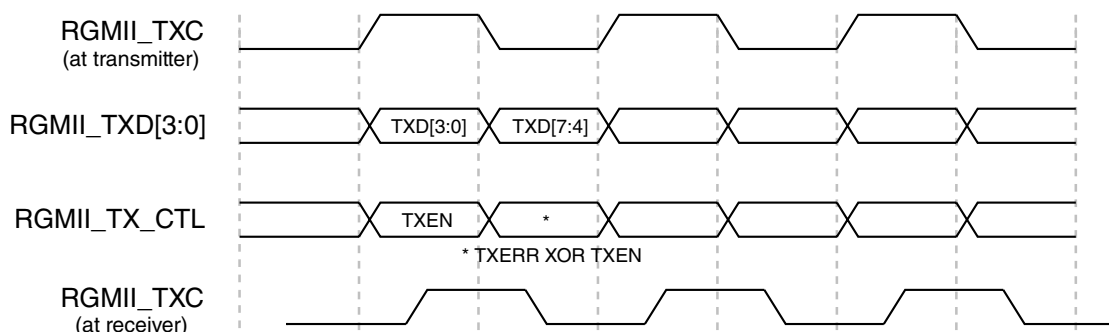

Figure 11-84. RGMII transmit operation

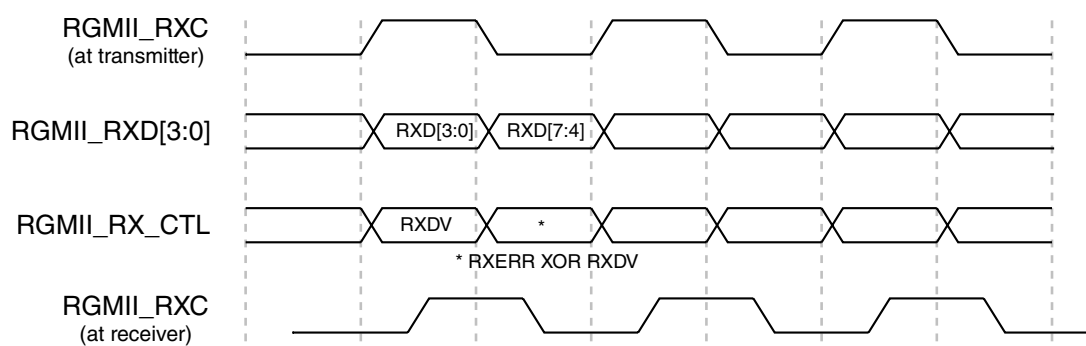

Figure 11-85. RGMII receive operation

11.5.6.18.3 MII Interface — transmit

On transmit, all data transfers are synchronous to MII_TXCLK rising edge. The MII data enable signal MII_TXEN is asserted to indicate the start of a new frame, and remains asserted until the last byte of the frame is present on the MII_TXD[3:0] bus.

Between frames, MII_TXEN remains deasserted.

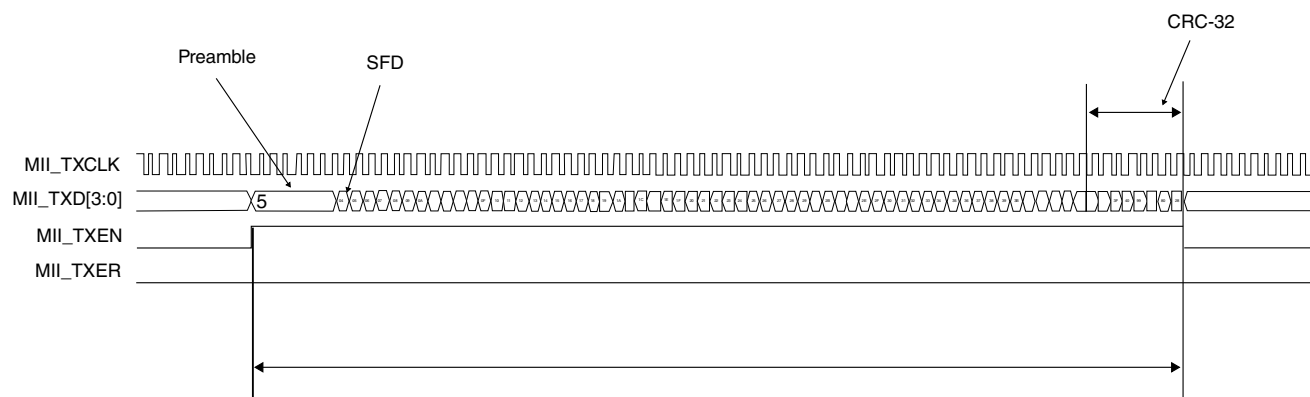

Figure 11-86. MII transmit operation

If a frame is received on the FIFO interface with an error (for example, RxBD[ME] set) the frame is subsequently transmitted with the MII_TXER error signal for one clock cycle at any time during the packet transfer.

Figure 11-87. MII transmit operation — errored frame

11.5.6.18.3.1 Transmit with collision — half-duplex

When a collision is detected during a frame transmission (MII_COL asserted), the MAC stops the current transmission, sends a 32-bit jam pattern, and re-transmits the current frame.

(See [Collision detection in half-duplex mode](#) for details)

Figure 11-88. MII transmit operation — transmission with collision

11.5.6.18.4 MII interface — receive

On receive, all signals are sampled on the MII_RXCLK rising edge. The MII data enable signal, MII_RXDV, is asserted by the PHY to indicate the start of a new frame and remains asserted until the last byte of the frame is present on MII_RXD[3:0] bus.

Between frames, MII_RXDV remains deasserted.

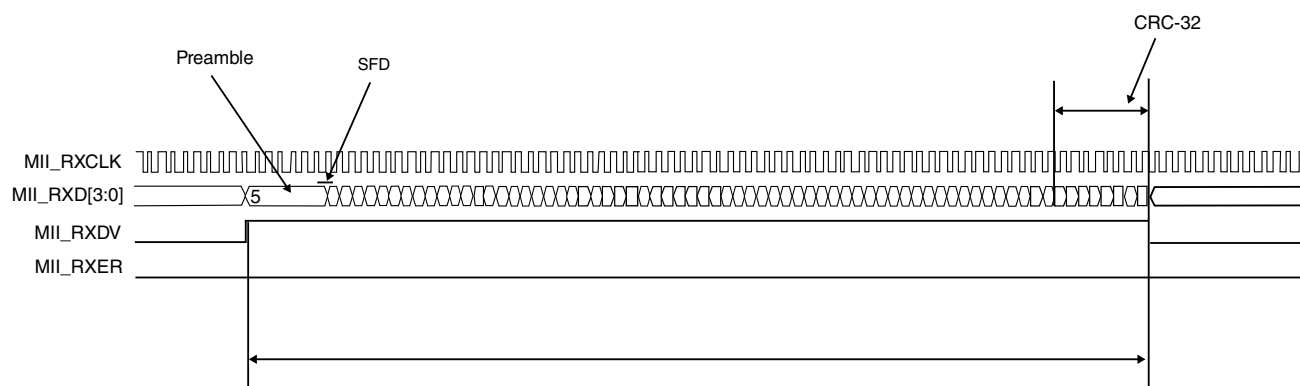

Figure 11-89. MII receive operation

If the PHY detects an error on the frame received from the line, the PHY asserts the MII error signal, MII_RXER, for at least one clock cycle at any time during the packet transfer.

Figure 11-90. MII receive operation — errored frame

A frame received on the MII interface with a PHY error indication is subsequently transferred on the FIFO interface with RxBD[ME] set.

11.5.6.19 AVB configuration

The following steps give an example of how to initialize the ENET module for AVB.

1. Set up ENET_QOS:
 - Set TX_SCHEME to 000b, credit-based scheme.
 - Set RX_FLUSH0 to 1, enable RX flush for ring 0.
2. Set up TX BD ring and RX BD ring for each queue, 0-2.
 - Program ENET_MRBR, ENET_TDSR, and ENET_RDSR.
 - Program ENET_MRBR1, ENET_TDSR1, and ENET_RDSR1.
 - Program ENET_MRBR2, ENET_TDSR2, and ENET_RDSR2.
 - Program each TX and RX BD ring queue for all classes used in memory.

NOTE

If using credit-based scheme, ensure that enhanced transmit buffer descriptor FTYPE field matches BD ring queue, for example:

- FTYPE = 0h corresponds to ENET_TDSR
- FTYPE = 1h corresponds to ENET_TDSR1
- FTYPE = 2h corresponds to ENET_TDSR2

3. Program ENET_DMA1CFG and ENET_DMA2CFG for class 1 and class 2 corresponding to BD ring queue 1 and 2. DMA_CLASS_EN must be set to one for

that class to be enabled. See [DMA Class Based Configuration \(ENET_DMA \$n\$ CFG\)](#) for information on how to program IDLE_SLOPE.

4. Program ENET_RCMR1 and ENET_RCMR2 for class 1 and class 2 matching for receive.

NOTE

Even if a match occurs, if ENET_DMA n CFG[DMA_CLASS_EN] is zero for the corresponding class, the RX frame will be automatically forwarded to BD ring queue 0.

5. Program the other ENET registers according to application requirements.
6. Program ENET_RDAR, ENET_RDAR1, ENET_RDAR2, ENET_TDAR, ENET_TDAR1, and ENET_TDAR2 to 0100_0000h according to the classes used.
7. Set ENET_ECR[ETHEREN] to one.

11.5.6.20 Interrupt coalescence

The purpose of the interrupt coalescing is to reduce the number of interrupts generated by the MAC so as to reduce the CPU loading.

To facilitate this interrupt coalescing for each queue, these registers are available with the same control and configuration fields.

- [Transmit Interrupt Coalescing Register \(ENET_TXIC \$n\$ \)](#) where $n=0,1,2$ for queue/class 0,1,2.
- [Receive Interrupt Coalescing Register \(ENET_RXIC \$n\$ \)](#) where $n=0,1,2$ for queue/class 0,1,2.

When coalescing is enabled by asserting the corresponding ICEN field and such interrupt is also enabled by the corresponding interrupt mask of the EIMR register, the MAC generates an interrupt when the threshold number of frames is reached (defined by ICFT) or when the threshold timer expires (defined by ICTT).

When coalescing is disabled by de-asserting ICEN, but interrupt is enabled by the corresponding interrupt mask of the EIMR register, the MAC generates an interrupt as they are received without using coalescing. Interrupt coalescing is done for each transmit and receive queue/class independently.

11.5.6.20.1 Interrupt coalescence setup

Interrupt coalescence supports both legacy and enhanced BDs. The following guidelines are recommended when setting up interrupt coalescence.

- When the MAC is configured for enhanced (IEEE 1588) mode, that is, enhanced BDs:
 - Set the INT bit in the enhanced received buffer descriptor to one.
 - Set the INT bit in the enhanced transmit buffer descriptor(s) to one.
- Clear the RXB, RXB1, and RXB2 fields in the EIMR register.
- Clear the TXB, TXB1, and TXB2 fields in the EIMR register.

11.5.6.20.2 Updating the frame count threshold on-the-fly

To update the ICFT field in the RXIC n and TXIC n registers:

1. Disable interrupt coalescence by clearing the appropriate ICEN field. This will allow the internal interrupt coalescence counter to reset to zero.

NOTE

When disabling interrupt coalescence, if an interrupt event is pending, that is, the interrupt counter is not zero, then an interrupt will occur.

2. Write the new threshold value to the ICFT field.
3. Set ICEN to one.

NOTE

The ICFT field can be updated on-the-fly without disabling the ICEN field. The hardware interrupt will continue and there is a possibility that an interrupt will occur depending on the state of the hardware counter and the previous ICFT value.

11.5.6.20.3 Updating the timer threshold on-the-fly

To update the ICTT field in the RXIC n and TXIC n registers:

1. Disable interrupt coalescence by clearing the appropriate ICEN field. This will allow the internal interrupt coalescence counter to reset to zero.

NOTE

When disabling interrupt coalescence, if an interrupt event is pending, that is, the interrupt counter is not zero, then an interrupt will occur.

2. Write the new timer value to the ICTT field.
3. Set ICEN to one.

Chapter 12

Timers

12.1 General Purpose Timer (GPT)

12.1.1 Overview

This chapter describes the General Purpose Timer (GPT) module interface. It is also a reference for software driver programming. The GPT has a 32-bit up-counter. The timer counter value can be captured in a register using an event on an external pin. The capture trigger can be programmed to be a rising or/and falling edge. The GPT can also generate an event on the output compare pins and an interrupt when the timer reaches a programmed value. The GPT has a 12-bit prescaler, which provides a programmable clock frequency derived from multiple clock sources.

Figure 12-1. GPT Block Diagram

Figure 12-2. GPT Counter Clocks Diagram

12.1.1.1 Features

- One 32-bit up-counter with clock source selection, including external clock.
- Two input capture channels with a programmable trigger edge.
- Three output compare channels with a programmable output mode. A "forced compare" feature is also available.
- Can be programmed to be *active* in low power and debug modes.
- Interrupt generation at capture, compare, and rollover events.
- Restart or free-run modes for counter operations.

12.1.1.2 Modes and Operation

The GPT supports the modes described in the indicated sections:

- [Operating Modes](#)
 - [Restart Mode](#)
 - [Free-Run Mode](#)

12.1.2 Functional Description

This section provides a complete functional description of the GPT.

12.1.2.1 Operating Modes

The GPT counter can be programmed to work in either of two modes: Restart mode or Free-Run mode.

12.1.2.1.1 Restart Mode

In Restart mode (selectable through the GPT Control Register GPT_CR), when the counter reaches the compared value, the counter resets and starts again from 0x00000000. The Restart feature is associated only with Compare Channel 1.

Any write access to the Compare register of Channel 1 will reset the GPT counter. This is done to avoid possibly missing a compare event when compare value is changed from a higher value to lower value while counting is proceeding.

For the other two compare channels, when the compare event occurs the counter is *not reset*.

12.1.2.1.2 Free-Run Mode

In Free-Run mode, when compare events occur for all 3 channels, the counter is *not reset*; instead the counter continues to count until 0xffffffff, and then rolls over (to 0x00000000).

12.1.2.2 Operation

The General Purpose Timer (GPT) has a single counter (GPT_CNT) that is a 32-bit free-running *up-counter*, which starts counting *after it is enabled by software* (EN=1). The counter's clock source is the output of the prescaler labelled "Prescaler output" in [Figure 12-1](#).

- If the GPT timer is disabled (EN=0), then the Main Counter *and* Prescaler Counter freeze their current count values. The ENMOD bit determines the value of the GPT counter when the EN bit is set and the Counter is enabled again.
 - If the ENMOD bit is set (=1), then the Main Counter and Prescaler Counter values are reset to 0, when GPT is enabled (EN=1).
 - If ENMOD bit is programmed to 0, then the Main Counter and Prescaler Counter restart counting from their frozen values, when GPT is enabled again (EN=1).
- If GPT is programmed to be disabled in a low power mode (STOP/WAIT), then the Main Counter and Prescaler Counter freeze at their current count values *when* GPT enters low power mode. When GPT exits a low power mode, the Main Counter and Prescaler Counter start counting from their frozen values *regardless* of the ENMOD

bit value. Note that the GPT_CNT can be read *at any time* by the processor, and that *both* Input Capture Channels use the *same* counter (GPT_CNT).

- A hardware reset resets all the GPT registers to their respective reset values. All registers except the Output Compare Registers (OCR1, OCR2, OCR3) obtain a value of 0x0. The Compare registers are reset to 0xFFFF_FFFF.
- The software reset (SWR bit in the GPT_CR control register) resets *all* of the register bits *except* the EN, ENMOD, STOPEN, WAITEN, and DBGEN bits. The state of these bits is not affected by a software reset. Note that a software reset can be given *while the GPT is disabled*.

12.1.2.2.1 Input Capture

There are two Input Capture Channels, and each Input Capture Channel has a dedicated capture pin, capture register and input edge detection/selection logic. Each input capture function has an associated status flag, and can cause the processor to make an interrupt service request.

When a selected edge transition occurs on an Input Capture pin, the contents of the GPT_CNT is captured on the corresponding capture register and the appropriate interrupt status flag is set. An interrupt request can be generated when the transition is detected *if* its corresponding enable bit is set (in the Interrupt Register). The capture can be programmed to occur on the input pin's rising edge, falling edge, on both rising and falling edges, or the capture can be disabled. The events are synchronized with the clock that was selected to run the counter. Only those transitions that occur at least one clock cycle *after* the previous recorded transition will be guaranteed to trigger a capture event. There can be up to one clock cycle of uncertainty in the latching of the input transition. The Input Capture registers can be read *at any time* without affecting their values.

Figure 12-3. Input Capture Event Timing

12.1.2.2.2 Output Compare

The three Output Compare Channels *use the same counter* (GPT_CNT) as the Input Capture Channels. When the programmed content of an Output Compare register matches the value in GPT_CNT, an output compare status flag is set and an interrupt is generated (if the corresponding bit is set in the interrupt register). Consequently, the Output Compare timer pin will be set, cleared, toggled, not affected at all or provide an active-low pulse for one input clock period (subject to the restriction on the maximum frequency allowed on the pad) according to the mode bits (that were programmed).

There is also a "forced-compare" feature that allows the software to generate a compare event when required, *without the condition of the counter value that is equal to the compare value*. The action taken as a result of a forced compare is the same as when an output compare match occurs, *except that the status flags are not set and no interrupt can be generated*. Forced channels take programmed action immediately after the write to the force-compare bits. These bits are self-negating and always read as zeros.

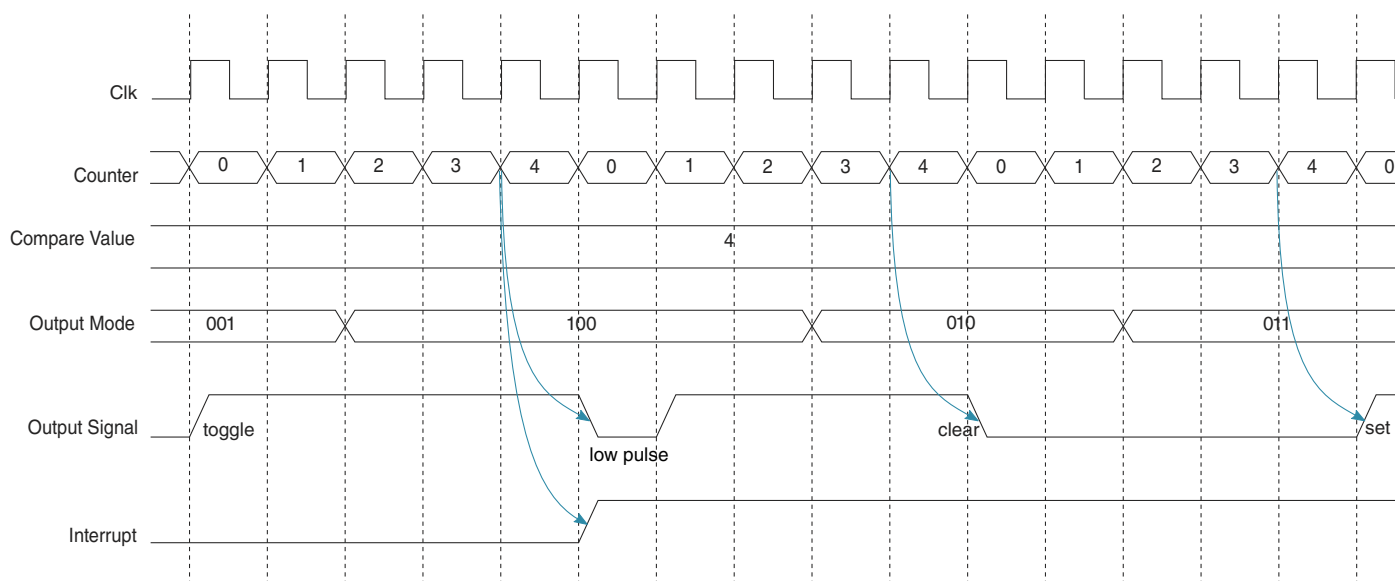

Figure 12-4. Output Compare and Interrupt Timing

12.1.2.2.3 Interrupts

There are 6 different interrupts that are generated by the GPT. If the selected clock for running the counter is available, then *all interrupts can be generated in Low Power and Debug modes*.

- Rollover Interrupt

The Rollover Interrupt is generated when the GPT counter reaches 0xffffffff, then resets to 0x00000000 and continues counting. The Rollover Interrupt is enabled by the ROVIE bit in the GPT_IR register; the associated status bit is the ROV bit in the GPT_SR register.

- Input Capture Interrupt 1, 2

After a capture event occurs, the associated Input Capture Channel generates an interrupt. The "capture event" interrupts are enabled by the IF2IE and IF1IE bits (in the GPT_IR register); the associated status bits are IF2 and IF1 (in the GPT_SR register). The capture of the counter value because of a capture event is *not affected by a pending capture interrupt*. The Capture register is updated with a new counter value when a capture event occurs, regardless of whether that Capture Channels' interrupt has been serviced or not.

- Output Compare Interrupt 1, 2, 3

After a compare event occurs, the associated Output Compare Channel generates an interrupt. The "compare event" interrupts are enabled by the OF3IE, OF2IE, and OF1IE bits (in the GPT_IR register); the associated status bits are OF3, OF2, and OF1 (in the GPT_SR register). A "forced compare" does not generate an interrupt.

A *cumulative* interrupt line is also present, which is asserted whenever any of the above interrupts are posted. The cumulative interrupt line has *no* associated enables or status bits.

12.1.2.2.4 Low Power Mode Behavior

In Low Power modes, if the clock from the selected clock source is available (except for the External Clock (GPT_CLK), which can be used *only if* the Peripheral Clock (ipg_clk) is available), the counter will continue to run depending on whether the control bit for that mode is set. If the clock is not present or if the corresponding low power bit in the GPT_CR control register is 0, the Main Counter and the Prescaler Counter freeze at their current values and resume counting (from their frozen values) when the Low Power mode is exited.

12.1.2.2.5 Debug Mode Behavior

In Debug mode, the modules in the device have the option of continuing to run or be halted.

- If the DBGEN bit is set, then the GPT timer will continue to run in Debug mode.
- If the DBGEN bit is not set (in the GPT_CR control register), then the GPT timer is halted.

12.1.3 Initialization/ Application Information

12.1.3.1 Selecting the Clock Source

The CLKSRC field in the GPT_CR register selects the clock source. The CLKSRC field value should be changed only after disabling the GPT (EN=0).

The software sequence to be followed while changing clock source is:

1. Disable GPT by setting EN=0 in GPT_CR register.
2. Disable GPT interrupt register (GPT_IR).
3. Configure Output Mode to unconnected/ disconnected—Write zeros in OM3, OM2, and OM1 in GPT_CR
4. Disable Input Capture Modes—Write zeros in IM1 and IM2 in GPT_CR
5. Change clock source CLKSRC to the desired value in GPT_CR register.
6. Assert the SWR bit in GPT_CR register.
7. Clear GPT status register (GPT_SR) (i.e., w1c).
8. Set ENMOD=1 in GPT_CR register, to bring GPT counter to 0x00000000.
9. Enable GPT (EN=1) in GPT_CR register.
10. Enable GPT interrupt register (GPT_IR).

12.1.4 GPT Memory Map/Register Definition

The GPT has 10 user-accessible 32-bit registers, which are used to configure, operate, and monitor the state of the GPT.

An IP bus write access to the GPT Control Register (GPT_CR) and the GPT Output Compare Register1 (GPT_OCR1) results in *one cycle of wait state*, while other valid IP bus accesses incur 0 wait states.

Irrespective of the Response Select signal value, a Write access to the GPT Status Registers (Read-only registers GPT_ICR1, GPT_ICR2, GPT_CNT) will generate a bus exception.

- If the Response Select signal is driven Low, then the Read/Write access to the *unimplemented* address space of GPT (*ips_addr* is greater than or equal to \$BASE + \$028) will generate a bus exception.
- If the Response Select is driven High, then the Read/Write access to the unimplemented address space of GPT will *not* generate any error response (like a bus exception).

12.1.4.1 GPT Control Register (GPTx_CR)

The GPT Control Register (GPT_CR) is used to program and configure GPT operations. An IP Bus Write to the GPT Control Register occurs after one cycle of wait state, while an IP Bus Read occurs after 0 wait states.

Address: Base address + 0h offset

GPTx_CR field descriptions

12.1.4.5 GPT Output Compare Register 1 (GPTx_OCR1)

The GPT Compare Register 1 (GPT_OCR1) holds the value that determines when a compare event will be generated on Output Compare Channel 1. Any write access to the Compare register of Channel 1 while in Restart mode (FRR=0) will reset the GPT counter.

An IP Bus Write access to the GPT Output Compare Register1 (GPT_OCR1) occurs *after* one cycle of wait state; an IP Bus Read access occurs *immediately* (0 wait states).

Address: Base address + 10h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

GPTx_OCR1 field descriptions

Field	Description
COMP	Compare Value. When the counter value equals the COMP bit field value, a compare event is generated on Output Compare Channel 1.

12.1.4.6 GPT Output Compare Register 2 (GPTx_OCR2)

The GPT Compare Register 2 (GPT_OCR2) holds the value that determines when a compare event will be generated on Output Compare Channel 2.

Address: Base address + 14h offset

GPTx OCR2 field descriptions

Field	Description
COMP	Compare Value. When the counter value equals the COMP bit field value, a compare event is generated on Output Compare Channel 2.

12.1.4.7 GPT Output Compare Register 3 (GPTx_OCR3)

The GPT Compare Register 3 (GPT_OCR3) holds the value that determines when a compare event will be generated on Output Compare Channel 3.

Address: Base address + 18h offset

GPTx_OCR3 field descriptions

Field	Description
COMP	Compare Value. When the counter value equals the COMP bit field value, a compare event is generated on Output Compare Channel 3.

12.1.4.8 GPT Input Capture Register 1 (GPTx_ICR1)

The GPT Input Capture Register 1 (GPT_ICR1) is a read-only register that holds the value *that was in the counter during the last capture event* on Input Capture Channel 1.

Address: Base address + 1Ch offset

GPTx_ICR1 field descriptions

Field	Description
CAPT	<p>Capture Value.</p> <p>After a capture event on Input Capture Channel 1 occurs, the current value of the counter is loaded into GPT Input Capture Register 1.</p>

12.1.4.9 GPT Input Capture Register 2 (GPTx_ICR2)

The GPT Input capture Register 2 (GPT_ICR2) is a read-only register which holds the value that was in the counter during the last capture event on input capture channel 2.

Address: Base address + 20h offset

GPTx_ICR2 field descriptions

Field	Description
CAPT	<p>Capture Value.</p> <p>After a capture event on Input Capture Channel 2 occurs, the current value of the counter is loaded into GPT Input Capture Register 2.</p>

12.1.4.10 GPT Counter Register (GPTx_CNT)

The GPT Counter Register (GPT_CNT) is the main counter's register. GPT_CNT is a read-only register and can be read *without affecting the counting process* of the GPT.

Address: Base address + 24h offset

GPTx_CNT field descriptions

Field	Description
COUNT	Counter Value. The COUNT bits show the current count value of the GPT counter.

12.2 Pulse Width Modulation (PWM)

12.2.1 Overview

The Pulse Width Modulation (PWM) has a 16-bit counter, and is optimized to generate sound from stored sample audio images and it can also generate tones. It uses 16-bit resolution and a 4 x 16 data FIFO.

This section presents an overview of the PWM. A block diagram of the PWM module is shown in the figure below.

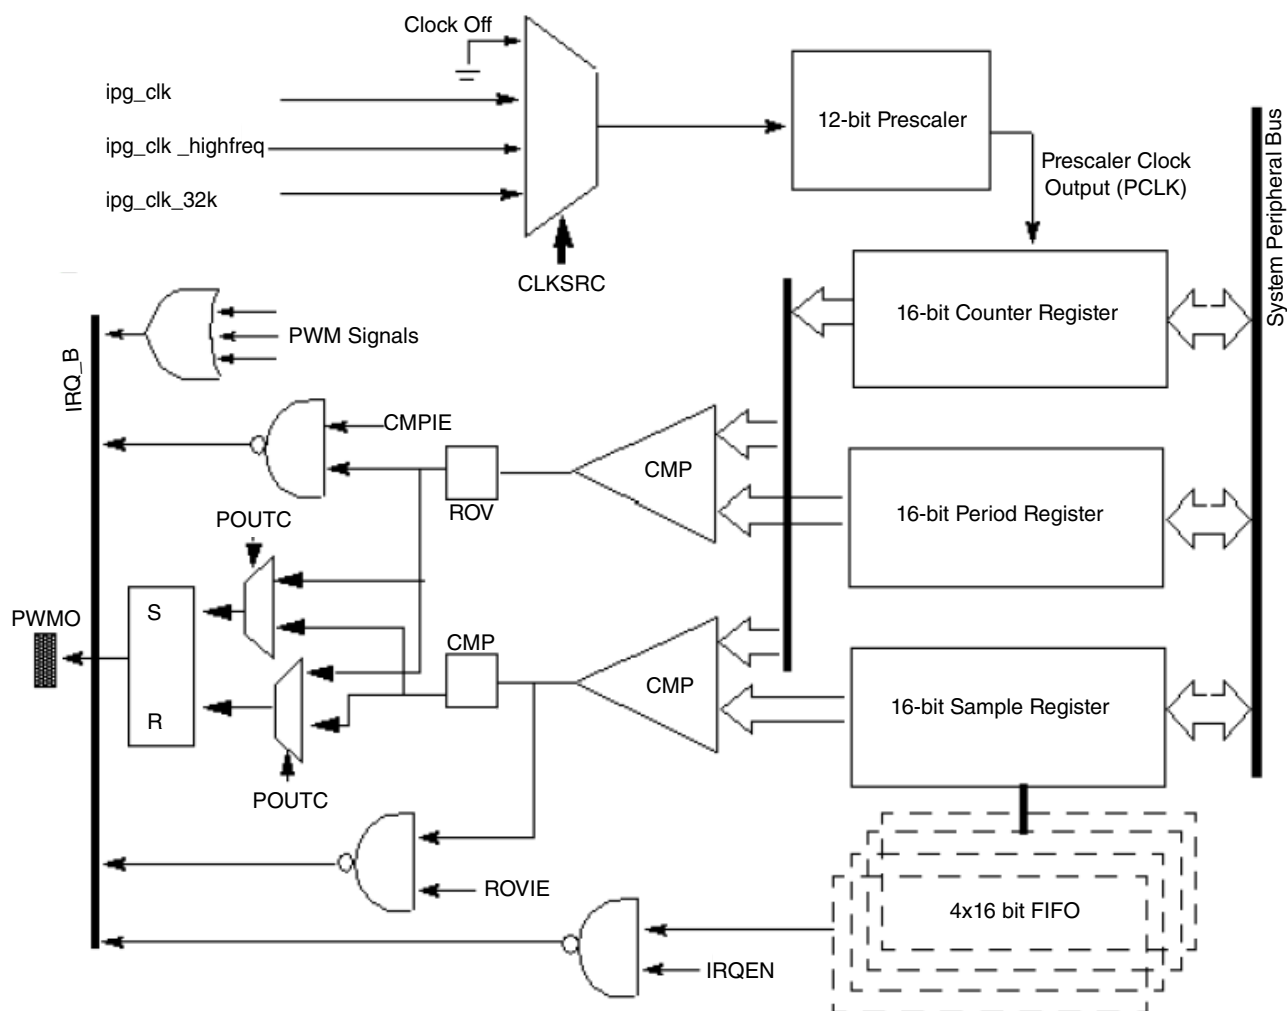

Figure 12-5. Pulse-Width Modulator Block Diagram

The following features characterize the PWM:

- 16-bit up-counter with clock source selection
- 4 x 16 FIFO to minimize interrupt overhead
- 12-bit prescaler for division of clock
- Sound and melody generation
- Active high or active low configured output
- Can be programmed to be active in low-power mode
- Can be programmed to be active in debug mode
- Interrupts at compare and rollover

12.2.2 Functional Description

The following sections detail the PWM operation and function.

12.2.2.1 Operation

The output of the PWM is a toggling signal whose frequency and duty cycle can be modulated by programming the appropriate registers. It has a 16-bit up counter which counts from 0x0000 until the counter value equals the PWM_PR + 1. After this match occurs the counter is reset to 0x0000.

At the beginning of a count period cycle, the PWM0 pin is set to one (default) and the counter begins counting up from 0x0000. The sample value in the sample FIFO is compared on each count of prescaler clock. When the sample and count values match, the PWM0 signal is cleared to zero (default). The counter continues counting until the period match occurs and subsequently another period cycle begins.

When the PWM is enabled, the counter starts running and generates an output with the reset values in the period and sample registers. It is recommended that the programming of these registers be done before PWM is enabled.

A hardware reset results in all the PWM count and sample registers being cleared and the FIFO being flushed. The control register shows that FIFO is empty and it can be written into, and the PWM is disabled. A software reset has the same results, however the state of the DBGEN, STOPEN, DOZEN, and WAITEN bits in the control register are not affected. Software reset can be asserted even when the PWM is in disabled state.

12.2.2.1.1 FIFO

Digital sample values can be loaded into the pulse-width modulator as 16-bit words. The endianness can be changed using the BCTR and HCTR bits of the control register. A 4-word (16-bit) FIFO minimizes interrupt overhead. A maskable interrupt is generated when the number of data words fall below the water level set by the FWM field in the control register.

A write to the PWM_SAR sample register results in the value being stored into the FIFO if it is not full. A write when the FIFO is full sets FWE (FIFO write error) bit in the status register and the FIFO contents remain unchanged. The FIFO can be written at any time, but can be read only when the PWM is enabled. The PWM_SR[FIFOAV] field shows how many data words are currently contained in the FIFO and whether or not it can be written into.

A read on the sample register yields the current FIFO value that is being used, or will be used, by the PWM for generation on the output signal. Therefore, a write and a subsequent read on the sample register may result in different values being obtained.

12.2.2.1.2 Rollover and Compare Event

The counter is reset to 0x0000 after its value equals the PWM_PR[PERIOD] + 1 and resumes counting thereafter. This event is referred to as a rollover. For example, if PWM_PR[PERIOD] = 0x0000, the counter is reset when it equals 0x0001. When PWM_PR[PERIOD] = 0xFFFF or 0xFFFE, the counter is reset when it equals 0xFFFF. For more information, see the PWM Period Register (PWM_PR) description.

During a rollover event the output is either set (default), reset or has no effect according to the programming of the POUTC field in the control register. This event can also generate an interrupt if the respective interrupt enable bit is set in the control register.

When the counter value reaches the sample value, the output of the PWM is reset (default), set or has no effect according to the programming of the POUTC field of control register. This event is referred to as a compare event. This event can also generate an interrupt if the respective interrupt enable bit is set in the control register.

If the rollover event sets the PWM output signal, the compare event will reset it and vice versa for a particular programming configuration of POUTC field.

12.2.2.1.3 Low Power Mode Behavior

In low power mode, if the clock from the selected clock source is available, the PWM counter continues to run and an output is produced, depending on whether the control bit for that mode is set or not. In the absence of the clock itself, or if the corresponding low power bit in the control register is 0, the counter is reset and resumes counting when it exits the low power mode.

12.2.2.1.4 Debug Mode Behavior

In debug mode, PWM has the option of continuing to run or be halted. If the DBGEN bit is not set in the PWM_PWMCR, the PWM is halted. If the DBGEN bit is set, then the PWM will continue to run in the debug mode.

12.2.3 Enable Sequence for the PWM

The sequence found here should be used to enable the PWM.

1. Configure the desired settings for the PWM Control Register (PWMx_PWMCR) while keeping the PWM disabled (PWMx_PWMCR[0]=0).
2. Enable the desired interrupts in the PWM Interrupt Register (PWMx_PWMIR).
3. One to three initial samples may be written to the PWM Sample Register (PWMx_PWMSAR). The initial sample values will be loaded into the PWM FIFO even if the PWM is not yet enabled. Do not write a 4th sample because the FIFO will become full and trigger a FIFO Write Error (FWE). This error will prevent the PWM from starting once it is enabled.
4. Check the FIFO Write Error status bit (FWE), the Compare status bit (CMP) and the Roll-over status bit (ROV) in the PWM Status Register (PWMx_PWMSR) to make sure they are all zero. Any non-zero status bits should be cleared by writing a 1 to them.
5. Write the desired period to the PWM Period Register (PWMx_PWMPR).
6. Enable the PWM by writing a 1 to the PWM Enable bit, PWMx_PWMCR[0], while maintaining the other register bits in their previously configured state.

12.2.4 Disable Sequence for the PWM

The PWM can be disabled at any time by clearing the PWM enable bit, PWMx_PWMCR[0] to 0.

Any data remaining in the FIFO will not be produced at the PWM output after the PWM has been disabled and will remain in the FIFO until the PWM is enabled again. A software reset (setting PWMx_PWMCR[3] to 1) or a hardware reset will clear the FIFO and any remaining data will be lost.

12.2.5 PWM Memory Map/Register Definition

The PWM includes six user-accessible 32-bit registers.

PWM memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
3066_0000	PWM Control Register (PWM1_PWMCR)	32	R/W	0000_0000h	12.2.5.1/3852

12.2.5.1 PWM Control Register (PWMx_PWMCR)

The PWM control register (PWM_PWMCR) is used to configure the operating settings of the PWM. It contains the prescaler for the clock division.

Address: Base address + 0h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

PWMx_PWMCR field descriptions

Field	Description
31–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–26 FWM	FIFO Water Mark. These bits are used to set the data level at which the FIFO empty flag will be set and the corresponding interrupt generated 00 FIFO empty flag is set when there are more than or equal to 1 empty slots in FIFO 01 FIFO empty flag is set when there are more than or equal to 2 empty slots in FIFO 10 FIFO empty flag is set when there are more than or equal to 3 empty slots in FIFO 11 FIFO empty flag is set when there are more than or equal to 4 empty slots in FIFO
25 STOPEN	Stop Mode Enable. This bit keeps the PWM functional while in stop mode. When this bit is cleared, the input clock is gated off in stop mode. This bit is not affected by software reset. It is cleared by hardware reset. 0 Inactive in stop mode 1 Active in stop mode
24 DOZEN	Doze Mode Enable. This bit keeps the PWM functional in doze mode. When this bit is cleared, the input clock is gated off in doze mode. This bit is not affected by software reset. It is cleared by hardware reset. 0 Inactive in doze mode 1 Active in doze mode
23 WAITEN	Wait Mode Enable. This bit keeps the PWM functional in wait mode. When this bit is cleared, the input clock is gated off in wait mode. This bit is not affected by software reset. It is cleared by hardware reset.

Table continues on the next page...

PWMx_PWMCR field descriptions (continued)

Field	Description
	0 Inactive in wait mode 1 Active in wait mode
22 DBGEN	Debug Mode Enable. This bit keeps the PWM functional in debug mode. When this bit is cleared, the input clock is gated off in debug mode. This bit is not affected by software reset. It is cleared by hardware reset. 0 Inactive in debug mode 1 Active in debug mode
21 BCTR	Byte Data Swap Control. This bit determines the byte ordering of the 16-bit data when it goes into the FIFO from the sample register. 0 byte ordering remains the same 1 byte ordering is reversed
20 HCTR	Half-word Data Swap Control. This bit determines which half word data from the 32-bit IP Bus interface is written into the lower 16 bits of the sample register. 0 Half word swapping does not take place 1 Half words from write data bus are swapped
19–18 POUTC	PWM Output Configuration. This bit field determines the mode of PWM output on the output pin. 00 Output pin is set at rollover and cleared at comparison 01 Output pin is cleared at rollover and set at comparison 10 PWM output is disconnected 11 PWM output is disconnected
17–16 CLKSRC	Select Clock Source. These bits determine which clock input will be selected for running the counter. After reset the system functional clock is selected. The input clock can also be turned off if these bits are set to 00. This field value should only be changed when the PWM is disabled 00 Clock is off 01 ipg_clk 10 ipg_clk_highfreq 11 ipg_clk_32k
15–4 PRESCALER	Counter Clock Prescaler Value. This bit field determines the value by which the clock will be divided before it goes to the counter. 0x000 Divide by 1 0x001 Divide by 2 0xff Divide by 4096
3 SWR	Software Reset. PWM is reset when this bit is set to 1. It is a self clearing bit. A write 1 to this bit is a single wait state write cycle. When the block is in reset state this bit is set and is cleared when the reset procedure is over. Setting this bit resets all the registers to their reset values except for the DBGEN, STOPEN, DOZEN, and WAITEN bits in this control register. 0 PWM is out of reset 1 PWM is undergoing reset
2–1 REPEAT	Sample Repeat. This bit field determines the number of times each sample from the FIFO is to be used. 00 Use each sample once 01 Use each sample twice 10 Use each sample four times 11 Use each sample eight times

Table continues on the next page...

PWMx_PWMCR field descriptions (continued)

Field	Description
0 EN	<p>PWM Enable. This bit enables the PWM. If this bit is not enabled, the clock prescaler and the counter is reset. When the PWM is enabled, it begins a new period, the output pin is set to start a new period while the prescaler and counter are released and counting begins.</p> <p>To make the PWM work with softreset and disable/enable, users can do software reset by setting the SWR bit, wait software reset done, configure the registers, and then enable the PWM by setting this bit to "1"</p> <p>Users can also disable/enable the PWM if PWM would like to be stopped and resumed with same registers configurations .</p> <p>0 PWM disabled 1 PWM enabled</p>

12.2.5.2 PWM Status Register (PWMx_PWMSR)

The PWM status register (PWM_PWMSR) contains seven bits which display the state of the FIFO and the occurrence of rollover and compare events. The FIFOAV bit is read-only but the other four bits can be cleared by writing 1 to them. The FE, ROV, and CMP bits are associated with FIFO-Empty, Roll-over, and Compare interrupts, respectively.

Address: Base address + 4h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

PWMx_PWMSR field descriptions

Field	Description
31–7 Reserved	<p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>
6 FWE	<p>FIFO Write Error Status. This bit shows that an attempt has been made to write FIFO when it is full.</p> <p>0 FIFO write error not occurred 1 FIFO write error occurred</p>
5 CMP	<p>Compare Status. This bit shows that a compare event has occurred.</p> <p>0 Compare event not occurred 1 Compare event occurred</p>

Table continues on the next page...

PWMx_PWMSR field descriptions (continued)

Field	Description
4 ROV	Roll-over Status. This bit shows that a roll-over event has occurred. 0 Roll-over event not occurred 1 Roll-over event occurred
3 FE	FIFO Empty Status Bit. This bit indicates the FIFO data level in comparison to the water level set by FWM field in the control register. 0 Data level is above water mark 1 When the data level falls below the mark set by FWM field
FIFOAV	FIFO Available. These read-only bits indicate the data level remaining in the FIFO. An attempted write to these bits will not affect their value and no transfer error is generated. 000 No data available 001 1 word of data in FIFO 010 2 words of data in FIFO 011 3 words of data in FIFO 100 4 words of data in FIFO 101 unused 110 unused 111 unused

12.2.5.3 PWM Interrupt Register (PWMx_PWMIR)

The PWM Interrupt register (PWM_PWMIR) contains three bits which control the generation of the compare, rollover and FIFO empty interrupts.

Address: Base address + 8h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PWMx_PWMIR field descriptions

Field	Description
31–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 CIE	Compare Interrupt Enable. This bit controls the generation of the Compare interrupt.

Table continues on the next page...

PWMx_PWMIR field descriptions (continued)

Field	Description
	0 Compare Interrupt not enabled 1 Compare Interrupt enabled
1 RIE	Roll-over Interrupt Enable. This bit controls the generation of the Rollover interrupt. 0 Roll-over interrupt not enabled 1 Roll-over Interrupt enabled
0 FIE	FIFO Empty Interrupt Enable. This bit controls the generation of the FIFO Empty interrupt. 0 FIFO Empty interrupt disabled 1 FIFO Empty interrupt enabled

12.2.5.4 PWM Sample Register (PWMx_PWMSAR)

The PWM sample register (PWM_PWMSAR) is the input to the FIFO. 16-bit words are loaded into the FIFO. The FIFO can be written at any time, but can be read only when the PWM is enabled. The PWM will run at the last set duty-cycle setting if all the values of the FIFO has been utilized, until the FIFO is reloaded or the PWM is disabled. When a new value is written, the duty cycle changes after the current period is over.

A value of zero in the sample register will result in the PWMO output signal always being low/high (POUTC = 00 it will be low and POUTC = 01 it will be high), and no output waveform will be produced. If the value in this register is higher than the PERIOD + 1, the output will never be set/reset depending on POUTC value.

Address: Base address + Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																SAMPLE															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PWMx_PWMSAR field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
SAMPLE	Sample Value. This is the input to the 4x16 FIFO. The value in this register denotes the value of the sample being currently used.

12.2.5.5 PWM Period Register (PWMx_PWMPR)

The PWM period register (PWM_PWMPR) determines the period of the PWM output signal. After the counter value matches PERIOD + 1, the counter is reset to start another period.

$$\text{PWMO (Hz)} = \text{PCLK(Hz)} / (\text{period} + 2)$$

A value of zero in the PWM_PWMPR will result in a period of two clock cycles for the output signal. Writing 0xFFFF to this register will achieve the same result as writing 0xFFFE.

A change in the period value due to a write in PWM_PWMPR results in the counter being reset to zero and the start of a new count period.

NOTE

Settings PWM_PWMPR to 0xFFFF when PWMx_PWMCR REPEAT bits are set to non-zero values is not allowed.

Address: Base address + 10h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PWMx_PWMCNR field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
COUNT	Counter Value. These bits are the counter register value and denotes the current count state the counter register is in.

Chapter 13

Multimedia

13.1 Multimedia Overview

13.1.1 Multimedia Overview

13.1.1.1 Display Interface

The display and camera subsystem consists of four major blocks: LCDIF, CSI, MIPI CSI and MIPI DSI.

- The LCDIF is a simple display controller which has been widely used on i.MX chips. The key features of the display controller include:
 - Support 8-bit / 16-bit / 18-bit / 24-bit / 32-bit pixel depth
 - Support DOTCLK mode for MIPI-DPI interface
 - Support resolution up to 1920x1080p60 and 1800x1200p60
 - Support one base layer and one graphics overlay with alpha blending
- This chip supports one 4-lane MIPI DSI display with pixels from the LCDIF. The key features of the MIPI DSI (controller and PHY) include:
 - Compliant to MIPI-DSI standard v1.1
 - Support up to 4 data lanes
 - Support 80Mbps - 1.5Gbps data rate in high speed operation
 - Support 10Mbps data rate in low power operation
- The CSI is a simple camera interface. It captures the MIPI CSI input and saves the pixels into memory. The key features of the CSI include:
 - Configurable interface logic to support most commonly available CMOS sensors
 - 8-bit / 16-bit / 24-bit data port for YCbCr, YUV, or RGB data input
 - Full control of 8-bit/pixel, 10-bit/pixel or 16-bit / pixel data format to 64-bit receive
 - Support up to 1080p@60fps video capture
- The chip supports one 4-lane MIPI CSI2 camera input. The key features of the MIPI CSI2 (controller and PHY) include:

- Compliant to MIPI-CSI2 standard
- Support up to 4 data lanes
- Support 80Mbps - 1.5Gbps data rate in high speed operation
- Support 10Mbps data rate in low power operation
- Support 5M pixel at 15 fps, 1080p60, 720p60, VGA at 60 fps

13.1.1.2 Graphics Processing Unit (GPU)

The GPU consists of a 3D graphics core and a 2D graphics core.

3D graphics core features include:

- Run up to 800MHz (CLK2X) at nominal voltage (0.8V +/- 10%)
- Run up to 1000MHz (CLK2X) at overdrive voltage (0.9V +5%/-10%)
- Support 40M triangles/sec at 800MHz, 50M triangles/sec at 1000MHz
- Support 400M pixel/sec fill rate at 800MHz, 500M pixel/sec fill rate at 1000MHz
- Support 6.4 GFLOPs at 800MHz, 8 GFLOPs at 1000MHz
- Support OpenGL ES 1.1, 2.0
- Support OpenVG 1.1
- TrustZone support using a local MMU to manage secure regions
- AXI clock 800MHz at both nominal and overdrive voltage

2D graphics core features include:

- Run up to 800MHz (CLK2X) at nominal voltage (0.8V +/- 10%)
- Run up to 1000MHz (CLK2X) at overdrive voltage (0.9V +5%/-10%)
- Support multi-source composition
- Support one-pass filter
- Support tile format from GCNanoUltra
- AXI clock 800MHz at both nominal and overdrive voltage

The GPU is powered by a dedicated power VDD_GPU. In order to support DVFS for both high-performance and low power use cases, it should support following operating range:

- 0.8V (0.8V +/-10%), up to 800MHz
- 0.9V (0.9V +5%/-10%), up to 1000MHz

13.1.1.3 Video Processing Unit (VPU)

The chip supports video decoding for various video format using the Hantro G2 + G1.

Features include:

- 1080p60 VP9 Profile 0, 2 (10 bit) decoder (Hantro G2), input video stream can be 10-bit, the output decoded video is always 8-bit after post-processing in G2 core

- 1080p60 HEVC/H.265 decoder (Hantro G2)
- 1080p60 AVC/H.264 Baseline, Main, High decoder (Hantro G1)
- 1080p60 VP8 decoder (Hantro G1)
- 1080p60 AVC/H.264 Encoder (Hantro H1)
- 1080p60 VP8 Encoder (Hantro H1)
- TrustZone support

The VPU are powered by a dedicated power VDD_VPU. In order to support DVFS for both high-performance and low power use cases, it should support following operating range:

- 0.8V (0.8V +/-10%), G1/G2/H1 target frequency 600MHz
- 0.9V (0.9V +5%/-10%), G1/H1 target frequency 800MHz, G2 target frequency 700MHz
- AXI clock target frequency 800MHz at both 0.8V and 0.9V case
- Support 1080p60 decoding and 1080p60 encoding at 0.8V, with overdrive to 0.9V, higher frame rate is expected.

13.1.1.4 Audio Interface

The device supports multiple audio interfaces as listed below:

Table 13-1. Audio Interface Summary

Interface	Function	RX Data Line	TX Data Line	Note
SAI-1	External audio	8	8	
SAI-2	External audio	2	2	
SAI-3	External audio	2	2	
SAI-5	External audio	4	4	
SAI-6	External audio	1	1	
SPDIF-1	External audio	1	1	
PDM	External audio	4		

Besides the general audio input/output function, the audio interfaces will supports following features:

- SAI-1 supports up to 16-channels TX (8 lanes) and 16-channels RX (8 lanes) at 384KHz/32-bit
- SAI-5 supports up to 8-channels TX (4 lanes) and 8-channels RX (4 lanes) at 384KHz/32-bit
- SAI-2/3 support up to 4-channels TX (2 lanes) and 4-channels RX (2 lanes) at **768KHz/32-bit**
- SAI-6 support to up to 2-channels TX (1 lanes) and 2-channels RX (1 lanes) at 384KHz/32-bit

- SAI-1/2/3 supports glue-less switching between PCM and DSD operation for popular audio DACs
- SPDIF-1 supports raw capture mode that can save all incoming bits into an audio buffer
- PDM supports up to 8-channels (4 lanes)

The SAI-1/2/3/5/6, SPDIF-1 and PDM share GPIO pads on the chip through IOMUX. Common use cases supported by the audio interfaces are listed in the table below (many other configurations are possible). The number is the data lanes supported

Table 13-2. Audio Interface Use Cases

		UC 1	UC 2	UC 3	UC 4	UC 5	UC 6	UC 7	UC 8
SAI-1	TX	8 + DSD	8 + DSD	8 + DSD	8	8	8	4	4
	RX	8	8	8	8	8	8	4	4
SAI-2	TX	1		1		1	1		1
	RX	1		1		1	1		1
SAI-3	TX	1			1	1	1	1	1
	RX	1			1	1	1	1	1
SAI-5	TX		4		4	1		4	1
	RX		4	4	4	1	4	4	1
SAI-6	TX							1	1
	RX							1	1
SPDIF-1	TX	1	1	1	1	1	1	1	1
	RX	1	1	1	1	1	1	1	1

13.1.1.4.1 SAI Master Clock Inputs/Outputs

The MCLK pin on each SAI module can be configured as either an input or an output. When configured as an output, the SAI_{In}_CLK_ROOT from the CCM is routed to the pad output. When configured as an input, the external input to the pad is routed to SAI_{In}_MCLK, which can be used as master clock for SAI. Below is the diagram showing the both input/output options, by using SAI1 as the example.

Figure 13-1. SAI MCLK Input and Output

Each SAI module supports up to 3 master clock inputs. The TX and RX sub-module inside each SAI can independently select one of the clock inputs as its master clock. This allows TX and RX of one SAI to run from different clock sources. The master clock inputs have the following options:

- SAI_n_MCLK[1] can be selected from SAI_n_CLK_ROOT from CCM or SAI_n_MCLK from IOMUX. This is the most straight-forward clock routing in which SAI_n only uses its own clock source from CCM or IO pad
- SAI_n_MCLK[2] can be selected from the following clock sources:
 - Any of the SAI_n_CLK_ROOT from CCM
 - Any of the SAI_n_MCLK from IOMUX
 - Other clock sources from SPIDF
- SAI_n_MCLK[3] has the same clock source options as SAI_n_MCLK[2]. This allows both TX and RX can have access to all the options without any dependency between each other

The clock options for master clock on SAI are shown in the diagram blow, by using SAI-1 as an example.

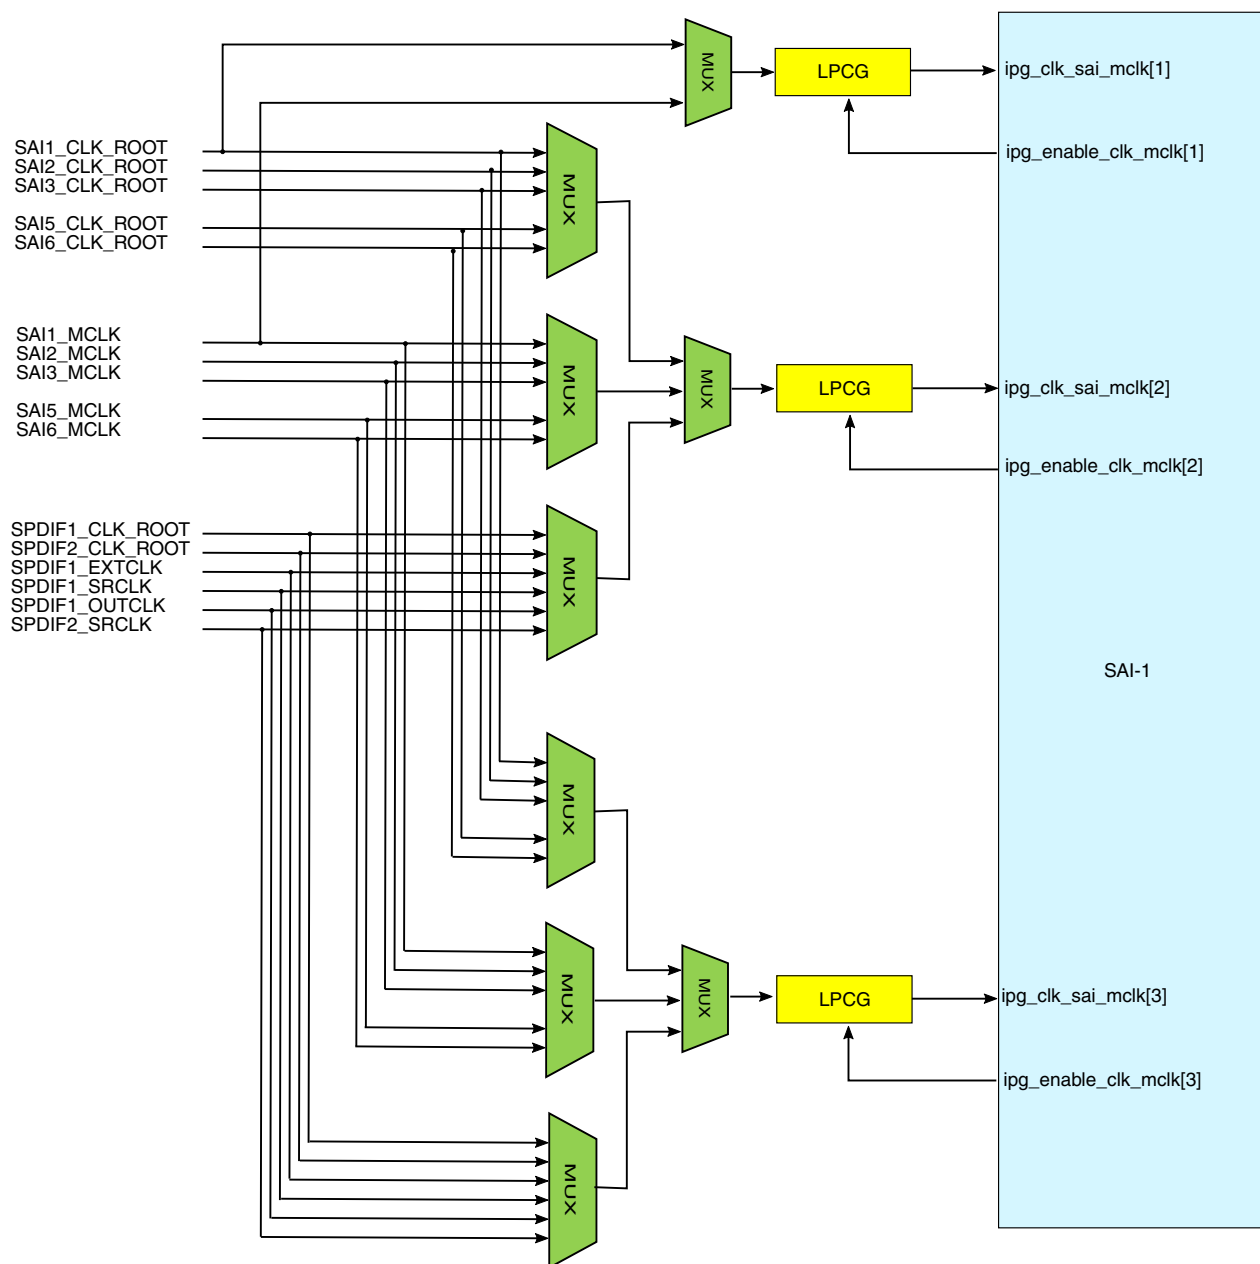

Figure 13-2. SAI Master Clock Options

The options on MCLK[1] are also available on MCLK[2] and MCLK[3]. This provides a similar SAI clock structure as i.MX6/i.MX7 processors.

The configuration of the MUX for master clock is controlled by IOMUXC_GPR registers. They should be configured before the SAI clock is enabled to avoid glitches on the clock.

13.1.1.4.2 SDMA Support

All the SAI and SPDIF instances have SDMA support. In order to meet the audio data rate, two dedicated SDMA modules are used. The DMA request from all audio interface modules will be routed to both SDMA modules, and both SDMA modules' IPG master port are connected to the SPBA. (SPBA has 3 master ports, one for chip-level IPG bus, two for the two SDMAs). With this implementation, the two SDMA modules can be flexibly allocated to all the audio interfaces, based on the needs of audio use cases.

The SDMA-2/3 target frequency is 400MHz IPG and 400MHz AHB, always 1:1 mode, to make sure there is enough throughput for all the audio use cases.

Table 13-3. SDMA Assignment for Audio Interface

SDMA	Audio Interface	Note
SDMA-2/3	SAI-2	2 TX + 2 RX
	SAI-3	2 TX + 2 RX
	SPDIF-1	TX + RX
	PDM	8 RX
	SAI-1	8 TX + 8 RX
	SAI-5	4 TX + 4 RX
	SAI-6	1 TX + 1 RX

13.2 Enhanced LCD Interface (eLCDIF)

13.2.1 Overview

The enhanced Liquid Crystal Display Interface (LCDIF) is a general purpose display controller used to drive a wide range of display devices varying in size and capability.

The LCDIF block supports the following:

- Displays with an asynchronous parallel MPU interface for command and data transfer to an integrated frame buffer.
- Displays that support moving pictures and require the RGB interface mode (DOTCLK interface).
- VSYNC mode for high-speed data transfers.
- Digital video encoders that accept ITU-R BT.656 format 4:2:2 YCbCr digital component video and convert it to analog TV signals.

The LCDIF provides fully programmable functionality to supported interfaces:

- Bus master interface to source frame buffer data for display refresh. This interface can also be used to drive data for "Smart" displays.

- PIO interface to manage data transfers between "Smart" displays and SoC.
- 8/16/18/24/32 bit LCD data bus support available.
- Programmable timing and parameters for MPU, VSYNC, and DOTCLK LCD interfaces to support a wide variety of displays.
- ITU-R BT.656 mode (called Digital Video Interface or DVI mode here) including progressive-to-interlace feature and RGB to YCbCr 4:2:2 color space conversion to support 525/60 and 625/50 operation.

13.2.2 Functional Description

[Bus Interface Mechanisms](#) through [Initializing the LCDIF](#), describe the internal pipeline for the LCDIF interfaces. Differences for each mode are then described in separate sections, as follows:

- [MPU Interface](#)
- [VSYNC Interface](#)
- [DOTCLK Interface](#)
- [ITU-R BT.656 Digital Video Interface \(DVI\)](#)

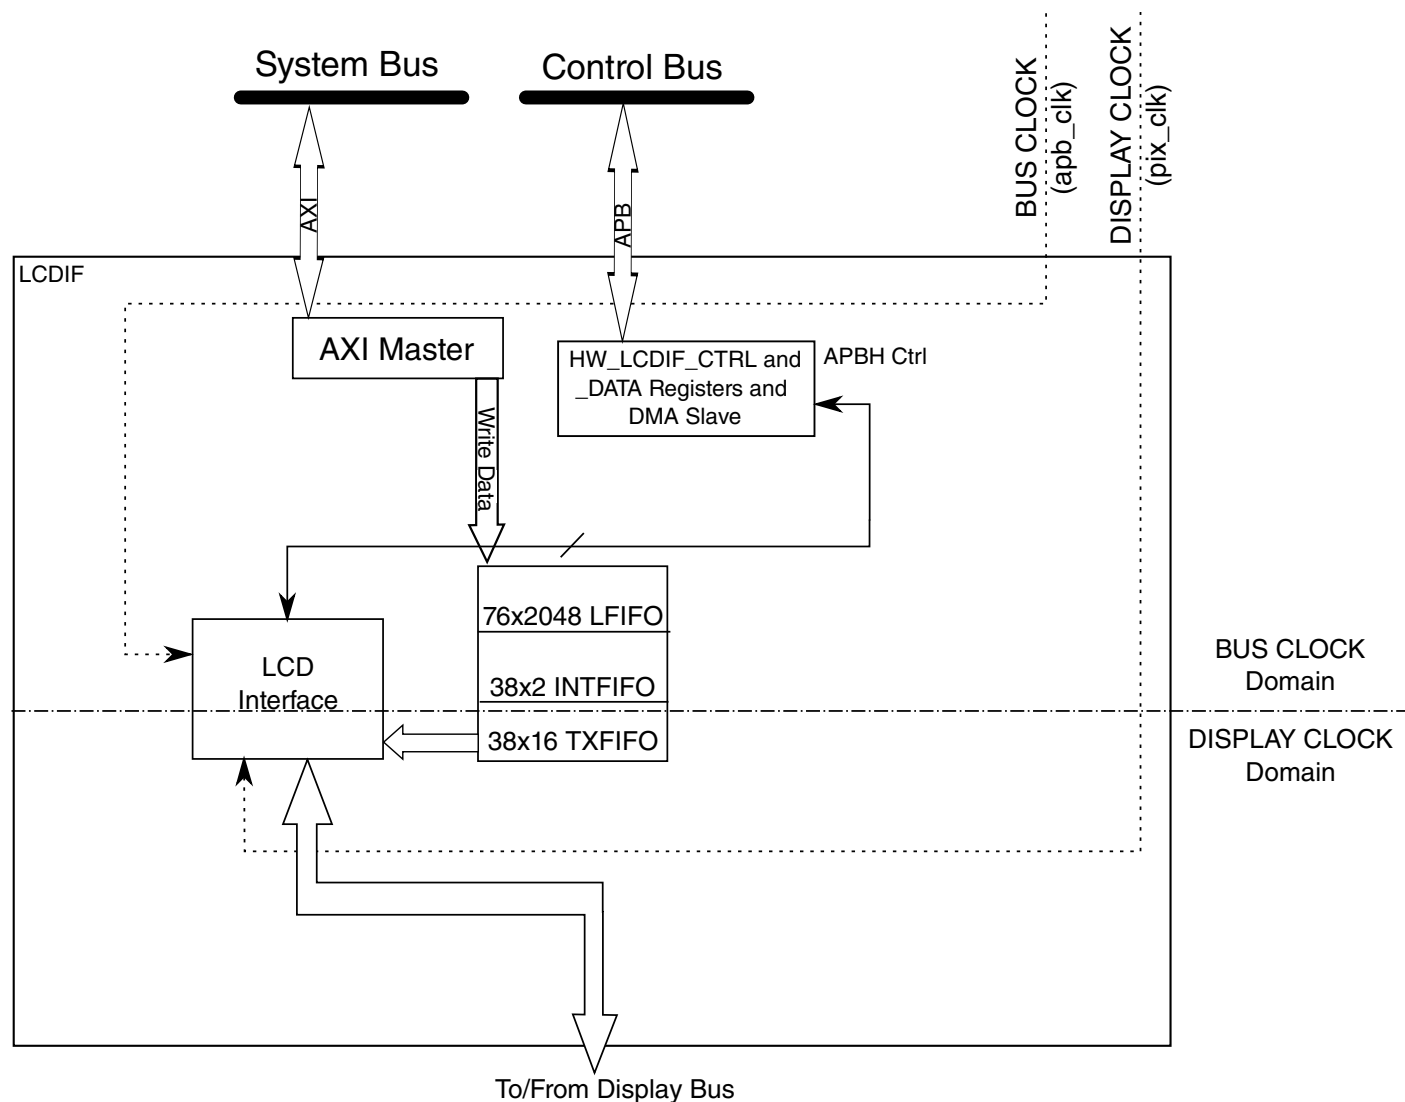

Figure 13-3. Top-Level Block Diagram of LCDIF subsystem

13.2.2.1 Bus Interface Mechanisms

The LCDIF module has memory-mapped control, data and status registers. It provides several interfaces to transfer data between the display and SoC.

The bus master interface is used to initiate the requests to transfer data from external memory to the display. It is completely autonomous, or no CPU intervention is required, to manage the cyclical nature of refreshing standard display types. Bus mastering can also be used for MPU mode data writes.

The PIO interface is used to interface to "Smart" displays to transfer frame buffer data and control information to/from the external display. The host CPU executes display drivers to manage the display solution. The following sections describe the system bus interface mechanisms.

13.2.2.1.1 Bus Master Operation in Write/Display Modes

The LCDIF block has a bus master interface that initiates requests for data to drive the display. The LCDIF_MASTER bit must be set to 1 to enable the bus master interface. Software should program all control registers required to transfer the frame sequence.

In the MPU and VSYNC mode, single frames are transferred. When a complete frame is transferred, LCDIF enters idle and clears the RUN bit in the CTRL register. For subsequent frame transmission, the LCDIF setup sequence should be repeated.

The DOTCLK and DVI mode is used to refresh the display at the desired refresh rate and resolution, and drive displays that don't integrate a display buffer memory. When the display is refreshed, the LCDIF will automatically update the LCDIF_CUR_BUF_ADDR register with the value in LCDIF_NEXT_BUF_ADDR at the end of current frame and start fetching the next frame from the new address. If the LCDIF_NEXT_BUF_ADDR register was not updated within a frame refresh cycle, LCDIF will keep transmitting the last frame until a new value is programmed into that register.

LCDIF also provides the capability of interlacing a progressive frame by fetching odd lines in the first field and then fetching even lines in the second field. This feature can be used in the DVI mode and can be turned on by setting the INTERLACE_FIELDS bit in the LCDIF_CTRL1 register.

13.2.2.1.2 System Bus Master Performance

The performance of the LCDIF block can be controlled by changing the burst length and the outstanding cycle issuing capability depending on the memory bandwidth requirements. Two fields in the LCDIF_CTRL2 register will throttle system memory requests. The LCDIF_CTRL2_OUTSTANDING_REQS field will control how many requests the LCDIF can have in flight on any given clock cycle. This should be programmed based on the expected system bus latency for returned read data. Also, the LCDIF_CTRL2_BURST_LEN_8 bit will set the number of 64 bit words requested for each LCDIF system bus request to either 8 or 16 QWORDS. Generally, 4 outstanding requests of length 16 will provide enough performance to drive any standard display resolution. These configuration bits are intended to change the access pattern of the LCDIF to optimize system bus throughput when other system masters will contend for system memory resources.

The LCDIF_THRES register can also be used to optimize bus throughput and power consumption.

The LCDIF_THRES_PANIC value can be used to raise the priority of requests initiated by the LCDIF to alter how the LCDIF requests are arbitrated by the system bus infrastructure. The panic output control signal is raised when the number of 32bpp pixel equivalents in the LFIFO is less than this programmed value. Since the LFIFO is arranged as a $8 * 256 \times 64$ bit quadword FIFO, it contains two 32bpp pixels per quadword, or 512 32bpp pixels total. To set the panic output when 3/4s of the LFIFO is empty, set the LCDIF_THRES_PANIC value to $3/4 * 512$, or 128. The panic signal output is used to assess higher priority to LCDIF system requests to avoid LCDIF under run errors during periods of high system bandwidth utilization.

The features available with the LCDIF_THRES register require support from system clocking and dynamic priority control. Refer to the appropriate block documentation to assess the system support for these features.

13.2.2.2 Write Data Path

LCDIF supports raster based frame buffers and there is no support for tiled buffers.

There are several options to accommodate endianness of display buffers in memory before the data is processed for the external display. The LCDIF_CTRL[INPUT_DATA_SWIZZLE] field provides the following options for data word multiplexing:

```
00 (0): No swizzle (little-endian)
01 (1): Swap bytes 0 and 3, swap bytes 1 and 2 (big-endian)
10 (2): Swap half-words
11 (3): Swap bytes within each half-word
```

The LCDIF_CTRL[WORD_LENGTH] field indicates the input data/pixel format. LCDIF_TRANSFER_COUNT register denotes how much data is contained in each frame. The LCDIF_TRANSFER_COUNT[H_COUNT] field indicates the number of pixels per line and LCDIF_TRANSFER_COUNT[V_COUNT] indicates the total number of lines per frame. The LCDIF_CTRL1[BYTE_PACKING_FORMAT] field can be used to specify which bytes within the 32-bit word are going to be valid. For example, if the entire 32-bit word is valid, LCDIF_CTRL1[BYTE_PACKING_FORMAT] should be set to 0xF, if only lower 3 bytes of each word in the frame buffer are valid, then LCDIF_CTRL1[BYTE_PACKING_FORMAT] should be set to 0x7.

The LCDIF_CTRL[LCD_DATABUS_WIDTH] field suggests the width of the bus going to the display controller. There is an option to source all 32 bits of the input word and transfer it to the output display interface. If the LCDIF_CTRL[LCD_DATABUS_WIDTH] is not the same as

LCDIF_CTRL[WORD_LENGTH], LCDIF will perform RGB to RGB color space conversion. For example, if the input frame has fewer bits per pixel than the display, as in a 16 bpp input frame going to 24 bpp LCD, LCDIF will pad the MSBs of each color to the LSBs of the same color for each pixel. If the input frame has more bits per pixel than the display, for example, 24 bpp input frame going to 16 bpp LCD, LCDIF will drop the LSBs of each color channel to convert to the lower color depth. LCDIF also has the capability to support delta pixel displays by swizzling the R, G and B colors of each pixel in the odd and even lines of the frame separately by programming the LCDIF_CTRL2[ODD_LINE_PATTERN] and the LCDIF_CTRL2[EVEN_LINE_PATTERN] bit fields. This operation occurs after the RGB-to-RGB color space conversion operation.

LCDIF also supports RGB to YCbCr 4:2:2 color space conversion. This is useful in the DVI mode since the TV encoder requires input in YCbCr 4:2:2 format. The LCDIF_CSC* registers have complete programmability over the CSC coefficients and offsets. The values must be written into these registers in the signed two's complement format.

The following list shows how the different input/output combinations can be obtained:

- LCDIF_CTRL[WORD_LENGTH]=1 indicates that the input is 8-bit data. This is most likely going to be used for sending commands in MPU interface, or maybe a gray scale image. Any combination of LCDIF_CTRL1[BYTE_PACKING_FORMAT] is permissible.

Limitation: LCDIF_TRANSFER_COUNT[H_COUNT] must be a multiple of the sum of BYTE_PACKING_FORMAT [3], BYTE_PACKING_FORMAT [2], BYTE_PACKING_FORMAT [1] and BYTE_PACKING_FORMAT [0].
LCDIF_CTRL[LCD_DATABUS_WIDTH] must be 1, indicating an 8-bit data bus.

- LCDIF_CTRL[WORD_LENGTH]=0 implies the input frame buffer is RGB 16 bits per pixel. LCDIF_CTRL[DATA_FORMAT_16_BIT] field determines the pixels are RGB 555 or RGB 565.

Limitation: LCDIF_CTRL1[BYTE_PACKING_FORMAT] should be 0x3 or 0xC if there is only one pixel per word. If there are two pixels per word, it should be 0xF and LCDIF_TRANSFER_COUNT[H_COUNT] will be restricted to be a multiple of 2 pixels.

- LCDIF_CTRL[WORD_LENGTH]=2 indicates that input frame buffer is RGB 18 bits per pixel, that is, RGB 666. The valid RGB values can be left-aligned or right-aligned within a 32-bit word. The alignment of the valid 18 bits within a word is indicated by the LCDIF_CTRL[DATA_FORMAT_18_BIT] bit.

Limitation: LCDIF_CTRL1[BYTE_PACKING_FORMAT] can be 0x7, 0xE or 0xF.
 Packed pixels are not supported in this case.
 LCDIF_TRANSFER_COUNT[H_COUNT] can be any number.

- LCDIF_CTRL[WORD_LENGTH]=3 indicates that the input frame-buffer is RGB 24 bits per pixel (RGB 888). If LCDIF_CTRL1[BYTE_PACKING_FORMAT] is 0x7, it indicates that there is only one pixel per 32-bit word and there is no restriction on LCDIF_TRANSFER_COUNT[H_COUNT].

Limitation: If LCDIF_CTRL1[BYTE_PACKING_FORMAT] is 0xF, it indicates that the pixels are packed, that is, there are 4 pixels in 3 words or 12 bytes and LCDIF_TRANSFER_COUNT[H_COUNT] must be a multiple of 4 pixels.

- LCDIF_CTRL1[YCBCR422_INPUT]=1 implies that the input frame is in YCbCr 4:2:2 format. LCDIF_CTRL1[BYTE_PACKING_FORMAT] must be 0xF.

Limitation: LCDIF_CTRL[LCD_DATABUS_WIDTH] must be 8-bit and LCDIF_TRANSFER_COUNT[H_COUNT] must be a multiple of 2 pixels.

LCDIF_CTRL2[ODD_LINE_PATTERN] and
 LCDIF_CTRL2[EVEN_LINE_PATTERN] must be 0 when any of
 LCDIF_CTRL[RGB_TO_YCBCR422_CSC] or
 LCDIF_CTRL1[INTERLACE_FIELDS] or LCDIF_CTRL[YCBCR422_INPUT]
 bits is 1.

After the RGB to RGB or RGB to YCbCr 4:2:2 color space conversions, there is one more opportunity to swizzle the data before sending it out to the display or the encoder. This can be done with the LCDIF_CTRL[CSC_DATA_SWIZZLE] field, and it provides the same options as the LCDIF_CTRL[INPUT_DATA_SWIZZLE] register.

Finally, there is an option to shift the output data before sending it out to the display. This is done based on the LCDIF_CTRL[SHIFT_DIR] and
 LCDIF_CTRL[SHIFT_NUM_BITS] fields.

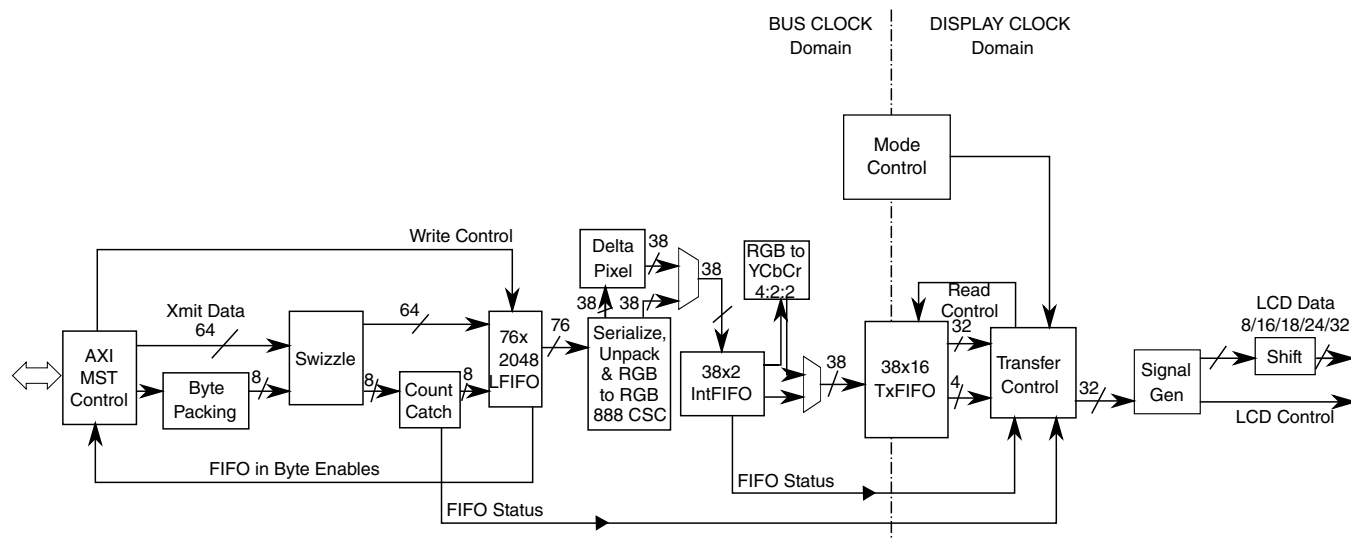

Figure 13-4. General Operations in Write Data Path

The examples in the following figures illustrate some different combinations of register programming for write mode. Assume that the data transferred over the system bus within a 32 bit word is organized as {A7-A0, B7-B0, C7-C0, D7-D0} in 8-bit mode and {A15-A0, B15-B0} in 16-bit mode.

In this example, all 32 bits of the input word are transferred out over an 8 bit display bus. Each byte within the 32 bit word is shifted to the right with zeros appended to bits D[7:6]. The input data bits [7:2] are shifted to the right by 2 bits and presented on the D[5:0].

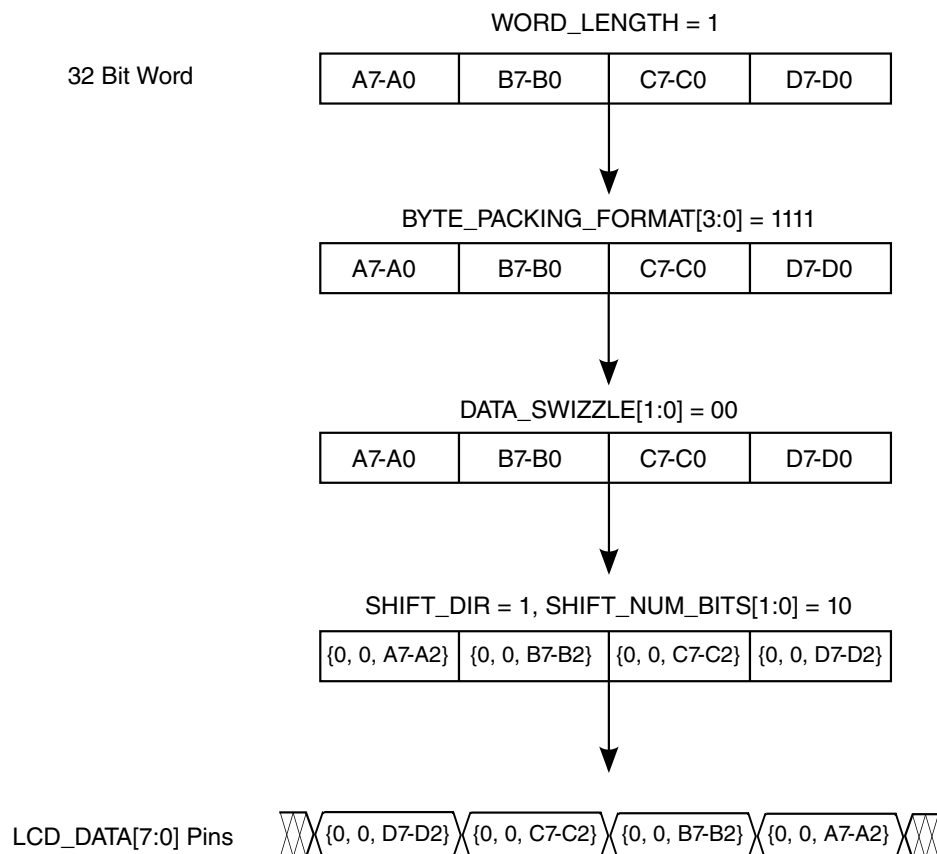

Figure 13-5. Register programming for write mode

In this 8 bit display interface example, one byte of the input word is deleted and not transferred over the external 8 bit display interface. This mode could be used to transfer 24bpp pixels over the 8 bit interface. In this case, the 4th unused byte is not transferred.

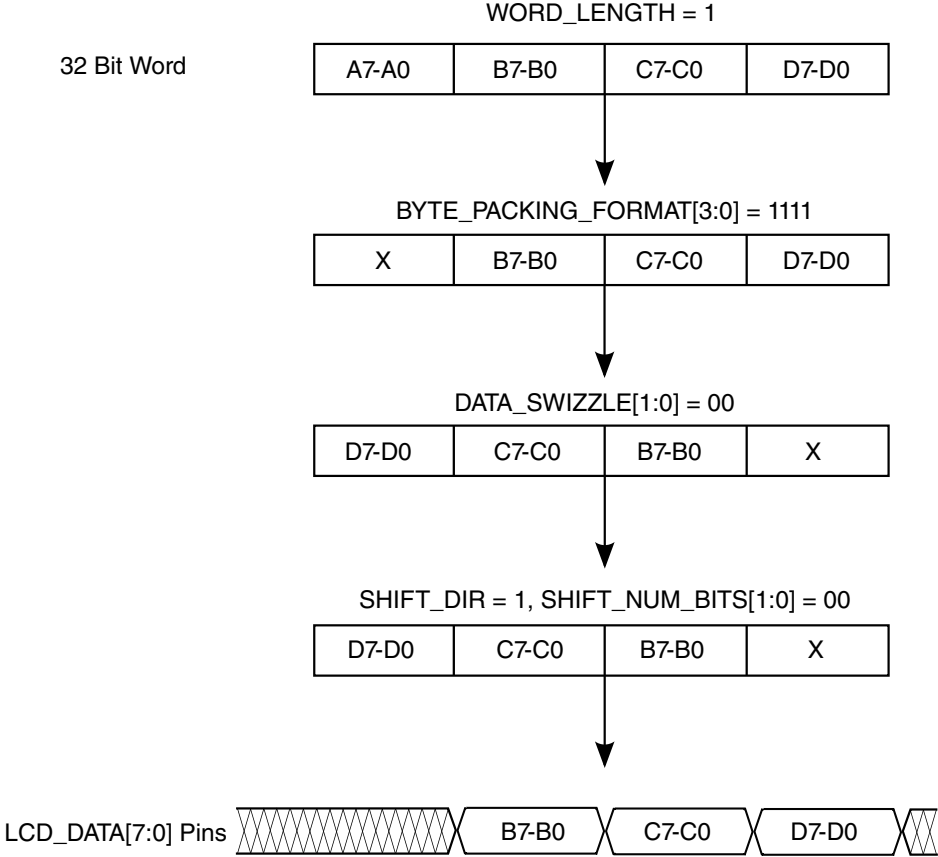

Figure 13-6. Register programming for write mode

The following example uses a 16 bit display interface. Each 16 bit half word is shifted to the right by two bits with zeros appended to the most significant two bits.

Figure 13-7. Register programming for write mode

This example indicates how an unpacked frame buffer can be sourced for display. Only a single 16 bit half word within the 32 bit word is transferred out via the 16 display bus.

Figure 13-8. Register programming for write mode

13.2.2.3 Read Data Path

Figure 13-9 shows the MPU read data path in detail.

LCDIF can read from an external display that follows the 6800/8080 MPU protocol.

The display bus width is determined by the LCD_DATABUS_WIDTH bit field. The data sampled at every read strobe is called a subword and the number of subwords that can be packed in a 32-bit word is given by the READ_MODE_NUM_PACKED_SUBWORDS bit field. The INITIAL_DUMMY_READ bit field directs the LCDIF to skip the number of programmed subwords before starting to process read data. This feature is useful in the case of an LCD controller that returns the last written data the first time a read is issued, and then sends the correct data thereafter. SHIFT_DIR and SHIFT_NUM_BITS bit fields indicate whether the data needs to be shifted before getting stored in the internal registers. For example, a value of 2 in READ_MODE_NUM_PACKED_SUBWORDS if lcd databus width is 8 bits indicates two bytes should be packed in a 32-bit word, while if the lcd databus width is 16 bits, it indicates that two half words (or 4 bytes) should be packed.

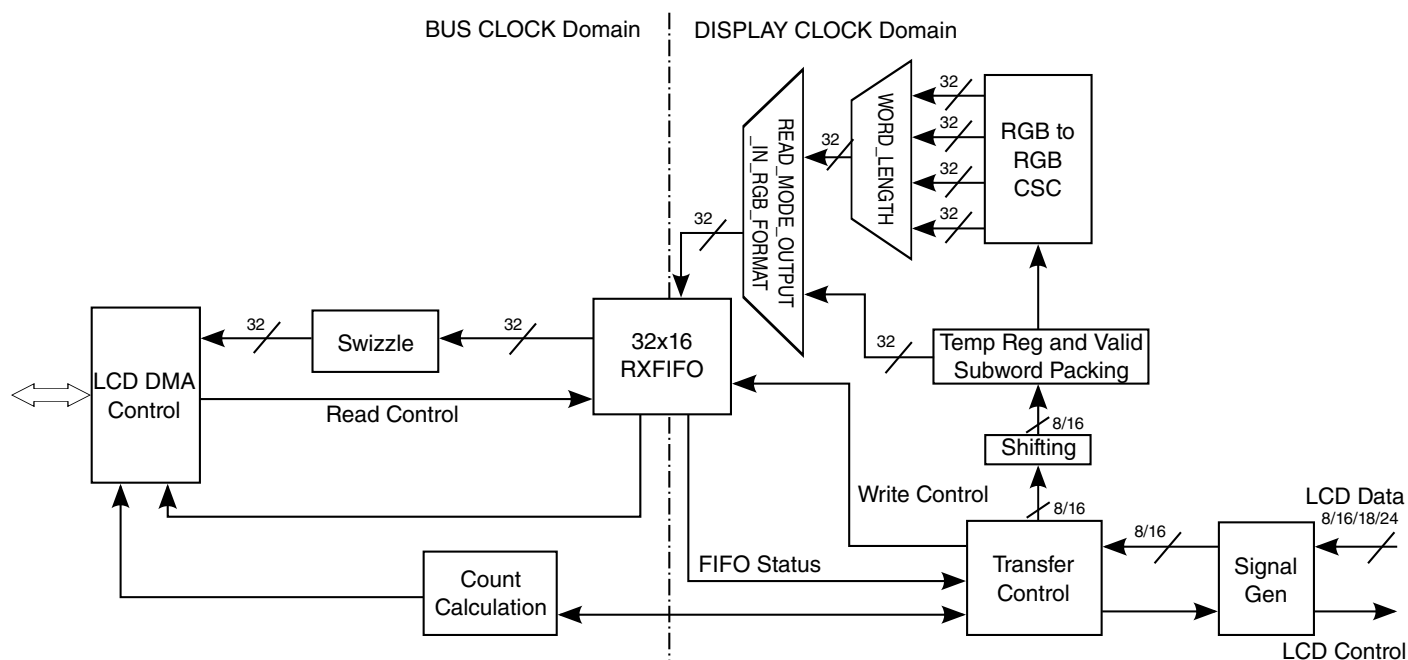

Figure 13-9. MPU Read Data Path

After the last subword within a word is reached, the block looks at the `READ_PACK_DIR` in the `HW_LCDIF_CTRL2` register. If this bit is set, the block will swizzle the data, but only within the valid bytes, unlike in the write mode, where swizzle occurs across all 4 bytes. If the `READ_MODE_OUTPUT_IN_RGB_FORMAT` bit is set, LCDIF will convert the data obtained from the `READ_PACK_DIR` operation into 24-bit unpacked RGB and then re-convert it into 16/18/24 bpp RGB depending on the `WORD_LENGTH` field. The `DATA_FORMAT_16/18/24_BIT` bit fields are also considered while converting to 24-bit unpacked RGB format. For example, if `DATA_FORMAT_18_BIT` is 1, the RGB666 data will be packed in the upper bits [31:4] of a 32-bit word, and that bit is 0, the data will be packed in the lower bits [17:0]. After all these operations, the data gets written into the RXFIFO.

The following figures show some examples of how data is handled in different MPU read modes.

Enhanced LCD Interface (eLCDIF)

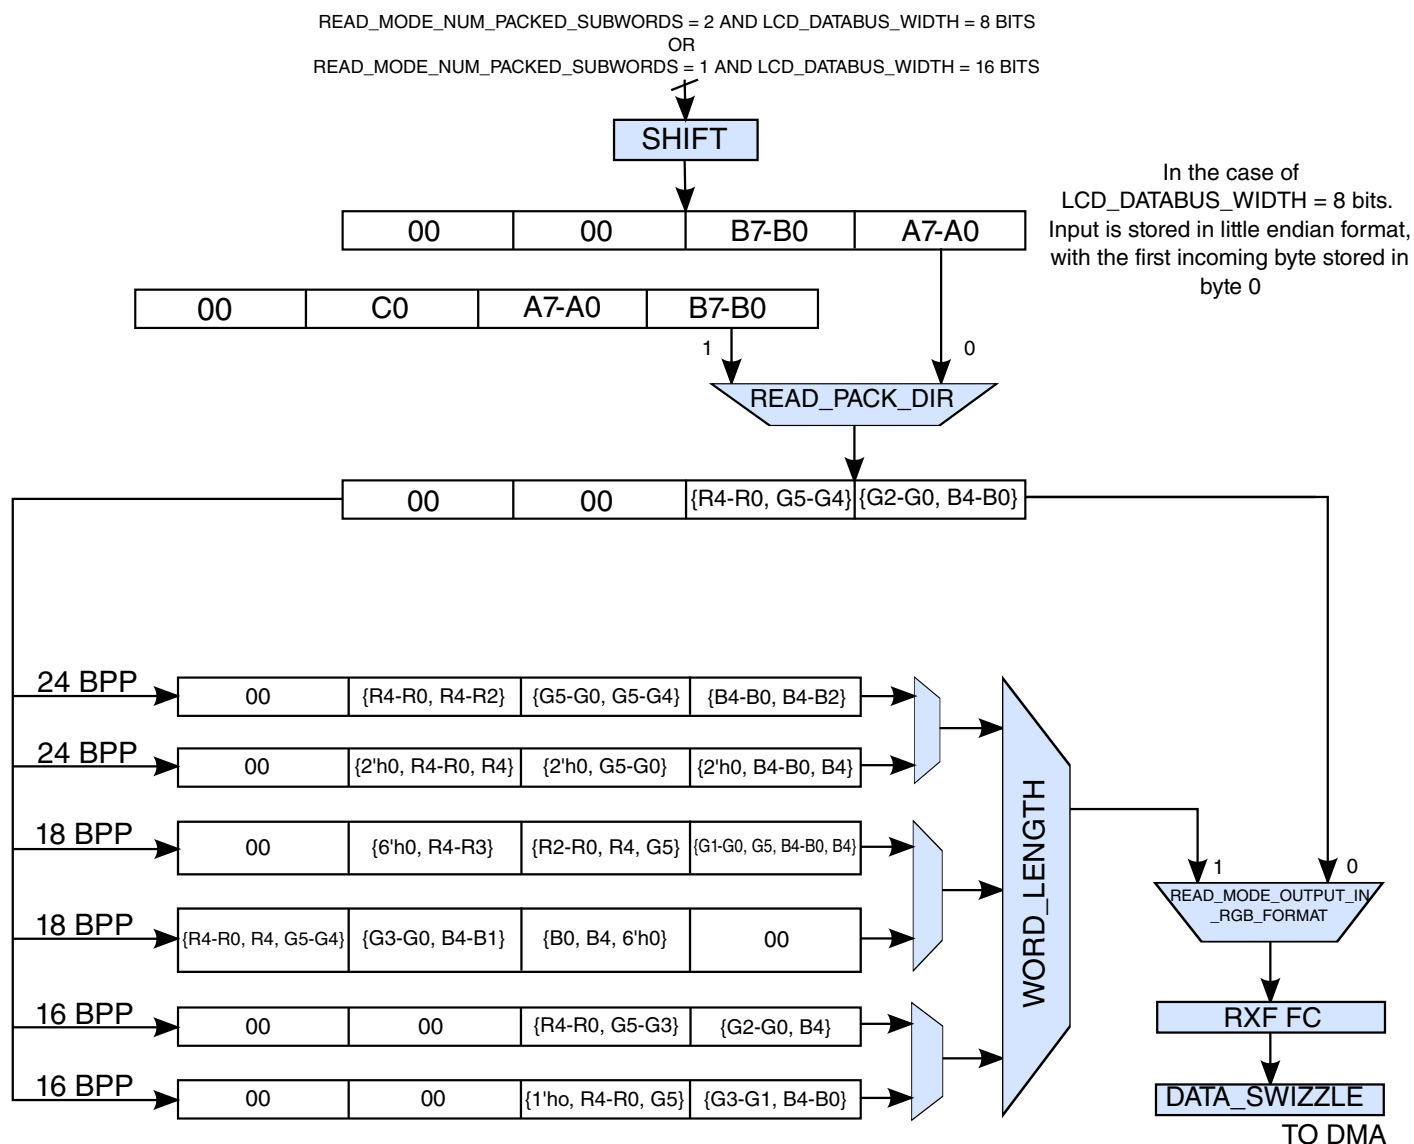

Figure 13-10. Data in MPU read mode

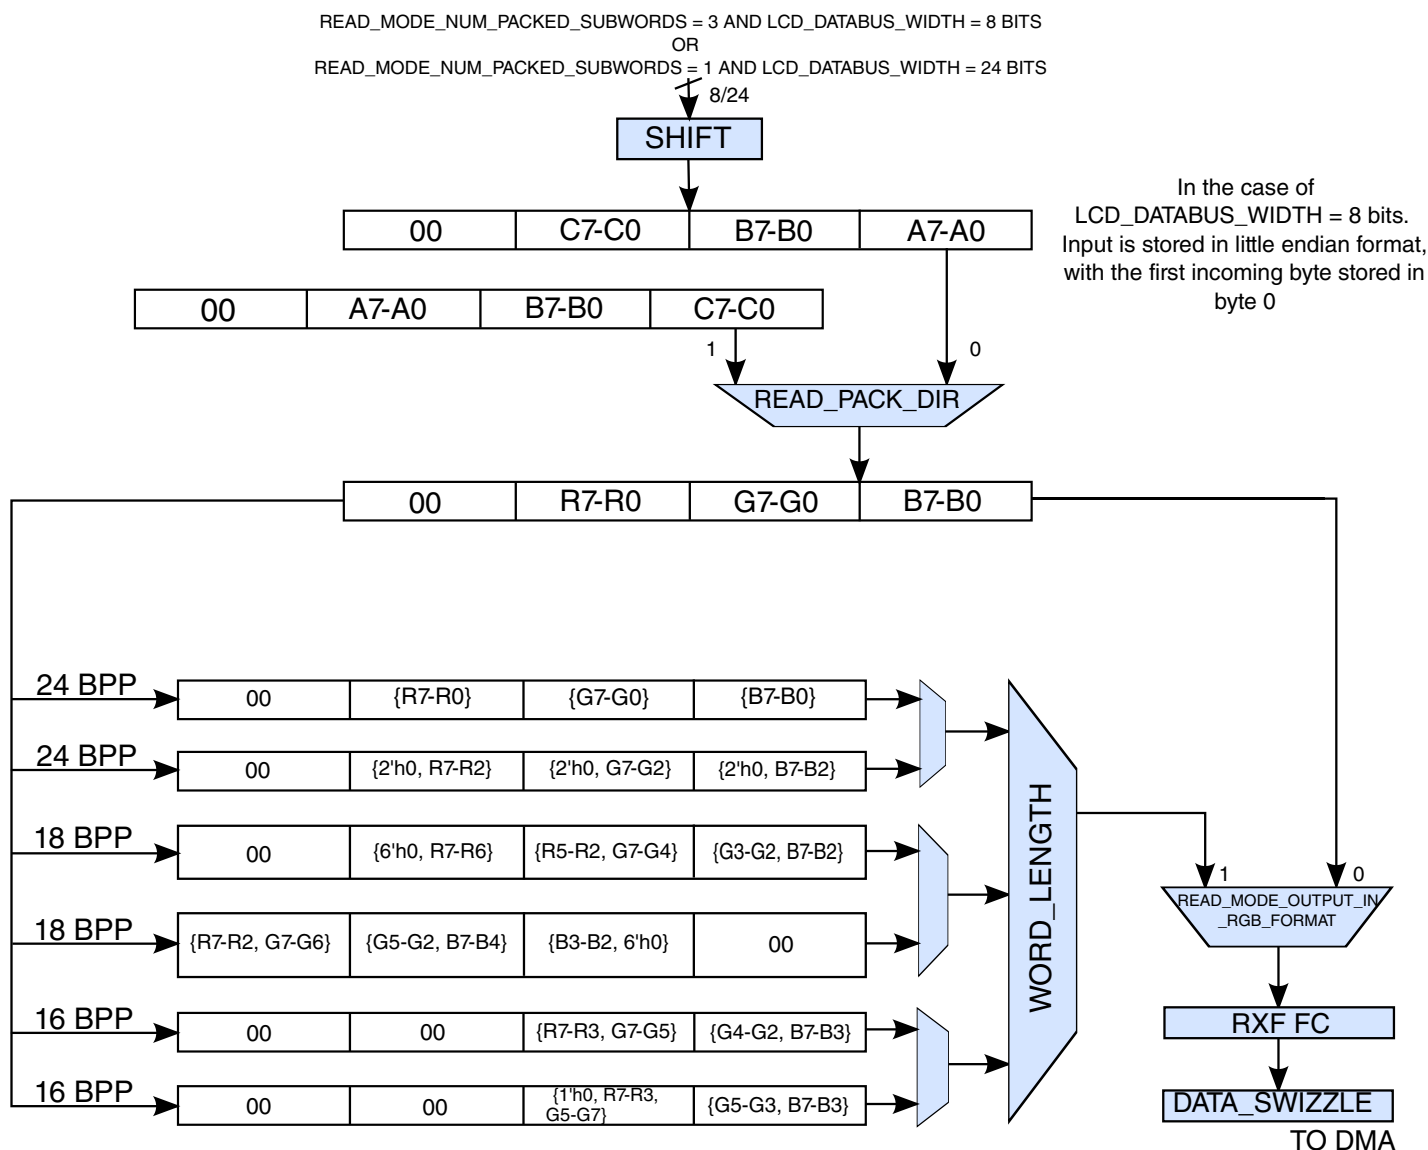

Figure 13-11. Data in MPU read mode

READ_MODE_NUM_PACKED_SUBWORDS = 1 AND LCD_DATABUS_WIDTH = 18 BITS

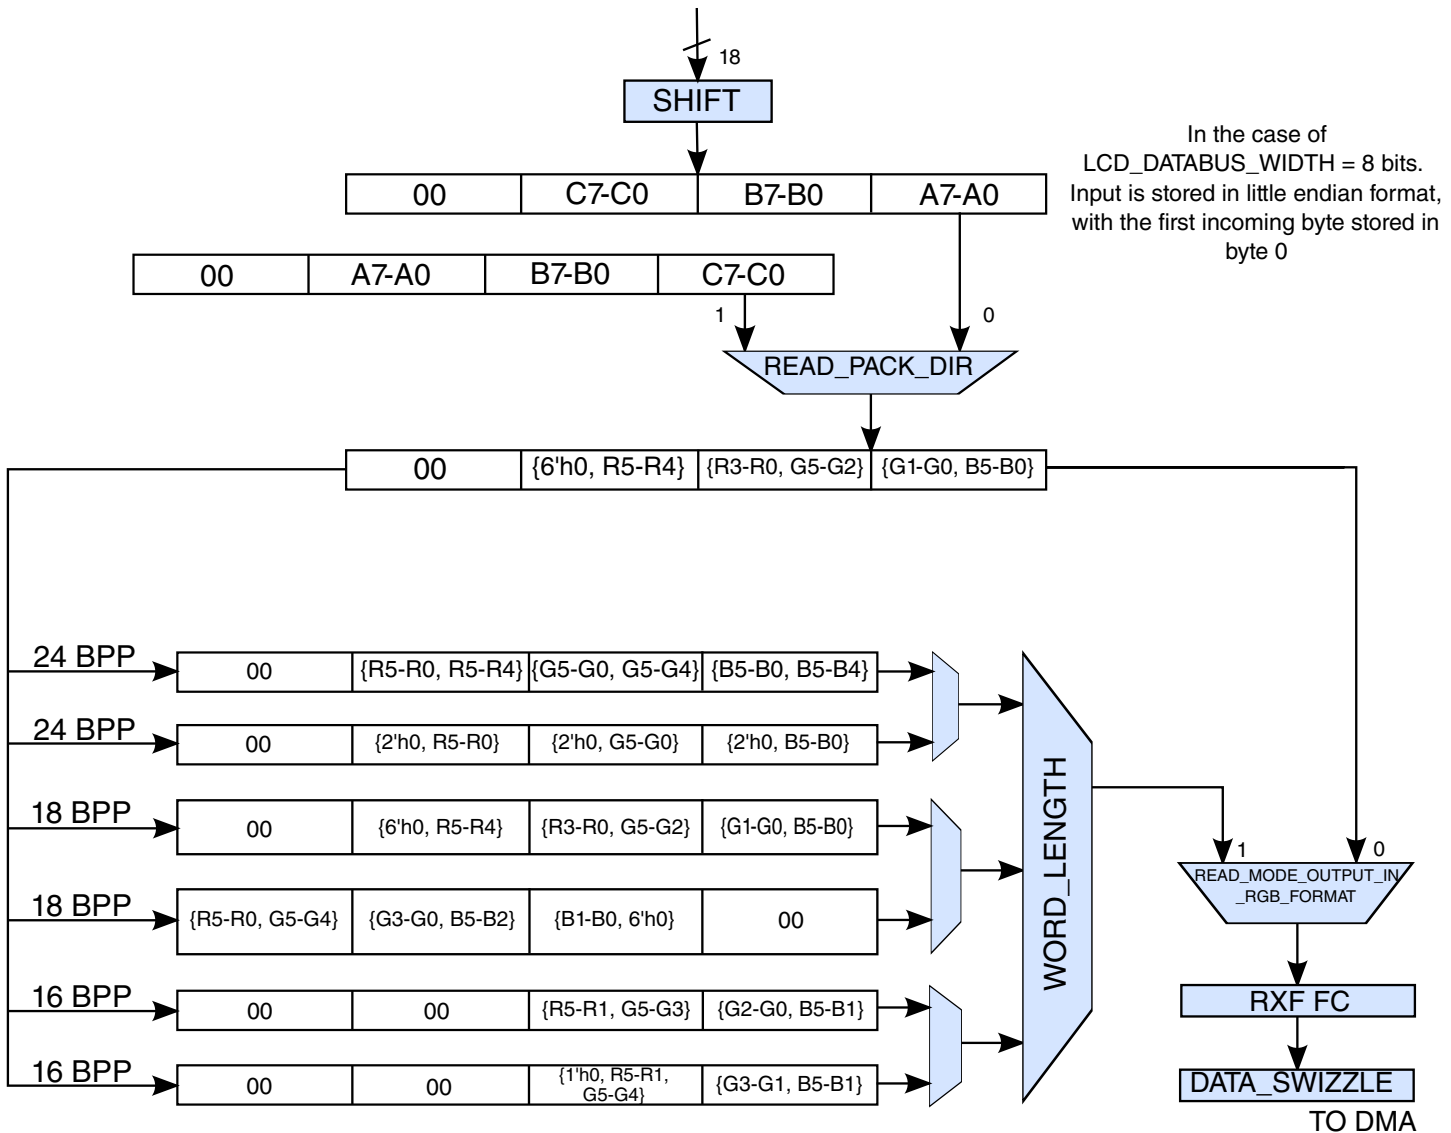

Figure 13-12. Data in MPU read mode

Restrictions:

READ_PACK_DIR should only be used if it is required to swizzle the subwords before doing RGB to RGB CSC, otherwise the DATA_SWIZZLE field should be used to swizzle across bytes.

READ_PACK_DIR must be 0 if LCD_DATABUS_WIDTH is 8 bits and READ_MODE_NUM_PACKED_SUBWORDS = 1

If READ_MODE_OUTPUT_IN_RGB_FORMAT bit is set, the following restrictions should be followed:

- If LCD_DATABUS_WIDTH = 8 bits, then
READ_MODE_NUM_PACKED_SUBWORDS <= 3.
- If LCD_DATABUS_WIDTH = 16/18/24 bits, then
READ_MODE_NUM_PACKED_SUBWORDS = 1.

13.2.2.4 LCDIF Interrupts

LCDIF supports a number of interrupts to aid controlling and status reporting of the block.

All the interrupts have individual mask bits for enabling or disabling each of them. They all get funneled through a single interrupt line connected to the interrupt collector (ICOLL).

The following list describes the different interrupts supported by LCDIF:

- Underflow interrupt is asserted when the clock domain crossing FIFO (TXFIFO) becomes empty but the block is in active display portion during that time. Software should take corrective action to make sure that this does not happen.
- In the bus master mode, the overflow interrupt will be asserted if the block has requested more data than it's FIFOs could hold. In the read mode, it will be asserted if the RxFIFO becomes full and the block reads more data.
- VSYNC edge interrupt will be asserted every time a leading VSYNC edge occurs.
- Cur_frame_done interrupt occurs at the end of every frame in all modes except DVI. In DVI mode, if IRQ_ON_ALTERNATE_FIELDS bit is set, it will occur at the end of every frame, otherwise it will occur at the end of every field.

13.2.2.5 Initializing the LCDIF

This section describes write modes and MPU read mode.

13.2.2.5.1 Write Modes

The following initialization steps are common to all LCDIF write modes of operation before entering any particular mode.

Initialization steps:

1. Configure the external I/Os to correctly interface the external display, when required.
2. Start the DISPLAY CLOCK (pix_clk) clock and set the appropriate frequency by programming the registers in CCM.

3. Start the BUS CLOCK (apb_clk) and set the appropriate frequency by programming the registers in CCM.
4. Bring the LCDIF out of soft reset and disable the clock gate bit.
5. Reset the LCD controller by setting LCDIF_CTRL1[RESET] bit appropriately, being careful to observe the reset requirements of the controller. See [Behavior During Reset](#) for more information on Reset requirements.
6. Make sure LCDIF_CTRL[READ_WRITEB] bit is 0.
7. Set the transfer mode of operation to bus master. The LCDIF_CTRL[MASTER] bit determines the transfer mode selected. Bus master (LCDIF_CTRL[MASTER] =1), or PIO (LCDIF_CTRL[MASTER] =0) mode is the transfer mode to select.
8. Set the LCDIF_CTRL[INPUT_DATA_SWIZZLE] according to the endianness of the LCD controller. Also, set the LCDIF_CTRL[DATA_SHIFT_DIR] and LCDIF_CTRL[SHIFT_NUM_BITS] if it is required to shift the data left or right before it is output.
9. Set the LCDIF_CTRL[WORD_LENGTH] field appropriately: 0 = 16-bit input, 1 = 8-bit input, 2 = 18-bit input, 3 = 24/32-bit input. Also, select the correct 16/18/24 bit data format with the corresponding fields in LCDIF_CTRL register.
10. Set the LCDIF_CTRL1[BYTE_PACKING_FORMAT] field according to the input frame.
11. Set the LCDIF_CTRL[LCD_DATABUS_WIDTH] appropriately: 0 = 16-bit output, 1 = 8-bit output, 2 = 18-bit output, 3 = 24/32-bit output.
12. Enable the necessary IRQs.

13.2.2.5.2 MPU Read Mode

The following initialization steps should be done to enter the MPU read mode of operation:

Initialization steps:

1. Configure the external I/Os to correctly interface the external display.
2. Start the DISPLAY CLOCK (pix_clk) and set the appropriate frequency by programming the registers in CCM.
3. Start the BUS CLOCK (apb_clk) and set the appropriate frequency by programming the registers in CCM.
4. Bring the LCDIF out of soft reset and clock gate.
5. Reset the LCD controller by setting LCDIF_CTRL1_RESET bit appropriately, being careful to observe the reset requirements of the controller.
6. Set the READ_WRITEB bit in LCDIF_CTRL register to 1.
7. Set the LCDIF_MASTER bit in LCDIF_CTRL register to 0. Bus master mode is not supported for reading data from the display.

8. Also, set the DATA_SHIFT_DIR and SHIFT_NUM_BITS if it is required to shift the data left or right before it is output.
9. Indicate if the read data needs to color-space-converted and stored in a different RGB format by setting the READ_MODE_OUTPUT_IN_RGB_FORMAT field accordingly.
10. Set the WORD_LENGTH field appropriately: 0 = 16-bit input, 1 = 8-bit input, 2 = 18-bit input, 3 = 24-bit input if READ_MODE_OUTPUT_IN_RGB_FORMAT is required. Also, select the correct 16/18/24 bit data format with the corresponding fields in LCDIF_CTRL register.
11. Set the READ_MODE_NUM_PACKED_SUBWORDS field in LCDIF_CTRL2 according to the number of subwords per word required to be packed.
12. Set the READ_PACK_DIR to 1 if it is required to store the data in big-endian format.
13. Set the LCD_DATABUS_WIDTH appropriately: 0 = 16-bit output, 1 = 8-bit output, 2 = 18-bit output, 3 = 24-bit output.
14. Enable the necessary IRQs.

13.2.2.6 MPU Interface

The MPU interface is used to transfer data and commands between the SoC via the LCDIF and the external display at modest data rates.

Bus master or PIO transactions using the LCDIF_DATA register can be used for MPU mode write operations. For MPU mode read operations, only PIO can be used. LCDIF can support the 6800 as well as the 8080 MPU protocol. If DOTCLK_MODE, DVI_MODE and VSYNC_MODE bits in LCDIF_CTRL registers are 0, it implies that the block is in MPU interface mode of operation. The LCDIF MPU mode has four basic timing parameters: Setup and Hold for the Command/Data register selection (TCS, TCH) and Setup and Hold for the Data bus (TDS, TDH). These parameters are expressed in DISPLAY CLOCK (pix_clk) cycles. The LCD_WR signal is used as the write strobe while LCD_RS signal is typically used to switch between command and data modes.

Enhanced LCD Interface (eLCDIF)

Figure 13-13. Timing in write mode of 6800 and 8080 protocols

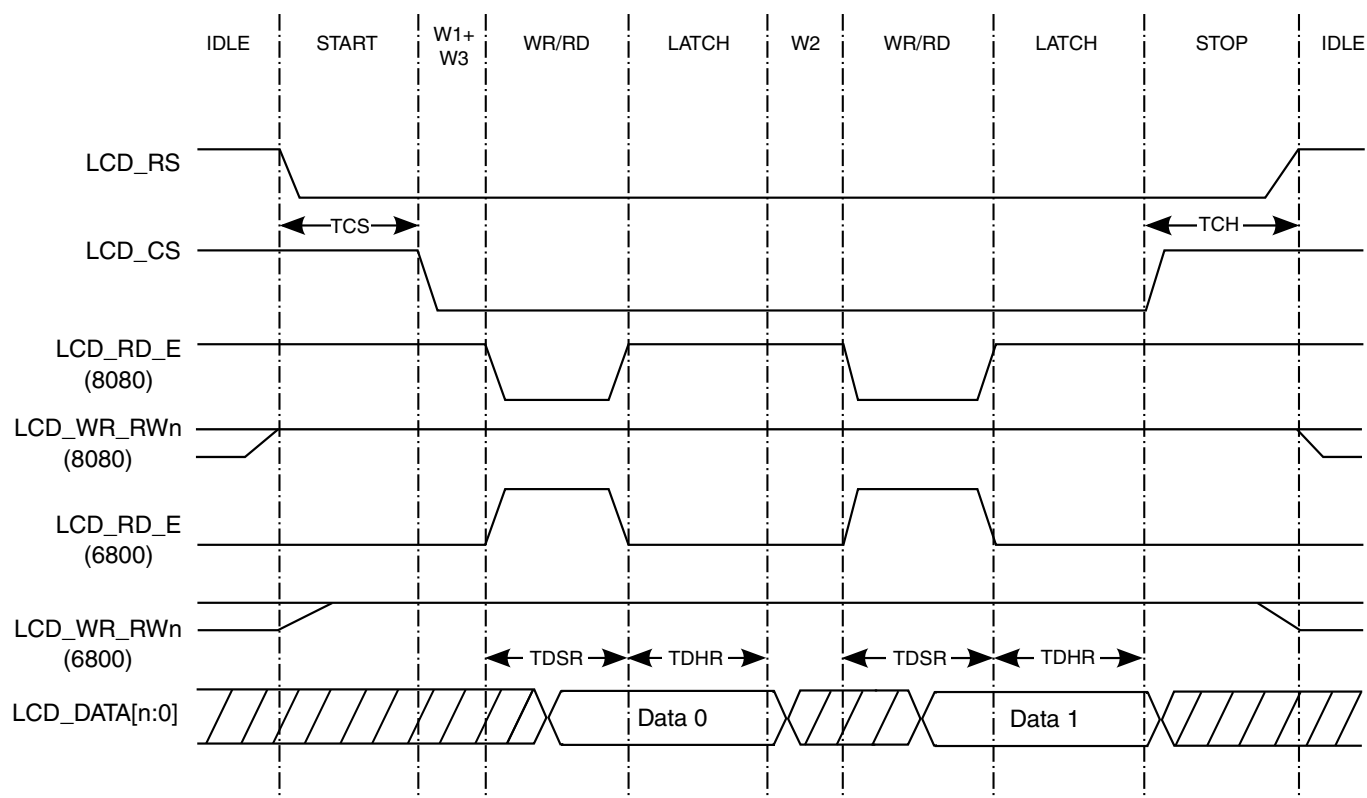

Figure 13-14. Read timing interface in 6800 and 8080 protocols

The LCDIF has flexible pin and strobe timings which enable it to optimally support a wide range of LCDs. The minimum cycle time is two DISPLAY CLOCK (pix_clk) cycles (TDS=TDH=1). For example, this results in a maximum LCD data rate of 12 MB/s when DISPLAY CLOCK (pix_clk) is 24 MHz. TDS and TDH are 8-bit values, so the minimum LCDIF period is 510 DISPLAY CLOCK (pix_clk) cycles (47 KHz with a 24 MHz DISPLAY CLOCK (pix_clk)). The timings are not automatically adjusted if the DISPLAY CLOCK (pix_clk) frequency changes, so it may be necessary to adjust the timings if DISPLAY CLOCK (pix_clk) changes.

In the MPU interface mode, the LCDIF_CTRL_BYPASS_COUNT bit must be 0. The RUN bit is cleared automatically once the LCDIF has received/transmitted all the data as per the LCDIF_TRANSFER_COUNT register and has completed the transfer to the panel. The current transfer can be cancelled/aborted if the RUN bit is manually made 0.

13.2.2.6.1 Code Example to Initialize the LCDIF in MPU Write Mode

```
// Note: Common initialization steps in Initializing the LCDIF must also be
// executed along with the following code
BF_CS1(LCDIF_CTRL, DATA_SELECT, 1); // 0 if sending command, 1 if sending data. Note that the
// idle state for LCD_RS signal is high, regardless of the
// programming of the DATA_SELECT register.
BF_CS1 (LCDIF_CTRL, MODE86, 8080_MODE);
BF_CS1 (LCDIF_CTRL, READ_WRITEB, 0);
BF_CS1 (LCDIF_CTRL, BYPASS_COUNT, 0); //Must be 0 in MPU mode
BF_CS1 (LCDIF_CTRL1, BUSY_ENABLE, 1); //Only if LCD controller implements a busy line
BF_CS4 (LCDIF_TIMING, CMD_HOLD, 2, CMD_SETUP, 2, DATA_HOLD, 2, DATA_SETUP, 2); //Values
based
// on DISPLAY CLOCK (pix_clk) frequency and timing requirements
of controller.
// Note that these register must be non-zero for correct
operation.
BF_CS2 (LCDIF_TRANSFER_COUNT, H_COUNT, 320, V_COUNT, 240); //For a 320 RGB x 240 display
BF_CS1 (LCDIF_CTRL, RUN, 1);
```

The LCDIF is now ready to receive data via bus master PIO write transactions using the LCDIF_DATA register. Note that when using the PIO write operations to the LCDIF_DATA register, the software will need to poll the FIFO STATUS bits to ensure that it does not overflow the LCDIF data buffers. When LCDIF is done transmitting H_COUNT x V_COUNT pixels, it will stop, turn off the RUN bit and assert the cur_frame_done interrupt.

13.2.2.7 VSYNC Interface

The VSYNC interface uses the same protocol as the MPU interface, with an additional signal VSYNC at the frame rate of the display, as shown in the figure given in MPU Interface section.

It is used in the moving picture display mode where data has to be written to the internal LCD buffer at a speed higher than the display rate and displayed in synchronization with the VSYNC signal. This mode is selected by setting the VSYNC_MODE bit in LCDIF_CTRL register. The VSYNC signal is programmable for period, polarity and direction. Many other programmable parameters are shared with the MPU interface. The VSYNC_OEB bit in LCDIF_VDCTRL0 register indicates whether the display controller will send the VSYNC signal, or whether it should be generated by LCDIF. The timing of the VSYNC signal is based on the DISPLAY CLOCK (pix_clk) (make sure VSYNC_PULSE_WIDTH_UNIT = VSYNC_PERIOD_UNIT = 0 and VSYNC_ONLY = 1) and it is determined by the VSYNC_PERIOD, VSYNC_PULSE_WIDTH and VSYNC_POL fields in LCDIF_VDCTRL0-4 registers. The SYNC_SIGNALS_ON bit in LCDIF_VDCTRL4 register must be set if the target requires the VSYNC signal to be generated by LCDIF. If the WAIT_FOR_VSYNC_EDGE bit in LCDIF_CTRL register is set, it indicates that the hardware should wait until it sees the leading VSYNC edge before starting the data transfer. The VERTICAL_WAIT_CNT indicates the number of DISPLAY CLOCK (pix_clk) cycles from the leading VSYNC edge after which data transfer will be started on the interface.

In the VSYNC interface mode, the LCDIF_CTRL_BYPASS_COUNT bit must be 0. The RUN bit is cleared automatically once the LCDIF has received/transmitted all the data as per the LCDIF_TRANSFER_COUNT register and has completed the transfer to the panel. The current transfer can be cancelled/aborted if the RUN bit is manually made 0.

13.2.2.7.1 Code Example to Initialize LCDIF in VSYNC Mode

```
// Note: Common initialization steps in Initializing the LCDIF must also be
// executed along with the following code
BF_CS1 (LCDIF_CTRL, DATA_SELECT, 1); // 0 if sending command, 1 if sending data. Note that
//the idle state for LCD_RS signal is high, regardless of the programming of the DATA_SELECT
//register.

BF_CS1 (LCDIF_CTRL, MODE86, 8080_MODE);
BF_CS1 (LCDIF_CTRL, BYPASS_COUNT, 0); //Must be 0 in MPU mode
BF_CS1 (LCDIF_CTRL1, BUSY_ENABLE, 0);
BF_CS4 (LCDIF_TIMING, CMD_HOLD, 2, CMD_SETUP, 2, DATA_HOLD, 2, DATA_SETUP, 2); //Values
//based on DISPLAY CLOCK (pix_clk) frequency and timing requirements of controller. Note
that these
//register must be non-zero for the MPU and VSYNC modes.
BF_CS2 (LCDIF_TRANSFER_COUNT, H_COUNT, 320, V_COUNT, 240); //For a 320 RGB x 240 display
//The following section indicates setting up the VSYNC signal timing when VSYNC is an output
BF_CS1 (LCDIF_VDCTRL0, VSYNC_OEB, 0); //Making VSYNC signal an output
BF_CS1 (LCDIF_VDCTRL4, VSYNC_ONLY, 1); //Only need to generate VSYNC signal
BF_CS1 (VDCTRL0, VSYNC_POL, 0); //Setting the polarity of VSYNC signal to be low during
//VSYNC PULSE WIDTH time
BF_CS2 (LCDIF_VDCTRL0, VSYNC_PERIOD_UNIT, 0, VSYNC_PULSE_WIDTH_UNIT, 0);
BF_CS2 (LCDIF_VDCTRL1, VSYNC_PERIOD, 400000, VSYNC_PULSE_WIDTH, 100); //Frame display rate in
//terms of number of DISPLAY CLOCKS (pix_clk).
BF_CS2 (LCDIF_VDCTRL2, HSYNC_PULSE_WIDTH, 0, HSYNC_PERIOD, 0);
BF_CS1 (LCDIF_VDCTRL3, VERTICAL_WAIT_CNT, 50);
BF_CS1 (LCDIF_VDCTRL4, SYNC_SIGNALS_ON, 1);
BF_CS2 (LCDIF_CTRL, VSYNC_MODE, 1, WAIT_FOR_VSYNC_EDGE, 1); //set WAIT_FOR_VSYNC_EDGE if
```

```
//software wishes to transfer the next frame after the VSYNC edge occurs.
BF_CS1 (LCDIF_CTRL, RUN, 1);
```

The LCDIF is now ready to receive data via bus master requests or PIO writes to the LCDIF_DATA register. When LCDIF is done transmitting $H_COUNT \times V_COUNT$ pixels, it will stop, turn off the RUN bit and assert the `cur_frame_done` interrupt.

13.2.2.8 DOTCLK Interface

The DOTCLK interface is another mode used in moving picture displays.

It includes the VSYNC, HSYNC, DOTCLK and (optional) ENABLE signals. The interface is popularly called the RGB interface if the ENABLE signal is present.

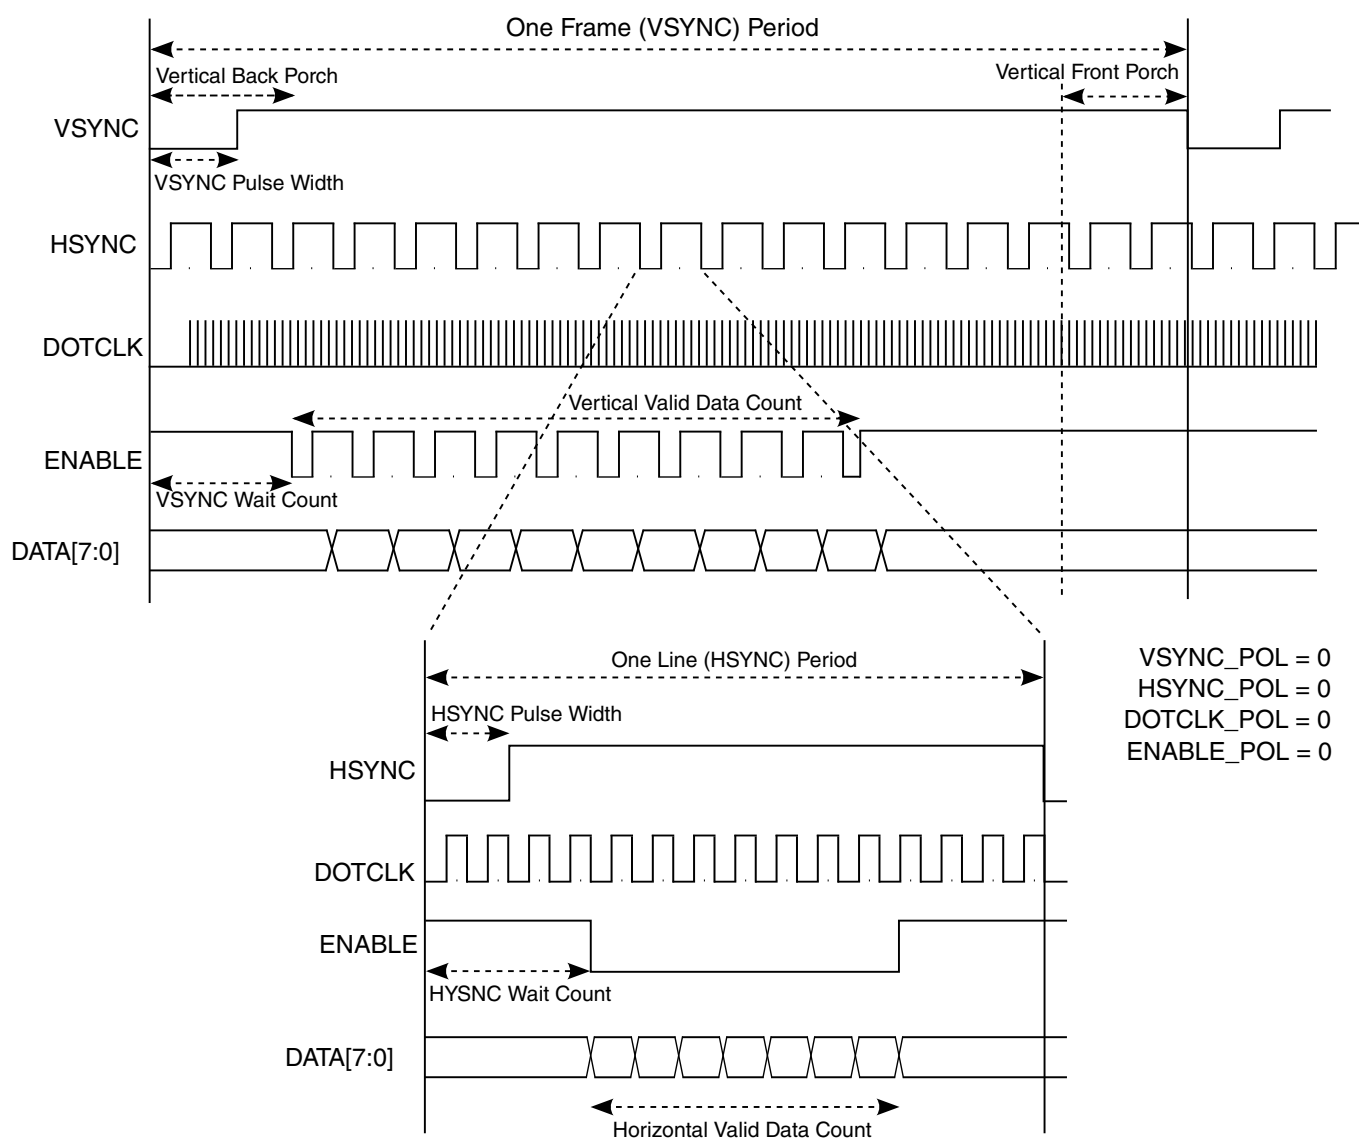

Figure 13-15. DOTCLK protocol with programmable parameters

The DOTCLK mode writes data at high speed to the LCD, and the display operation is synchronized with the VSYNC, HSYNC, ENABLE and DOTCLK signals. The polarities, periods and pulse-widths of the sync signals are programmable using the LCDIF_VDCTRL0-4 registers. The units for the VSYNC signal must be number of horizontal lines and can be selected using the VSYNC_PULSE_WIDTH_UNIT and VSYNC_PERIOD_UNIT bit fields. The VERTICAL_WAIT_CNT is by default given the same unit as the VSYNC_PERIOD. The DISPLAY CLOCK (pix_clk) frequency is managed by the CCM.

In DOTCLK mode, LCDIF_CTRL_BYPASS_COUNT bit must be set to 1. To end the current transfer, the software should make the DOTCLK_MODE bit 0, so that all data that is currently in the LCDIF LFIFO and TXFIFO is transmitted. Once that transfer is complete, the block will automatically clear the RUN bit and issue the cur_frame_done interrupt.

13.2.2.8.1 Code Example

The following code shows an example for programming a 320x240 display.

NOTE

Setting up the display must be done through the MPU mode or via SPI.

```
// Note: Common initialization steps in Initializing the LCDIF must also be
// executed along with the following code
BF_CS1 (LCDIF_CTRL, DOTCLK_MODE, 1);
BF_CS1 (LCDIF_CTRL, BYPASS_COUNT, 1); //Always for DOTCLK mode
BF_CS1 (LCDIF_VDCTRL0, VSYNC_OEB, 0); //Vsync is always an output in the DOTCLK mode
BF_CS4 (LCDIF_VDCTRL0, VSYNC_POL, 0, HSYNC_POL, 0, DOTCLK_POL, 0, ENABLE_POL, 0);
BF_CS1 (LCDIF_VDCTRL0, ENABLE_PRESENT, 1);
BF_CS2 (LCDIF_VDCTRL0, VSYNC_PERIOD_UNIT, 1, VSYNC_PULSE_WIDTH_UNIT, 1);
BF_CS1 (LCDIF_VDCTRL0, VSYNC_PULSE_WIDTH, 2);
BF_CS1 (LCDIF_VDCTRL1, VSYNC_PERIOD, 280);
BF_CS2 (LCDIF_VDCTRL2, HSYNC_PULSE_WIDTH, 10, HSYNC_PERIOD, 360); //Assuming
                                                                    // LCD_DATABUS_WIDTH is 24bit
BF_CS2 (LCDIF_VDCTRL3, VSYNC_ONLY, 0);
BF_CS2 (LCDIF_VDCTRL3, HORIZONTAL_WAIT_CNT, 20, VERTICAL_WAIT_CNT, 20);
BF_CS1 (LCDIF_VDCTRL4, DOTCLK_H_VALID_DATA_CNT, 320); //Note that DOTCLK_V_VALID_DATA_CNT is
                                                                    //implicitly assumed to be HW_LCDIF_TRANSFER_COUNT_V_COUNT
BF_CS1 (LCDIF_VDCTRL4, SYNC_SIGNALS_ON, 1);
BF_CS1 (LCDIF_CTRL, RUN, 1);
```

To stop the transfer completely, the ideal way is to make DOTCLK_MODE = 0. In that case, the block will transmit the contents in the FIFO and reset the RUN bit.

13.2.2.9 Alpha Blending Interface

The LCDIF have the capability to add an extra overlay on the normal display buffer, LCDIF can fetch data from two buffers and combine them before display, one buffer data can have the alpha value with the RGB pixels. With LCDIF_AS_CTRL[AS_ENABLE] is set, the LCDIF will start fetching alpha surface buffer data in bus master mode and combine it with another buffer.

The LCDIF_AS_CTRL[ALPHA_CTRL] bits determines how the alpha value is constructed for the alpha surface and alpha blending process is as same as in PXP block, for the alpha blend and color key process refer to the PXP block descriptions.

13.2.2.10 ITU-R BT.656 Digital Video Interface (DVI)

ITU-R BT.656 Digital Video Interface shown below transmits 4:2:2 YCbCr digital component video to a digital video encoder that can translate it into 525/60 or 625/50 analog TV signal.

Unique timing codes (timing reference signals) are embedded within the video stream to indicate the different timing events that would have been otherwise indicated by VSYNC, HSYNC and BLANK signals. The hardware supports 8-bit data transfers; the pins are shared with the lower 8 bits of LCD data bus. The LCD_RS pin is shared with the clock signal of the interface (called CCIRCLK here for uniqueness). CCIRCLK also can be obtained on the LCD_DOTCLK pin. The mode shares the write FIFO with the LCD interface and the associated pipeline. The programmable parameters in registers LCDIF_DVICTRL0-3 allow setting the total number of horizontal lines per frame, vertical and horizontal blanking interval, odd and even field start and end positions, and so on. In short, these parameters are provided to ensure that the hardware has enough flexibility to generate the right 525/60 or 625/50 data streams. Most of the initialization steps in [Initializing the LCDIF](#) such as data shifting, swizzle, and so on, are applicable to DVI mode also. The register descriptions in the programmable registers section at the end of this chapter include example code for programming the DVICTRL0-3 registers.

In DVI mode, LCDIF_CTRL_BYPASS_COUNT bit must be set to 1. To end the current transfer, the software should make the DVI_MODE bit the value 0, so that all data that is currently in the LCDIF LFIFO and TXFIFO is transmitted. Once that transfer is complete, the block will automatically clear the RUN bit and assert the cur_frame_done interrupt.

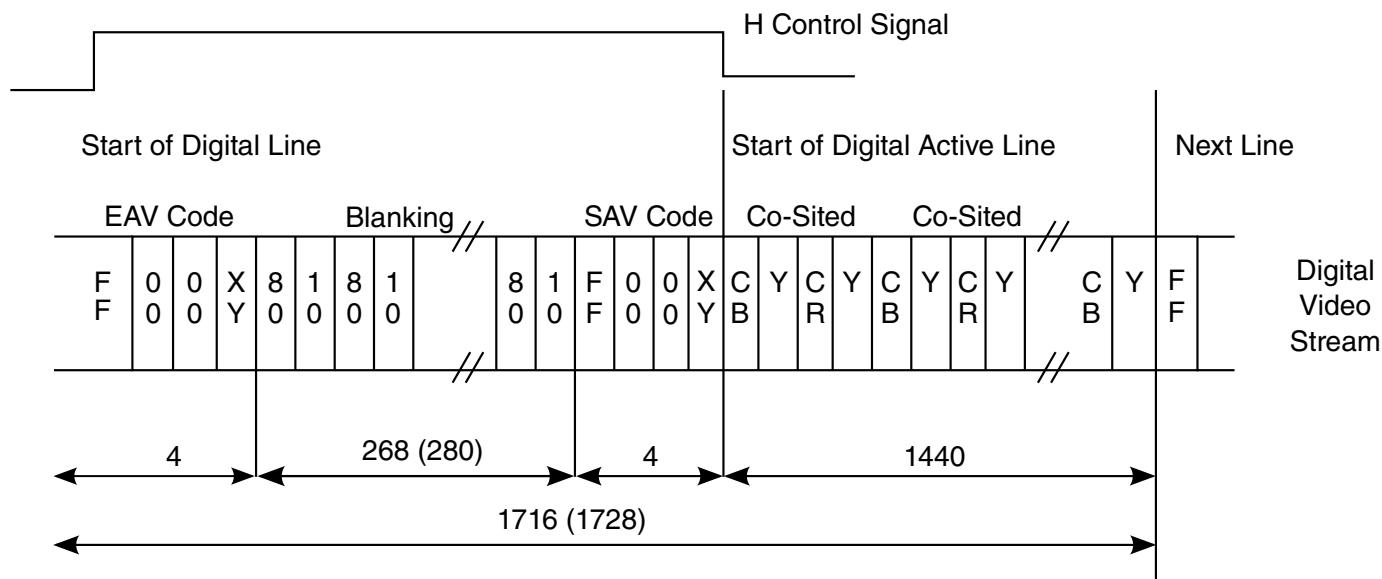

Figure 13-16. Digital Video Interface

13.2.2.11 Panel Interface Generator (Pigeon Mode)

There are several panel interface signal outputs (CLK signal not included), each of them with dedicated timing purpose as default. This is called "Legacy Mode". Pigeon Mode is a timing mode which can be independently enabled on any of the timing signals, with a unified flexible configuration. Signals within pigeon mode can be programmed into any supported signals, and are interchangeable. The following are the legacy timing signals which support pigeon mode:

- PIGEON[00] – LCD_DATA16
- PIGEON[01] – LCD_DATA17
- PIGEON[02] – LCD_DATA18
- PIGEON[03] – LCD_DATA19
- PIGEON[04] – LCD_DATA20
- PIGEON[05] – LCD_DATA21
- PIGEON[06] – LCD_DATA22
- PIGEON[07] – LCD_DATA23
- PIGEON[08] – LCD_ENABLE
- PIGEON[09] – LCD_HSYNC
- PIGEON[10] – LCD_VSYNC
- PIGEON[11] – LCD_CLK

Each pigeon signal has one local counter with a configurable start point and incremental condition. It will be compared to configuration register value for signal assertion/de-assertion control, plus delta offset for data alignment and other options like polarity/logic operation. A detailed running scenario is as follows:

1. Start local counter on the MASK rising edge (reference point/start point)
2. Increment on event selected through INC_SEL
3. Count and match SET_CNT: assert signal, reset counter (SET_CNT==0 means assert immediately on MASK's rising edge)
4. Count and match CLR_CNT: de-assert signal, stop counter (CLR_CNT==0 means de-assert on MASK's falling edge)

NOTE

When local counter is running, further changes to MASK are not cared unless CLR_CNT==0

MASK is the start point for local counter created using a combination any of the options (ANDed) from below:

1. STATE_MASK= (FS|FB|FD|FE) AND (LS|LB|LD|LE)

In this case you have 8 bits to select in which vertical/horizontal state your counter starts ticking. This is the most common use-case because timing signals generally relate to scan states.

For example, for a line timing signal start on Line Begin phase during Frame Begin/Frame Data lines, use the configuration below:

Table 13-4. State Mask Combinations

STATE_MASK	LS	LB=1	LD	LE
FS				
FB=1		X		
FD=1		X		
FE				

2. MASK_CNT/MASK_CNT_SEL (global counter)

Sometimes a more accurate reference point is required, such as "line 20 in a frame", or "line 12 in Frame Begin state" or "pixel 23 in LD phase". For such use-cases, several Global Counters shared by all pigeons are provided. Global counter type (line counter/frame counter/state counter, etc.) is selected using MASK_CNT_SEL, when global counter matches the MASK_CNT value. The pigeon local counter will start ticking.

3. Use another pigeon signal as mask (SIG_LOGIC=MASK)

For some tightly coupled signals it is possible to use one as a reference to generate another.

INC_SEL- select local counter tick event

- a. pclk - pixel clk
- b. line - line start pulse
- c. frame - frame start pulse
- d. another - another pigeon signal

OFFSET- offset on pclk basis: Some signals need to come out slightly earlier or later than programmed. For example, the CE type signal usually aligns with the Line Data phase, but some panels need it as one cycle pulse before Line Data. The user can set OFFSET to a negative value to achieve this.

Global counters (selectable through MASK_CNT_SEL):

- HCNT / VCNT : normal pclk counter / line counter
- HSTATE_CNT / VSTATE_CNT: similar to above, but reset when state changes
- HSTATE_CYCLE / VSTATE_CYCLE: (see figure below for definition of CYCLE/ PERIOD/CNT)

Some panels have multiple Gate Drivers/Source Drivers, so Frame Data / Line Data state may be further split to match each driver, and signals such as CE[n] are only valid during part n of Line Data. For such signals, use

LCDIF_PIGEON_CTRL[*_PERIOD] to specify PERIOD where CNT is reset and CYCLE is included. Then the user can select CYCLE as MASK_CNT to generate mask for CE[n].

- FRAME_CNT / FRAME_CYCLE (only for frame-crossing signals): frame cycle counter doesn't have a reset condition; use LCDIF_PIGEON_CTRL1[FRAME_CNT_CYCLES] to reset it.

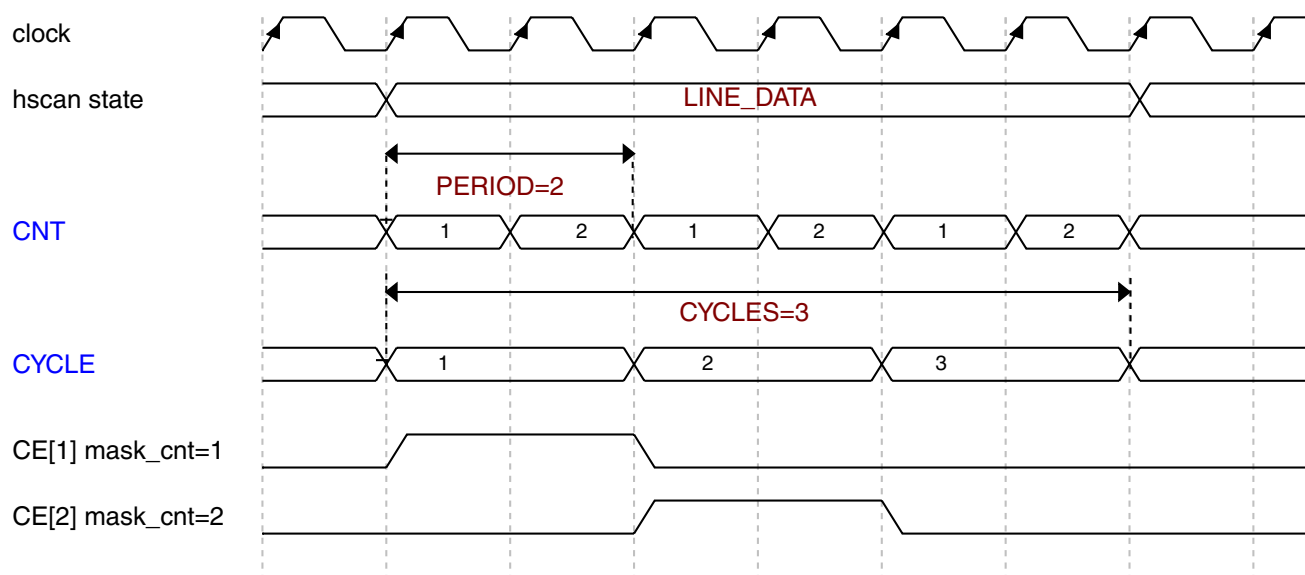

Figure 13-17. Definition of CNT, CYCLE, PERIOD

The following are register settings for the figure above:

- LCDIF_PIGEON_CTRL0[LD_PERIOD]=2
- MASK_CNT_SEL = 1 // HSTATE_CYCLE
- MASK_CNT = 1 // CE[1]
- MASK_CNT = 2 // CE[2]

13.2.3 Behavior During Reset

BUS CLOCK (apb_clk) and DISPLAY CLOCK (pix_clk) must be running before making any changes to SFTRST or CLKGATE bits.

A soft reset (SFTRST) can take multiple clock periods to complete, so do not set CLKGATE when setting SFTRST.

The reset process gates the clocks automatically.

13.2.4 LCDIF Memory Map/Register Definition

Some of the LCDIF registers (XXX_SET, XXX_CLR, and XXX_TOG) allow direct bit field masking and access.

- When writing 1 to XXX_SET bit fields, these registers allow setting the masked 1 bit fields, while keeping unchanged all bit fields which remain on 0 logic state.

- When writing 1 to XXX_CLR bit fields, these registers allow clearing the masked 1 bit fields, while keeping unchanged all other bit fields which remained on 0 logic state.
- When writing 1 to XXX_TOG bit fields, these registers allow inverting the logic state of all masked 1 bit fields, while they keep unchanged the remaining bit fields which were kept on 0 logic state.

LCDIF Hardware Register Format Summary

LCDIF memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
32E0_0000	LCDIF General Control Register (LCDIF_CTRL)	32	R/W	C000_0000h	13.2.4.1/3899

13.2.4.1 LCDIF General Control Register (LCDIF_CTRLn)

The LCD Interface Control Register provides overall control of the LCDIF block. The LCDIF Control Register provides a variety of control functions to the programmer. These functions allow the interface to be very flexible to work with a variety of LCD controllers, and to minimize overhead and increase performance of LCD programming. The register has been organized such that switching between the different LCD modes can be done with minimum PIO writes.

Address: 32E0_0000h base + 0h offset + (4d × i), where i=0d to 3d

LCDIF_CTRLn field descriptions

Field	Description
31 SFTRST	This bit must be set to zero to enable normal operation of the LCDIF. When set to one, it forces a block level reset.
30 CLKGATE	This bit must be set to zero for normal operation. When set to one it gates off the clocks to the block.
29 YCBCR422_INPUT	Zero implies input data is in RGB color space. One implies input data is in YCbCr 4:2:2 format, such that YCbYCr are packed in a 32-bit word. It also means that there are 2 pixels in 4 bytes. If this bit is set, software should program the H_COUNT field in the TRANSFER_COUNT register to the total number of pixels that will have to be fetched by the LCDIF block per line and the BYTE_PACKING_FORMAT should be 0xF. The WORD_LENGTH does not matter in this case.

Table continues on the next page...

LCDIF_CTRLn field descriptions (continued)

Field	Description
28 READ_WRITEB	By default, LCDIF is in the write mode. Setting this bit to 1 will make the hardware go into 6800/8080 MPU read mode. The LCDIF_MASTER bit must be 0, since bus master mode can only be used for writing the display.
27 WAIT_FOR_VSYNC_EDGE	Setting this bit to 1 will make the hardware wait for the triggering VSYNC edge before starting write transfers to the LCD. Used only in the VSYNC mode of operation.
26 DATA_SHIFT_DIR	Use this bit to determine the direction of shift of transmit data. In the DVI mode, it works only on the active data, not on the timing codes and ancillary data. 0x0 TXDATA_SHIFT_LEFT — Data to be transmitted is shifted LEFT by SHIFT_NUM_BITS bits. 0x1 TXDATA_SHIFT_RIGHT — Data to be transmitted is shifted RIGHT by SHIFT_NUM_BITS bits.
25–21 SHIFT_NUM_BITS	The data to be transmitted is shifted left or right by this number of bits.
20 DVI_MODE	Set this bit to 1 to get into the ITU-R BT.656 digital video interface mode. Toggle this bit from 1 to 0 to make the hardware go out of DVI mode after completing all data transfer and after the RUN bit has been deasserted.
19 BYPASS_COUNT	When this bit is 0, it means that LCDIF will stop the block operation and turn off the RUN bit after the amount of data indicated by the LCDIF_TRANSFER_COUNT register has been transferred out. When this bit is set to 1, the block will continue normal operation indefinitely until it is told to stop. This bit must be 0 in MPU and VSYNC modes, and must be 1 in DOTCLK and DVI modes of operation.
18 VSYNC_MODE	Setting this bit to 1 will make the LCDIF hardware go into VSYNC mode. WAIT_FOR_VSYNC_EDGE can be used only if this bit is set. If VSYNC signal is required to be an output from the block, SYNC_SIGNALS_ON bit in LCDIF_VDCTRL4 register must be set.
17 DOTCLK_MODE	Set this bit to 1 to make the hardware go into the DOTCLK mode, i.e. VSYNC/HSYNC/DOTCLK/ENABLE interface mode. ENABLE is optional, selected by the ENABLE_PRESENT bit. Toggle this bit from 1 to 0 to make the hardware go out of DOTCLK mode after completing all data transfer and deasserting the RUN bit.
16 DATA_SELECT	Command Mode polarity bit. This bit should only be changed when RUN is 0. 0x0 CMD_MODE — Command Mode. LCD_RS signal is Low. 0x1 DATA_MODE — Data Mode. LCD_RS signal is High.
15–14 INPUT_DATA_SWIZZLE	This field specifies how to swap the bytes fetched by the bus master interface. The swizzle function is independent of the WORD_LENGTH bit. The supported swizzle configurations are: 0x0 NO_SWAP — No byte swapping.(Little endian) 0x0 LITTLE_ENDIAN — Little Endian byte ordering (same as NO_SWAP). 0x1 BIG_ENDIAN_SWAP — Big Endian swap (swap bytes 0,3 and 1,2). 0x1 SWAP_ALL_BYTES — Swizzle all bytes, swap bytes 0,3 and 1,2 (aka Big Endian). 0x2 HWD_SWAP — Swap half-words. 0x3 HWD_BYTE_SWAP — Swap bytes within each half-word.
13–12 CSC_DATA_SWIZZLE	This field specifies how to swap the bytes after the data has been converted into an internal representation of 24 bits per pixel and before it is transmitted over the LCD interface bus. The data is always transmitted with the least significant byte/hword (half word) first after the swizzle takes place. So, INPUT_DATA_SWIZZLE takes place first on the incoming data, and then CSC_DATA_SWIZZLE is applied. The swizzle function is independent of the WORD_LENGTH or the LCD_DATABUS_WIDTH fields. If RGB_TO_YCRCB422_CSC bit is set, the swizzle occurs on the Y, Cb, Cr values. The supported swizzle configurations are: 0x0 NO_SWAP — No byte swapping.(Little endian)

Table continues on the next page...

LCDIF_CTRLn field descriptions (continued)

Field	Description
	0x0 LITTLE_ENDIAN — Little Endian byte ordering (same as NO_SWAP). 0x1 BIG_ENDIAN_SWAP — Big Endian swap (swap bytes 0,3 and 1,2). 0x1 SWAP_ALL_BYTES — Swizzle all bytes, swap bytes 0,3 and 1,2 (aka Big Endian). 0x2 HWD_SWAP — Swap half-words. 0x3 HWD_BYTE_SWAP — Swap bytes within each half-word.
11–10 LCD_DATABUS_WIDTH	LCD Data bus transfer width. 0x0 16_BIT — 16-bit data bus mode. 0x1 8_BIT — 8-bit data bus mode. 0x2 18_BIT — 18-bit data bus mode. 0x3 24_BIT — 24-bit data bus mode.
9–8 WORD_LENGTH	Input data format. 0x0 16_BIT — Input data is 16 bits per pixel. 0x1 8_BIT — Input data is 8 bits wide. 0x2 18_BIT — Input data is 18 bits per pixel. 0x3 24_BIT — Input data is 24 bits per pixel.
7 RGB_TO_YCBCR422_CSC	Set this bit to 1 to enable conversion from RGB to YCbCr colorspace. See the LCDIF_CSC_ registers for further details.
6 ENABLE_PXP_HANDSHAKE	If this bit is set and LCDIF_MASTER bit is set, the LCDIF will act as bus master and the handshake mechanism between LCDIF and PXP will be turned on. If LCDIF_MASTER bit is not set, this bit becomes a don't care.
5 MASTER	Set this bit to make the LCDIF act as a bus master.
4 RSRVD0	This field is reserved. Reserved bits. Write as 0.
3 DATA_FORMAT_16_BIT	When this bit is 1 and WORD_LENGTH = 0, it implies that the 16-bit data is in ARGB555 format. When this bit is 0 and WORD_LENGTH = 0, it implies that the 16-bit data is in RGB565 format. When WORD_LENGTH is not 0, this bit does not care.
2 DATA_FORMAT_18_BIT	Used only when WORD_LENGTH = 2, i.e. 18-bit. 0x0 LOWER_18_BITS_VALID — Data input to the block is in 18 bpp format, such that lower 18 bits contain RGB 666 and upper 14 bits do not contain any useful data. 0x1 UPPER_18_BITS_VALID — Data input to the block is in 18 bpp format, such that upper 18 bits contain RGB 666 and lower 14 bits do not contain any useful data.
1 DATA_FORMAT_24_BIT	Used only when WORD_LENGTH = 3, i.e. 24-bit. Note that this applies to both packed and unpacked 24-bit data. 0x0 ALL_24_BITS_VALID — Data input to the block is in 24 bpp format, such that all RGB 888 data is contained in 24 bits. 0x1 DROP_UPPER_2_BITS_PER_BYTE — Data input to the block is actually RGB 18 bpp, but there is 1 color per byte, hence the upper 2 bits in each byte do not contain any useful data, and should be dropped.
0 RUN	When this bit is set by software, the LCDIF will begin transferring data between the SoC and the display. This bit must remain set until the operation is complete.

13.2.4.2 LCDIF General Control1 Register (LCDIF_CTRL1n)

The LCDIF Control Register provides overall control of the LCDIF block.

The LCDIF Control1 Register provides additional programming to the LCDIF. It implements some bits which are unlikely to change often in a particular application. It also carries interrupt-related bits which are common across more than one mode of operation.

Address: 32E0_0000h base + 10h offset + (4d × i), where i=0d to 3d

LCDIF_CTRL1n field descriptions

Field	Description
31 -	This field is reserved. Reserved bits. Write as 0.
30 -	This field is reserved. Reserved bits. Write as 0.
29–28 -	This field is reserved. Reserved bits. Write as 0.
27 COMBINE_MPU_WR_STRB	If this bit is not set, the write strobe will be driven on LCD_WR_RWn pin in the 8080 mode and on the LCD_RD_E pin in the 6800 mode. If it is set, the write strobe of both the 6800 and 8080 modes will be driven only on the LCD_WR_RWn pin. Note that this does not work for read strobe.
26 BM_ERROR_IRQ_EN	This bit is set to enable bus master error interrupt in the LCDIF master mode.

Table continues on the next page...

LCDIF_CTRL1n field descriptions (continued)

Field	Description
25 BM_ERROR_IRQ	This bit is set to indicate that an interrupt is requested by the LCDIF block. This bit is cleared by software by writing a one to its SCT clear address. This bit will be set when the LCDIF is in master mode and an error response was returned by the slave. 0x0 NO_REQUEST — No Interrupt Request Pending. 0x1 REQUEST — Interrupt Request Pending.
24 RECOVER_ON_UNDERFLOW	Set this bit to enable the LCDIF block to recover in the next field/frame if there was an underflow in the current field/frame.
23 INTERLACE_FIELDS	Set this bit if it is required that the LCDIF block fetches odd lines in one field and even lines in the other field. It will work only in LCDIF_MASTER is set to 1.
22 START_INTERLACE_FROM_SECOND_FIELD	The default is to grab the odd lines first and then the even lines. Set this bit if it is required to grab the even lines first and then the odd lines. (Line numbers start from 1, so odd lines are 1,3,5,etc. and even lines are 2,4,6, etc.)
21 FIFO_CLEAR	Set this bit to clear all the data in the latency FIFO (LFIFO), TXFIFO and the RXFIFO.
20 IRQ_ON_ALTERNATE_FIELDS	If this bit is set, the LCDIF block will assert the cur_frame_done interrupt only on alternate fields, otherwise it will issue the interrupt on both odd and even field. This bit is mostly relevant if INTERLACE_FIELDS is set.
19–16 BYTE_PACKING_FORMAT	This bitfield is used to show which data bytes in a 32-bit word are valid. Default value 0xf indicates that all bytes are valid. For 8-bit transfers, any combination in this bitfield will mean valid data is present in the corresponding bytes. In the 16-bit mode, a 16-bit half-word is valid only if adjacent bits [1:0] or [3:2] or both are 1. A value of 0x0 will mean that none of the bytes are valid and should not be used. For example, set the bit field value to 0x7 if the display data is arranged in the 24-bit unpacked format (A-R-G-B where A value does not have to be transmitted). When input data is in YCbCr 4:2:2 format (YCBCR422_INPUT is 1), H_COUNT should be the number of pixels that should be fetched by the block and the BYTE_PACKING_FORMAT should be 0xF. (Note - YCBCR422_INPUT = 1 implies 2 pixels per 32 bits).
15 OVERFLOW_IRQ_EN	This bit is set to enable an overflow interrupt in the TXFIFO in the write mode.
14 UNDERFLOW_IRQ_EN	This bit is set to enable an underflow interrupt in the TXFIFO in the write mode.
13 CUR_FRAME_DONE_IRQ_EN	This bit is set to 1 enable an interrupt every time the hardware enters in the vertical blanking state.
12 VSYNC_EDGE_IRQ_EN	This bit is set to enable an interrupt every time the hardware encounters the leading VSYNC edge in the VSYNC and DOTCLK modes, or the beginning of every field in DVI mode.
11 OVERFLOW_IRQ	This bit is set to indicate that an interrupt is requested by the LCDIF block. This bit is cleared by software by writing a one to its SCT clear address. A latency FIFO (LFIFO) overflow in the write mode (MPU/VSYNC/DOTCLK/DVI mode) was detected, data samples have been lost. 0x0 NO_REQUEST — No Interrupt Request Pending. 0x1 REQUEST — Interrupt Request Pending.

Table continues on the next page...

LCDIF_CTRL1n field descriptions (continued)

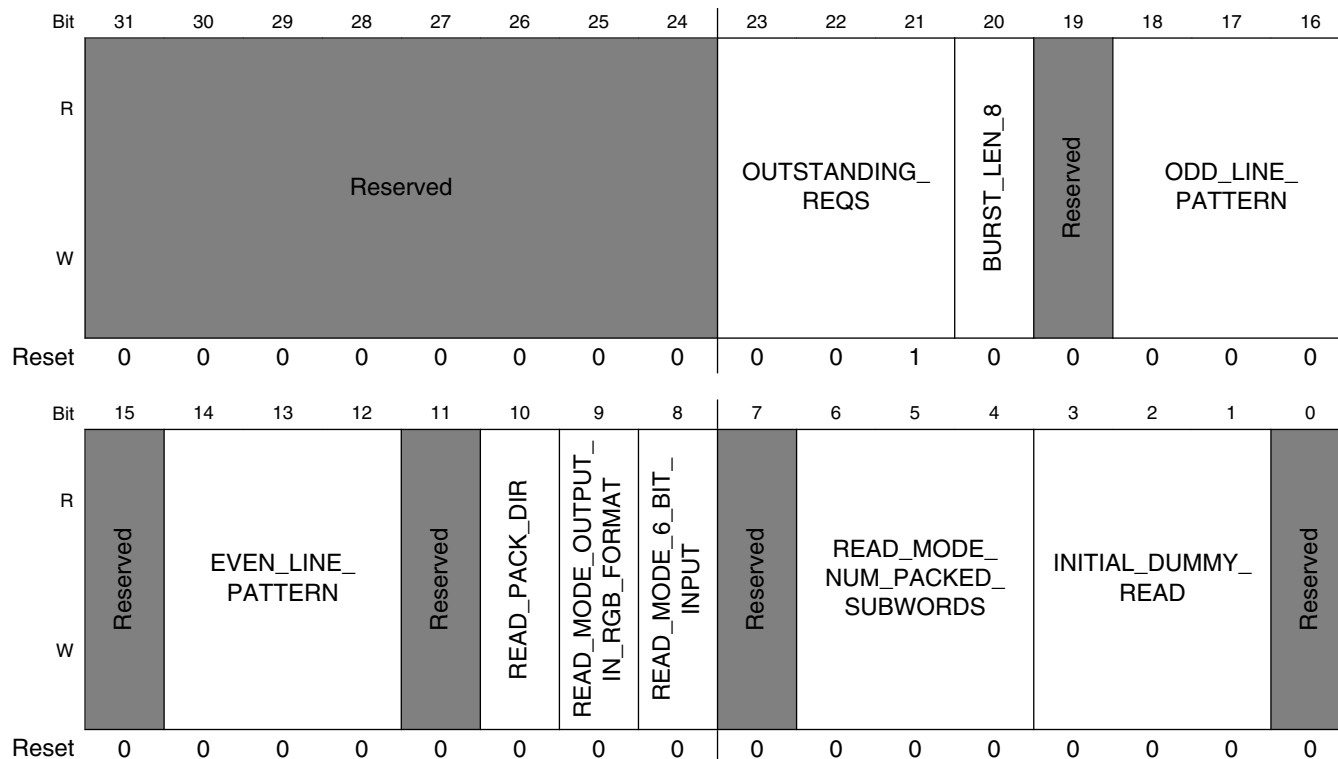

Field	Description
10 UNDERFLOW_ IRQ	<p>This bit is set to indicate that an interrupt is requested by the LCDIF block. This bit is cleared by software by writing a one to its SCT clear address. A TXFIFO underflow in the write mode (MPU/VSYNC/DOTCLK/DVI mode) was detected. Could produce an error in the DOTCLK / DVI modes.</p> <p>0x0 NO_REQUEST — No Interrupt Request Pending. 0x1 REQUEST — Interrupt Request Pending.</p>
9 CUR_FRAME_ DONE_IRQ	<p>This bit is set to indicate that an interrupt is requested by the LCDIF block. This bit is cleared by software by writing a one to its SCT clear address. It indicates that the hardware has completed transmitting the current frame and is in the vertical blanking period in the DOTCLK/DVI modes. In the MPU and VSYNC modes, this IRQ is asserted at the end of the data transfer indicated by LCDIF_TRANSFER_COUNT register.</p> <p>0x0 NO_REQUEST — No Interrupt Request Pending. 0x1 REQUEST — Interrupt Request Pending.</p>
8 VSYNC_EDGE_ IRQ	<p>This bit is set to indicate that an interrupt is requested by the LCDIF block. This bit is cleared by software by writing a one to its SCT clear address. It is set whenever the leading VSYNC edge is detected in the VSYNC and DOTCLK modes. In the DVI mode, it is asserted every time the block enters a new field.</p> <p>0x0 NO_REQUEST — No Interrupt Request Pending. 0x1 REQUEST — Interrupt Request Pending.</p>
7–3 RSRVD0	<p>This field is reserved. Reserved bits. Write as 0.</p>
2 BUSY_ENABLE	<p>This bit enables the use of the interface's busy signal input. This should be enabled for LCD controllers that implement a busy line (to stall the LCDIF from sending more data until ready). Otherwise this bit should be cleared.</p> <p>0x0 BUSY_DISABLED — The busy signal from the LCD controller will be ignored. 0x1 BUSY_ENABLED — Enable the use of the busy signal from the LCD controller.</p>
1 MODE86	<p>This bit is used to select between the 8080 and 6800 series of microprocessor modes. This bit should only be changed when RUN is 0.</p> <p>0x0 8080_MODE — Pins LCD_WR_RWn and LCD_RD_E function as active low WR and active low RD signals respectively. 0x1 6800_MODE — Pins LCD_WR_RWn and LCD_RD_E function as Read/Write and active high Enable signals respectively.</p>
0 RESET	<p>Reset bit for the external LCD controller. This bit can be changed at any time. It CANNOT be reset by SFTIRST.</p> <p>0x0 LCDRESET_LOW — LCD_RESET output signal is low. 0x1 LCDRESET_HIGH — LCD_RESET output signal is high.</p>

13.2.4.3 LCDIF General Control2 Register (LCDIF_CTRL2n)

The LCDIF Control Register provides overall control of the LCDIF block.

The LCDIF Control2 Register provides additional programming to the LCDIF. It implements some bits which are unlikely to change often in a particular application.

Address: 32E0_0000h base + 20h offset + (4d × i), where i=0d to 3d

LCDIF_CTRL2n field descriptions

Field	Description
31–24 RSRVD5	This field is reserved. Reserved bits. Write as 0.
23–21 OUTSTANDING_ REQS	This bitfield indicates the maximum number of outstanding transactions that LCDIF should request when it is acting as a bus master. Default is 2 outstanding transactions. 0x0 REQ_1 — 0x1 REQ_2 — 0x2 REQ_4 — 0x3 REQ_8 — 0x4 REQ_16 —
20 BURST_LEN_8	By default, when the LCDIF is in the bus master mode, it will issue AXI bursts of length 16 (except when in packed 24 bpp mode, it will issue bursts of length 15). When this bit is set to 1, the block will issue bursts of length 8 (except when in packed 24 bpp mode, it will issue bursts of length 9). Note that this bitfield is only applicable when LCDIF_MASTER is set to 1.
19 RSRVD4	This field is reserved. Reserved bits. Write as 0.
18–16 ODD_LINE_ PATTERN	This field determines the order of the RGB components of each pixel in ODD lines (line numbers 1,3,5,...). This bitfield must be 0 in DVI mode. 0x0 RGB — 0x1 RBG — 0x2 GBR — 0x3 GRB —

Table continues on the next page...

LCDIF_CTRL2n field descriptions (continued)

Field	Description
	0x4 BRG — 0x5 BGR —
15 RSRVD3	This field is reserved. Reserved bits. Write as 0.
14–12 EVEN_LINE_ PATTERN	This field determines the order of the RGB components of each pixel in EVEN lines (line numbers 2,4,6,...). This bitfield must be 0 in DVI mode. 0x0 RGB — 0x1 RBG — 0x2 GBR — 0x3 GRB — 0x4 BRG — 0x5 BGR —
11 RSRVD2	This field is reserved. Reserved bits. Write as 0.
10 READ_PACK_DIR	The default value of 0 indicates data is stored in the little endian format. When LCD_DATABUS_WIDTH is 8-bit, this bit provides the option of rearranging the data byte-wise in the big endian format. For example, if READ_MODE_NUM_PACKED_SUBWORDS = 3 and the order of incoming data is 0x11, 0x22 and 0x33, then setting this bit to 1 will cause the data to be stored as 0x00112233 as opposed to the default 0x00332211. This operation occurs after the shifting operation done by SHIFT_NUM_BITS bitfield.
9 READ_MODE_ OUTPUT_IN_ RGB_FORMAT	Setting this bit will enable the LCDIF to convert the incoming data to the RGB format given by WORD_LENGTH bitfield. This feature is not available when WORD_LENGTH is set to 8 bits. LCDIF performs this operation of converting to RGB format after the endianness has been determined by the READ_PACK_DIR bitfield.
8 READ_MODE_6_ BIT_INPUT	Setting this bit to 1 indicates to LCDIF that even though LCD_DATABUS_WIDTH is set to 8 bits, the input data is actually only 6 bits wide and exists on D5-D0.
7 RSRVD1	This field is reserved. Reserved bits. Write as 0.
6–4 READ_MODE_ NUM_PACKED_ SUBWORDS	Indicates the number of valid 8/16/18/24-bit subwords that will be packed into the 32-bit word in read mode. The subword size (8,16, 18 or 24 bits) is determined by the LCD_DATABUS_WIDTH field. The swizzle operation is performed after READ_MODE_NUM_PACKED_SUBWORDS number of subwords has been received and stored in little-endian format. For example, if LCD_DATABUS_WIDTH is set to 8-bit and data to be read back has to be stored in memory in 24-bit unpacked RGB format, set READ_MODE_NUM_PACKED_SUBWORDS to 0x3 so that each 32-bit word will contain only 3 valid bytes (RGB). Maximum value of READ_MODE_NUM_PACKED_SUBWORDS is 4 for 8-bit databus, 2 for 16-bit databus and 1 for 18/24-bit databus.
3–1 INITIAL_DUMMY_ READ	The value in this field determines the number of dummy 8/16/18/24-bit subwords that have to be read back from the LCD panel/controller. They will then not be stored in the read FIFO.
0 RSRVD0	This field is reserved. Reserved bits. Write as 0.

13.2.4.4 LCDIF Horizontal and Vertical Valid Data Count Register (LCDIF_TRANSFER_COUNT)

This register tells the LCDIF how much data will be sent for this frame, or transaction. The total number of words is a product of the V_COUNT and H_COUNT fields. The word size is specified by the WORD_LENGTH field.

This register gives the dimensions of the input frame. For normal operation, but V_COUNT and H_COUNT should be non-zero.

Address: 32E0_0000h base + 30h offset = 32E0_0030h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

LCDIF_TRANSFER_COUNT field descriptions

Field	Description
31–16 V_COUNT	Number of horizontal lines per frame which contain valid data. In DOTCLK mode, V_COUNT should be the same as the number of active horizontal lines in a progressive frame. In DVI mode, V_COUNT should be the number of active horizontal lines per frame, and not per field.
H_COUNT	Total valid data (pixels) in each horizontal line. The data size is given by the WORD_LENGTH. When input data is in YCbCr 4:2:2 format (YCBCR422_INPUT is 1), H_COUNT should be the number of 32-bit words that should be fetched by the block and the BYTE_PACKING_FORMAT should be 0xF. In 24-bit packed format (WORD_LENGTH=0x3, BYTE_PACKING_FORMAT=0xF), the H_COUNT must be a multiple of 4 pixels. In 16-bit packed format (WORD_LENGTH=0x0, BYTE_PACKING_FORMAT=0xF), the H_COUNT must be a multiple of 2 pixels.

13.2.4.5 LCD Interface Current Buffer Address Register (LCDIF_CUR_BUF)

This register indicates the address of the current frame being transmitted by LCDIF.

When the LCDIF is behaving as a master, this address points to the address of the current frame of data being sent out via the LCDIF. When the current frame is done, the LCDIF block will assert the cur_frame_done interrupt for software to take action. The block will also copy the LCDIF_NEXT_BUF_ADDR into this bitfield so that the software can program the next frame address into the LCDIF_NEXT_BUF_ADDR bitfield. This address must always be double-word aligned.

Address: 32E0_0000h base + 40h offset = 32E0_0040h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

LCDIF_CUR_BUF field descriptions

Field	Description
ADDR	Address of the current frame being transmitted by LCDIF.

13.2.4.6 LCD Interface Next Buffer Address Register (LCDIF_NEXT_BUF)

This register indicates the address of next frame that will be transmitted by LCDIF.

When the LCDIF is behaving as a master, this address points to the address of the next frame of data that will be sent out via the LCDIF. It is up to the software to make sure that this register is programmed before the end of the current frame, otherwise it might result in old data going out the LCDIF. This address must always be double-word aligned.

Address: 32E0_0000h base + 50h offset = 32E0_0050h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

LCDIF_NEXT_BUF field descriptions

Field	Description
ADDR	Address of the next frame that will be transmitted by LCDIF.

13.2.4.7 LCD Interface Timing Register (LCDIF_TIMING)

The LCD interface timing register controls the various setup and hold times enforced by the LCD interface in the 6800/8080 MPU and VSYNC modes of operation.

The values used in this register are dependent on the particular LCD controller used, consult the users manual for the particular controller for required timings. Each field of the register must be non-zero, therefore the minimum value is: 0x01010101. NOTE: the timings are not automatically adjusted if the DISPLAY CLOCK (pix_clk) frequency changes—it may be necessary to adjust the timings if DISPLAY CLOCK (pix_clk) changes. NOTE: Each field in this register must be non-zero for the MPU and VSYNC modes to function. The settings in this register do not affect the DOTCLK and DVI modes.

Address: 32E0_0000h base + 60h offset = 32E0_0060h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

LCDIF_TIMING field descriptions

Field	Description
31–24 CMD_HOLD	Number of DISPLAY CLOCK (pix_clk) cycles that the LCD_RS signal is active after LCD_CS is deasserted.
23–16 CMD_SETUP	Number of DISPLAY CLOCK (pix_clk) cycles that the LCD_RS signal is active before LCD_CS is asserted.
15–8 DATA_HOLD	Data bus hold time in DISPLAY CLOCK (pix_clk) cycles. Also the time that the data strobe is deasserted in a cycle
DATA_SETUP	Data bus setup time in DISPLAY CLOCK (pix_clk) cycles. Also the time that the data strobe is asserted in a cycle.

13.2.4.8 LCDIF VSYNC Mode and Dotclk Mode Control Register0 (LCDIF_VDCTRL0n)

This register is used to control the VSYNC and DOTCLK modes of the LCDIF so as to work with different types of LCDs like moving picture displays and delta pixel displays.

This register gives general programmability to the VSYNC signal including polarity, direction, pulse width, etc.

Address: 32E0_0000h base + 70h offset + (4d × i), where i=0d to 3d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LCDIF_VDCTRL0n field descriptions

Field	Description
31–30 RSRVD2	This field is reserved. Reserved bits. Write as 0.
29 VSYNC_OEB	0 means the VSYNC signal is an output, 1 means it is an input. Should be set to 0 in the DOTCLK mode. 0x0 VSYNC_OUTPUT — The VSYNC pin is in the output mode and the VSYNC signal has to be generated by the LCDIF block. 0x1 VSYNC_INPUT — The VSYNC pin is in the input mode and the LCD controller sends the VSYNC signal to the block.
28 ENABLE_PRESENT	Setting this bit to 1 will make the hardware generate the ENABLE signal in the DOTCLK mode, thereby making it the true RGB interface along with the remaining three signals VSYNC, HSYNC and DOTCLK.
27 VSYNC_POL	Default 0 active low during VSYNC_PULSE_WIDTH time and will be high during the rest of the VSYNC period. Set it to 1 to invert the polarity.
26 HSYNC_POL	Default 0 active low during HSYNC_PULSE_WIDTH time and will be high during the rest of the HSYNC period. Set it to 1 to invert the polarity.
25 DOTCLK_POL	Default is data launched at negative edge of DOTCLK and captured at positive edge. Set it to 1 to invert the polarity. Set it to 0 in DVI mode.
24 ENABLE_POL	Default 0 active low during valid data transfer on each horizontal line.
23–22 RSRVD1	This field is reserved. Reserved bits. Write as 0.
21 VSYNC_PERIOD_UNIT	Default 0 for counting VSYNC_PERIOD in terms of DISPLAY CLOCK (pix_clk) cycles. Set it to 1 to count in terms of complete horizontal lines. DISPLAY CLOCK (pix_clk) cycles should be used in the VSYNC mode, while horizontal line should be used in the DOTCLK mode.
20 VSYNC_PULSE_WIDTH_UNIT	Default 0 for counting VSYNC_PULSE_WIDTH in terms of DISPLAY CLOCK (pix_clk) cycles. Set it to 1 to count in terms of complete horizontal lines.
19 HALF_LINE	Setting this bit to 1 will make the total VSYNC period equal to the VSYNC_PERIOD field plus half the HORIZONTAL_PERIOD field (i.e. VSYNC_PERIOD field plus half horizontal line), otherwise it is just VSYNC_PERIOD. Should be only used in the DOTCLK mode, not in the VSYNC interface mode.
18 HALF_LINE_MODE	When this bit is 0, the first field (VSYNC period) will end in half a horizontal line and the second field will begin with half a horizontal line. When this bit is 1, all fields will end with half a horizontal line, and none will begin with half a horizontal line.
VSYNC_PULSE_WIDTH	Number of units for which VSYNC signal is active. For the DOTCLK mode, the unit is determined by the VSYNC_PULSE_WIDTH_UNIT. If the VSYNC_PULSE_WIDTH_UNIT is 0 for DOTCLK mode, VSYNC_PULSE_WIDTH must be less than HSYNC_PERIOD. For the VSYNC interface mode, it should be in terms of number of DISPLAY CLOCK (pix_clk) cycles only.

13.2.4.9 LCDIF VSYNC Mode and Dotclk Mode Control Register1 (LCDIF_VDCTRL1)

This register is used to control the VSYNC signal in the VSYNC and DOTCLK modes of the block.

This register determines the period and duty cycle of the VSYNC signal when it is generated in the block.

Address: 32E0_0000h base + 80h offset = 32E0_0080h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

LCDIF_VDCTRL1 field descriptions

Field	Description
VSYNC_PERIOD	Total number of units between two positive or two negative edges of the VSYNC signal. If HALF_LINE is set, it is implicitly calculated to be VSYNC_PERIOD plus half HSYNC_PERIOD.

13.2.4.10 LCDIF VSYNC Mode and Dotclk Mode Control Register2 (LCDIF_VDCTRL2)

This register is used to control the HSYNC signal in the DOTCLK mode of the block.

This register determines the period and duty cycle of the HSYNC signal when it is generated in the block.

Address: 32E0_0000h base + 90h offset = 32E0_0090h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

LCDIF_VDCTRL2 field descriptions

Field	Description
31–18 HSYNC_PULSE_WIDTH	Number of DISPLAY CLOCK (pix_clk) cycles for which HSYNC signal is active.
HSYNC_PERIOD	Total number of DISPLAY CLOCK (pix_clk) cycles between two positive or two negative edges of the HSYNC signal.

13.2.4.11 LCDIF VSYNC Mode and Dotclk Mode Control Register3 (LCDIF_VDCTRL3)

This register is used to determine the vertical and horizontal wait counts.

This register determines the back porches of HSYNC and VSYNC signals when they are generated by the block.

Enhanced LCD Interface (eLCDIF)

Address: 32E0_0000h base + A0h offset = 32E0_00A0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	VERTICAL_WAIT_CNT															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LCDIF_VDCTRL3 field descriptions

Field	Description
31–30 RSRVD0	This field is reserved. Reserved bits, write as 0.
29 MUX_SYNC- SIGNALS	When this bit is set, the LCDIF block will internally mux HSYNC with LCD_D14, DOTCLK with LCD_D13 and ENABLE with LCD_D12, otherwise these signals will go out on separate pins. This feature can be used to maintain backward compatible with 37xx.
28 VSYSN_ONLY	This bit must be set to 1 in the VSYNC mode of operation, and 0 in the DOTCLK mode of operation.
27–16 HORIZONTAL- WAIT_CNT	In the DOTCLK mode, wait for this number of clocks from falling edge (or rising if HSYNC_POL is 1) of HSYNC signal to account for horizontal back porch plus the number of DOTCLKs before the moving picture information begins.
VERTICAL- WAIT_CNT	In the VSYNC interface mode, wait for this number of DISPLAY CLOCK (pix_clk) cycles from the falling VSYNC edge (or rising if VSYNC_POL is 1) before starting LCD transactions and is applicable only if WAIT_FOR_VSYNC_EDGE is set. Minimum is CMD_SETUP+5. In the DOTCLK mode, it accounts for the vertical back porch lines plus the number of horizontal lines before the moving picture begins. The unit for this parameter is inherently the same as the VSYNC_PERIOD_UNIT.

13.2.4.12 LCDIF VSYNC Mode and Dotclk Mode Control Register4 (LCDIF_VDCTRL4)

This register is used to control the DOTCLK mode of the block.

This register determines the active data in each horizontal line in the DOTCLK mode. Note that the total number of active horizontal lines in the DOTCLK mode is the same as the V_COUNT bitfield in the LCDIF_TRANSFER_COUNT register.

Address: 32E0_0000h base + B0h offset = 32E0_00B0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	DOTCLK_H_VALID_DATA_CNT															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LCDIF_VDCTRL4 field descriptions

Field	Description
31–29 DOTCLK_DLY_SEL	This bitfield selects the amount of time by which the DOTCLK signal should be delayed before coming out of the LCD_DOTCK pin. 0 = 2ns; 1=4ns;2=6ns;3=8ns. Remaining values are reserved.
28–19 RSRVD0	This field is reserved. Reserved bits, write as 0.
18 SYNC_SIGNALS_ON	Set this field to 1 if the LCD controller requires that the VSYNC or VSYNC/HSYNC/DOTCLK control signals should be active at least one frame before the data transfers actually start and remain active at least one frame after the data transfers end. The hardware does not count the number of frames automatically. Rather, the VSYNC edge interrupt can be monitored by software to count the number of frames that have occurred after this bit is set and then the RUN bit can be set to start the data transactions. This bit must always be set in the DOTCLK mode of operation, and it must be set in the VSYNC mode of operation when VSYNC signal is an output.
DOTCLK_H_VALID_DATA_CNT	Total number of DISPLAY CLOCK (pix_clk) cycles on each horizontal line that carry valid data in DOTCLK mode.

13.2.4.13 Digital Video Interface Control0 Register (LCDIF_DVCTRL0)

The Digital Video interface Control0 register provides the overall control of the Digital Video interface.

This register gives information about the horizontal active, horizontal blanking and total number of lines in the ITU-R BT.656 interface.

EXAMPLE

```
//525/60 video system
```

Enhanced LCD Interface (eLCDIF)

```
HW_LCDIF_DVICTRL0_H_ACTIVE_CNT_WR(0x5A0); //1440
HW_LCDIF_DVICTRL0_H_BLANKING_CNT_WR(0x106); //262
//625/50 video system
HW_LCDIF_DVICTRL0_H_ACTIVE_CNT_WR(0x5A0); //1440
HW_LCDIF_DVICTRL0_H_BLANKING_CNT_WR(0x112); //274
```

Address: 32E0_0000h base + C0h offset = 32E0_00C0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

LCDIF_DVICTRL0 field descriptions

Field	Description
31–28 RSRVD1	This field is reserved. Reserved bits, write as 0.
27–16 H_ACTIVE_CNT	Number of active video samples to be transmitted. (Mostly will be 1440 for both PAL and NTSC). Must always be a multiple of 4.
15–12 RSRVD0	This field is reserved. Reserved bits, write as 0.
H_BLANKING_CNT	Number of blanking samples to be inserted between EAV and SAV during horizontal blanking interval.

13.2.4.14 Digital Video Interface Control1 Register (LCDIF_DVICTRL1)

The Digital Video interface Control1 register provides the overall control of the Digital Video interface.

This register contains information about the Field1 start and end, and the Field2 start in the ITU-R BT.656 interface.

EXAMPLE

```
//525/60 video system
HW_LCDIF_DVICTRL1_F1_START_LINE_WR(0x4); //4
HW_LCDIF_DVICTRL1_F1_END_LINE_WR(0x109); //265
HW_LCDIF_DVICTRL1_F2_START_LINE_WR(0x10A); //266
//625/50 video system
HW_LCDIF_DVICTRL1_F1_START_LINE_WR(0x1); //1
HW_LCDIF_DVICTRL1_F1_END_LINE_WR(0x138); //312
HW_LCDIF_DVICTRL1_F2_START_LINE_WR(0x139); //313
```

Address: 32E0_0000h base + D0h offset = 32E0_00D0h

LCDIF_DVICTRL1 field descriptions

Field	Description
31–30 RSRVD0	This field is reserved. Reserved bits, write as 0.
29–20 F1_START_LINE	Vertical line number from which Field 1 begins.
19–10 F1_END_LINE	Vertical line number at which Field1 ends.
F2_START_LINE	Vertical line number from which Field 2 begins.

13.2.4.15 Digital Video Interface Control2 Register (LCDIF_DVICTRL2)

The Digital Video interface Control2 register provides the overall control of the Digital Video interface.

This register contains information about the Field2 end, and the Vertical Blanking1 interval in the ITU-R BT.656 interface.

EXAMPLE

```
//525/60 video system
HW_LCDIF_DVICTRL2_F2_END_LINE_WR(0x3); //3
HW_LCDIF_DVICTRL2_V1_BLANK_START_LINE_WR(0x108); //264
HW_LCDIF_DVICTRL2_V1_BLANK_END_LINE_WR(0x11A); //282
//625/50 video system
HW_LCDIF_DVICTRL2_F2_END_LINE_WR(0x271); //625
HW_LCDIF_DVICTRL2_V1_BLANK_START_LINE_WR(0x137); //311
HW_LCDIF_DVICTRL2_V1_BLANK_END_LINE_WR(0x14F); //335
```

Address: 32E0_0000h base + E0h offset = 32E0_00E0h

LCDIF_DVICTRL2 field descriptions

Field	Description
31–30 RSRVD0	This field is reserved. Reserved bits, write as 0.
29–20 F2_END_LINE	Vertical line number at which Field 2 ends.
19–10 V1_BLANK_START_LINE	Vertical line number towards the end of Field1 where first Vertical Blanking interval starts.
V1_BLANK_END_LINE	Vertical line number in the beginning part of Field2 where first Vertical Blanking interval ends.

13.2.4.16 Digital Video Interface Control3 Register (LCDIF_DVICTRL3)

The Digital Video interface Control3 register provides the overall control of the Digital Video interface.

This register contains information about the Vertical Blanking2 interval in the ITU-R BT. 656 interface.

EXAMPLE

```
//525/60 video system
HW_LCDIF_DVICTRL3_V2_BLANK_START_LINE_WR(0x1); //1
HW_LCDIF_DVICTRL3_V2_BLANK_END_LINE_WR(0x13); //19
HW_LCDIF_DVICTRL0_V_LINES_CNT_WR(0x20D); //525
//625/50 video system
HW_LCDIF_DVICTRL3_V2_BLANK_START_LINE_WR(0x270); //624
HW_LCDIF_DVICTRL3_V2_BLANK_END_LINE_WR(0x16); //22
HW_LCDIF_DVICTRL0_V_LINES_CNT_WR(0x271); //625
```

Address: 32E0_0000h base + F0h offset = 32E0_00F0h

LCDIF_DVICTRL3 field descriptions

Field	Description
31–30 RSRVD0	This field is reserved. Reserved bits, write as 0.

Table continues on the next page...

LCDIF_DVICTRL3 field descriptions (continued)

Field	Description
29–20 V2_BLANK_START_LINE	Vertical line number towards the end of Field2 where second Vertical Blanking interval starts.
19–10 V2_BLANK_END_LINE	Vertical line number in the beginning part of Field1 where second Vertical Blanking interval ends.
V_LINES_CNT	Total number of vertical lines per frame (generally 525 or 625)

13.2.4.17 Digital Video Interface Control4 Register (LCDIF_DVICTRL4)

The Digital Video interface Control4 register provides the overall control of the Digital Video interface.

This register is used to add side borders to the output if the input frame width is less than 720 pixels.

EXAMPLE

```
//If input frame has only 640 pixels per line, but output is supposed to have
720 pixels per line.
HW_LCDIF_DVICTRL4_H_FILL_CNT_WR(0x50); //80
HW_LCDIF_DVICTRL4_Y_FILL_VALUE_WR(0x10); //16
HW_LCDIF_DVICTRL4_CB_FILL_VALUE_WR(0x80); //128
HW_LCDIF_DVICTRL4_CR_FILL_VALUE_WR(0x80); //128
```

Address: 32E0_0000h base + 100h offset = 32E0_0100h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

LCDIF_DVICTRL4 field descriptions

Field	Description
31–24 Y_FILL_VALUE	Value of Y component of filler data
23–16 CB_FILL_VALUE	Value of CB component of filler data
15–8 CR_FILL_VALUE	Value of CR component of filler data.
H_FILL_CNT	Number of active video samples that have to be filled with the filler data in the front and back portions of the active horizontal interval. Must be a multiple of 4. This field will have to be programmed if the input frame has less than 720 pixels per line.

13.2.4.18 RGB to YCbCr 4:2:2 CSC Coefficient0 Register (LCDIF_CSC_COEFF0)

LCDIF_CSC_COEFF0 register provides overall control over color space conversion from RGB to 4:2:2 YCbCr. The equations for the conversion are given by: $Y = C0 \cdot R + C1 \cdot G + C2 \cdot B + Y_offset$ $Cb = C3 \cdot R + C4 \cdot G + C5 \cdot B + CbCr_offset$ $Cr = C6 \cdot R + C7 \cdot G + C8 \cdot B + CbCr_offset$

This register carries programming information about RGB to YCbCr 4:2:2 CSC.

EXAMPLE

```
HW_LCDIF_CSC_COEFF0_C0_WR(0x41) ; // 0.257x256=65
HW_LCDIF_CSC_COEFF0_CSC_SUBSAMPLE_FILTER_WR(0x3) ;
```

Address: 32E0_0000h base + 110h offset = 32E0_0110h

LCDIF_CSC_COEFF0 field descriptions

Field	Description
31–26 RSRVD1	This field is reserved. Reserved bits, write as 0.
25–16 C0	Two's complement red multiplier coefficient for Y
15–2 RSRVD0	This field is reserved. Reserved bits, write as 0.
CSC_	This register describes the filtering and subsampling scheme to be performed on the chroma components in order to convert from YCbCr 4:4:4 to YCbCr 4:2:2 space. Note that the following descriptions apply individually to Cb and Cr.
SUBSAMPLE_	
FILTER	
0x0	
0x1	
0x2	INTERSTITIAL — Chroma samples numbered 2n and 2n+1 are averaged (weights 1/2, 1/2) and that chroma value replaces the two chroma values at 2n and 2n+1. This chroma now exists horizontally halfway between the two luma samples.
0x3	COSITED — Chroma samples numbered 2n-1, 2n, and 2n+1 are averaged (weights 1/4, 1/2, 1/4) and that chroma value exists at the same site as the luma sample numbered 2n and the chroma samples at 2n+1 are discarded.

13.2.4.19 RGB to YCbCr 4:2:2 CSC Coefficient1 Register (LCDIF_CSC_COEFF1)

LCDIF_CSC_COEFF1 register provides overall control over color space conversion from RGB to 4:2:2 YCbCr. The equations for the conversion are given by: $Y = C0 \cdot R + C1 \cdot G + C2 \cdot B + Y_offset$ $Cb = C3 \cdot R + C4 \cdot G + C5 \cdot B + CbCr_offset$ $Cr = C6 \cdot R + C7 \cdot G + C8 \cdot B + CbCr_offset$

This register carries programming information about RGB to YCbCr 4:2:2 CSC.

EXAMPLE

```
HW_LCDIF_CSC_COEFF1_C1_WR(0x81) ; // 0.504x256=129
HW_LCDIF_CSC_COEFF1_C2_WR(0x19) ; // 0.098x256=25
```

LCDIF_CSC_COEFF1 field descriptions

Field	Description
31–26 RSRVD1	This field is reserved. Reserved bits, write as 0.
25–16 C2	Two's complement blue multiplier coefficient for Y
15–10 RSRVD0	This field is reserved. Reserved bits, write as 0.
C1	Two's complement green multiplier coefficient for Y

13.2.4.20 RGB to YCbCr 4:2:2 CSC Coefficient2 Register (LCDIF_CSC_COEFF2)

LCDIF_CSC_COEFF2 register provides overall control over color space conversion from RGB to 4:2:2 YCbCr. The equations for the conversion are given by: $Y = C0 \cdot R + C1 \cdot G + C2 \cdot B + Y_offset$ $Cb = C3 \cdot R + C4 \cdot G + C5 \cdot B + CbCr_offset$ $Cr = C6 \cdot R + C7 \cdot G + C8 \cdot B + CbCr_offset$

This register carries programming information about RGB to YCbCr 4:2:2 CSC.

EXAMPLE

```
HW_LCDIF_CSC_COEFF2_C3_WR(0x3DB); //-0.148x256=-37
HW_LCDIF_CSC_COEFF2_C4_WR(0x3B6); //-0.291x256=-74
```

Address: 32E0_0000h base + 130h offset = 32E0_0130h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

LCDIF_CSC_COEFF2 field descriptions

Field	Description
31–26 RSRVD1	This field is reserved. Reserved bits, write as 0.
25–16 C4	Two's complement green multiplier coefficient for Cb
15–10 RSRVD0	This field is reserved. Reserved bits, write as 0.
C3	Two's complement red multiplier coefficient for Cb

13.2.4.21 RGB to YCbCr 4:2:2 CSC Coefficient3 Register (LCDIF_CSC_COEFF3)

LCDIF_CSC_COEFF3 register provides overall control over color space conversion from RGB to 4:2:2 YCbCr. The equations for the conversion are given by: $Y = C0 \cdot R + C1 \cdot G + C2 \cdot B + Y_offset$ $Cb = C3 \cdot R + C4 \cdot G + C5 \cdot B + CbCr_offset$ $Cr = C6 \cdot R + C7 \cdot G + C8 \cdot B + CbCr_offset$

This register carries programming information about RGB to YCbCr 4:2:2 CSC.

EXAMPLE

```
HW_LCDIF_CSC_COEFF3_C5_WR(0x70); //0.439x256=112
HW_LCDIF_CSC_COEFF3_C6_WR(0x70); //0.439x256=112
```

Address: 32E0_0000h base + 140h offset = 32E0_0140h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Field	Description
31–26 RSRVD1	This field is reserved. Reserved bits, write as 0.

Table continues on the next page...

LCDIF_CSC_COEFF3 field descriptions (continued)

Field	Description
25–16 C6	Two's complement red multiplier coefficient for Cr
15–10 RSRVD0	This field is reserved. Reserved bits, write as 0.
C5	Two's complement blue multiplier coefficient for Cb

13.2.4.22 RGB to YCbCr 4:2:2 CSC Coefficient4 Register (LCDIF_CSC_COEFF4)

LCDIF_CSC_COEFF4 register provides overall control over color space conversion from RGB to 4:2:2 YCbCr. The equations for the conversion are given by: $Y = C0 \cdot R + C1 \cdot G + C2 \cdot B + Y_offset$ $Cb = C3 \cdot R + C4 \cdot G + C5 \cdot B + CbCr_offset$ $Cr = C6 \cdot R + C7 \cdot G + C8 \cdot B + CbCr_offset$

This register carries programming information about RGB to YCbCr 4:2:2 CSC.

EXAMPLE

```
HW_LCDIF_CSC_COEFF4_C7_WR(0x3A2); // -0.368x256 = -94
HW_LCDIF_CSC_COEFF4_C8_WR(0x3EE); // -0.071x256 = -18
```

Address: 32E0_0000h base + 150h offset = 32E0_0150h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

LCDIF_CSC_COEFF4 field descriptions

Field	Description
31–26 RSRVD1	This field is reserved. Reserved bits, write as 0.
25–16 C8	Two's complement blue multiplier coefficient for Cr
15–10 RSRVD0	This field is reserved. Reserved bits, write as 0.
C7	Two's complement green multiplier coefficient for Cr

13.2.4.23 RGB to YCbCr 4:2:2 CSC Offset Register (LCDIF_CSC_OFFSET)

LCDIF_CSC_ register provides overall control over color space conversion from RGB to 4:2:2 YCbCr. The equations for the conversion are given by: $Y = C0*R + C1*G + C2*B + Y_offset$
 $Cb = C3*R + C4*G + C5*B + CbCr_offset$
 $Cr = C6*R + C7*G + C8*B + CbCr_offset$

This register carries programming information about RGB to YCbCr 4:2:2 CSC.

Address: 32E0_0000h base + 160h offset = 32E0_0160h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved								CBCR_OFFSET								Reserved								Y_OFFSET							
W	Reserved								CBCR_OFFSET								Reserved								Y_OFFSET							
Reset	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

LCDIF_CSC_OFFSET field descriptions

Field	Description
31–25 RSRVD1	This field is reserved. Reserved bits, write as 0.
24–16 CBCR_OFFSET	Two's complement offset for the Cb and Cr components
15–9 RSRVD0	This field is reserved. Reserved bits, write as 0.
Y_OFFSET	Two's complement offset for the Y component

13.2.4.24 RGB to YCbCr 4:2:2 CSC Limit Register (LCDIF_CSC_LIMIT)

LCDIF_CSC_CTRL0 register provides overall control over color space conversion from RGB to 4:2:2 YCbCr. The equations for the conversion are given by: $Y = C0*R + C1*G + C2*B + Y_offset$
 $Cb = C3*R + C4*G + C5*B + CbCr_offset$
 $Cr = C6*R + C7*G + C8*B + CbCr_offset$

This register carries programming information about RGB to YCbCr 4:2:2 CSC. Note that the values in this register are unsigned.

EXAMPLE

```
HW_LCDIF_CSC_LIMIT_CBCR_MIN_WR(0x10); //16
HW_LCDIF_CSC_LIMIT_CBCR_MAX_WR(0xF0); //240
HW_LCDIF_CSC_LIMIT_Y_MIN_WR(0x10); //16
HW_LCDIF_CSC_LIMIT_Y_MAX_WR(0xEB); //235
```

Address: 32E0_0000h base + 170h offset = 32E0_0170h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

LCDIF_CSC_LIMIT field descriptions

Field	Description
31–24 CBCR_MIN	Lower limit of Cb and Cr after RGB to 4:2:2 YCbCr conversion
23–16 CBCR_MAX	Upper limit of Cb and Cr after RGB to 4:2:2 YCbCr conversion
15–8 Y_MIN	Lower limit of Y after RGB to 4:2:2 YCbCr conversion
Y_MAX	Upper limit of Y after RGB to 4:2:2 YCbCr conversion

13.2.4.25 LCD Interface Data Register (LCDIF_DATA)

This register is used to transfer data using the PIO interface mode of operation. In MPU mode, data written to this register will be transferred out to the display device. When receiving data from the display, data is read from this register using PIO operations. During write operations, data can be written to this register (from the processor's perspective) as bytes, half-words (16 bits), or words (32 bits) as desired.

This register holds the 32-bit word written by the Arm platform into LCDIF. This data then gets sent out by the block across the interface.

Address: 32E0_0000h base + 180h offset = 32E0_0180h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

LCDIF_DATA field descriptions

Field	Description
31–24 DATA_THREE	Byte 3 (most significant byte) of data written to LCDIF.
23–16 DATA_TWO	Byte 2 of data written to LCDIF.
15–8 DATA_ONE	Byte 1 of data written to LCDIF.
DATA_ZERO	Byte 0 (least significant byte) of data written to LCDIF.

13.2.4.26 Bus Master Error Status Register (LCDIF_BM_ERROR_STAT)

This register reflects the virtual address at which the AXI master received an error response from the slave.

When the BM_ERROR_IRQ is asserted, the address of the bus error is updated in the register.

Address: 32E0_0000h base + 190h offset = 32E0_0190h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

LCDIF_BM_ERROR_STAT field descriptions

Field	Description
ADDR	Virtual address at which bus master error occurred.

13.2.4.27 CRC Status Register (LCDIF_CRC_STAT)

This register reflects the CRC value of each frame sent out by LCDIF. The CRC is done on the final output bus, so the value will be dependent on the LCD_DATABUS_WIDTH bitfield even if the input data is the same.

This register will be updated when the CUR_FRAME_DONE_IRQ is asserted. In the case of DVI mode, the CRC is calculated for the entire frame, not separately for each field in the frame.

Address: 32E0_0000h base + 1A0h offset = 32E0_01A0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

LCDIF_CRC_STAT field descriptions

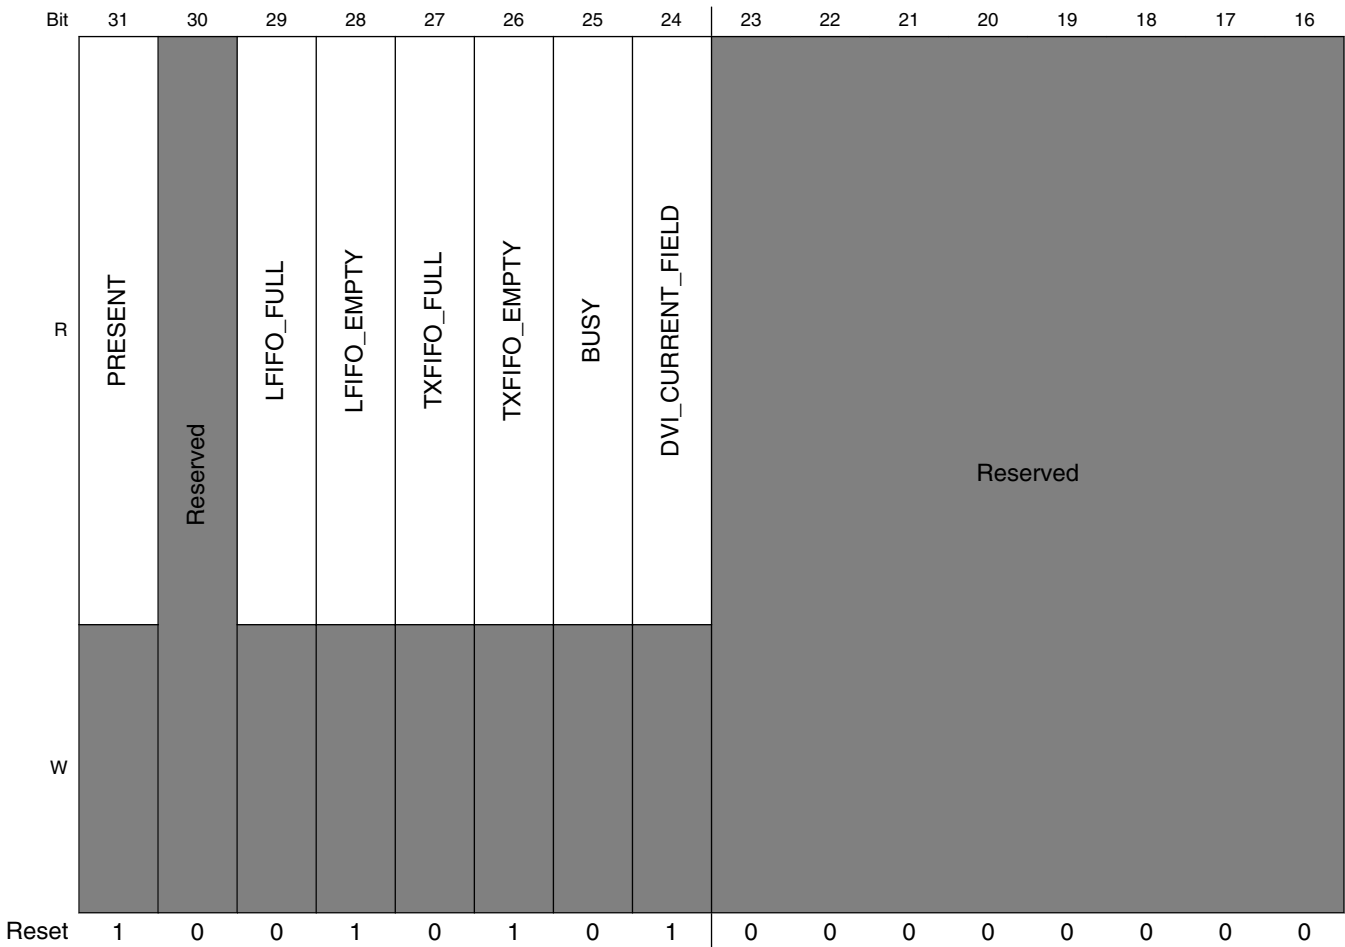

Field	Description
CRC_VALUE	Calculated CRC value.

13.2.4.28 LCD Interface Status Register (LCDIF_STAT)

The LCD interface status register can be used to check the current status of the LCDIF block.

The LCD interface status register that contains read only views of some parameters or current state of the block.

Address: 32E0_0000h base + 1B0h offset = 32E0_01B0h

Enhanced LCD Interface (eLCDIF)

LCDIF_STAT field descriptions

Field	Description
31 PRESENT	0: LCDIF not present on this product 1: LCDIF is present.
30 -	This field is reserved. Reserved.
29 LFIFO_FULL	Read only view of the signals that indicates LCD LFIFO is full.
28 LFIFO_EMPTY	Read only view of the signals that indicates LCD LFIFO is empty.
27 TXFIFO_FULL	Read only view of the signals that indicates LCD TXFIFO is full.
26 TXFIFO_EMPTY	Read only view of the signals that indicates LCD TXFIFO is empty.
25 BUSY	Read only view of the input busy signal from the external LCD controller.
24 DVI_CURRENT_FIELD	Read only view of the current field being transmitted. DVI_CURRENT_FIELD = 0 means field 1. DVI_CURRENT_FIELD = 1 means field 2.
23–9 RSRVD0	This field is reserved. Reserved bits. Write as 0.
LFIFO_COUNT	Read only view of the current count in Latency buffer (LFIFO).

13.2.4.29 LCDIF Threshold Register (LCDIF_THRES)

This register is used to activate control signals when the number of pixels reaches the programmed threshold. These control signals, in turn, can be used to manipulate access priority or dynamically change the input clock frequency to meet the required pixel throughput.

Memory request priority threshold register.

Address: 32E0_0000h base + 200h offset = 32E0_0200h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved								FASTCLOCK								Reserved								PANIC							
W	Reserved								FASTCLOCK								Reserved								PANIC							
Reset	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1

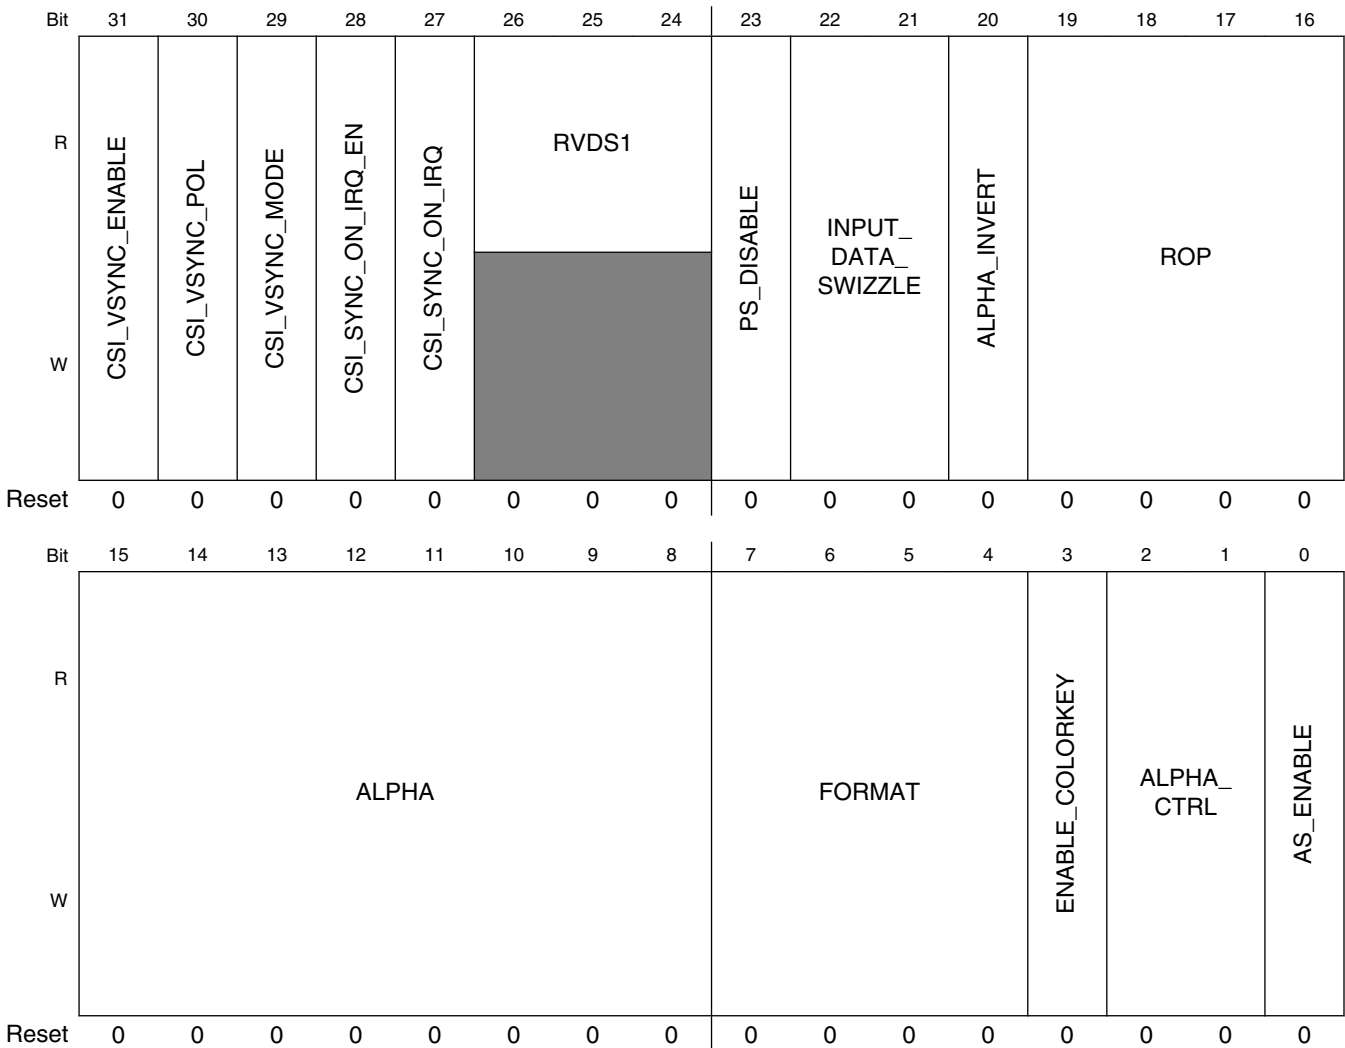

LCDIF_THRES field descriptions

Field	Description
31–25 RSRVD2	This field is reserved. Reserved bits. Write as 0.
24–16 FASTCLOCK	This value should be set to a value of pixels, from 0 to 511. When the number of pixels in the input pixel FIFO is LESS than this value, the fast clock control output will be raised. This signal can be used to reduce the system bus clock frequency to save power during horizontal or vertical blanking intervals. This value should also be programmed to a value that is greater than the "PANIC" threshold value. This will allow a faster clock to recover the number of pixels in the FIFO before a "panic" level is encountered.
15–9 RSRVD1	This field is reserved. Reserved bits. Write as 0.
PANIC	This value should be set to a value of pixels from 0 to 511. When the number of pixels in the input pixel FIFO is less than this value, the internal panic control output will be raised. This signal can be used to raise the access LCDIF's access priority.

13.2.4.30 LCDIF AS Buffer Control Register (LCDIF_AS_CTRL)

The Alpha Surface Parameter register provides additional controls for AS.

Address: 32E0_0000h base + 210h offset = 32E0_0210h

LCDIF_AS_CTRL field descriptions

Field	Description
31 CSI_VSYNC_ENABLE	When this bit is set by software, the LCDIF work as sync mode with CSI input.
30 CSI_VSYNC_POL	Default 0 active low during VSYNC_PULSE_WIDTH time and will be high during the rest of the VSYNC period. Set it to 1 to invert the polarity.

Table continues on the next page...

LCDIF_AS_CTRL field descriptions (continued)

Field	Description
29 CSI_VSYNC_MODE	this bit is set by software to decide which vsync generate mode. LCDIF vsync generate by internal counter when set to 0, LCDIF vsync delayed by each csi_vsync_in when set to 1; INT_SYNC_MODE = 0x0 LCDIF vsync generate by internal counter. EXT_SYNC_MODE = 0x1 LCDIF vsync delayed by each csi_vsync_in.
28 CSI_SYNC_ON_IRQ_EN	This bit is set to enable an interrupt when LCDIF lock with CSI vsync input.
27 CSI_SYNC_ON_IRQ	this bit is set by software to decide which vsync generate mode. LCDIF vsync generate by internal counter when set to 0, LCDIF vsync delayed by each csi_vsync_in when set to 1; INT_SYNC_MODE = 0x0 LCDIF vsync generate by internal counter. EXT_SYNC_MODE = 0x1 LCDIF vsync delayed by each csi_vsync_in.
26–24 RVDS1	Reserved, always set to zero.
23 PS_DISABLE	When this bit is set by software, the LCDIF will disable PS buffer data.
22–21 INPUT_DATA_SWIZZLE	This field specifies how to swap the bytes either in the HW_LCDIF_DATA register or those fetched by the AXI master part of LCDIF. The swizzle function is independent of the WORD_LENGTH bit. See the explanation of the HW_LCDIF_DATA below for names and definitions of data register fields. The supported swizzle configurations are: NO_SWAP = 0x0 No byte swapping.(Little endian) LITTLE_ENDIAN = 0x0 Little Endian byte ordering (same as NO_SWAP). BIG_ENDIAN_SWAP = 0x1 Big Endian swap (swap bytes 0, 3 and 1, 2). SWAP_ALL_BYTES = 0x1 Swizzle all bytes, swap bytes 0, 3 and 1, 2 (aka Big Endian). HWD_SWAP = 0x2 Swap half-words. HWD_BYTE_SWAP = 0x3 Swap bytes within each half-word.
20 ALPHA_INVERT	Setting this bit to logic 0 will not alter the alpha value. A logic 1 will invert the alpha value and apply (1-alpha) for image composition.
19–16 ROP	Indicates a raster operation to perform when enabled. Raster operations are enabled through the ALPHA_CTRL field. MASKAS = 0x0 AS AND PS MASKNOTAS = 0x1 nAS AND PS MASKASNOT = 0x2 AS AND nPS MERGEAS = 0x3 AS OR PS MERGENOTAS = 0x4 nAS OR PS MERGEASNOT = 0x5 AS OR nPS NOTCOPYAS = 0x6 nAS NOT = 0x7 nPS NOTMASKAS = 0x8 AS NAND PS NOTMERGEAS = 0x9 AS NOR PS XORAS = 0xA AS XOR PS NOTXORAS = 0xB AS XNOR PS

Table continues on the next page...

LCDIF_AS_CTRL field descriptions (continued)

Field	Description
15–8 ALPHA	Alpha modifier used when the ALPHA_MULTIPLY or ALPHA_OVERRIDE values are programmed in REG_AS_CTRL[ALPHA_CTRL]. The output alpha value will either be replaced (ALPHA_OVERRIDE) or scaled (ALPHA_MULTIPLY) when selected.
7–4 FORMAT	Indicates the input buffer format for AS. ARGB8888 = 0x0 32-bit pixels with alpha RGB888 = 0x4 32-bit pixels without alpha (unpacked 24-bit format) ARGB1555 = 0x8 16-bit pixels with alpha ARGB4444 = 0x9 16-bit pixels with alpha RGB555 = 0xC 16-bit pixels without alpha RGB444 = 0xD 16-bit pixels without alpha RGB565 = 0xE 16-bit pixels without alpha
3 ENABLE_ COLORKEY	Indicates that colorkey functionality is enabled for this alpha surface. Pixels found in the alpha surface colorkey range will be displayed as transparent (the PS pixel will be used).
2–1 ALPHA_CTRL	Determines how the alpha value is constructed for this alpha surface. Indicates that the value in the ALPHA field should be used instead of the alpha values present in the input pixels. Embedded = 0x0 Indicates that the AS pixel alpha value will be used to blend the AS with PS. The ALPHA field is ignored. Override = 0x1 Indicates that the value in the ALPHA field should be used instead of the alpha values present in the input pixels. Multiply = 0x2 Indicates that the value in the ALPHA field should be used to scale all pixel alpha values. Each pixel alpha is multiplied by the value in the ALPHA field. ROPs = 0x3 Enable ROPs. The ROP field indicates an operation to be performed on the alpha surface and PS pixels.
0 AS_ENABLE	When this bit is set by software, the LCDIF will start fetching AS buffer data in bus master mode and combine it with another buffer.

13.2.4.31 Alpha Surface Buffer Pointer (LCDIF_AS_BUF)

This register is used to indicate the base address of the AS buffer.

Address: 32E0_0000h base + 220h offset = 32E0_0220h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

LCDIF_AS_BUF field descriptions

Field	Description
ADDR	Address pointer for the alpha surface 0 buffer.

13.2.4.32 LCDIF_AS_NEXT_BUF

When the LCDIF is behaving as a master, this address points to the address of the next frame of data that will be sent out via the LCDIF. It is upto the software to make sure that this register is programmed before the end of the current frame, otherwise it might result in old data going out the LCDIF. This address must always be double-word aligned.

Address: 32E0_0000h base + 230h offset = 32E0_0230h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

13.3 CSI Bridge (CSI)

13.3.1 Overview

This chapter presents the CMOS Sensor Interface (CSI) architecture, operation principles, and programming model.

The CSI enables the chip to connect directly to external CMOS image sensors. CMOS image sensors are separated into two classes, dumb and smart. Dumb sensors are those that support only traditional sensor timing (Vertical SYNC and Horizontal SYNC) and output only Bayer and statistics data, while smart sensors support CCIR656 video decoder formats and perform additional processing of the image (for example, image compression, image pre-filtering, and various data output formats).

The capabilities of the CSI include:

- Configurable interface logic to support most commonly available CMOS sensors.
- Support for CCIR656 video interface as well as traditional sensor interface.
- 8-bit / 16-bit / 24-bit data port for YCbCr, YUV, or RGB data input.
- 8-bit / 10-bit / 16-bit data port for Bayer data input.
- Full control of 8-bit/pixel, 10-bit/pixel or 16-bit / pixel data format to 64-bit receive FIFO packing.
- 256 x 64 FIFO to store received image pixel data.
- Receive FIFO overrun protection mechanism.
- Embedded DMA controllers to transfer data from receive FIFO or statistic FIFO through AHB bus.
- Support 2D DMA transfer from the receive FIFO to the frame buffers in the external memory.

- Support double buffering two frames in the external memory.
- Single interrupt source to interrupt controller from maskable interrupt sources: Start of Frame, End of Frame, Change of Field, FIFO full, FIFO overrun, DMA transfer done, CCIR error and AHB bus response error.
- Configurable master clock frequency output to sensor.
- Statistic data generation for Auto Exposure (AE) and Auto White Balance (AWB) control of the camera (only for Bayer data and 8-bit/pixel format).
- Supports simple deinterlacing of interlaced input.

13.3.2 Principles of Operation

The information found here describes the modes of operation of the sensor interface.

The CSI is designed to support generic sensor interface timing as well as CCIR656 video interface timing. Traditional CMOS sensors typically use VSYNC (SOF), HSYNC (BLANK), and PIXCLK signals to output Bayer or YUV data. Smart CMOS sensors, that come with on-chip imaging processing, usually support video mode transfer. They use an embedded timing codec to replace the VSYNC and HSYNC signal. The timing codec is defined by the CCIR656 standard.

The CSI can support connection with the sensor as follows.

- To connect with one 8-bit sensor, the sensor data interface should connect to CSI_DATA[9:2].
- To connect with one 10-bit sensor, the sensor data interface should connect to CSI_DATA[9:0].
- To connect with one 16-bit sensor, the sensor data interface should connect to CSI_DATA[15:0].

13.3.2.1 Data Transfer with the Embedded DMA Controllers

The CSI has two embedded DMA controllers, one for the receive FIFO and the other for the statistic FIFO. It supports 2D DMA transfer from the receive FIFO to the frame buffers in the external memory and linear DMA transfer from the statistic FIFO.

To transfer data from the RxFIFO to the external memory, the user should set the start address in the frame buffer where the transferred data is stored, the parameters of the frame buffers, and the parameters of the image coming from the sensor. The user can have two frame buffers in the external memory. Each one will store a frame of image coming from the sensor. The embedded DMA controller will first write the frame buffer1 and then frame buffer2. These two frame buffers will be written by turns. The start address should be aligned in double words and set in the CSIDMASA-FB1 and CSIDMASA-FB2 registers. In the CSIFBUF_PARA register, the user should set the stride of the frame buffer to show how many double words to skip before starting to write the next row of the image. In the CSIIMAG_PARA register, the user should set the width and height of the image coming from the sensor. The RxFF_LEVEL and DMA_REQ_EN_RFF bits in CSICR3 registers also need to be set before the data transfer starts. When the number of the data in the RxFIFO reaches the trigger level, a DMA request will be sent to the embedded DMA controller and the data will be read out from the RxFIFO and written through AHB bus into the external frame buffers. The burst type of transfer can be INCR4, INCR8 and INCR16 by setting DMA_BURST_TYPE_RFF bits in CSICR2 register. After all data in an image frame are transferred, the DMA_TSF_DONE_FB1 or DMA_TSF_DONE_FB2 bit will be set in CSISR register and the interrupt can be triggered if the corresponding enable bit is set in CSICR1 register. The DMA_REFLASH_RFF bit in CSICR3 can be used to activate or restart the embedded DMA controller.

The RxFIFO has the overrun protection mechanism in case the RxFIFO is overrun during data transfer. If the RxFIFO is full and more data needs to be received during the data transfer, the RxFIFO will be overwritten continuously and all 128 words of data in the RxFIFO before overrun occurred will be discarded; the corresponding 128 words memory space in the frame buffer will keep the previous values.

To transfer data from the statistic FIFO to the external memory, the user should set the start address of the external memory where the transferred data is stored and the total transfer sizes. The start address and the transfer sizes are all aligned in double words and should be set in the CSIDMASA-STATFIFO and CSIDMATS-STATFIFO registers. The STATFF_LEVEL and DMA_REQ_EN_SFF bits in CSICR3 registers should also be set before the data transfer starts. When the number of the data in the STATFIFO reaches the trigger level, a dma request will be sent to the embedded DMA controller and the data will be read out from the STATFIFO and written through AHB bus into the external memory. The burst type of transfer can be INCR4, INCR8 and INCR16 by setting

DMA_BURST_TYPE_SFF bits in CSICR2 register. After all expected data (defined by the total transfer sizes) are transferred, the DMA_TSF_DONE_SFF bit will be set in CSISR register and an interrupt can be triggered if the SFF_DMA_DONE_INTEN is enabled in CSICR1 register. The DMA_REFLASH_SFF bit in CSICR3 can be used to activate or re-start the embedded DMA controller.

13.3.2.2 Gated Clock Mode

VSYNC, HSYNC, and PIXCLK signals are used in gated clock mode.

A frame starts with an active edge on VSYNC, then HSYNC asserts and holds for the entire line. The Pixel clock is valid as long as HSYNC is asserted. Data is latched at the active edge of the valid pixel clocks. HSYNC deasserts at the end of line. Pixel clocks then become invalid and CSI stops receiving data from the stream. For the next line the HSYNC timing repeats. For the next frame the VSYNC timing repeats.

13.3.2.3 Non-Gated Clock Mode

In non-gated clock mode, only the VSYNC and PIXCLK signals are used; the HSYNC signal is ignored.

Figure 13-18. Non-Gated Clock Mode Timing Diagram

The overall timing of non-gated mode is the same as the gated-clock mode, except for the HSYNC signal. HSYNC signal is ignored by the CSI. All incoming pixel clocks are valid and cause data to be latched into RxFIFO. The PIXCLK signal is inactive (states low) until valid data is ready to be transmitted over the bus.

Figure 13-18 shows the timing of a typical sensor. Other sensors may have the slightly different timing from that shown. The CSI can be programmed to support rising/falling-edge triggered VSYNC, active-high/low HSYNC, and rising/falling-edge triggered PIXCLK.

13.3.2.4 CCIR656 Interlace Mode

In CCIR656 interlace mode, only the PIXCLK and CSI_DATA[9:2] signals are used. The start of frame and blank signals are replaced by a timing codec which is embedded in the data stream. Each active line starts with an Start of Active Video (SAV) code and ends with an End of Active Video (EAV) code. In some cases, digital blanking is inserted in between EAV and SAV code. The CSI decodes and filters out the timing-coding from the data stream, recovering VSYNC and HSYNC signals for internal use, such as statistical block control. Data is forwarded to the data receive and packing block in a sequential manner without reordering—that is, field 1 followed by field 2. The fields must be reordered in software to get back the original image.

Change of Field (COF) interrupt is triggered upon every field change. The interrupt service routine reads the status register to check for the current field.

According to the CCIR656 specification, the image must be in 625/50 PAL or 525/60 NTSC format. In addition, the image is interlaced into odd and even fields with vertical and horizontal blank data being filled into certain lines. Data must be in YCbCr422 format, each pixel contains 2 bytes, either Y + Cr or Y + Cb. These requirements are set for TV systems. The CSI module supports PAL and NTSC format only.

The following figure describes the frame structure in PAL system, showing vertical and horizontal blanking.

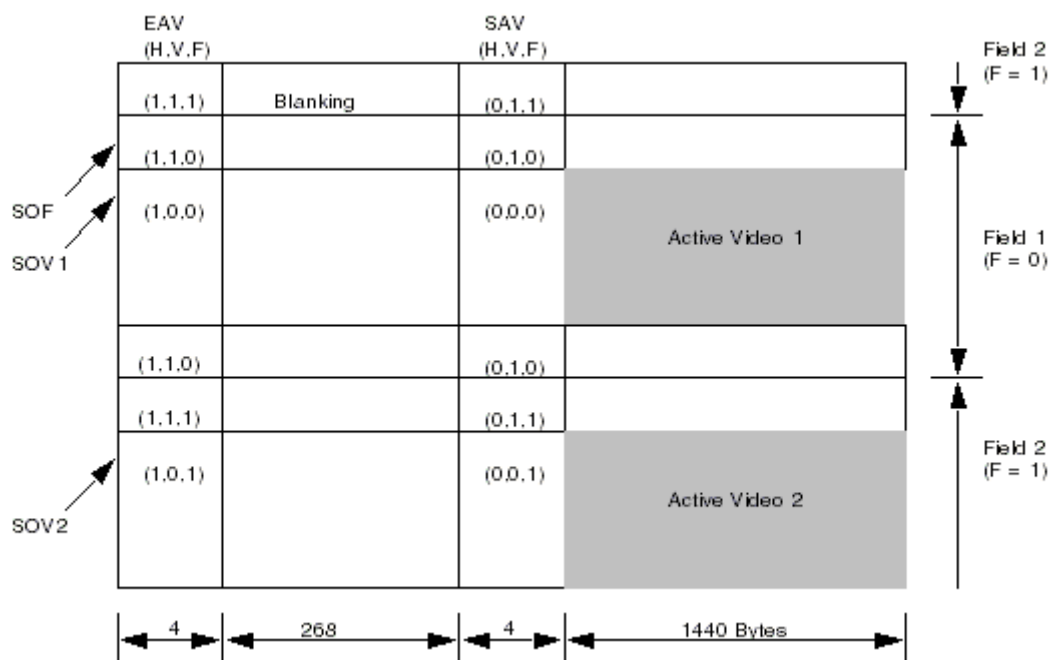

Figure 13-19. CCIR656 Interlace Mode (PAL)

The following figure describes the general timing for a single line, showing SAV and EAV.

Figure 13-20. CCIR656 General Line Timing

The coding tables recommended by the CCIR656 specification are shown below. It is used in the CCIR656 mode to decode the video stream. An interrupt is generated for SOF, which is decoded from the embedded timing codec.

Table 13-6. Coding for SAV and EAV

Table 13-8. Representations by F-Bit

F-Bit	Representations
0	ODD FIELD (FIELD 1)
1	EVEN FIELD (FIELD 2)

13.3.2.5 CCIR656 Progressive Mode

For a CMOS camera system of VGA or CIF resolution, strict adherence to the interlace requirements stated in the CIR standard is not required.

The image is considered to have only 1 active field which is scanned in a progressive manner. This active field is regarded as field 1 and the F-bit in the timing codec is ignored by the decoder. Most sensors support CCIR timing in this mode (progressive) by default.

The following figure shows the typical flow of progressive mode.

Figure 13-21. CCIR656 Progressive Mode (General Case)

An interrupt is generated for SOF but not for COF. In the general case, when SOF information is retrieved from the embedded coding, it is known as internal VSYNC mode. In other cases, when the VSYNC signal is provided by the sensor, it is known as external VSYNC mode. The CSI can be operated in internal or external VSYNC mode.

13.3.2.6 Error Correction for CCIR656 Coding

According to the algorithm for CCIR coding, protection bits in the SAV and EAV are encoded in the way that allows a 1-bit error to be corrected, or a 2-bit error to be detected by the decoder. This feature is supported by the interlace mode CCIR decoder in CSI.

For the 1-bit error case, users can select the error to be corrected automatically, or simply shown as a status flag instead. For the 2-bit error case, because the decoder is unable to make a correction, the error would be shown as a status flag only.

An interrupt can be generated upon the detection of an error. This signal can be enabled or disabled without affecting the operation of the status bit.

13.3.2.7 Deinterlacer

Deinterlacing is the process of converting interlaced video, such as CCIR656 input, into a non-interlaced form.

The CSI uses the weaving method to do deinterlacing. Weaving is done by adding consecutive fields together. CSI uses top-field detection function. No matter input is NTSC or PAL mode, the combined frame will always put the top-field first and then bottom-field.

13.3.3 Interrupt Generation

The information found here describes CSI events that generate interrupts.

13.3.3.1 Start Of Frame Interrupt (SOF_INT)

The source of an SOF interrupt is dependent on the mode of operation.

In traditional mode, VSYNC signal is taken from sensor and SOF_INT is generated at the rising or falling edge (programmable) of VSYNC.

In CCIR interlace mode, the SOF interrupt information is retrieved from the embedded coding and SOF_INT is generated.

In CCIR progressive mode, there are two sources of an SOF interrupt:

- In *internal* VSYNC mode, SOF is retrieved from the embedded coding.
- In *external* VSYNC mode, VSYNC is taken from the sensor and SOF is generated at the rising edge of VSYNC.

13.3.3.2 End Of Frame Interrupt (EOF_INT)

An EOF interrupt is generated when the frame ends and the complete frame data in RXFIFO is read.

The EOF event triggering works with the RX count register (CSIRXCNT). Software sets the RX count register to the frame size (in words). The CSI RX logic then counts the number of pixel data being received and compares it with the RX count. If the preset value is reached, an EOF interrupt is generated and the data in the RXFIFO are read. If a SOF event is detected before this happens, the EOF interrupt is not generated.

13.3.3.3 Change Of Field Interrupt (COF_INT)

The Change of Field interrupt is only valid in CCIR Interlace mode. The COF interrupt is generated when the field toggles, either from field 1 to field 2, or field 2 to field 1.

Software should first check COF_INT bit in the CSI Status Register (CSISTAT) before checking that F1_INT or F2_INT is turned on.

In PAL systems, the field changes at the beginning of the frame and coincides with SOF. For the first field, a COF interrupt is not generated, only an SOF. The COF interrupt is generated for the second field.

13.3.3.4 CCIR Error Interrupt (ECC_INT)

The CCIR Error Interrupt is only valid for CCIR Interlace mode. An ECC interrupt is generated when an error is found on the SAV or EAV codes in the incoming stream. When this happens, the ECC_INT status bit is set.

13.3.3.5 RxFIFO Full Interrupt (RxFF_INT)

A RxFIFO full interrupt is generated when the number of data in RXFIFO reaches the water mark defined by RxFF_LEVEL in CSICR3.

13.3.3.6 Statistic FIFO Full Interrupt (STATFF_INT)

A StatFIFO full interrupt is generated when the number of data in STATFIFO reaches the water mark defined by STATFF_LEVEL in CSICR3.

13.3.3.7 RxFIFO Overrun Interrupt (RFF_OR_INT)

A RxFIFO Overrun interrupt is generated when the RxFIFO has 128 words data and more data is being written in.

13.3.3.8 Statistic FIFO Overrun Interrupt (SFF_OR_INT)

A StatFIFO Overrun interrupt is generated when the STATFIFO has 64 words data and more data is being written in.

13.3.3.9 Frame Buffer1 DMA Transfer Done Interrupt (DMA_TSF_DONE_FB1)

A DMA transfer done interrupt of frame buffer1 is generated when one frame of data are transferred from RxFIFO to the frame buffer1 in the external memory.

13.3.3.10 Frame Buffer2 DMA Transfer Done Interrupt (DMA_TSF_DONE_FB2)

A DMA transfer done interrupt of frame buffer2 is generated when one frame of data are transferred from RxFIFO to the frame buffer2 in the external memory.

13.3.3.11 Statistic FIFO DMA Transfer Done Interrupt (DMA_TSF_DONE_SFF)

A StatFIFO DMA transfer done interrupt is generated when all the data are transferred from StatFIFO to the external memory. The transfer size is defined in the STATFIFO DMA Transfer Size Register.

13.3.3.12 AHB Bus Response Error Interrupt (HRESP_ERR_INT)

An AHB Bus response error interrupt is generated when a bus error is detected.

13.3.4 Data Packing Style

Careful attention to endianness is needed given the different port sizes at different stages of the image capture path.

To enable flexible packing of image data before storage in the FIFOs, the CSI module can swap data fields by use of the PACK_DIR and the SWAP16_EN bit in CSI Control Register 1 (CSICR1).

The CSI module accepts 8-bit, 10-bit or 16-bit data from the sensor by configuring PIXEL_BIT bit in CSI Control Register 1 (CSICR1) and TWO_8BIT_SENSOR bit in CSI Control Register3 (CSICR3). The input data is packed according to the setting of PACK_DIR bit. The packed data is stored in the RX FIFO according to the setting of the SWAP16_EN bit.

For 10-bit per pixel data format, each pixel is expanded to 16 bits by appending 6 zeros bits to the most significant bit.

13.3.4.1 RX FIFO Path

13.3.4.1.1 Bayer Data

Bayer data is a type of raw data from the image sensor. This byte-wide data must be converted to the RGB space or YUV space by software. The data path for Bayer data is from the CSI to memory. If the system is in little endian, then the PACK_DIR bit should be set to 0. 8-bit data format from a sensor is packed to 64 bits as

P7.P6.P5.P4.P3.P2.P1.P0, where P0 is the pixel coming in time slot 0 (first data) and P3 is the pixel coming in time slot 3 (the last data in the 64-bit word). When the data is addressed as bytes by software, P0 is transferred first, P1 is transferred next, and so on. 10-bit data format is packed to 64 bits as 000000.P3.000000.P2.000000.P1.000000.P0, where P0 is the 10-bit data coming in time slot 0 (first pixel) and P3 is the 10-bit data coming in time slot 3 (fourth pixel). 16-bit data is packed to 64 bits as P7.P6.P5.P4.P3.P2.P1.P0.

13.3.4.1.2 RGB565 Data

RGB565 data is processed data from the image sensor, which can be put directly into the display buffer. The data is 16 bits wide. The data path is from CSI to memory to the display controller. On the sensor side, data must be transmitted as P0 first, followed by P1, and so on. For each pixel, whether the MSB or LSB is sent first depends on the endianness of the sensor. Data is 16 bits wide with the MSB labeled RG, and the LSB labeled GB. P0 is represented as RG0 and GB0.

CSI receives data in one of the following sequence:

- RG0, GB0, RG1, GB1, while RG0 comes out at time slot 0 (first data), and GB1 comes out at time slot 3 (last data)
- GB0, RG0, GB1, RG1

Using the first sequence as an example, and assuming the system is running in little endian, the data is presented as:

- 8-bit data from sensor: RG0, GB0, RG1, GB1, ...
- 64-bit data before storage in the CSI RX FIFO (PACK_DIR bit = 1):
RG0GB0RG1GB1RG2GB2RG3GB3
- 64-bit data in CSI RX FIFO (SWAP16_EN bit enabled):
RG3GB3RG2GB2RG1GB1RG0GB0
- 64-bit transfer to system memory: RG3GB3RG2GB2RG1GB1RG0GB0
- 16-bit read by display controller: RG0GB0, RG1GB1

13.3.4.1.3 RGB888 Data

This is another kind of processed data from image sensor, which can be used for further image processing directly. Each of the data consist of 8-bit Red, 8-bit Green, and 8-bit Blue data. An example of timing scheme is shown in the following figure.

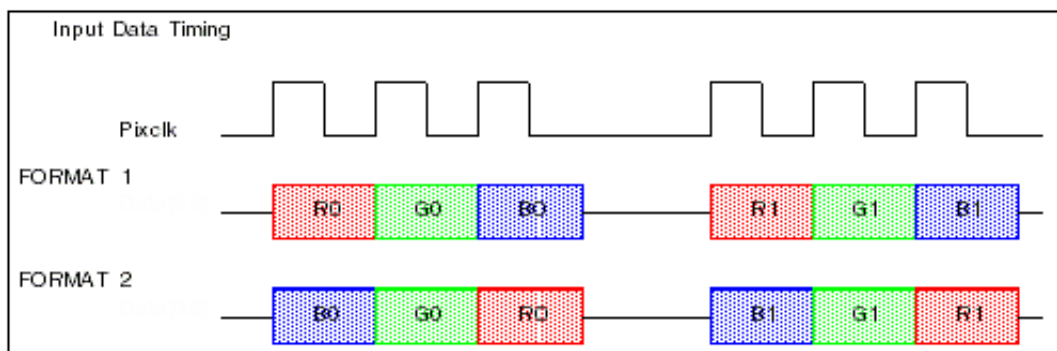

Figure 13-22. Sample Timing Diagram for RGB888 8 bits/cycle Data

An optional scheme to pack a dummy byte is provided. For every group of 3 bytes data, a dummy zero is packed to form a 32-bit word as shown in the following figure. The dummy zero can be packed at the LSB position or MSB position. Using `RGB888A_FORMAT_SEL` in `CSI_CSICR18[18]` to determine to put the dummy bytes packed at LSB or MSB position.

13.3.4.2 STAT FIFO Path

Statistics only works for Bayer data in 8-bit per pixel format. It generates 16-bit statistical output from the 8-bit Bayer input (CSI_DATA[13:6]). The outputs are Sum of Green (G), Sum of Red (R), Sum of Blue (B), and Auto Focus (F). Each output is 16-bits wide.

The settings of PACK_DIR and SWAP16_EN bits in the CSICR1 register have no effect on the input path. The PACK_DIR only controls how the 16-bit stat output is packed into the 32-bit STAT FIFO.

When the PACK_DIR bit = 1, the stat data is packed as:

First 32-bit: RG

Second 32-bit: BF

...

When the PACK_DIR bit = 0, the stat data is packed as:

First 32-bit GR

Second 32-bit: FB

...

13.3.5 CSI Memory Map/Register Definition

All the 32-bit registers of the CSI module are summarized in the Memory Map below:

CSI memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
32E2_0000	CSI Control Register 1 (CSI_CSICR1)	32	R/W	4000_0800h	13.3.5.1/3954
32E2_0004	CSI Control Register 2 (CSI_CSICR2)	32	R/W	0000_0000h	13.3.5.2/3958
32E2_0008	CSI Control Register 3 (CSI_CSICR3)	32	R/W	0000_0000h	13.3.5.3/3960
32E2_000C	CSI Statistic FIFO Register (CSI_CSISTATFIFO)	32	R	0000_0000h	13.3.5.4/3962

Table continues on the next page...

CSI memory map (continued)

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/page
32E2_0010	CSI RX FIFO Register (CSI_CSIRFIFO)	32	R	0000_0000h	13.3.5.5/3962
32E2_0014	CSI RX Count Register (CSI_CSIRXCNT)	32	R/W	0000_9600h	13.3.5.6/3963
32E2_0018	CSI Status Register (CSI_CSISR)	32	R/W	0000_4000h	13.3.5.7/3964
32E2_0020	CSI DMA Start Address Register - for STATFIFO (CSI_CSIDMASA_STATFIFO)	32	R/W	0000_0000h	13.3.5.8/3967
32E2_0024	CSI DMA Transfer Size Register - for STATFIFO (CSI_CSIDMATS_STATFIFO)	32	R/W	0000_0000h	13.3.5.9/3967
32E2_0028	CSI DMA Start Address Register - for Frame Buffer1 (CSI_CSIDMASA_FB1)	32	R/W	0000_0000h	13.3.5.10/3968

CSI_CSICR1 field descriptions

Field	Description
31 SWAP16_EN	<p>SWAP 16-Bit Enable. This bit enables the swapping of 16-bit data. Data is packed from 8-bit or 10-bit to 32-bit first (according to the setting of PACK_DIR) and then swapped as 16-bit words before being put into the RX FIFO. The action of the bit only affects the RX FIFO and has no affect on the STAT FIFO.</p> <p>NOTE: Example of swapping enabled: Data input to FIFO = 0x11223344 Data in RX FIFO = 0x 33441122</p> <p>NOTE: Example of swapping disabled: Data input to FIFO = 0x11223344 Data in RX FIFO = 0x11223344</p>

Table continues on the next page...

CSI_CSICR1 field descriptions (continued)

Field	Description
	0 Disable swapping 1 Enable swapping
30 EXT_VSYNC	External VSYNC Enable. This bit controls the operational VSYNC mode. NOTE: This only works when the CSI is in CCIR progressive mode. 0 Internal VSYNC mode 1 External VSYNC mode
29 EOF_INT_EN	End-of-Frame Interrupt Enable. This bit enables and disables the EOF interrupt. 0 EOF interrupt is disabled. 1 EOF interrupt is generated when RX count value is reached.
28 PrP_IF_EN	CSI-PrP Interface Enable. This bit controls the CSI to PrP bus. When enabled the RxFIFO is detached from the AHB bus and connected to PrP. All CPU reads or DMA accesses to the RxFIFO register are ignored. All CSI interrupts are also masked. 0 CSI to PrP bus is disabled 1 CSI to PrP bus is enabled
27 VIDEO_MODE	Video mode select. This bit controls the video mode in CCIR mode. 0 Progressive mode is selected 1 Interlace mode is selected
26 COF_INT_EN	Change Of Image Field (COF) Interrupt Enable. This bit enables the COF interrupt. This bit works only in CCIR interlace mode which is when CCIR_EN = 1 and CCIR_MODE = 1. 0 COF interrupt is disabled 1 COF interrupt is enabled
25 SF_OR_INTEN	STAT FIFO Overrun Interrupt Enable. This bit enables the STATFIFO overrun interrupt. 0 STATFIFO overrun interrupt is disabled 1 STATFIFO overrun interrupt is enabled
24 RF_OR_INTEN	RxFIFO Overrun Interrupt Enable. This bit enables the RX FIFO overrun interrupt. 0 RxFIFO overrun interrupt is disabled 1 RxFIFO overrun interrupt is enabled
23 -	This field is reserved. Reserved. This bit is reserved and should read 0.
22 SFF_DMA_DONE_INTEN	STATFIFO DMA Transfer Done Interrupt Enable. This bit enables the interrupt of STATFIFO DMA transfer done. 0 STATFIFO DMA Transfer Done interrupt disable 1 STATFIFO DMA Transfer Done interrupt enable
21 STATFF_INTEN	STATFIFO Full Interrupt Enable. This bit enables the STAT FIFO interrupt. 0 STATFIFO full interrupt disable 1 STATFIFO full interrupt enable
20 FB2_DMA_DONE_INTEN	Frame Buffer2 DMA Transfer Done Interrupt Enable. This bit enables the interrupt of Frame Buffer2 DMA transfer done.

Table continues on the next page...

CSI_CSICR1 field descriptions (continued)

Field	Description
	0 Frame Buffer2 DMA Transfer Done interrupt disable 1 Frame Buffer2 DMA Transfer Done interrupt enable
19 FB1_DMA_DONE_INTEN	Frame Buffer1 DMA Transfer Done Interrupt Enable. This bit enables the interrupt of Frame Buffer1 DMA transfer done. 0 Frame Buffer1 DMA Transfer Done interrupt disable 1 Frame Buffer1 DMA Transfer Done interrupt enable
18 RXFF_INTEN	RxFIFO Full Interrupt Enable. This bit enables the RxFIFO full interrupt. 0 RxFIFO full interrupt disable 1 RxFIFO full interrupt enable
17 SOF_POL	SOF Interrupt Polarity. This bit controls the condition that generates an SOF interrupt. 0 SOF interrupt is generated on SOF falling edge 1 SOF interrupt is generated on SOF rising edge
16 SOF_INTEN	Start Of Frame (SOF) Interrupt Enable. This bit enables the SOF interrupt. 0 SOF interrupt disable 1 SOF interrupt enable
15–12 Reserved	This field is reserved. Reserved. This field is reserved.
11 HSYNC_POL	HSYNC Polarity Select. This bit controls the polarity of HSYNC. This bit only works in gated-clock-that is, GCLK_MODE = 1 and CCIR_EN = 0. 0 HSYNC is active low 1 HSYNC is active high
10 CCIR_EN	CCIR656 Interface Enable. This bit selects the type of interface used. When the CCIR656 timing decoder is enabled, it replaces the function of timing interface logic. 0 Traditional interface is selected. Timing interface logic is used to latch data. 1 CCIR656 interface is selected.
9 Reserved	This field is reserved. This field is reserved.
8 FCC	FIFO Clear Control. This bit determines how the RXFIFO and STATFIFO are cleared. When Synchronous FIFO clear is selected the RXFIFO and STATFIFO are cleared, and STAT block is reset, on every SOF. FIFOs and STAT block restarts immediately after reset. For information on the operation when Asynchronous FIFO clear is selected, refer to the descriptions for the CLR_RXFIFO and CLR_STATFIFO bits. 0 Asynchronous FIFO clear is selected. 1 Synchronous FIFO clear is selected.
7 PACK_DIR	Data Packing Direction. This bit Controls how 8-bit/10-bit image data is packed into 32-bit RX FIFO, and how 16-bit statistical data is packed into 32-bit STAT FIFO. 0 Pack from LSB first. For image data, 0x11, 0x22, 0x33, 0x44, it will appear as 0x44332211 in RX FIFO. For stat data, 0xAAAA, 0xBBBB, it will appear as 0xB BBBBAAAA in STAT FIFO. 1 Pack from MSB first. For image data, 0x11, 0x22, 0x33, 0x44, it will appear as 0x11223344 in RX FIFO. For stat data, 0xAAAA, 0xBBBB, it will appear as 0xAAAABBBB in STAT FIFO.

Table continues on the next page...

Field	Description
6 CLR_STATFIFO	<p>Asynchronous STATFIFO Clear. This bit clears the STATFIFO and Reset STAT block.</p> <p>This bit works only in async FIFO clear mode-that is, FCC = 0. Otherwise this bit is ignored.</p> <p>Writing 1 will clear STATFIFO and reset STAT block immediately, STATFIFO and STAT block then wait and restart after the arrival of next SOF.</p> <p>The bit is restored to 0 automatically after finish. Normally reads 0.</p>
5 CLR_RXFIFO	<p>Asynchronous RXFIFO Clear. This bit clears the RXFIFO.</p> <p>This bit works only in async FIFO clear mode-that is, FCC = 0. Otherwise this bit is ignored.</p> <p>Writing 1 clears the RXFIFO immediately, RXFIFO restarts immediately after that.</p> <p>The bit is restored to 0 automatically after finish. Normally reads 0.</p>
4 GCLK_MODE	<p>Gated Clock Mode Enable. Controls if CSI is working in gated or non-gated mode.</p> <p>This bit works only in traditional mode-that is, CCIR_EN = 0. Otherwise this bit is ignored.</p> <p>0 Non-gated clock mode. All incoming pixel clocks are valid. HSYNC is ignored.</p> <p>1 Gated clock mode. Pixel clock signal is valid only when HSYNC is active.</p>
3 INV_DATA	<p>Invert Data Input. This bit enables or disables internal inverters on the data lines.</p> <p>0 CSI_D[7:0] data lines are directly applied to internal circuitry</p> <p>1 CSI_D[7:0] data lines are inverted before applied to internal circuitry</p>
2 INV_PCLK	<p>Invert Pixel Clock Input. This bit determines if the Pixel Clock (CSI_PIXCLK) is inverted before it is applied to the CSI module.</p> <p>0 CSI_PIXCLK is directly applied to internal circuitry</p> <p>1 CSI_PIXCLK is inverted before applied to internal circuitry</p>
1 REDGE	<p>Valid Pixel Clock Edge Select. Selects which edge of the CSI_PIXCLK is used to latch the pixel data.</p> <p>0 Pixel data is latched at the falling edge of CSI_PIXCLK</p> <p>1 Pixel data is latched at the rising edge of CSI_PIXCLK</p>
0 PIXEL_BIT	<p>Pixel Bit. This bit indicates the bayer data width for each pixel. This bit should be configured before activating or re-starting the embedded DMA controller.</p> <p>0 8-bit data for each pixel</p> <p>1 10-bit data for each pixel</p>

13.3.5.2 CSI Control Register 2 (CSI_CSICR2)

This register provides the statistic block with data about which live view resolution is being used, and the starting sensor pixel of the Bayer pattern. It also contains the horizontal and vertical count used to determine the number of pixels to skip between the 64 x 64 blocks of statistics when generating statistics on live view image that are greater than 512 x 384.

Address: 32E2_0000h base + 4h offset = 32E2_0004h

CSI_CSICR2 field descriptions

Field	Description
31–30 DMA_BURST_TYPE_RFF	Burst Type of DMA Transfer from RxFIFO. Selects the burst type of DMA transfer from RxFIFO. X0 INCR8 01 INCR4 11 INCR16
29–28 DMA_BURST_TYPE_SFF	Burst Type of DMA Transfer from STATFIFO. Selects the burst type of DMA transfer from STATFIFO. X0 INCR8 01 INCR4 11 INCR16

CSI_CSIRFIFO field descriptions

Field	Description
IMAGE	Received image data

13.3.5.6 CSI RX Count Register (CSI_CSIRXCNT)

This register works for EOF interrupt generation. It should be set to the number of words to receive that would generate an EOF interrupt.

There is an internal counter that counts the number of words read from the RX FIFO. Whenever the RX FIFO is being read, by either the CPU or the embedded DMA controller, the counter value is updated and compared with this register. If the values match, then an EOF interrupt is triggered.

Address: 32E2_0000h base + 14h offset = 32E2_0014h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

CSI_CSIRXCNT field descriptions

Field	Description
31–22 -	This field is reserved. Reserved. These bits are reserved and should read 0.
RXCNT	RxFIFO Count. This 22-bit counter for RxFIFO is updated each time the RxFIFO is read by CPU or DMA. This counter should be set to the expected number of words to receive that would generate an EOF interrupt.

13.3.5.7 CSI Status Register (CSI_CSISR)

This read/write register shows sensor interface status, and which kind of interrupt is being generated. The corresponding interrupt bits must be set for the status bit to function. Status bits should function normally even if the corresponding interrupt enable bits are not enabled.

Address: 32E2_0000h base + 18h offset = 32E2_0018h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	-			BASEADDR_CHHANGE_ERROR	DMA_FIELD0_DONE	DMA_FIELD1_DONE	SF_OR_INT	RF_OR_INT	Reserved	DMA_TSF_DONE_SFF	STATFF_INT	DMA_TSF_DONE_FB2	DMA_TSF_DONE_FB1	RxFF_INT	EOF_INT	SOF_INT
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	F2_INT	F1_INT	COF_INT	Reserved				HRESP_ERR_INT	Reserved						ECC_INT	DRDY
W																
Reset	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CSI_CSISR field descriptions

Field	Description
31–29 -	Reserved. These bits are reserved and should read 0.
28 BASEADDR_CHHANGE_ERROR	When using base address switching enable, this bit will be 1 when switching occur before DMA complete. This bit will be clear by writing 1. When this interrupt happens, follow the steps listed below. 1. Unassert the CSI enable, CSIx_CSICR18 bit31, 2. Reflash the DMA, assert the CSIX_CSICR3 bit 14, 3. Assert the CSI enable, CSIx_CSICR18 bit31.
27 DMA_FIELD0_DONE	When DMA field 0 is complete, this bit will be set to 1 (clear by writing 1).

Table continues on the next page...

CSI_CSISR field descriptions (continued)

Field	Description
26 DMA_FIELD1_DONE	When DMA field 0 is complete, this bit will be set to 1 (clear by writing 1).
25 SF_OR_INT	STATFIFO Overrun Interrupt Status. Indicates the overflow status of the STATFIFO register. (Cleared by writing 1) 0 STATFIFO has not overflowed. 1 STATFIFO has overflowed.
24 RF_OR_INT	RxFIFO Overrun Interrupt Status. Indicates the overflow status of the RxFIFO register. (Cleared by writing 1) 0 RxFIFO has not overflowed. 1 RxFIFO has overflowed.
23 -	This field is reserved. Reserved. This bit is reserved and should read 0.
22 DMA_TSF_DONE_SFF	DMA Transfer Done from StatFIFO. Indicates that the dma transfer from StatFIFO is completed. It can trigger an interrupt if the corresponding enable bit is set in CSICR1. This bit can be cleared by writing 1 or reflashing the StatFIFO dma controller in CSICR3. (Cleared by writing 1) 0 DMA transfer is not completed. 1 DMA transfer is completed.
21 STATFF_INT	STATFIFO Full Interrupt Status. Indicates the number of data in the STATFIFO reaches the trigger level. (this bit is cleared automatically by reading the STATFIFO) 0 STATFIFO is not full. 1 STATFIFO is full.
20 DMA_TSF_DONE_FB2	DMA Transfer Done in Frame Buffer2. Indicates that the DMA transfer from RxFIFO to Frame Buffer2 is completed. It can trigger an interrupt if the corresponding enable bit is set in CSICR1. This bit can be cleared by by writing 1 or reflashing the RxFIFO dma controller in CSICR3. (Cleared by writing 1) 0 DMA transfer is not completed. 1 DMA transfer is completed.
19 DMA_TSF_DONE_FB1	DMA Transfer Done in Frame Buffer1. Indicates that the DMA transfer from RxFIFO to Frame Buffer1 is completed. It can trigger an interrupt if the corresponding enable bit is set in CSICR1. This bit can be cleared by by writing 1 or reflashing the RxFIFO dma controller in CSICR3. (Cleared by writing 1) 0 DMA transfer is not completed. 1 DMA transfer is completed.
18 RxFF_INT	RxFIFO Full Interrupt Status. Indicates the number of data in the RxFIFO reaches the trigger level. (this bit is cleared automatically by reading the RxFIFO) 0 RxFIFO is not full. 1 RxFIFO is full.
17 EOF_INT	End of Frame (EOF) Interrupt Status. Indicates when EOF is detected. (Cleared by writing 1) 0 EOF is not detected. 1 EOF is detected.
16 SOF_INT	Start of Frame Interrupt Status. Indicates when SOF is detected. (Cleared by writing 1)

Table continues on the next page...

CSI_CSISR field descriptions (continued)

Field	Description
	0 SOF is not detected. 1 SOF is detected.
15 F2_INT	CCIR Field 2 Interrupt Status. Indicates the presence of field 2 of video in CCIR mode. (Cleared automatically when current field does not match) NOTE: Only works in CCIR Interlace mode. 0 Field 2 of video is not detected 1 Field 2 of video is about to start
14 F1_INT	CCIR Field 1 Interrupt Status. Indicates the presence of field 1 of video in CCIR mode. (Cleared automatically when current field does not match) NOTE: Only works in CCIR Interlace mode. 0 Field 1 of video is not detected. 1 Field 1 of video is about to start.
13 COF_INT	Change Of Field Interrupt Status. Indicates that a change of the video field has been detected. Only works in CCIR Interlace mode. Software should read this bit first and then dispatch the new field from F1_INT and F2_INT. (Cleared by writing 1) 0 Video field has no change. 1 Change of video field is detected.
12–8 -	This field is reserved. Reserved. These bits are reserved and should read 0.
7 HRESP_ERR_INT	Hresponse Error Interrupt Status. Indicates that a hresponse error has been detected. (Cleared by writing 1) 0 No hresponse error. 1 Hresponse error is detected.
6–2 -	This field is reserved. Reserved. These bits are reserved and should read 0.
1 ECC_INT	CCIR Error Interrupt. This bit indicates an error has occurred. This only works in CCIR Interlace mode. (Cleared by writing 1) 0 No error detected 1 Error is detected in CCIR coding
0 DRDY	RXFIFO Data Ready. Indicates the presence of data that is ready for transfer in the RxFIFO. (Cleared automatically by reading FIFO) 0 No data (word) is ready 1 At least 1 datum (word) is ready in RXFIFO.

13.3.5.8 CSI DMA Start Address Register - for STATFIFO (CSI_CSIDMASA_STATFIFO)

This register provides the start address for the embedded DMA controller of STATFIFO. The embedded DMA controller will read data from STATFIFO and write it to the external memory from the start address. This register should be configured before activating or restarting the embedded DMA controller.

Address: 32E2_0000h base + 20h offset = 32E2_0020h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	DMA_START_ADDR_SFF															Reserved
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CSI_CSIDMASA_STATFIFO field descriptions

Field	Description
31–2 DMA_START_ADDR_SFF	DMA Start Address for STATFIFO. Indicates the start address to write data. The embedded DMA controller will read data from STATFIFO and write it from this address through AHB bus. The address should be double words aligned.
-	This field is reserved. Reserved. These bits are reserved and should read 0.

13.3.5.9 CSI DMA Transfer Size Register - for STATFIFO (CSI_CSIDMATS_STATFIFO)

This register provides the total transfer size for the embedded DMA controller of STATFIFO. This register should be configured before activating or restarting the embedded DMA controller.

Address: 32E2_0000h base + 24h offset = 32E2_0024h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CSI_CSIDMATS_STATFIFO field descriptions

Field	Description
DMA_TSF_SIZE_SFF	DMA Transfer Size for STATFIFO. Indicates how many words to be transfered by the embedded DMA controller. The size should be double words aligned.

13.3.5.10 CSI DMA Start Address Register - for Frame Buffer1 (CSI_CSIDMASA_FB1)

This register provides the start address in the frame buffer1 for the embedded DMA controller of RxFIFO. The embedded DMA controller will read data from RxFIFO and write it to the frame buffer1 from the start address. This register should be configured before activating or restarting the embedded DMA controller.

Address: 32E2_0000h base + 28h offset = 32E2_0028h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

CSI_CSIDMASA_FB1 field descriptions

Field	Description
31–2 DMA_START_ADDR_FB1	DMA Start Address in Frame Buffer1. Indicates the start address to write data. The embedded DMA controller will read data from RxFIFO and write it from this address through AHB bus. The address should be double words aligned.
-	This field is reserved. Reserved. These bits are reserved and should read 0.

13.3.5.11 CSI DMA Transfer Size Register - for Frame Buffer2 (CSI_CSIDMASA_FB2)

This register provides the start address in the frame buffer2 for the embedded DMA controller of RxFIFO. The embedded DMA controller will read data from RxFIFO and write it to the frame buffer2 from the start address. This register should be configured before activating or restarting the embedded DMA controller.

Address: 32E2_0000h base + 2Ch offset = 32E2_002Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

CSI_CSIDMASA_FB2 field descriptions

Field	Description
31–2 DMA_START_ADDR_FB2	DMA Start Address in Frame Buffer2. Indicates the start address to write data. The embedded DMA controller will read data from RxFIFO and write it from this address through AHB bus. The address should be double words aligned.
-	This field is reserved. Reserved. These bits are reserved and should read 0.

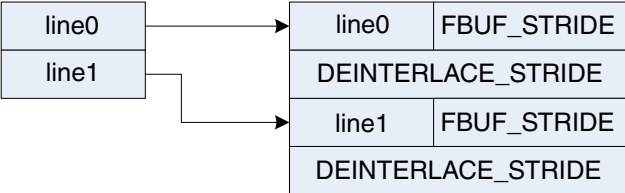

13.3.5.12 CSI Frame Buffer Parameter Register (CSI_CSIFBUF_PARA)

This register provides the stride of the frame buffer to show how many words to skip before starting to write the next row of the image. The width of the frame buffer minus the width of the image is the stride. This register should be configured before activating or restarting the embedded DMA controller.

Address: 32E2_0000h base + 30h offset = 32E2_0030h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

CSI_CSIFBUF_PARA field descriptions

Field	Description
31–16 DEINTERLACE_STRIDE	<p>DEINTERLACE_STRIDE is only used in the deinterlace mode. If line stride feature is supported in deinterlace mode, FBUF_STRIDE and DEINTERLACE_STRIDE need to be configured at the same time. DEINTERLACE_STRIDE is configured the same as line width. In normal line stride feature, only FBUF_STRIDE needs to be configured.</p>  <p>The diagram illustrates the relationship between line0 and line1 and their respective stride parameters. For line0, FBUF_STRIDE and DEINTERLACE_STRIDE are shown. For line1, FBUF_STRIDE and DEINTERLACE_STRIDE are also shown, indicating that DEINTERLACE_STRIDE is configured the same as line width.</p>
FBUF_STRIDE	<p>Frame Buffer Parameter. Indicates the stride of the frame buffer. The width of the frame buffer(in double words) minus the width of the image(in double words) is the stride. The stride should be double words aligned. The embedded DMA controller will skip the stride before starting to write the next row of the image.</p>

13.3.5.13 CSI Image Parameter Register (CSI_CSIIIMAG_PARA)

This register provides the width and the height of the image from the sensor. The width and height should be aligned in pixel. The width of the image multiplied by the height is the total pixel size that will be transferred in a frame by the embedded DMA controller. This register should be configured before activating or restarting the embedded DMA controller.

Address: 32E2_0000h base + 34h offset = 32E2_0034h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

CSI_CSIIIMAG_PARA field descriptions

Field	Description
31–16 IMAGE_WIDTH	<p>Image Width. Indicates how many pixels in a line of the image from the sensor.</p> <p>If the input data from the sensor is 8-bit/pixel format, the IMAGE_WIDTH should be a multiple of 8 pixels.</p> <p>If the input data from the sensor is 10-bit/pixel or 16-bit/pixel format, the IMAGE_WIDTH should be a multiple of 4 pixels.</p>
IMAGE_HEIGHT	<p>Image Height. Indicates how many pixels in a column of the image from the sensor.</p>

13.3.5.14 CSI Control Register 18 (CSI_CSICR18)

This read/write register acts as an extension of the functionality of the CSI Control register 1

Address: 32E2_0000h base + 48h offset = 32E2_0048h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

CSI_CSICR18 field descriptions

Field	Description
31 CSI_ENABLE	CSI global enable signal. Only when this bit is 1, CSI can start to receive the data and store to memory.
30–25 MIPI_DATA_FORMAT	Image Data Format Generic Short Packet: 0x08 ~ 0x0F Embedded 8-bit non Image: 0x12 YUV420 (8-bit) 0x18 YUV420 (10-bit) 0x19 YUV420 (8-bit legacy) 0x1A YUV420 (8-bit CSPS) 0x1C YUV420 (10-bit CSPS) 0x1D YUV422 (8-bit) 0x1E YUV422 (10-bit) 0x1F RGB444 0x20 (Not support) RGB555 0x21 (Not support) RGB565 0x22 RGB666 0x23 RGB888 0x24 RAW6 0x28 RAW7 0x29 RAW8 0x2A RAW10 0x2B RAW12 0x2C RAW14 0x2D User defined 1 0x30 User defined 2 0x31 User defined 3 0x32 User defined 4 0x33 User defined 5 0x34 User defined 6 0x35 User defined 7 0x36 User defined 8 0x37
24 LINE_STRIDE_EN	When the line width are not the multiple of the burst length, assert this bit.
23 -	Reserved
22 DATA_FROM_MIPI	0 Data from parallel sensor 1 Data from MIPI
21 MIPI_YU_SWAP	It only works in MIPI CSI YUV422 double component mode.
20 MIPI_DOUBLE_CMPNT	Double component per clock cycle in YUV422 formats. 0 Single component per clock cycle

Table continues on the next page...

CSI_CSICR18 field descriptions (continued)

Field	Description
	(half pixel per clock cycle) 1 Double component per clock cycle (a pixel per clock cycle)
19–18 MASK_OPTION	These bits used to choose the method to mask the CSI input. 00 Writing to memory from first completely frame, when using this option, the CSI_ENABLE should be 1. 01 Writing to memory when CSI_ENABLE is 1. 02 Writing to memory from second completely frame, when using this option, the CSI_ENABLE should be 1. 03 Writing to memory when data comes in, not matter the CSI_ENABLE is 1 or 0.
17–16 CSI_LCDIF_ BUFFER_LINES	The number of lines are used in handshake mode with LCDIF. 00 4 lines 01 8 lines 02 16 lines 03 16 lines
15–12 AHB_HPROT	Hprot value in AHB bus protocol.
11 -	This field is reserved.
10 RGB888A_ FORMAT_SEL	Output is 32-bit format. 0 {8'h0, data[23:0]} 1 {data[23:0], 8'h0}
9 BASEADDR_ CHANGE_ ERROR_IE	Base address change error interrupt enable signal.
8 LAST_DMA_ REQ_SEL	Choosing the last DMA request condition. 0 fifo_full_level 1 hburst_length
7 DMA_FIELD1_ DONE_IE	When in interlace mode, field 1 done interrupt enable. 0 Interrupt disabled 1 Interrupt enabled
6 FIELD0_DONE_ IE	In interlace mode, field 0 means interrupt enabled. 0 Interrupt disabled 1 Interrupt enabled
5 BASEADDR_ SWITCH_SEL	CSI 2 base addresses switching method. When using this bit, BASEADDR_SWITCH_EN is 1. 0 Switching base address at the edge of the vsync 1 Switching base address at the edge of the first data of each frame
4 BASEADDR_ SWITCH_EN	When this bit is enabled, CSI DMA will switch the base address according to BASEADDR_SWITCH_SEL rather than atomically by DMA completed.

Table continues on the next page...

CSI_CSICR18 field descriptions (continued)

Field	Description
3 PARALLEL24_ EN	When input is parallel rgb888/yuv444 24bit, this bit can be enabled.
2 DEINTERLACE_ EN	This bit is used to select the output method When input is standard CCIR656 video. 0 Deinterlace disabled 1 Deinterlace enabled
-	This field is reserved. Reserved.

13.4 MIPI CSI Host Controller (MIPI_CSI)

13.4.1 Overview

This chapter describes the camera interface for this chip. It works with the MIPI DPHY module to connect to the host processor.

13.4.1.1 Block Diagram

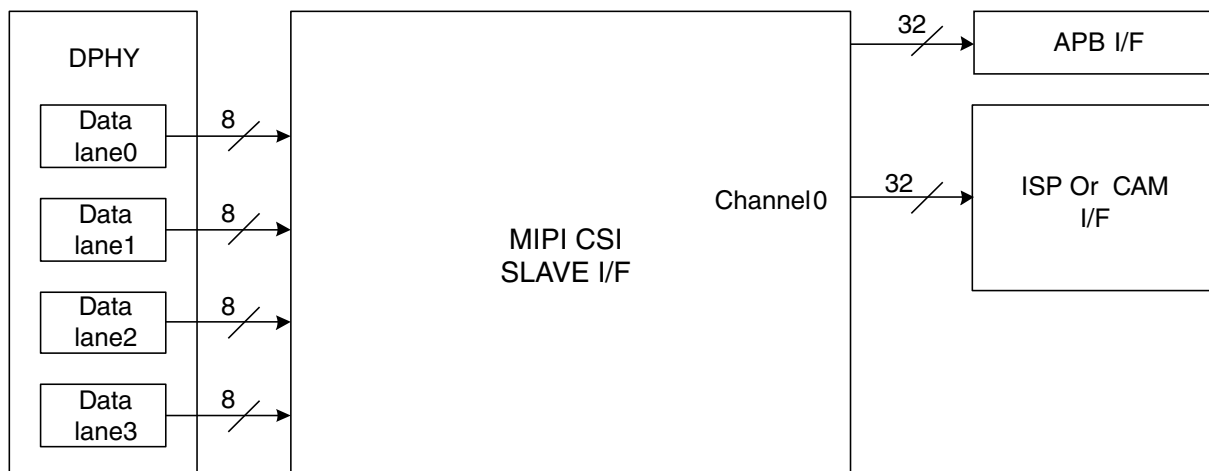

Figure 13-24. Block diagram of camera system with MIPI CSI Slave Interface

13.4.1.2 Features

- MIPI D-PHY specification V1.2 (Board Approved)

- Compliant to MIPI CSI2 Specification V1.3 except for C-PHY feature (Board Approved)
- Support primary and secondary Image format
 - YUV420, YUV420 (Legacy), YUV420 (CSPS), YUV422 of 8-bits and 10-bits
 - RGB565, RGB666, RGB888
 - RAW6, RAW7, RAW8, RAW10, RAW12, RAW14
 - All of User defined Byte-based Data packet
- Support up to 4 lanes of D-PHY
- Interfaces
 - Compatible to PPI(Protocol-to-PHY Interface) in MIPI D-PHY Specification
 - AMBA3.0 APB Slave for Register configuration.
 - Image output data buswidth : 32 bits
- Image memory
 - Size of SRAM is 4KB
- Pixel clock can be gated when no ppi data is coming.

13.4.1.3 MIPI CSI Slave and D-PHY I/F block diagram

Figure 13-25. PPI I/F block diagram

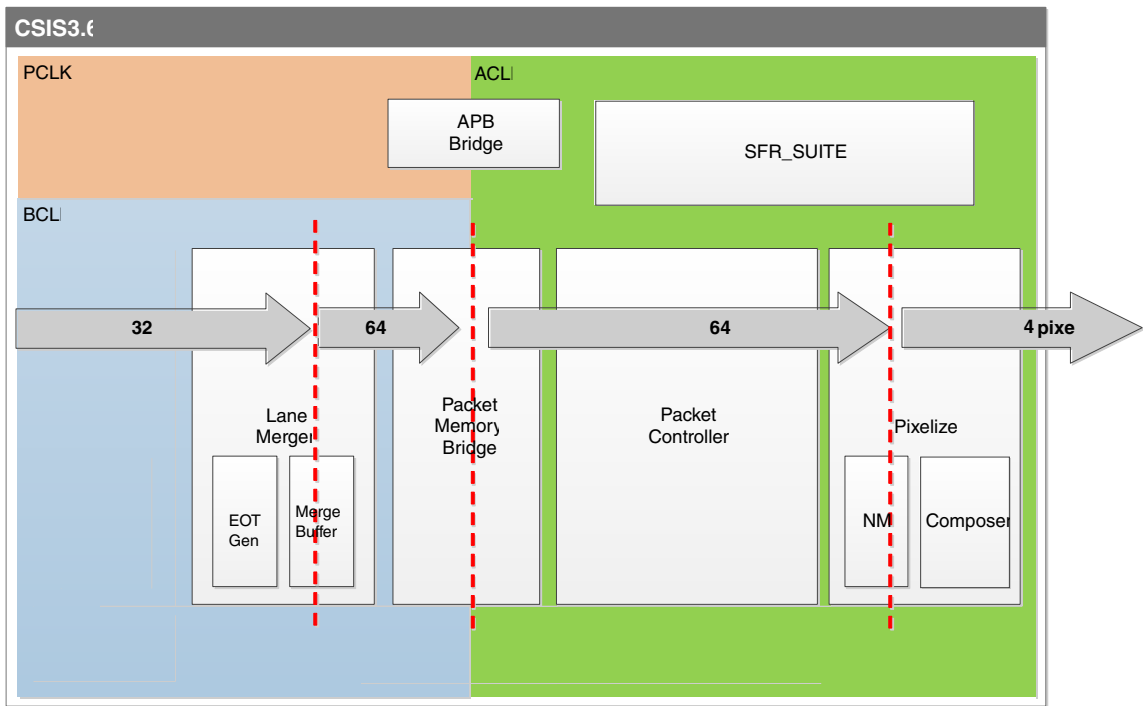

Figure 13-26. CSI Slave Module

13.4.1.4 Memory Bridge

The following table describes the configurable-sized memories.

Table 13-9. Memory bridge list

Usage	Memory Type	Size	Description
Image Data	2 port SRAM	4KB (1024 x 32bits)	Store the image data of virtual channel

There is the timing diagram for read memory in the figure below. If the mux for the split memories is needed, register for storing the address is necessary. Because the RDATA of memory is prepared at 1 clock later when the REN and RADDR are accepted.

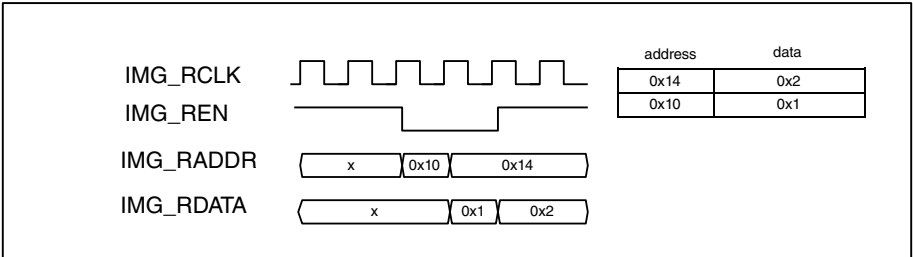

Figure 13-27. Timing diagram of Read memory

13.4.2 Initial Sequence

CSI Rx should be reset with D-PHY. Below Signal diagram is referred from Samsung D-PHY datasheet. This document describes the SFR setting and timing information.

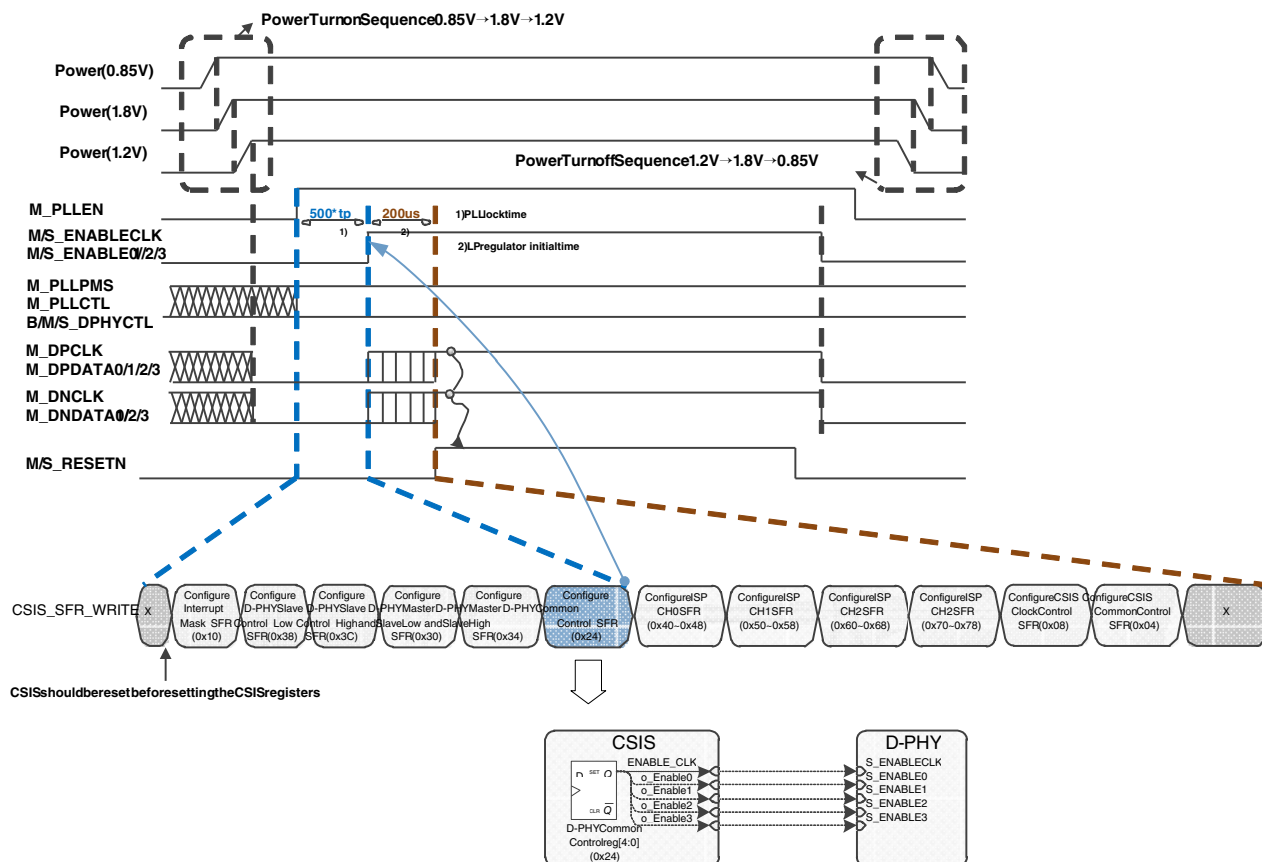

Figure 13-28. Initialize sequence

13.4.3 Protocol

13.4.3.1 D-PHY layer FSM

Figure 13-29. D-PHY Finite State Machine

CSIS V3.6.3 system supports HSDT(High Speed Data transfer) and ULPS(ULPM – Ultra-Low Power State or Mode) only. There is no trigger function, LPDT and BTA.

13.4.3.2 High Speed Data Transfer

In the following figure, the upper 5 signals are related with clock lane and the lower 6 signals are related with data lane. Dp and Dn of upper signals are D-PHY channel of clock lane. BYTE_CLK is generated clock in the D-PHY. Dp and Dn of lower signals are Data lane. Another signals of lower are Phy Status signals. STOPstate (and STOPstateClk) indicates that differential channel state of D-PHY is LP11 (the voltage level of Dp and Dn is 1.2V)

Figure 13-30. Timing Diagram of High Speed Data Transfer

13.4.3.3 Ultra-Low Power Mode

In the following figure, UlpsActiveNot* and STOPstate* is in PPI. ULPS command generated by D-PHY Tx is only for D-PHY Rx and it is decoded by D-PHY Rx and transferred to Link with Ulps data.

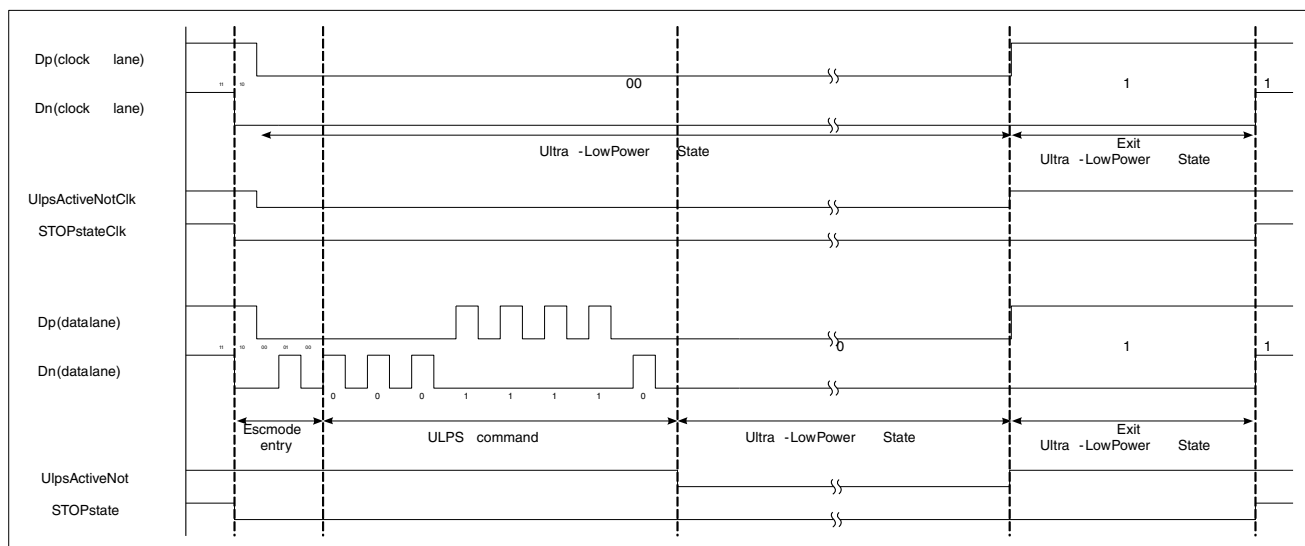

Figure 13-31. Timing Diagram of Ultra Low Power Mode

13.4.4 Interfaces

13.4.4.1 PPI Interface

Table 13-10. PPI I/F pin description

Port Name	I/O	Sync	Description
ENABLE_CLK	O	Async level	Enable clock lane module
STOP_STATE_CLK	I	Async level	Lanes in stop_state
ULPS_CLK	I	Async level	Clock lane is in Ultra Low-Power State (ULPS)
i_RxByteClkHS%	I	-	Rx byte clock in HS mode
i_RxValidHS%	I	Sync RX_BYTE_CLK_HS%	High-Speed receive data valid
i_RxDataHS%	I	Sync RX_BYTE_CLK_HS%	High-Speed receive data
i_ErrSotHS%	I	Sync RX_BYTE_CLK_HS%	Start of Transmission error (Pulse high)
o_Enable%	O	Async level	Enable Data lane module
i_Stopstate%	I	Async level	Lanes in stop_state
i_UlpsActiveNot%	I	Async level	Data Lane is in Ultra Low-Power State (ULPS)

ENABLE_CL

PPI I/F (Clocklane-Status)

STOP_STATE_CLK
(AsyncLevel)

ULPS_CLK
(Async Level)

Figure 13-32. PPI I/F (Clock lane) timing diagram

NOTE

DPHY should supply i_RxByteClkHS% at least 15 clock period after falling i_RxValidHS%

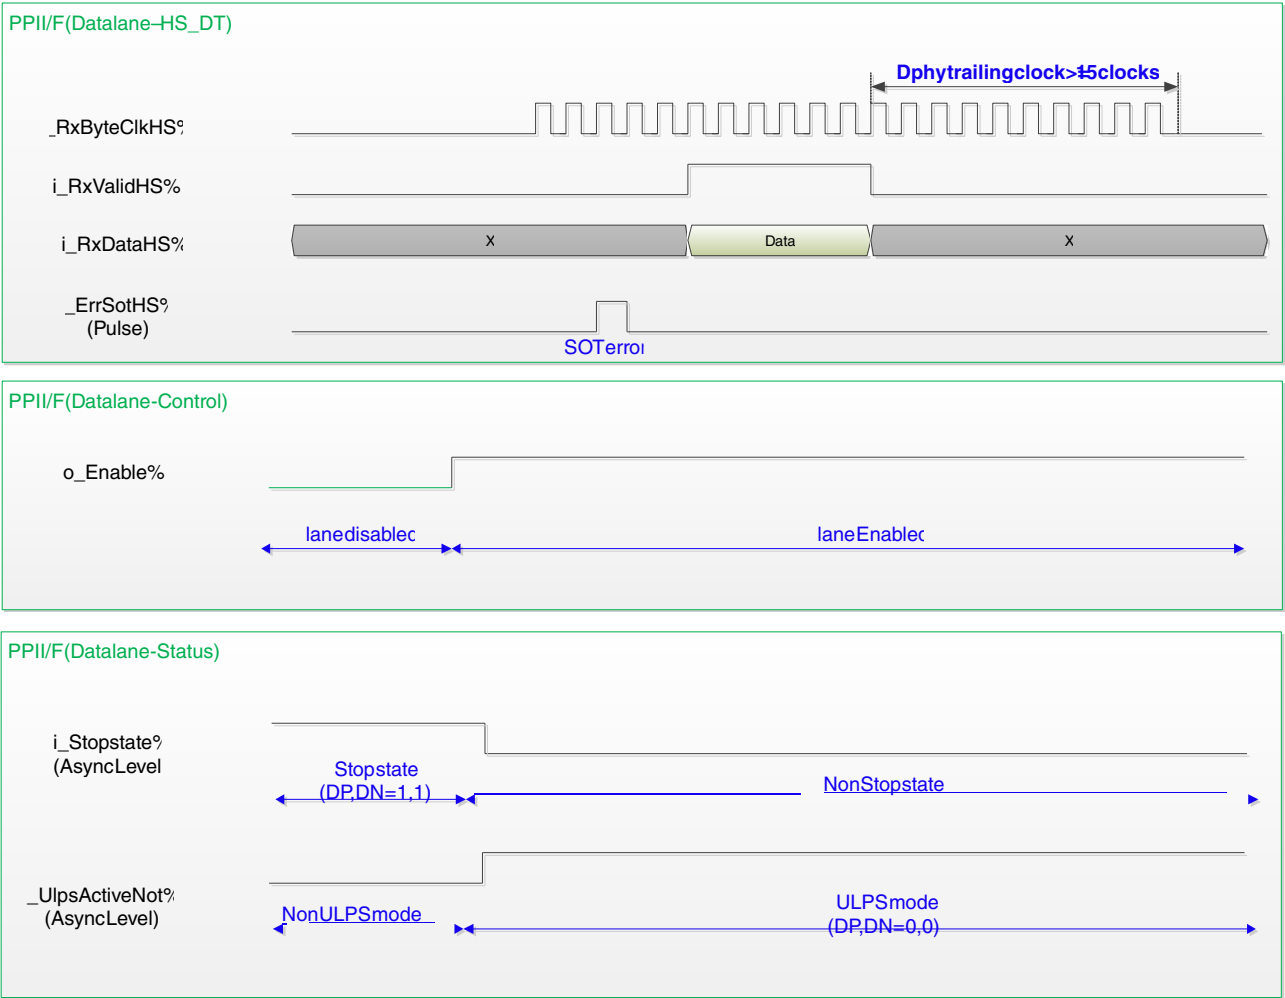

Figure 13-33. PPI I/F (Data lane) timing diagram

13.4.4.2 ISP Interface

CSIS V3.6.3 has output signals which are PIX_CLK, VVALID, HVALID, BVALID, and DATA.

Table 13-11. ISP I/F pin description

Port Name	I/O	Sync	Description
O_PIXCLK	O	-	Pixel clock. This signal is generated from I_ACLK.

Table continues on the next page...

Table 13-11. ISP I/F pin description (continued)

Port Name	I/O	Sync	Description
O_VVALID	O	O_PIX_CLK	Vertical sync signal. This signal is set during whole frame.
O_HVALID	O	O_PIX_CLK	Horizontal sync signal. This signal is set during each line.
O_BVALID	O	O_PIX_CLK	Byte valid signal. This signal indicates the valid number of byte and only valid in the User defined type and Parallel mode.
O_DATA	O	O_PIX_CLK	Pixel data bus. The pixel is aligned based on its data type.

The following figure describes the timing diagram of ISP I/F. All signals are synchronized with the rising edge of PIXCLK.

Figure 13-34. Output protocol of ISP Wrapper of CSIS C3.6.3

The following figure describes the sync timing of frame.

Figure 13-35. Frame sync timing diagram

The elements in the following table control the interval in [Figure 13-35](#). Those elements are configurable by register in ISP SYNC register of CH0.

Table 13-12. Frame sync timing description

	Description	Minimum cycle (# PIX_CLK)	Maximum cycle (# PIX_CLK)
t1	Interval between rising of VVALID and first rising HVALID	1	-
t2	Interval between last falling of DVALID and falling HVALID	Hsync_Lintv + 1	-
t3	Interval between falling of HVALID and rising of next HVALID	1	-
t4	Interval between rising of HVALID and first rising of DVALID	0	-
t5	Interval between last falling of HVALID and falling of VVALID	1	-
t6	Interval between falling of VVALID and rising of next VVALID	1	-

13.4.4.3 SRAM Interface

CSIS V3.6.3 has output signals which are PIX_CLK, VVALID, HVALID, BVALID, and DATA.

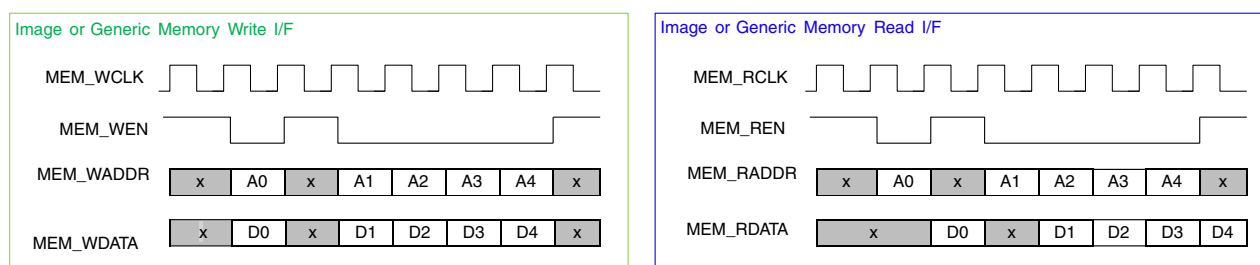

Table 13-13. SRAM interface description

Port Name	I/O	Sync	Description
O_IMG_MEM_WCLK	O	-	Write clock for the SRAM of IMG_MEM
O_IMG_MEM_WEN	O	O_IMG_MEM_WCLK	Write enable for the SRAM of IMG_MEM (active low)

Table continues on the next page...

Table 13-13. SRAM interface description (continued)

Port Name	I/O	Sync	Description
O_IMG_MEM_WADDR	O	O_IMG_MEM_WCLK	Write address for the SRAM of IMG_MEM
O_IMG_MEM_WDATA	O	O_IMG_MEM_WCLK	Write data for the SRAM of IMG_MEM
O_IMG_MEM_RCLK	O	O_IMG_MEM_WCLK	Read clock for the SRAM of IMG_MEM
O_IMG_MEM_REN	O	O_IMG_MEM_RCLK	Read enable for the SRAM of IMG_MEM (active low)
O_IMG_MEM_RADDR	O	O_IMG_MEM_RCLK	Read address for the SRAM of IMG_MEM
O_IMG_MEM_RDATA	I	O_IMG_MEM_RCLK	Read data from the SRAM of IMG_MEM

Figure 13-37. Pixel alignment

Pixel IF is adopted the little endian. If the current pixel mode is single, Pixel0 is a valid pixel. Higher pixels are the invalid signals. If the current pixel mode is dual, pixel0 and pixel1 is the valid pixels. In the case of Quad pixel mode, pixel0, pixel1, pixel2 and pixel3 is the valid pixels.

13.4.5.2 YUV data stream

Table 13-14. Output Image Stream of YUV formats

YUV format	Line	Image stream of content
YUV420 legacy	Odd	U1 Y1 Y2 U3 Y3 Y4 U5 Y5 ...
	Even	V1 Y1 Y2 V3 Y3 Y4 V5 Y5 ...
YUV420	Odd	Y1 Y2 Y3 Y4 Y5 Y6 Y7 Y8 ...
	Even	U1 Y1 V1 Y2 U3 Y3 V3 Y4 ...
YUV422	Odd/Even	U1 Y1 V1 Y2 U3 Y3 V3 Y4 ...

13.4.5.3 RGB swapped data alignment

When the “RGB_SWAP” bit of ISP_CONFIG_CH% register is set, the RGB data alignment of data bus is swapped. This is shown in the following figure.

Figure 13-38. RGB swapped data alignment

13.4.5.4 Parallel-memory-storing data alignment

When the “Parallel” bit of ISP_CONFIG_CH% register is set, the outer bus width is 32 bits. User should refer to figures in chapter12 of MIPI CSI-2 standard spec for the alignment of output data of CSIS V3.6.3. The signal diagram of Parallel mode is identical to the User defined packet format (2.7.1). If the byte count of the payload is not a multiple of 4, by performing the 0 padding makes the last data to 32bit.

13.4.6 Configuration

13.4.6.1 Image resolution

MIPI CSI Slave block needs the configuration of Image resolution to measure one line length exactly and detect frame end. Vertical resolution register has 16bits (16'h0001 ~ 16'hFFFF) Horizontal resolution register has 16bits (16'h0004 ~ 16'hFFFC).

13.4.6.2 Image data format

In CSIS V3.6.3, Image data format should be configured for transferring image data to ISP or CAM I/F.

13.4.6.3 YUV format

MIPI CSI2 supports YUV formats: YUV420 8bit, YUV420 10bit, YUV420 Legacy, YUV420 8bit Chroma Shifted Pixel Sampling, YUV420 10bit Chroma Shifted Pixel Sampling, YUV422 8bit, and YUV422 10bit The following table describes Data type of YUV packets.

Table 13-15. Data type of YUV packets

Data type	Description
0x18	YUV420 8-bit
0x19	YUV420 10-bit
0x1A	Legacy YUV420 8-bit
0x1B	Reserved
0x1C	YUV420 8-bit CSPA (Chroma Shifted Pixel Sampling)
0x1D	YUV420 10-bit CSPA (Chroma Shifted Pixel Sampling)
0x1E	YUV422 8-bit
0x1F	YUV422 10-bit

13.4.6.4 RGB format

MIPI CSI2 supports RGB formats: RGB444, RGB555, RGB565, RGB666, and RGB888. The following table describes Data type of RGB packets.

Table 13-16. Data type of RGB packets

Data type	Description
0x20	RGB444 (not supported)
0x21	RGB555 (not supported)
0x22	RGB565
0x23	RGB666
0x24	RGB888
0x25	Reserved
0x26	
0x27	

13.4.6.5 RAW format (Bayer RGB)

MIPI CSI2 supports RAW formats: RAW6, RAW7, RAW8, RAW10, RAW12, and RAW14. The following table describes Data type of RAW packets.

Table 13-17. Data type of RAW packets

Data type	Description
0x28	RAW6
0x29	RAW7
0x2A	RAW8
0x2B	RAW10
0x2C	RAW12
0x2D	RAW14
0x2E	Reserved
0x2F	

13.4.6.6 User defined Byte-based format (like JPEG)

CSIS V3.6.3 supports 8 formats of User defined Byte-based Data packet. The following table describes Data type of User defined packets.

Table 13-18. Data type of User defined packets

Data type	Description
0x30	User defined Byte-based packet 1
0x31	User defined Byte-based packet 2
0x32	User defined Byte-based packet 3
0x33	User defined Byte-based packet 4
0x34	User defined Byte-based packet 5
0x35	User defined Byte-based packet 6
0x36	User defined Byte-based packet 7
0x37	User defined Byte-based packet 8

13.4.6.7 Null and Blanking Data

For both the null and blanking data types CSIS V3.6.3 ignore the content of the packet payload data.

Table 13-19. Null and Blanking Data type

Data type	Description
0x10	Null
0x11	Blanking Data

13.4.7 User defined packet format

The User Defined Data Type values shall be used to transmit arbitrary byte-based data, such as JPEG and 1226 MPEG4 data, over the CSI-2 bus. The packet data size in bits shall be divisible by 8, i.e. whole number of bytes shall be transmitted.

For User Defined data:

1. The frame is transmitted as a sequence of arbitrary sized packets.
2. The packet size may vary from packet to packet.
3. The packet spacing may vary between packets.

13.4.7.1 ISP/CAM I/F for User defined packet

For supporting User defined packet, MIPI CSIS puts out more signals : 2 bits of byte validation. Byte validation signal indicates what is valid byte in data of word size. In the following figure, n is 0, 1, 2, or 3. See below table for more information.

Figure 13-39. Output protocol of CSIS V3.6.3 in User defined data type and Parallel mode

Table 13-20. Memory bridge list

BVALID[1:0]	Description
2'b00	All bytes in data bus are valid
2'b01	Only byte 0 is valid
2'b10	2 bytes from LSB are valid
2'b11	3 bytes from LSB are valid

13.4.8 Synchronization Short Packet Data type

Image Frame begins with a Frame Start and finishes with a Frame End packet. With these Frame synch packet, CSIS V3.6.3 generate Vertical Sync signal (VVALID). The Line synchronization packet (Line Start and Line End) generate Horizontal Sync signal (HVALID). But it can be generated by image data packet so that CSIS V3.6.3 doesn't support the Line Synchronization packets (0x02~0x03) and ignore it if it is received.

Table 13-21. Synchronization short packet data type

Data Type	Description
0x00	Frame Start Code
0x01	Frame End Code
0x02	Line Start Code (Not supported)

Table continues on the next page...

Table 13-21. Synchronization short packet data type (continued)

Data Type	Description
0x03	Line End Code (Not supported)
0x04 to 0x07	Reserved

Figure 13-40. Synchronization example

13.4.9 Synchronization Short Packet Data type

Image Frame begins with a Frame Start and finishes with a Frame End packet. With these Frame synch packet, CSIS V3.6.3 generate Vertical Sync signal (VVALID). The Line synchronization packet (Line Start and Line End) generate Horizontal Sync signal (HVALID). But it can be generated by image data packet so that CSIS V3.6.3 doesn't support the Line Synchronization packets (0x02~0x03) and ignore it if it is received.

Table 13-22. Synchronization short packet data type

Data Type	Description
0x00	Frame Start Code
0x01	Frame End Code
0x02	Line Start Code (Not supported)
0x03	Line End Code (Not supported)
0x04 to 0x07	Reserved

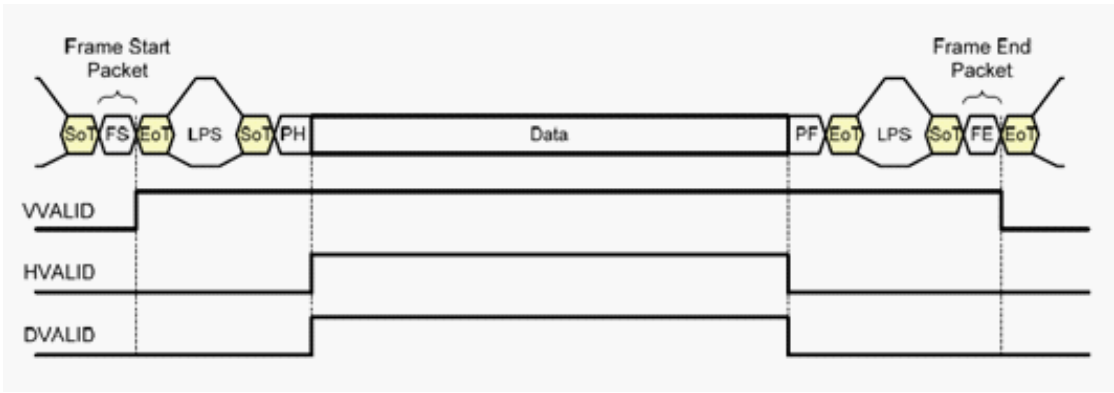

Figure 13-41. Synchronization example

13.4.10 Shadow Update

The configurations related to ISP registers (which are dataformat, vci, resolution and so on.) should not be varied during the run-time. So, they are updated by programming ‘update_shadow’ (in CSIS_CMN_CTRL register) in idle state. The scheme is described in the following figure.

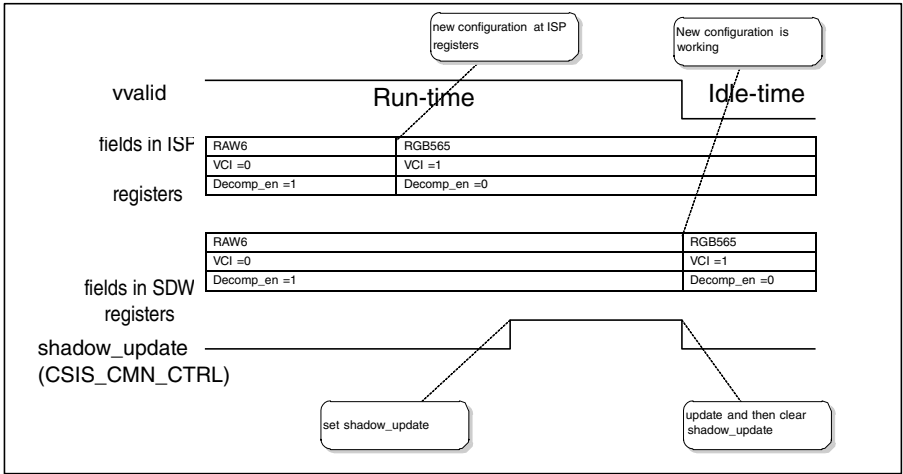

Figure 13-42. Operation of shadow_update

If the frame interleaving scheme (interleave_mode in CSIS_CMN_CTRL = 2 or 3) is used then the instance of entering idle_state at each ISP channels may be different. In this case, updating shadow registers can be delayed until that all isp channels are in idle state by setting update_shadow_ctrl.

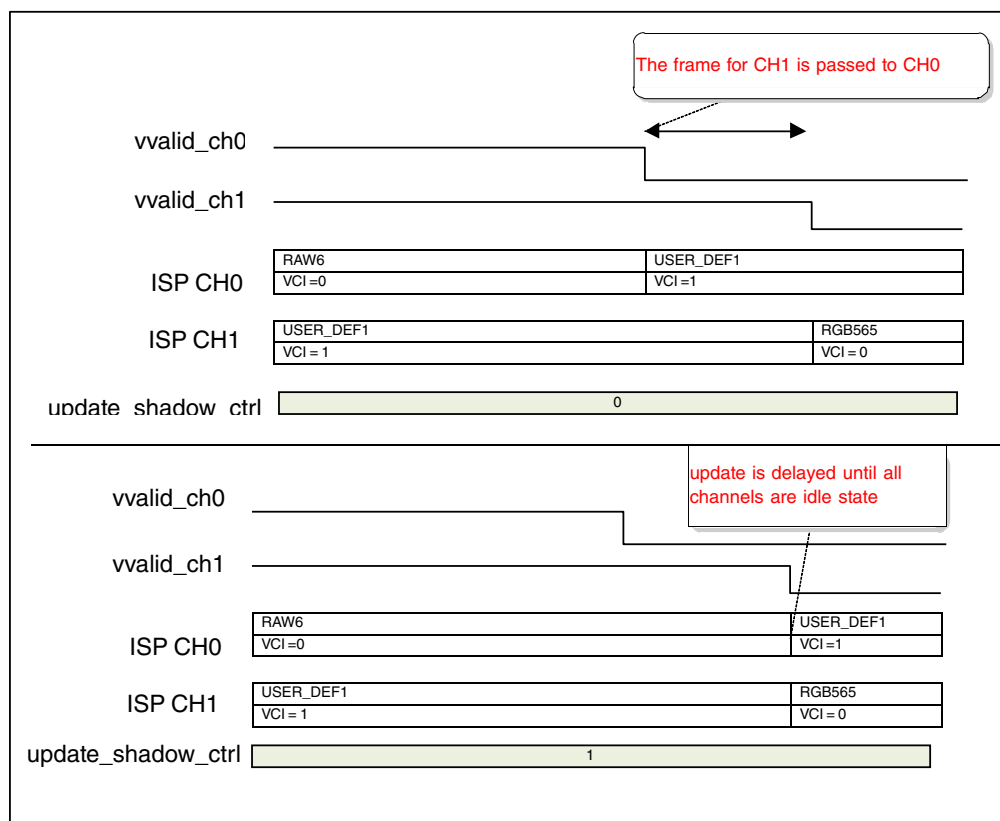

Figure 13-43. Operation of shadow_update_ctrl

13.4.11 Clock Specification

MIPI CSI have 3 clock sources: `RX_BYTE_CLK_HS%`, `I_PCLK`, and `I_WRAP_CLK`.

Table 13-23. Clock sources

Clock source	Description
<code>I_PCLK</code>	PCLK is system clock generated by general processor PLL.
<code>i_RxByteClkHS%</code>	This signal comes from data lane 0,1,2,3 of D-PHY.
<code>I_ACLK</code>	<code>I_ACLK</code> is external clock for pixel clock what is for using ISP or CAM I/F

13.4.12 Clock Domain

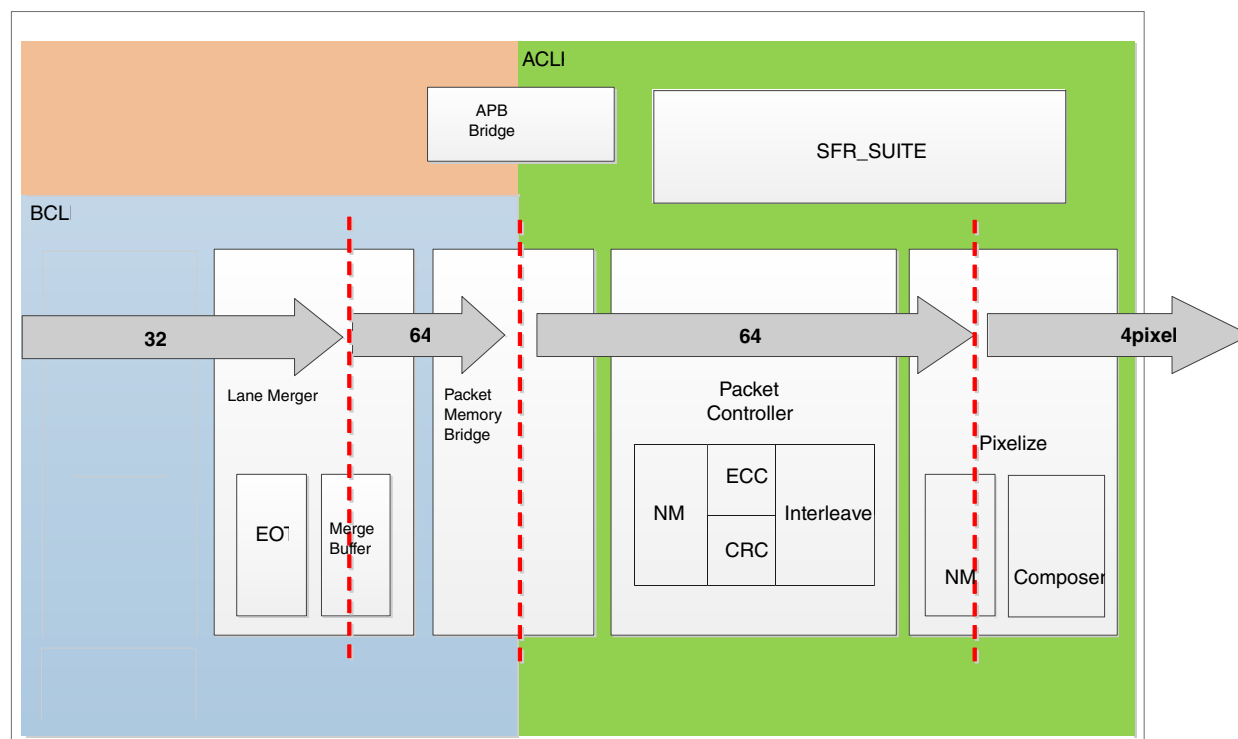

Figure 13-44. Block diagram of clock domain

The number of clock domain of CSIS V3.6.3 is 3:

- BYTE clock (RxByteCLKSH0)
- Pixel clock (I_ACLK)
- APB clock (I_PCLK)

The relationship between input and output bandwidth is that the output bandwidth should be faster than input bandwidth. There is an equation of previous relationship: **(FREQ. OF RX_BYTE_CLK_HS) X (NUMBER OF DATA LANE) X 8BITS ≤ (FREQ. OF PIXEL CLOCK) X (BITWIDTH OF IMAGE FORMAT) X (NUMBER OF PIXEL PER CLOCK)**

When parallel mod is on, **(BITWIDTH OF IMAGE FORMAT) X (NUMBER OF PIXEL PER CLOCK) = 32**

13.4.13 Interface Signals

13.4.13.1 Scalable

Our IP can change by setting parameters. Interface signals are generated by the parameter values. Parameter CH_NUM is the number of PHYsical channels of cam interface and affects cam if signals.

13.4.13.2 Reset and Clock signal

Table 13-24. Variation of clock and reset

Clock and reset	Frequency	Clock generator	Usage
I_PRESETn	-	-	Global Asynchronous reset
I_PCLK	-	System controller	Main control clock (system dependent)
i_RxByteClkHs0	Up to 250 Mhz (2G), 187.5MHz (1.5G), and 125MHz (1G)	Data lane 0 of D-PHY	MIPI CSI processes data with ByteCLK
I_ACLK	Up to 550Mhz	External clock source	Output pixel clock

13.4.13.3 PPI (PHY-Protocol Interface) Signals

BandCtrl and HSzeroCtl signals of following table are additional signals for D-PHY timing configuration. The other PPI signals in the table are compatible with MIPI D-PHY spec. v0.84r00 (See Annex A PPI Description informative).

Table 13-25. Protocol-to-PHY interface signal list

Signal	I/O	Description
Clock lane		
STOP_STATE_CLK	I	Stop state indicator (active high)
ULPS_CLK	I	ULPS state indicator (active low)
ENABLE_CLK	O	Clock lane enabler
Data lane (LANE -1 = %, 0<%<3, if LANE-1 is under 3, Lane3 is unused and should tie 0 to lane3's input ports)		
i_RxByteCLKHS%	I	Byte Clock
i_RxValidHS%	I	Received Data is valid.
i_RxDataHS%	I	Data bus for HS transfer
i_Stopstate%	I	Stop state indicator (active high)
i_UlpsActiveNot%	I	ULPS state indicator (active low)
i_ErrSotHS%	I	Error flag of Start of transmission in HS mode.

Table continues on the next page...

Table 13-25. Protocol-to-PHY interface signal list (continued)

Signal	I/O	Description
o_Enable%	O	Data lane enabler
D-PHY test		
I_DPHY_TESTMODE	I	D-PHY test mode
I_DTLPCLK	I	D-PHY Test clock
TXESCCLK%	O	Escape mode clock for D-PHY test
D-PHY config		
O_HS_SETTLE[7:0]	O	Configuration for tuning HS settle time
O_S_CLKSETTLECTRL[1:0]	O	Configuration for D-PHY control
O_B_DPHYCTRL[63:0]	O	Configuration for D-PHY ac characteristics
O_S_DPHYCTRL[63:0]	O	Configuration for D-PHY ac characteristics
O_S_DPDN_SWAP_CLK	O	Swapping Dp and Dn channel of clock lane in D-PHY.
O_S_DPDN_SWAP_DAT	O	Swapping Dp and Dn channel of data lanes in D-PHY.

13.4.13.4 AMBA Signal

Table 13-26. APB slave Interface signal list

Signal	I/O	Description
APB Slave		
I_PCLK	I	Main system clock
I_PRESETn	I	Main system reset
I_PADDR[31:0]	I	System address
I_PSEL	I	Module select strobe
I_PWRITE	I	Write strobe
I_PENABLE	I	enable strobe
I_PWDATA[31:0]	I	Write data to slave module
O_PREADY	O	Slave module is ready. (but tied high : always ready)
O_PSLVERR	O	Slave module with error
O_PRDATA[31:0]	O	Read data from slave module

13.4.13.5 Image Signal

Image output signals are duplicated for output channel 1 to 3.

Table 13-27. Image Output Interface signal list

Signal	I/O	Description
Pixel I/F (CH_NUM -1 = %, 0<%<3, if CH_NUM-1 is under 3, Channel3 is unused and that is not generated)		
O_PIXCLK[%]	O	Pixel clock for ISP or CAM I/F This is pixel clock for transferring image data to ISP or CAM I/F. The relationship of bandwidth between input and output is that output bandwidth should be faster than input bandwidth. The frequency of this clock is determined as following equation. (# of data lane) X (frequency of i_RxByteCLKHS0) ≤ (bitwidths of image format) X (frequency of PIXCLK). O_PIX_CLK[0]~[3] are worked when the corresponding channels are used
O_VVALID[%]	O	Vertical sync (level) O_VVALID[0]~[3] are worked when the corresponding channels are used
O_HVALID[%]	O	Horizontal sync (level) O_HVALID[0]~[3] are worked when the corresponding channels are used
O_DVALID[%]	O	Data valid O_DVALID[0]~[3] are worked when the corresponding channels are used
O_BVALID[CH_NUM*2-1:0]	O	Byte valid O_BVALID[1:0]~[7:6] are worked when the corresponding channels are used
O_DATA[CH_NUM*64- 1:0]	O	Pixel data O_DATA[0+:64]~[3*64+:64] are worked when the corresponding channels are used

13.4.13.6 Sideband Signal

Table 13-28. Sideband signal list

Signal	I/O	Description
Interrupt		
O_INT_CSIS	O	Interrupt request signal
I_INTGEN_SEL	I	This port shall be integrated to 1.

Table 13-28. Sideband signal list

Signal	I/O	Description
		1 : level interrupt generation

13.4.13.7 Memory I/F

Table 13-29. Memory I/F

Signal	I/O	Description
Memory for Image data		
O_IMG_MEM_WCLK	O	Write clock (ByteClk)
O_IMG_MEM_WEN	O	Image data Write enable strobe
O_IMG_MEM_WADDR[8:0]	O	Image data Write Address
O_IMG_MEM_WDATA[63:0]	O	Image data Write Data bus
O_IMG_MEM_RCLK	O	Read clock (PIXCLK)
O_IMG_MEM_RADDR[8:0]	O	Image data Read Address
O_IMG_MEM_REN	O	Image data Read enable strobe
I_IMG_MEM_RDATA[63:0]	I	Image data Read Data bus

13.4.14 Application Scenario

13.4.14.1 Programming Model

Table 13-30. Behavior programming each case

No.	Pseudo Code	Description
1	APB_WRITE(CSIS_INTR_MSK, -)	set Interrupt Mask
2	APB_WRITE(DPHY_BCTRL_L, -)	set DPHYBCTRL LSB
3	APB_WRITE(DPHY_BCTRL_H, -)	set DPHYBCTRL MSB
4	APB_WRITE(DPHY_CMN_CTRL, 0x11)	set DPHY HSSETTLE
5	APB_WRITE(ISP_CONFIG_CH0, -)	set ISP_CH0 configuration
6	APB_WRITE(ISP_RESOL_CH0, -)	set ISP_CH0 resolution
7	APB_WRITE(ISP_SYNC_CH0, -)	set ISP_CH0 sync
8	APB_WRITE(ISP_CONFIG_CH1, -)	set ISP_CH1 configuration
9	APB_WRITE(ISP_RESOL_CH1, -)	set ISP_CH1 resolution
10	APB_WRITE(ISP_SYNC_CH1, -)	set ISP_CH1 sync

13.5 MIPI DSI Host Controller (MIPI_DSI)

13.5.1 Overview

This chapter describes in detail about the MIPI Display Serial Interface (DSI) controller. This is a flexible, high-performance core that allows communication with MIPI DSI compliant peripherals.

13.5.1.1 Block Diagram

13.5.1.1.1 Total system block diagram

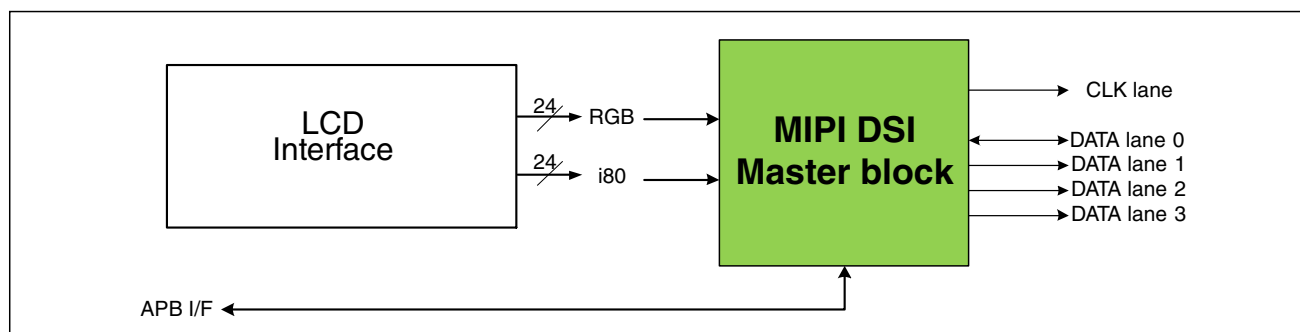

Figure 13-45. MIPI DSI master system block diagram

13.5.1.1.2 MIPI DSI master and D-PHY I/F block diagram

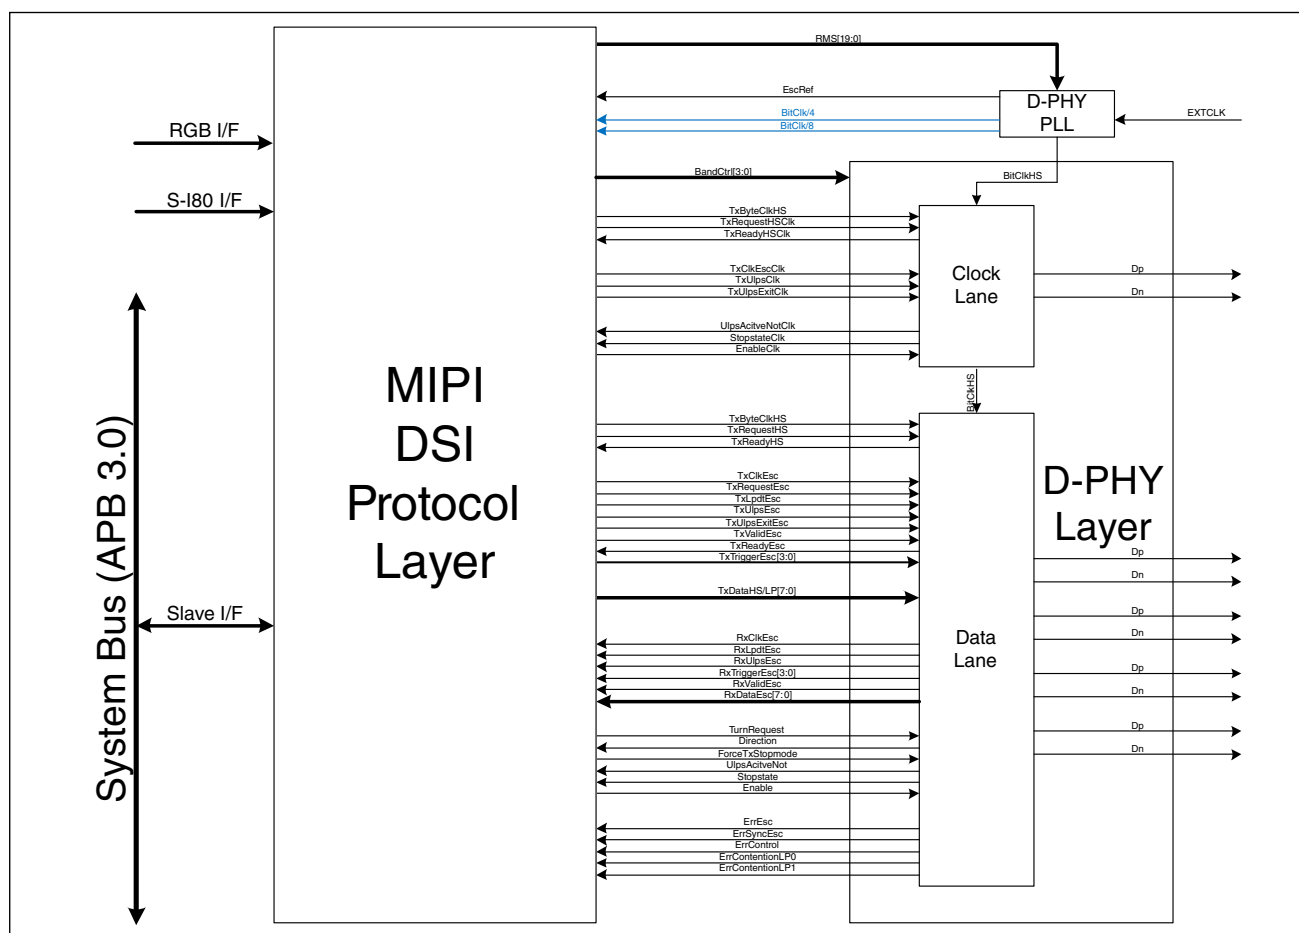

Figure 13-46. PPI I/F block diagram

13.5.1.1.3 MIPI DSI master block diagram

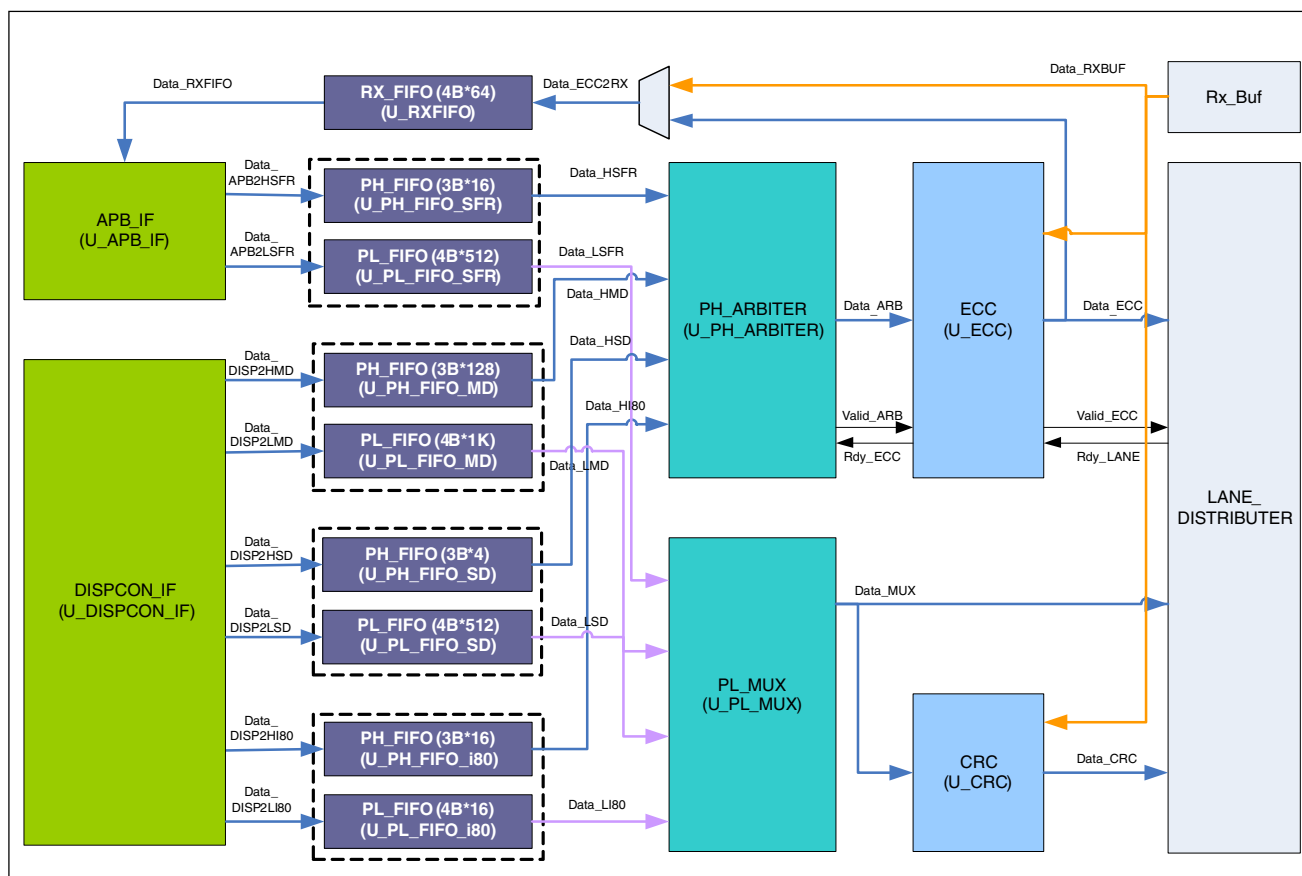

Figure 13-47. MIPI DSI master module block diagram

13.5.2 Features

The key features of MIPI DSI include:

- Complies to MIPI DSI Standard Specification V1.01r11
 - Maximum resolution ranges up to WQHD (1920x1080p60, 24bpp)
 - It should be decided on bandwidth between input clock (video clock) and output clock (D-PHY HS clock).
 - Supports 1, 2, 3, or 4 data lanes
 - Supports pixel format: 16bpp, 18bpp packed, 18bpp loosely packed (3 byte format), and 24bpp
- Interfaces
 - Complies with Protocol-to-PHY Interface (PPI) in 1.0Gbps / 1.5Gbps MIPI D-PHY
 - Supports RGB Interface for Video Image Input from general display controller

- Supports S-i80(Synchronous i80) Interface for Command Mode Image input from display controller
- Supports PMS control interface for PLL to configure byte clock frequency
- Supports Prescaler to generate escape clock from byte clock

13.5.3 Functional description

The following sections describe functional details of the MIPI DSI module.

13.5.3.1 Internal primary FIFOs

Table 13-31 describes configurable-sized primary FIFOs.

Table 13-31. Internal primary FIFO list

Port	FIFO type	Size	Description
Main display for RGB I/F and S-i80 I/F	Packet Header FIFO	3Byte X 128 depth	Packet header FIFO for main display
	Payload FIFO	4Byte X 1024 depth	Payload FIFO for main display image (SRAM used)
Sub display for S-i80 I/F image data	Packet Header FIFO	3Byte X 4 depth	Packet header FIFO for S-i80 I/F sub display
	Payload FIFO	4Byte X 512 depth	Payload FIFO for S-i80 I/F sub display image (SRAM used)
Command for S-i80 I/F command	Packet Header FIFO	3Byte X 16 depth	Packet header FIFO for S-i80 I/F command packet
	Payload FIFO	4Byte X 16 depth	Payload FIFO for S-i80 I/F command long packet payload
SFR for general packets	Packet Header FIFO	3Byte X 16 depth	Packet header FIFO for general packet
	Payload FIFO	4Byte X 512 depth	Payload FIFO for general long packet (SRAM used)
RX FIFO	Packet header and Payload FIFO	4Byte X 64 depth	Rx FIFO for LPDR. This FIFO is common for packet header and payload

13.5.3.2 Packet header arbitration

There are four-packet headers FIFOs for Tx, namely, main display, sub display, S-i80 INTERFACE command, and SFR FIFO. The main and sub display FIFO packet headers contain the image data, while the S-i80 INTERFACE command FIFO packet header contains the command packets. On the other hand, the SFR FIFO packet header contains command packets, sub display image data (in Video mode), and so on.

The packet header arbiter has a “Fixed priority” algorithm. Priority order is fixed as main display, sub display, S-i80 INTERFACE command, and SFR FIFO packet header.

In the Video mode, sub display and S-i80 INTERFACE command FIFO are not used. The SFR FIFO packet header checks if the main display FIFO is empty (no request) in not-active image region and then sends its request.

13.5.3.3 RxFIFO Structure

To read the packets received via low power data receiving mode, RxFIFO acts like an SFR. RxFIFO is an asynchronous FIFO with ByteClk and PCLK domains as input clock and output clock domains respectively. The Rx data is synchronized to RxClk. RXBUF has four Rx Byte buffers for aligning byte to word.

The packet headers of all the packets stored in RXFIFO are word-aligned, that is, the first byte of a packet is always stored in LSB. For example, if a long packet has 7-byte payload, the last byte is filled with dummy byte and the next packet is stored in the next word, as shown in Figure 13-48.

NOTE
CRC data is not stored in RxFIFO.

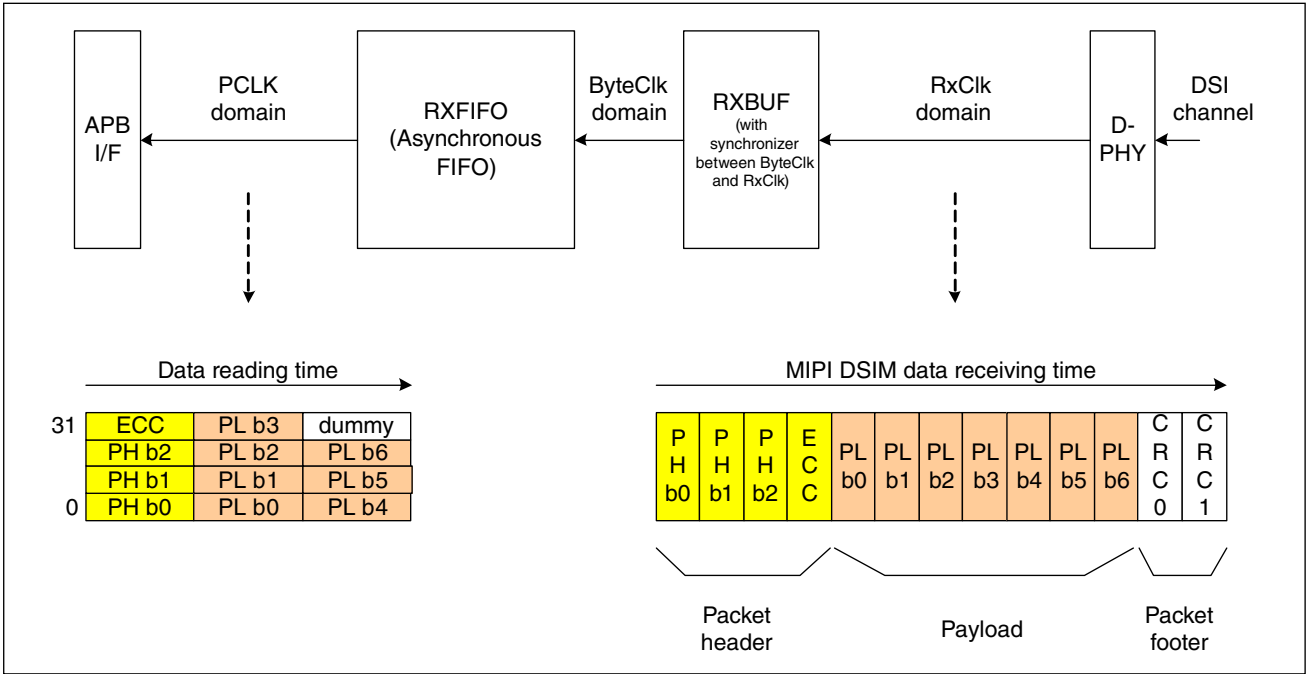

Figure 13-48. Rx data word alignment

13.5.3.4 Interfaces and protocol

Display Controller-to-DSI Conceptual Signal Converting Diagram in Video Mode.

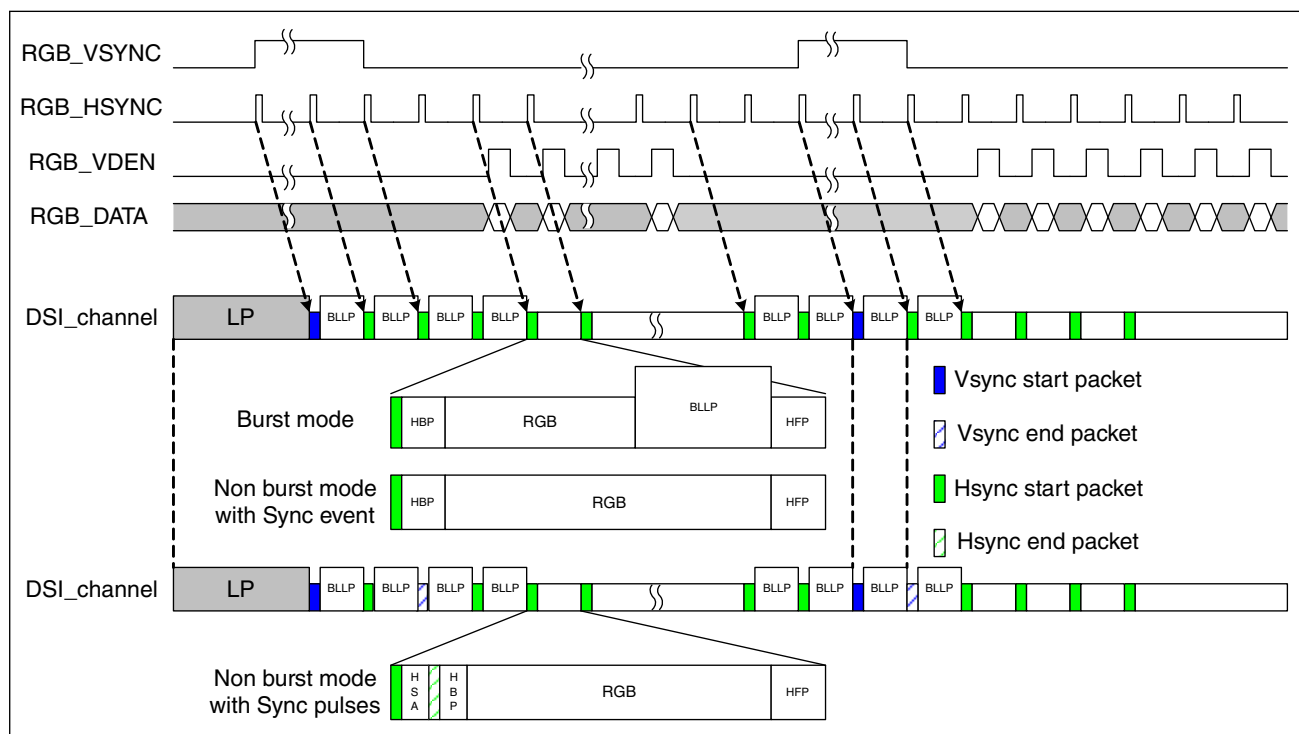

Figure 13-49. Signal converting diagram in video mode

13.5.3.5 Interface timing and protocol

13.5.3.5.1 Display controller interface

MIPI DSI Master has two-display controller interfaces, namely, RGB INTERFACE for main display and CPU INTERFACE (S-i80 INTERFACE) for main/ sub display. The Video mode uses RGB INTERFACE while the Command mode uses CPU INTERFACE.

The RGB image data is loaded on the data bus of RGB INTERFACE and S-i80 INTERFACE with the same order: RGB_VD[23:0] or SYS_VDOOUT[23:0] is {R[7:0],G[7:0],B[7:0]}. Each byte aligns to the most significant bit. For instance, in the 12-bit mode, only three 4-bit values are valid as R, G, and B each, that is, data[23:20], data[15:12], and data[7:4]. The DSIM ignores rest of the bits.

13.5.3.5.2 RGB interface

Vsync, Hsync, and VDEN are active high signals. Among the three signals, Vsync and Hsync are pulse types that spend several video clocks. RGB_VD[23:0] is {R[7:0],G[7:0],B[7:0]}. All sync signals are synchronized to the rising edge of RGB_VCLK. The display controller sends minimum one horizontal line length of Vsync pulse, V back porch, and V front porch. Hsync pulse width should be longer than 1-byte clock cycle.

13.5.3.5.2.1 HSA disable mode

HSA mode specifies the Horizontal Sync Pulse area disable mode.

Figure 13-50. Block timing diagram of HSA disable mode (HSA mode reset : DSIM_CONFIG[20] = 0)

Figure 13-51. Block timing diagram of HSA disable mode (HSA mode set : DSIM_CONFIG[20] = 1)

13.5.3.5.2.2 HBP disable mode

This is optional spec what is used only burst mode. HBP mode is Horizontal Back Porch disable mode.

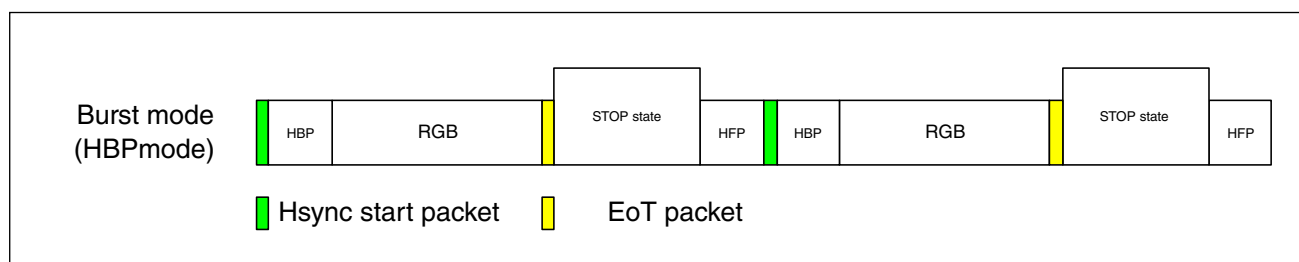

Figure 13-52. Block timing diagram of HBP disable mode (HBP mode reset : DSIM_CONFIG[21] = 0)

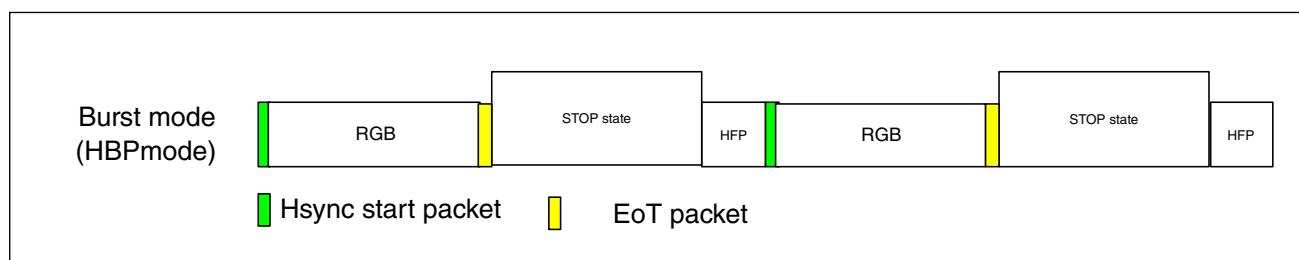

Figure 13-53. Block timing diagram of HBP disable mode (HBP mode set : DSIM_CONFIG[21] = 1)

13.5.3.5.2.3 HFP disable mode

This is optional spec what is used only burst mode. HFP mode is Horizontal Front Porch disable mode.

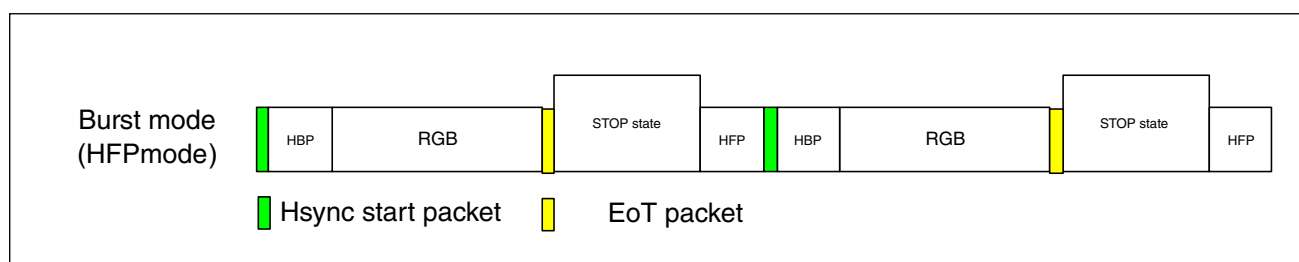

Figure 13-54. Block timing diagram of HFP disable mode (HFP mode set : DSIM_CONFIG[22] = 1)

13.5.3.5.2.4 HSE disable mode

HSE mode is Horizontal Sync End packet enable mode in Vsync pulse or Vporch area.

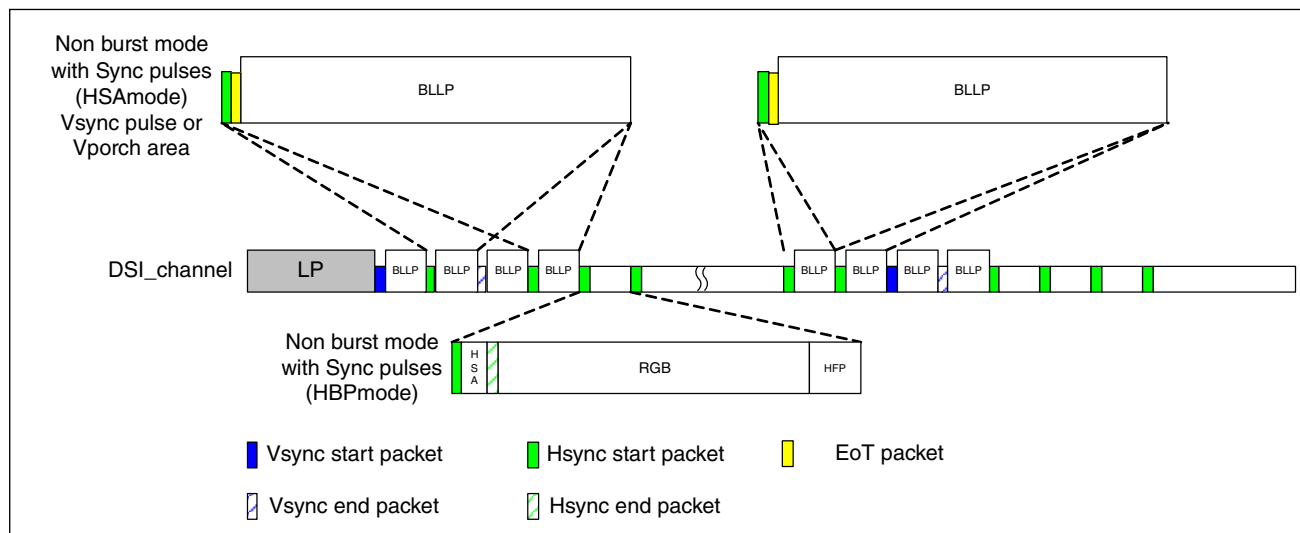

Figure 13-55. Block timing diagram of HSE disable mode (HSE mode reset : DSIM_CONFIG[23] = 0)

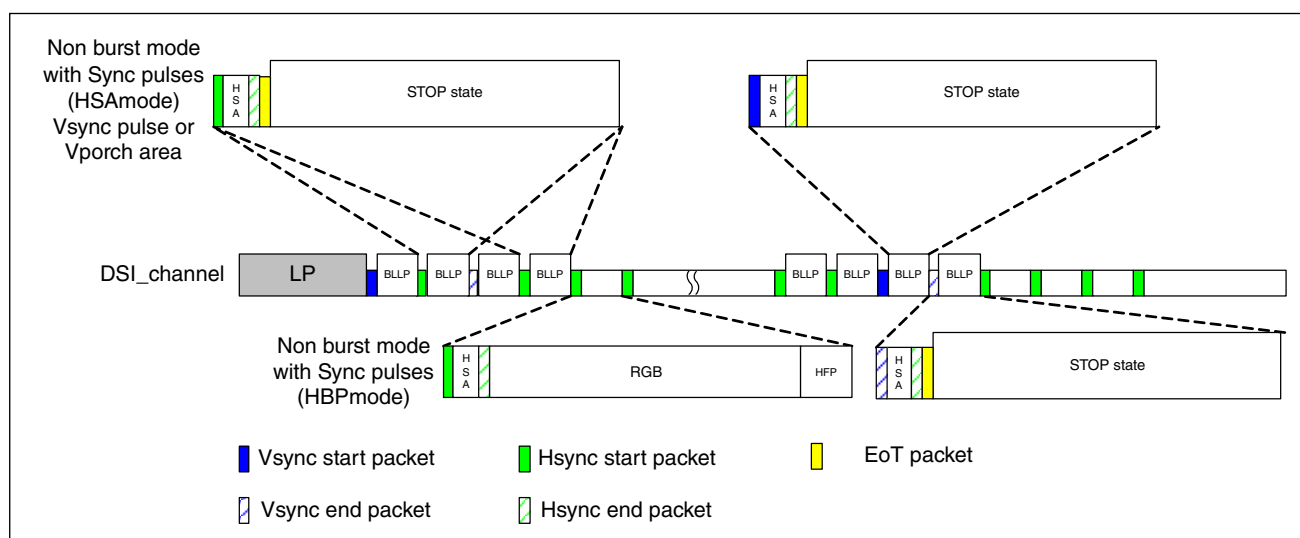

Figure 13-56. Block timing diagram of HSE disable mode (HSE mode set : DSIM_CONFIG[23] = 1)

13.5.3.5.2.5 Transfer general data in video mode

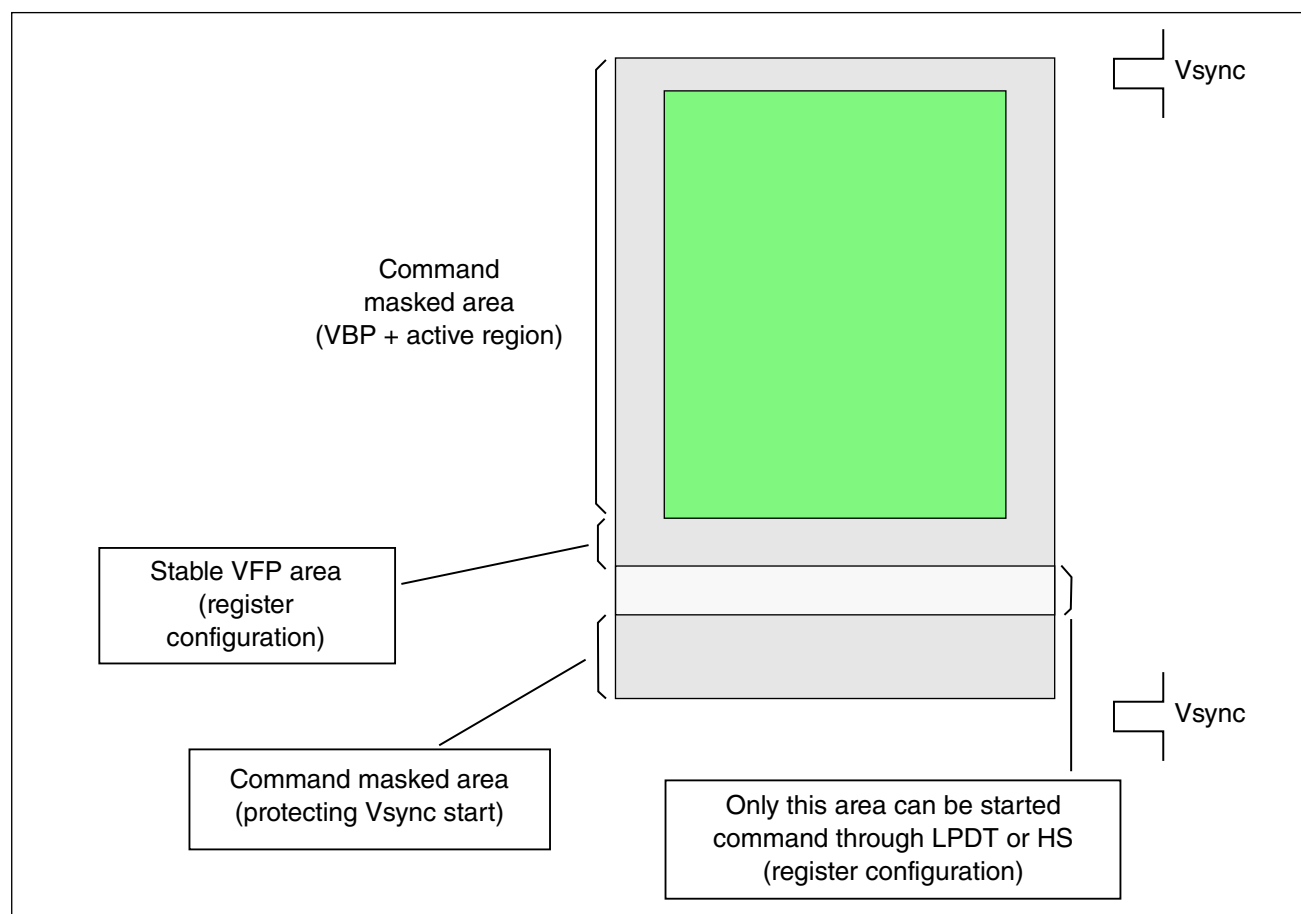

Figure 13-57. Stable VFP Area Before Command Transfer Allowing Area

MIPI DSIM Converts RGB Interface to Video Mode.

Vsync and Hsync packets are extremely important to protect image in Video mode. MIPI DSIM allows several lines in VFP area to transfer general data transfer. As shown in [Figure 13-57](#), the vertical front porch is divided into three areas, namely, Stable VFP area, Command allowed area, and Command masked area.

The register configures stable VFP area. Configuration boundary is 11'h000 ~ 11'h7FFF in DSIM_MVPORCH.

The register also configures the command allowed area. Configuration boundary is 4'h0 ~ 4'hF in DSIM_MVPORCH. Only this area is allowed to start "command transfer" through HS mode or LPDT. In LPDT, data transferring takes a long time to complete (approximately hundreds of microseconds or more). In this time, Hsync packet does not arrive due to LPDT long packet. MIPI DSIM comprises of big size FIFO for lost Hsync packet. After LPDT, MIPI DSIM transfers these Hsync packets immediately through HS mode.

To protect Vsync, command masked area is masked area. This area is calculated using LPDT bandwidth. For example, if EscClk is 10MHz, the maximum long packet payload size is 1KB and LPDT, LPDT transferring time is 824us (packet size: 1030byte, LPDT maximum bandwidth: 10Mbps). If one line time is 20us, the line timing violation occurs in 42 lines. Therefore, command masked area is larger than 42 + "block". This "block" is transferring time of the violated Hsync packets.

Display controller should be configured in such a way that VFP lines are sum of stable VFP, command allowed area, and command masked area.

13.5.3.5.3 S-i80 interface

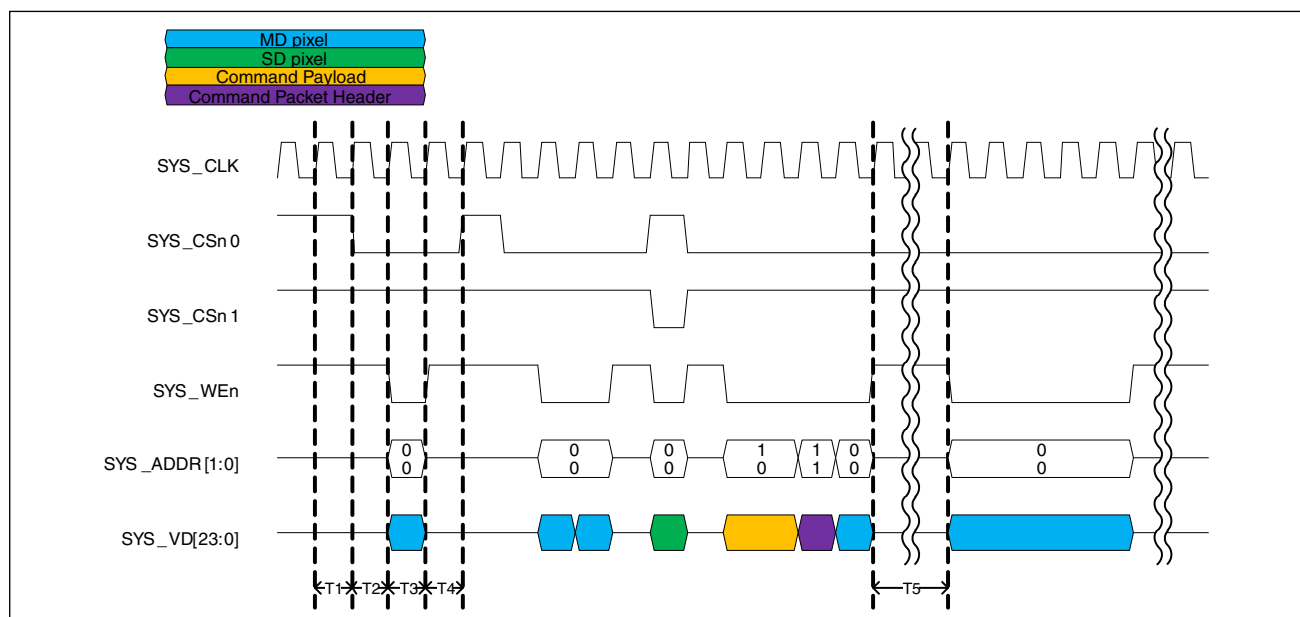

Figure 13-58. S-i80 I/F timing diagram

- $T1 \geq 1$ clock cycle.
- $T2 \geq 0$ clock cycle.
- $T3 \geq 1$ clock cycle.
- $T4 \geq 0$ clock cycle.
- $T2+T3+T4 > 1$ cycle of Byte clock.
- $T5 \geq 10$ clock cycle (every horizontal blank period).

A display controller generates these signals with its internal clock: SYS_CS0/CS1, SYS_WE, and SYS_VD. MIPI DSI master decodes the SYS_ADDR. [Table 13-32](#) describes the Command mode Interface address map.

Table 13-32. Command mode interface address map

SYS_ADDR[1:0]	Description
2'b00	Image data
2'b01	Reserved
2'b10	Payload data
2'b11	Packet Header

Figure 13-59 shows how MIPI DSI Master makes packet from the image data stream via S-i80 INTERFACE in Command mode. MIPI DSI master makes packet from the first line with DCS command “write_memory_start” and the other lines with DCS command "write_memory_continue".

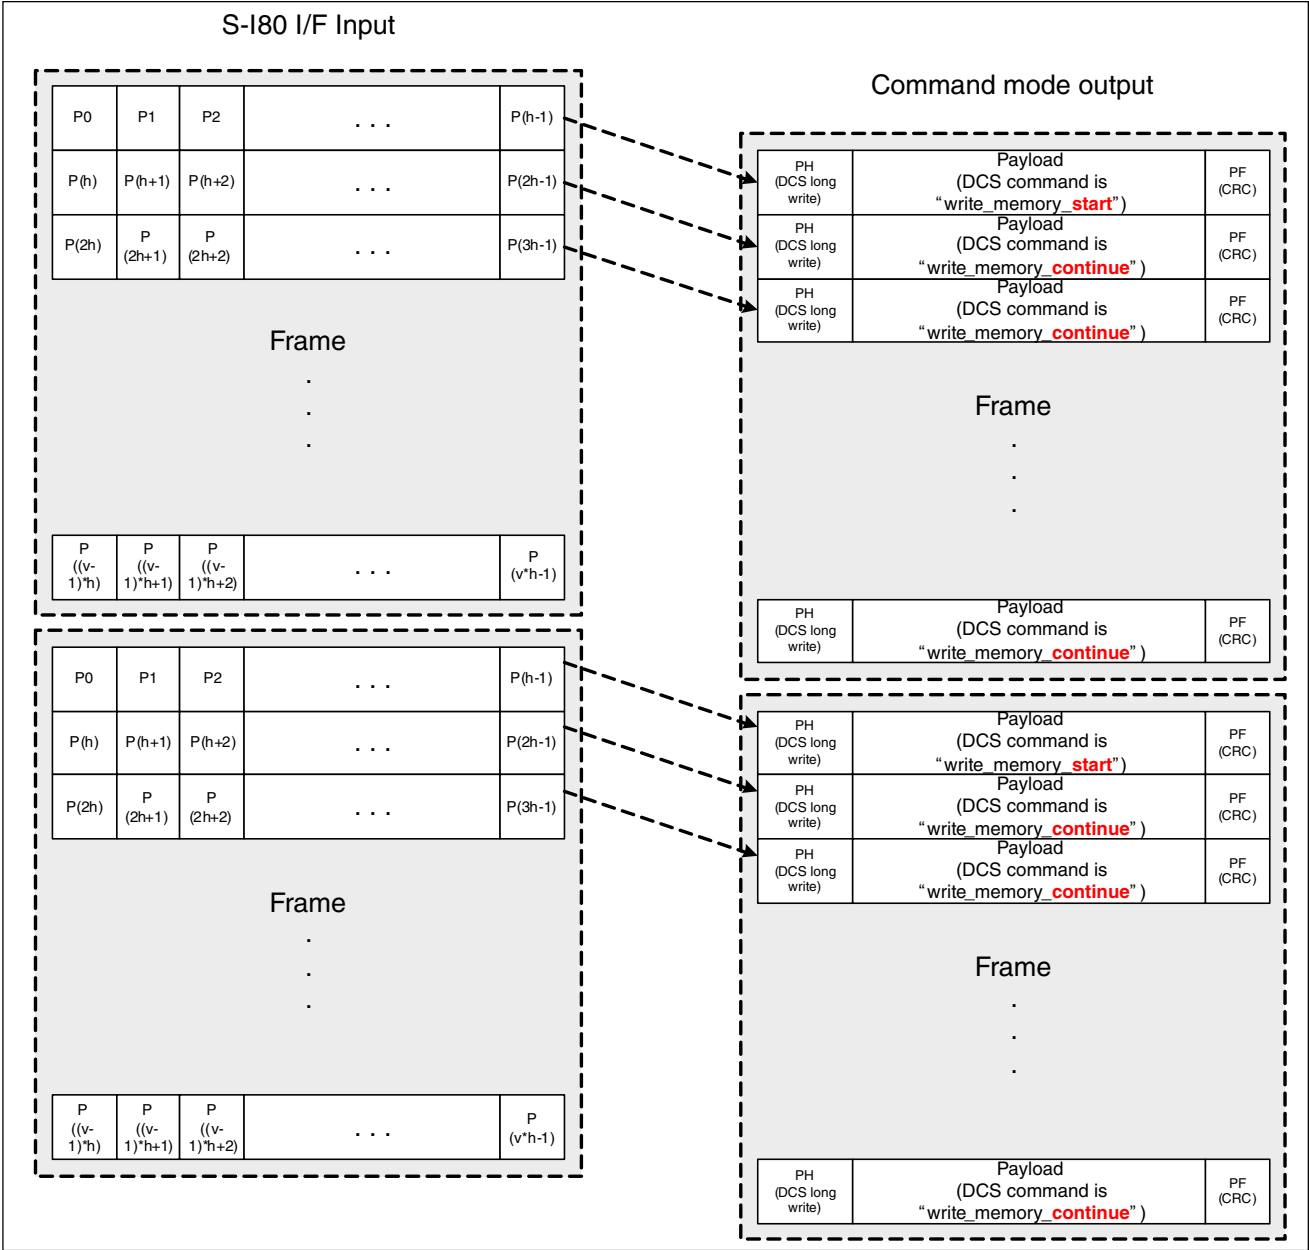

Figure 13-59. Packetizing for MIPI DSI command mode from S-i80 I/F

13.5.3.5.4 Relation between input transactions and DSI transactions

Table 13-33. Relation between input transactions and DSI transactions

Input Interface	Input transaction	DSI Transaction
RGB	RGB transaction	Specifies the RGB Packet. 888, 666, 666 (loosely packed), and 565 should be specified via register configuration.
RGB / S-i80	RGB / S-i80 Image Transaction	Specifies the Data type, that is, "DCS Long Write packet".

Table continues on the next page...

13.5.3.5.5.2 High speed data transfer

Figure 13-61. Timing diagram of high speed data transfer

13.5.3.5.5.3 Low power data transfer

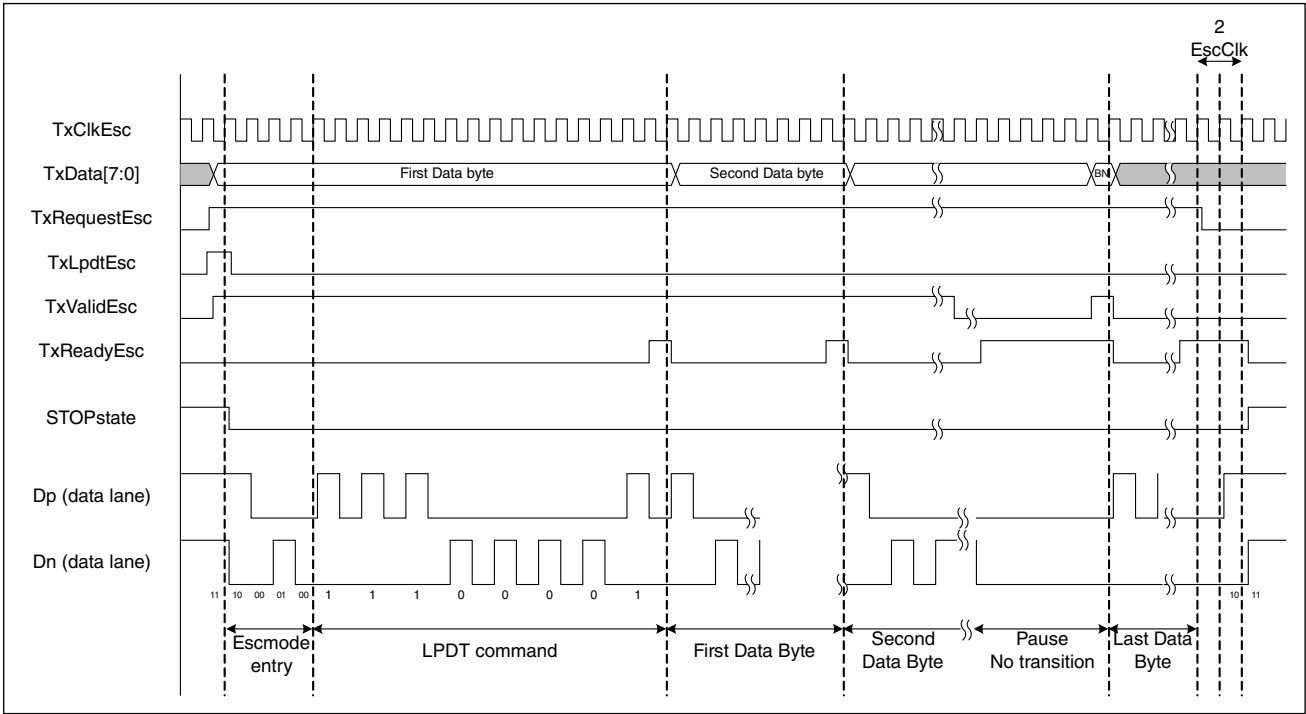

Figure 13-62. Timing diagram of low power data transfer

13.5.3.5.4 Ultra-Low power state

Figure 13-63. Timing diagram of ultra low power state

13.5.3.5.5 Trigger function

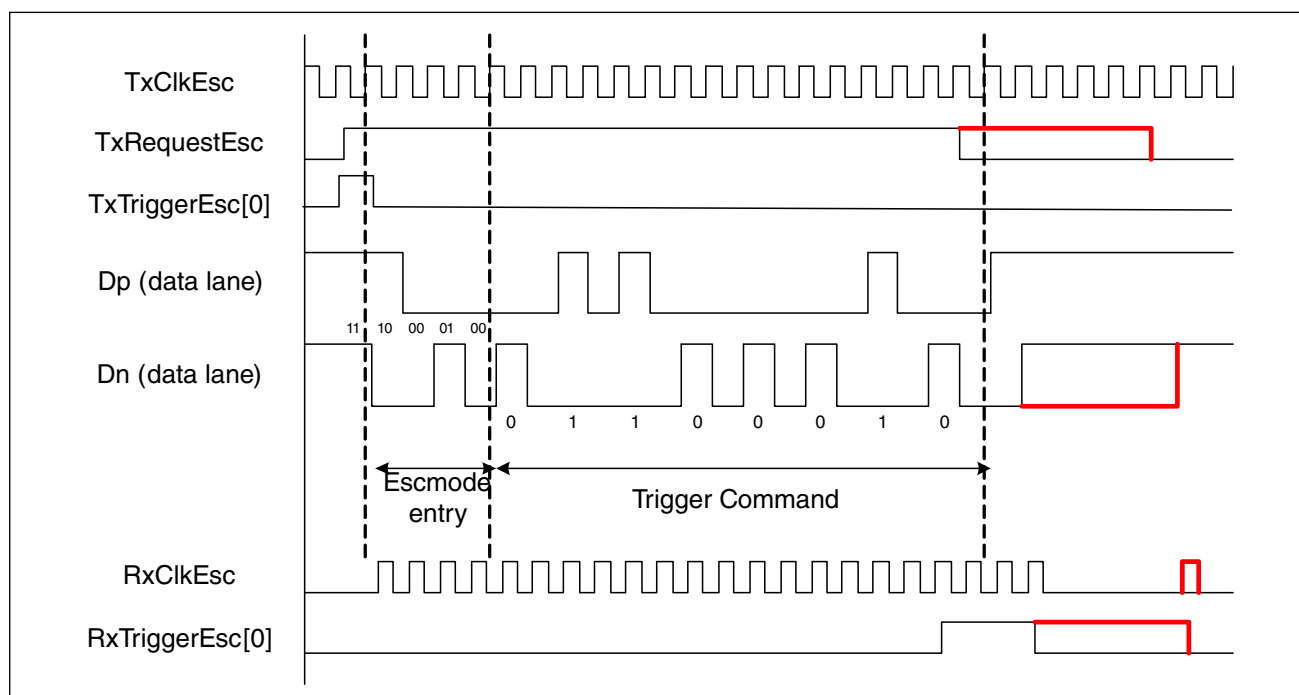

Figure 13-64. Diagram of trigger function "Remote Reset"

There are four types of trigger commands:

- 01100010 : remote reset – forward direction
- 01011101 : Tearing Effect – reverse direction
- 00100001 : Acknowledge – reverse direction
- 10100000 : Unknown

If DSI D-PHY received these signals, D-PHY indicates trigger function to protocol layer.

13.5.3.5.5.6 Turn-around and low power data receiving

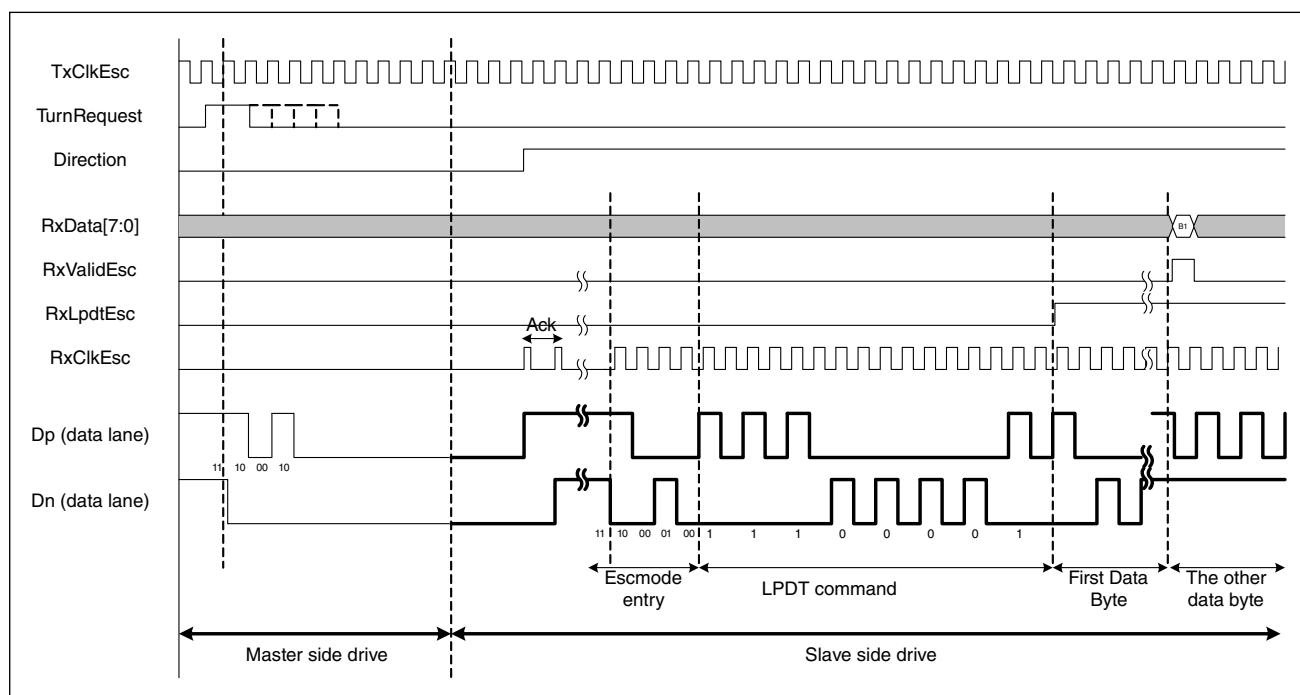

Figure 13-65. Timing diagram of Bus-Turn-Around

13.5.3.5.5.7 TE signaling

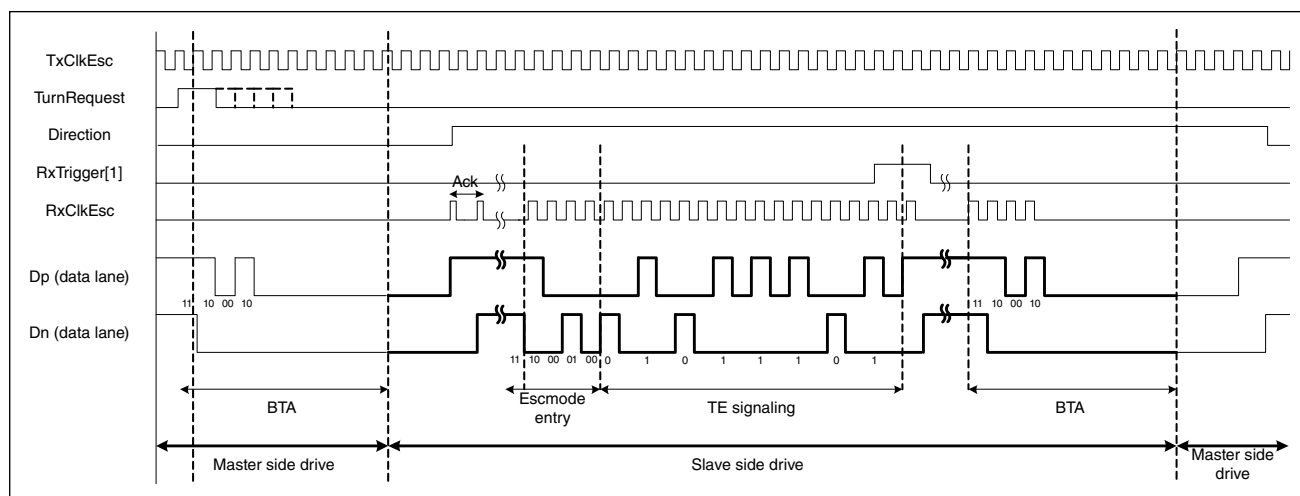

Figure 13-66. TE signaling

13.5.3.6 Configuration

13.5.3.6.1 Video mode VS Command mode

MIPI DSI Master Block supports two modes, namely, Video mode and Command mode. Command mode uses RGB interface and S-i80 interface. Mode can change via SFRs.

13.5.3.6.2 Dual display VS Single display

13.5.3.6.2.1 Dual display

MIPI DSI Master supports dual display configuration in Command mode only, that is, both main and sub display image should be transmitted via S-i80 INTERFACE.

13.5.3.6.2.2 Single display

For single display configuration, use video mode or command mode.

13.5.3.6.2.3 PLL

To transmit Image data, MIPI DSI Master Block needs high frequency clock (80MHz ~ 1GHz) generated by PLL.

To configure PLL, MIPI DSI Master comprises of SFRs and corresponding interface signals. PLL is embedded in PHY module.

13.5.3.6.2.4 Buffer

In MIPI DSI standard specification, DSI Master sends image stream in burst mode. The image stream transmits in high-speed and bit-clock frequency. This mode allows the device to stay in stop state longer to reduce power consumption. For this mode, MIPI DSI Master has a line buffer to store one complete line and send it faster at the next line time.

13.5.4 Application Scenario

13.5.4.1 Display mode

13.5.4.1.1 Video mode

Video mode starting sequence:

1. Set RGB I/F in Display Controller(RGB888), also set Video mode at MIPI DSI Master.
2. Configure all parameters for displaying image (define resolution, back porch, front porch, data lane number, HS clock frequency(byte clock), etc).
3. Start image transmission.

13.5.4.1.2 Command mode

Command mode starting sequence:

1. Set S-i80 I/F in Display Controller (RGB888), also set Command mode at MIPI DSI Master.
2. Configure all parameters for displaying image.
3. Set the command at MIPI DSI registers using MIPI DCS.
4. S-i80 I/F is just used to transmit image data. The users have to read display peripheral status and write command through MIPI DSI registers.

13.5.4.2 Programming Model

Table 13-34. Behavior programming each case

No.	Mode	Case	Pseudo Code
1	Video	Initialize	<pre> 1. reset or power on 2. SFR_Write(Display_Controller_registers, RGB_I/F_888); 3. SFR_Write(DSIM_CLKCNT,{16'h1000,Esc_prescaler}); //EscClk = ByteClk/Esc_prescaler; 4. SFR_Write(DSIM_MDRESOL,{M_vert,M_horizon}); 5. SFR_Write(DSIM_MVPORCH,M_Vback); 6. SFR_Write(DSIM_MHPORCH,{M_Hfront,M_Hback}); 7. SFR_Write(DSIM_MBLANK,{M_SBLLP,M_LBLLP}); 8. SFR_Write(DSIM_MSINC,{M_VSA,M_HSA}); // In SyncEvent mode, Ignore it 9. SFR_Write(DSIM_CONFIG,{HFPdismode, MainVC,MPix, SubVC,SPix,Sync_inform,BLLP,Burst, Videomode(1),NumofDatlane,Lane_EN); // set the value of each bit 10. SFR_Write(DSIM_PLLCTRL, {4'h0, Freq_band,4'h8,PMS}); // PLL enable 11. Wait for 100uS ~ 1mS using system timer after reset or power on. In this time, ForceSTOPstate at DSIM_CONFIG is assigned to D-PHY by default. 100uS ~ 1mS is not mandatory. Please see the DSI slave spec. 12. SFR_Write(DSIM_CONFIG, ForceSTOPstate(0)); // disable 13. while(~SFR_Read(DSIM_STATUS, StopstateClk, StopstateDat)); D-PHY & protocol layer(MIPI DSI Master block) in STOP state </pre>

9	Command	LP Data Transfer	<p>If user wants to send general command to display or transmit image to sub display from memory via LPDT.</p> <p>SFR_Write(DSIM_ESCMODE, TxLpdt);</p> <p>If DSIM transfer data in HS mode, DSIM will wait STOPstate and transfer mode change HS to LP.</p> <p>same as the previous test scenario cases.</p> <p>If user wants to send command to Sub display, User shall set “Sub display Virtual Channel field” in Packet Header(PKTHDR[7:6]).</p>																														
10	Command	ULPS	ULPS sequence is same the initialization process (test scenario #1), 13~20																														
11	Command	Trigger function	The process is as follows:																														

Table continues on the next page...

Table 13-34. Behavior programming each case (continued)

			<p>SFR_Write(DSIM_ESCMODE, TxTriggerRst);</p> <p>If DSI master state is not STOP state, DSIM will wait for LP stop mode and transmit trigger automatically.</p>
12	Command	BTA	<p>There are two cases of BTA. One case is after transferring general read data packet or DCS command write(set_tear_on) and the other one is BTA_req bit setting by software.</p> <p>Previous case is automatically setting BTA.</p> <p>Next case is as follows:</p> <p>If user read the state or data of display panel, user will use BTA.</p> <p>SFR_Write(DSIM_ESCMODE, BTA);</p> <p>If DSIM transfer data, DSIM will wait STOPstate.</p> <p>After BTA assert, DSIM release DSI channel.</p> <p>In reverse direction (DSI slave has DSI channel grant), all DSIM FIFO is flushed and masked Video/SFR inputs. Only LPRX data input is unmasked.</p> <p>If DSIS releases DSI channel to DSIM, "Int_BusTurnOver" is generated. After ISR, DSIM can transfer data.</p>
13	ISR (Error)		<p>SFR_Write(Global_INTC_MASK, INTMASK(DSIM));</p> <p>SFR_Read(Global_INTC_SRC);</p> <p>SFR_Write(DSIM_INTMSK, all_int_mask);</p> <p>SFR_Read(DSIM_INTSRC);</p> <p>Error reporting to application layer</p> <p>SFR_Write(DSIM_INTSRC, intsrc); // clear interrupt source</p> <p>SFR_Write(DSIM_INTMSK, all_int_unmask);</p> <p>SFR_Write(Global_INT_SRC, intsrc); // clear interrupt source</p> <p>SFR_Write(Global_INT_MASK, INTUNMASK(DSIM));</p> <p>SFR_Write(DSIM_CONFIG, ForceSTOPstate(1));</p> <p>enough time later</p> <p>SFR_Write(DSIM_CONFIG, ForceSTOPstate(0));</p>
14	ISR (Rx Data)		<p>After BTA, wait interrupt "Int_BusTurnOver". The process is as follows:</p> <p>SFR_Write(Global_INTC_MASK, INTMASK(DSIM));</p> <p>SFR_Read(Global_INTC_SRC);</p> <p>SFR_Write(DSIM_INTMSK, all_int_mask);</p> <p>SFR_Read(DSIM_INTSRC);</p> <p>SFR_Write(DSIM_INTSRC, {BusTurnOver,RxDone}); // clear interrupt source</p> <p>SFR_Write(DSIM_INTMSK, all_int_unmask);</p> <p>SFR_Write(Global_INT_SRC, intsrc); // clear interrupt source</p> <p>SFR_Write(Global_INT_MASK, INTUNMASK(DSIM));</p> <p>SFR_Read(DSIM_RXFIFO);</p>
15	ISR (trigger flag)		<p>After BTA, wait interrupt "Int_BusTurnOver". The process is as follows:</p> <p>SFR_Write(Global_INTC_MASK, INTMASK(DSIM));</p> <p>SFR_Read(Global_INTC_SRC);</p>

Table continues on the next page...

Table 13-34. Behavior programming each case (continued)

			SFR_Write(DSIM_INTMSK, all_int_mask); SFR_Read(DSIM_INTSRC); flag reporting to application layer SFR_Write(DSIM_INTSRC, {BusTurnOver, trigflags}); // clear interrupt source SFR_Write(DSIM_INTMSK, all_int_unmask); SFR_Write(Global_INT_SRC, intsrc); // clear interrupt source SFR_Write(Global_INT_MASK, INTUNMASK(DSIM));
16	Software reset	Function reset	If you want to assert Software reset, all clocks must be turned on because software reset is a synchronous reset. Turn on RGB_VCLK only from Display controller SFR_Write(DSIM_PLLTMR, PllTimer); SFR_Write(DSIM_CLKCTRL, {EscClkEn, EscPrescaler}); SFR_Write(DSIM_PLLCTRL, {PllEn,PMS}); wait Pll stable (polling status register or ISR) SFR_Write(DSIM_SWRST, FuncRst); wait for software reset release (polling status register or ISR) ready for operation
		Software reset	If you want to assert Software reset, all clocks must be turned on because software reset is synchronous reset. Turn on RGB_VCLK only from Display controller SFR_Write(DSIM_PLLTMR, PllTimer); SFR_Write(DSIM_CLKCTRL, {EscClkEn, EscPrescaler}); SFR_Write(DSIM_PLLCTRL, {PllEn,PMS}); wait Pll stable (polling status register or ISR) SFR_Write(DSIM_SWRST, SwRst); wait software reset release (polling status register or ISR) re-configure all registers ready for operation
17	Clock source changing from PLL to external clock source		Turn on RGB_VCLK(only clock) from Display controller and STOP data inputting to MIPI DSIM SFR_Write(DSIM_SWRST, FuncRst); or SFR_Write(DSIM_SWRST, SwRst); Turn off any inputs in MIPI DSIM. SFR_Write(DSIM_PLLCTRL, PLL disable); SFR_Write(DSIM_CLKCTRL, ByteClkSel); SFR_Write(DSIM_SWRST, FuncRst); or SFR_Write(DSIM_SWRST, SwRst); reconfiguration Turn on Display controller or input data to MIPI DSIM ready for operation
18	Usage of EoT packet		Video mode after turning on display controller FSM of Display controller I/F of MIPI DSIM generates EoT packet automatically

Table 13-34. Behavior programming each case

when user wants to transfer command packet through HS mode.	<p>Just write command or general packet in SFR FIFO</p> <p>Video mode after turning off/before turning on display controller</p> <p>Write command or general packet in SFR FIFO</p> <p>If user does not want to transfer general or command packet, user should write EoT packet in SFR FIFO.</p> <p>If general or command packets are transferred through LP mode, previous programming step is "don't care".</p>

13.5.5 Register Map

This section includes the MIPI DSI module memory map and detailed descriptions of the registers.

13.5.5.1 MIPI DSI register descriptions

13.5.5.1.1 MIPI_DSI Memory map

MIPI_DSI base address: 32E1_0000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Specifies the DSI version register. (DSI_VERSION)	32	RO	0106_0100h
4h	Specifies the status register. (DSI_STATUS)	32	RO	0010_010Fh
8h	Specifies the RGB FSM status register. (DSI_RGB_STATUS)	32	RO	0000_0001h
Ch	Specifies the software reset register. (DSI_SWRST)	32	RW	0000_0000h
10h	Specifies the clock control register. (DSI_CLKCTRL)	32	RW	0000_FFFFh
14h	Specifies the time out register. (DSI_TIMEOUT)	32	RW	00FF_FFFFh
18h	Specifies the configuration register. (DSI_CONFIG)	32	RW	0200_0000h
1Ch	Specifies the escape mode register. (DSI_ESCMODE)	32	RW	0000_0000h
20h	Specifies the main display image resolution register. (DSI_MDRE SOL)	32	RW	0300_0400h
24h	Specifies the main display Vporch register. (DSI_MVPORCH)	32	RW	F000_0000h
28h	Specifies the main display Hporch register. (DSI_MHPORCH)	32	RW	0000_0000h
2Ch	Specifies the main display Sync Area register. (DSI_MS SYNC)	32	RW	0000_0000h
30h	Specifies the sub display image resolution register. (DSI_SDRESOL)	32	RW	0300_0400h
34h	Specifies the interrupt source register. (DSI_INTSRC)	32	RW	0000_0000h
38h	Specifies the interrupt mask register. (DSI_INTMSK)	32	RW	BB37_FFFFh

Table continues on the next page...

Offset	Register	Width (In bits)	Access	Reset value
3Ch	Specifies the packet header FIFO register. (DSI_PKTHDR)	32	WO	0000_0000h
40h	Specifies the payload FIFO register. (DSI_PAYLOAD)	32	WO	0000_0000h
44h	Specifies the read FIFO register. (DSI_RXFIFO)	32	RO	Table 13-208
48h	Specifies the FIFO threshold level register. (DSI_FIFOTHLTD)	32	RW	0000_01FFh
4Ch	Specifies the FIFO status and control register. (DSI_FIFOCTRL)	32	RW	0155_551Fh
50h	Specifies the FIFO memory AC characteristic register. (DSI_MEMA_CCHR)	32	RW	0000_4040h
78h	Specifies the Multi Packet, Packet Go register. (DSI_MULTI_PKT)	32	RW	0000_0002h
90h	Specifies the 1Gbps D-PHY PLL control register. (DSI_PLLCTRL_1G)	32	RW	0000_0000h
94h	Specifies the PLL control register. (DSI_PLLCTRL)	32	RW	0000_0000h
98h	Specifies the PLL control register 1. (DSI_PLLCTRL1)	32	RW	0000_0000h
9Ch	Specifies the PLL control register 2. (DSI_PLLCTRL2)	32	RW	0000_0000h
A0h	Specifies the PLL timer register. (DSI_PLLTMR)	32	RW	FFFF_FFFFh
A4h	Specifies the D-PHY control register 1. (DSI_PHYCTRL_B1)	32	RW	0000_0000h
A8h	Specifies the D-PHY control register 2. (DSI_PHYCTRL_B2)	32	RW	0000_0000h
ACh	Specifies the D-PHY control register 1. (DSI_PHYCTRL_M1)	32	RW	0000_0000h
B0h	Specifies the D-PHY control register 2. (DSI_PHYCTRL_M2)	32	RW	0000_0000h
B4h	Specifies the D-PHY timing register. (DSI_PHYTIMING)	32	RW	0000_0000h
B8h	Specifies the D-PHY timing register 1. (DSI_PHYTIMING1)	32	RW	0000_0000h
BCh	Specifies the D-PHY timing register 2. (DSI_PHYTIMING2)	32	RW	0000_0000h

13.5.5.1.2 Specifies the DSI version register. (DSI_VERSION)

13.5.5.1.2.1 Offset

Register	Offset
DSI_VERSION	0h

13.5.5.1.2.2 Function

Specifies the DSI version register.

13.5.5.1.2.3 Diagram

13.5.5.1.2.4 Fields

Field	Function
31-0 Version	Specifies the DSI version information

13.5.5.1.3 Specifies the status register. (DSI_STATUS)

13.5.5.1.3.1 Offset

Register	Offset
DSI_STATUS	4h

13.5.5.1.3.2 Function

This register reads and checks internal and interface status. It also checks FSM status, Line buffer status, current image line number, and so on.

13.5.5.1.3.3 Diagram

13.5.5.1.3.4 Fields

Field	Function
31 PIIStable	D-phy pll generates stable byteclk.
30-21 —	Reserved
20 SwRstRIs	Specifies the software reset status. 0 = Reset state 1 = Release state
19-17 —	Reserved
16 Direction	Specifies the data direction indicator. 0 = Forward direction 1 = Backward direction
15-11 —	Reserved
10 TxReadyHsClk	Specifies the HS clock ready at clock lane. 0 = Not ready for transmitting HS data at clock lane 1 = Ready for transmitting HS data at clock lane
9 UlpSclk	Specifies the ULPS indicator at clock lane. 0 = No ULPS in clock lane 1 = ULSP in clock lane

Table continues on the next page...

Field	Function
8 StopstateClk	Specifies the stop state indicator at clock lane. 0 = No stop state in clock lane 1 = Stop state in clock lane
7-4 UlpDat	Specifies the ULPS indicator at data lanes. UlpDat[0]: Data lane 0 UlpDat[1]: Data lane 1 UlpDat[2]: Data lane 2 UlpDat[3]: Data lane 3 0 = No ULPS in each data lane 1 = ULPS in each data lane
3-0 StopstateDat	Specifies the stop state indicator at data lane. StopstateDat[0]: Data lane 0 StopstateDat[1]: Data lane 1 StopstateDat[2]: Data lane 2 StopstateDat[3]: Data lane 3 0 = No stop state in each data lane 1 = Stop state in each data lane

13.5.5.1.4 Specifies the RGB FSM status register. (DSI_RGB_STATUS)

13.5.5.1.4.1 Offset

Register	Offset
DSI_RGB_STATUS	8h

13.5.5.1.4.2 Function

Specifies the RGB FSM status register.

13.5.5.1.4.3 Diagram

13.5.5.1.4.4 Fields

Field	Function
31 CmdMode_InSel	Specifies the command mode input selection 0 = using RGB video interface 1 = using S-i80 interface
30-13 —	Reserved
12-0 RGBstate	Specifies the RGB packetize FSM status. 0x0001 = IDLE 0x0002 = STOP 0x0004 = VSyS 0x0008 = VSE 0x0010 = HSS 0x0020 = HSA 0x0040 = HSE 0x0080 = HBP 0x0100 = RGB 0x0200 = NULL 0x0400 = HFP 0x0800 = EOT 0x1000 = NHOLD

13.5.5.1.5 Specifies the software reset register. (DSI_SWRST)

13.5.5.1.5.1 Offset

Register	Offset
DSI_SWRST	Ch

13.5.5.1.5.2 Function

Specifies the software reset register.

13.5.5.1.5.3 Diagram

13.5.5.1.5.4 Fields

Field	Function
31-17 —	Reserved
16 FuncRst	<p>Specifies the software reset (High active).</p> <p>“Function reset” resets all FF in MIPI DSI (except SFRs: STATUS, RGB_STATUS, SWRST, CLKCTRL, TIMEOUT, CONFIG, ESCMODE¹, MDRESOL, MVPORCH, MHPORCH, MSYNC, INTMSK, SDRESOL, S3D_CTL, P3D_CTL, MIC_CTL, P3D_ON_MIC_OFF_HSA, P3D_OFF_MIC_ON_HSA, P3D_ON_MIC_ON_HSA, P3D_ON_MIC_OFF_HFP, P3D_OFF_MIC_ON_HFP, P3D_ON_MIC_ON_HFP, MULTI_PKT, FIFOTHLD, FIFOCTRL², MEMACCHR, PLLCTRL, PLLTMR, PHYACCHR, and VERINFORM).</p> <p>0 = Standby 1 = Reset</p>
15-1	Reserved

Table continues on the next page...

Field	Function
—	
0 SwRst	Specifies the software reset (High active). “Software reset” resets all FF in MIPI DSI (except some SFRs: STATUS, SWRST, CLKCTRL, PLLCTRL, PLLTMR, PHYTUNE and VERINFORM). 0 = Standby 1 = Reset

1. ForceStopstate, CmdLpdt, TxLpdt
2. nlnitRx, nlnitSfr, nlnitl80, nlnitSub, nlnitMD

13.5.5.1.6 Specifies the clock control register. (DSI_CLKCTRL)

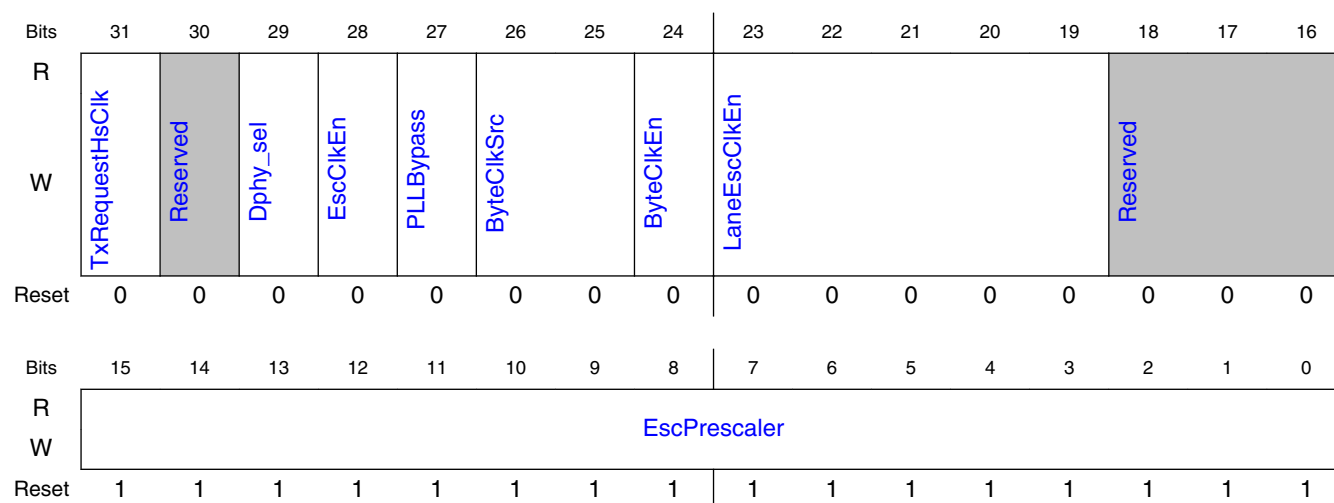

13.5.5.1.6.1 Offset

Register	Offset
DSI_CLKCTRL	10h

13.5.5.1.6.2 Function

Specifies the clock control register.

13.5.5.1.6.3 Diagram

13.5.5.1.6.4 Fields

Field	Function
31 TxRequestHsClk	Specifies the HS clock request for HS transfer at clock lane (Turn on HS clock)
30 —	Reserved
29 Dphy_sel	D-PHY select 0 = 1.5Gbps D-PHY (default) 1 = 1Gbps D-PHY
28 EscClkEn	Enables the escape clock generating prescaler. 0 = Disables 1 = Enables
27 PLLBypass	Sets the PLLBypass signal connected to D-PHY module input for selecting clock source bit. 0 = PLL output 1 = External Serial clock This bit must be set to 0.
26-25 ByteClkSrc	Selects byte clock source. (It must be 2'b00.) 00 = D-PHY PLL (default). PLL_out clock is used to generate ByteClk by dividing 8.
24 ByteClkEn	Enables byte clock. 0 = Disables 1 = Enables
23-19 LaneEscClkEn	Enables escape clock for D-phy lane. LaneEscClkEn[0] = Clock lane LaneEscClkEn[1] = Data lane 0 LaneEscClkEn[2] = Data lane 1 LaneEscClkEn[3] = Data lane 2 LaneEscClkEn[4] = Data lane 3 0 = Disables 1 = Enables
18-16 —	Reserved
15-0 EscPrescaler	Specifies the escape clock prescaler value. The escape clock frequency range varies up to 20MHz. NOTE: The requirement for BTA is that the Host Escclk frequency should range between 66.7 ~ 150% of the peripheral escape clock frequency. $\text{EscClk} = \text{ByteClk} / (\text{EscPrescaler})$

13.5.5.1.7 Specifies the time out register. (DSI_TIMEOUT)

13.5.5.1.7.1 Offset

Register	Offset
DSI_TIMEOUT	14h

13.5.5.1.7.2 Function

Specifies the time out register.

13.5.5.1.7.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved								BtaTout

R	LpdrTout															
W																
Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

13.5.5.1.7.4 Fields

Field	Function
31-24 —	Reserved
23-16 BtaTout	Specifies the timer for BTA. This register specifies time out from BTA request to change the direction with respect to Tx escape clock.
15-0 LpdrTout	Specifies the timer for LP Rx mode timeout. This register specifies time out on how long RxValid deasserts, after RxLpdt asserts with respect to Tx escape clock. RxValid specifies Rx data valid indicator. RxLpdt specifies an indicator that D-phy is under RxLpdt mode. RxValid and RxLpdt specifies signal from D-phy.

13.5.5.1.8 Specifies the configuration register. (DSI_CONFIG)

13.5.5.1.8.1 Offset

Register	Offset
DSI_CONFIG	18h

13.5.5.1.8.2 Function

This register configures MIPI DSI master such as data lane number, input interface, porch area, frame rate, BTA, LPDT, ULPS, and so on.

The figure below shows the timing diagram of the clock lane:

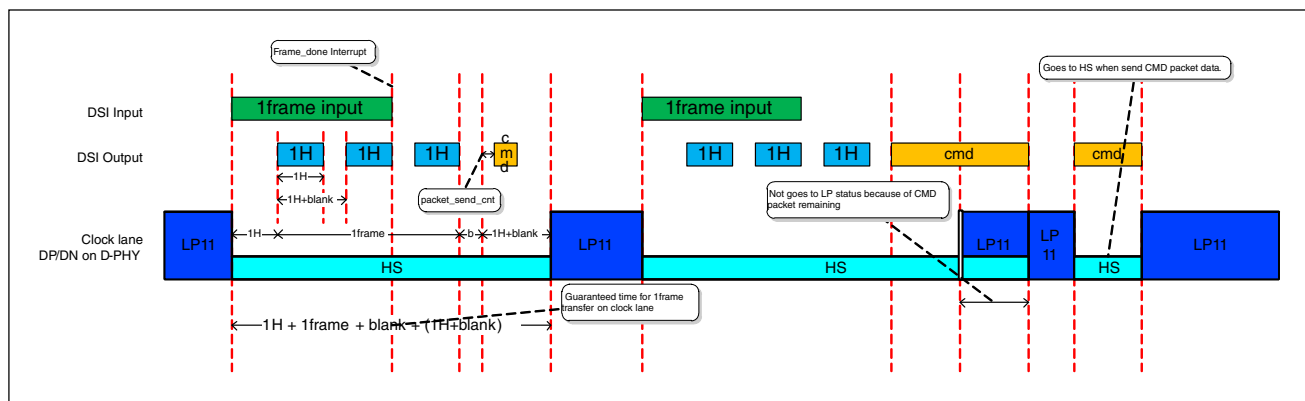

Figure 13-67. Non-continuous clock lane timing diagram

13.5.5.1.8.3 Diagram

13.5.5.1.8.4 Fields

Field	Function
31 Non_Continuous_clock_lane	<p>Non-continuous clock mode.</p> <p>This feature is D-PHY clock lane control DP/DN</p> <p>Please refer to the diagram above to view the clock lane timing diagram.</p> <p>Please refer to the DSI_MULTI_PKT register, which shows the configuration of count values.</p> <p>0 = Disable (default)</p> <p>1 = Enable</p>
30 ClkLane_Stop_Start	<p>PHY clock lane On/Off for ESD.</p> <p>It is operated when first HBP to second HFP in every VSYNC.</p> <p>This feature is not guaranteed on Command mode.</p> <p>0 = Disable (default)</p> <p>1 = Enable</p>
29 Mflush_VS	<p>Auto flush of MD FIFO using Vsync pulse.</p> <p>It needs that Main display FIFO should be flushed for deleting garbage data.</p> <p>0 = Enable (default)</p> <p>1 = Disable</p>

Table continues on the next page...

MIPI DSI Host Controller (MIPI_DSI)

Field	Function
28 EoT_r03	Disables EoT packet in HS mode. 0 = Enables EoT packet generation for V1.01r11 1 = Disables EoT packet generation for V1.01r03
27 SyncInform	Selects Sync Pulse or Event mode in Video mode. 0 = Event mode (non burst, burst) 1 = Pulse mode (non burst only) In command mode, this bit is ignored.
26 BurstMode	Selects Burst mode in Video mode In Non-burst mode, RGB data area is filled with RGB data and Null packets, according to input bandwidth of RGB interface. In Burst mode, RGB data area is filled with RGB data only. 0 = Non-burst mode 1 = Burst mode In command mode, this bit is ignored.
25 VideoMode	Specifies display configuration. 0 = Command mode 1 = Video mode
24 AutoMode	Specifies auto vertical count mode. In Video mode, the vertical line transition uses line counter configured by VSA, VBP, and Vertical resolution. If this bit is set to '1', the line counter does not use VSA and VBP registers. 0 = Configuration mode 1 = Auto mode In command mode, this bit is ignored.
23 HseDisableMode	In Vsync pulse and Vporch area, MIPI DSI master transfers only Hsync start packet to MIPI DSI slave at MIPI DSI spec 1.1r02. This bit transfers Hsync end packet in Vsync pulse and Vporch area (optional). 0 = Disables transfer 1 = Enables transfer In command mode, this bit is ignored.
22 HfpDisableMode	Specifies HFP disable mode. If this bit set, DSI master ignores HFP area in Video mode. 0 = Enables 1 = Disables In command mode, this bit is ignored.
21 HbpDisableMode	Specifies HBP disable mode. If this bit set, DSI master ignores HBP area in Video mode. 0 = Enables 1 = Disables In command mode, this bit is ignored.
20 HsaDisableMode	Specifies HSA disable mode. If this bit set, DSI master ignores HSA area in Video mode. 0 = Enables 1 = Disables In command mode, this bit is ignored.

Table continues on the next page...

Field	Function
19-18 MainVc	Specifies virtual channel number for main display.
17-16 SubVc	Specifies virtual channel number for sub display.
15 —	Reserved
14-12 MainPixelFormat	Specifies pixel stream format for main display. 000 = 3bpp (for Command mode only) 001 = 8bpp (for Command mode only) 010 = 12bpp (for Command mode only) 011 = 16bpp (for Command mode only) 100 = 16-bit RGB (565) (for Video mode only) 101 = 18-bit RGB (666: packed pixel stream) (for Video mode only) 110 = 18-bit RGB (666: loosely packed pixel stream) for Common 111 = 24-bit RGB (888) for common
11 —	Reserved
10-8 SubPixelFormat	Specifies pixel stream format for sub display. 000 = 3bpp (for Command mode only) 001 = 8bpp (for Command mode only) 010 = 12bpp (for Command mode only) 011 = 16bpp (for Command mode only) 100 = 16-bit RGB (565) (for Video mode only) 101 = 18-bit RGB (666: packed pixel stream) for Video mode only 110 = 18-bit RGB (666: loosely packed pixel stream) for common 111 = 24-bit RGB (888) (for Common)
7 —	Reserved
6-5 NumOfDatLane	Sets the data lane number. 00 = Data lane 0 (1 data lane) 01 = Data lane 0 ~ 1 (2 data lanes) 10 = Data lane 0 ~ 2 (3 data lanes) 11 = Data lane 0 ~ 3 (4 data lanes)
4-0 LaneEn	Enables the lane. If Lane_EN is disabled, the lane ignores input and drives initial value through output port. 0 = Lane is off. 1 = Lane is on. LaneEn[0] = Clock lane enabler LaneEn[1] = Data lane 0 enabler

MIPI DSI Host Controller (MIPI_DSI)

Field	Function
	LaneEn[2] = Data lane 1 enabler LaneEn[3] = Data lane 2 enabler LaneEn[4] = Data lane 3 enabler

13.5.5.1.9 Specifies the escape mode register. (DSI_ESCMODE)

13.5.5.1.9.1 Offset

Register	Offset
DSI_ESCMODE	1Ch

13.5.5.1.9.2 Function

This register configures MIPI DSI master.

13.5.5.1.9.3 Diagram

13.5.5.1.9.4 Fields

Field	Function
31-21 STOPstate_Cnt	After transmitting read packet or write “set_tear_on” command, BTA requests to D-phy automatically. This counter value specifies the interval value between transmitting read packet (or write “set_tear_on” command) and BTA request. 11'h000 = 2 EscClk 11'h001 = 2 EscClk + 1 EscClk 11'h3FF = 2 EscClk + 1023 EscClk
20 ForceStopstate_	Forces Stopstate for D-PHY.
19-17 —	Reserved
16 ForceBta	Forces Bus Turn Around. 1 = Sends the protocol layer request to D-PHY. MIPI DSI peripheral becomes master after BTA sequence. This bit clears automatically after receiving BTA acknowledge from MIPI DSI peripheral.
15-8 —	Reserved
7 CmdLpdt	Specifies LPDT transfers command in SFR FIFO. 0 = HS Mode 1 = LP Mode
6 TxLpdt	Specifies data transmission in LP mode (all data transfer in LPDT). 0 = HS Mode 1 = LP Mode
5 —	Reserved
4 TxTriggerRst	Specifies remote reset trigger function. After trigger operation, these bits will be cleared automatically.
3 TxUlpsDat	Specifies ULPS request for data lane. Manually clears after ULPS exit.
2 TxUlpsExit	Specifies ULPS exit request for data lane. Manually clears after ULPS exit.
1 TxUlpsClk	Specifies ULPS request for clock lane. Manually clears after ULPS exit.
0 TxUlpsClkExit	Specifies ULPS exit request for clock lane. Manually clears after ULPS exit.

13.5.5.1.10 Specifies the main display image resolution register. (DSI_MDRESOL)

13.5.5.1.10.1 Offset

Register	Offset
DSI_MDRESOL	20h

13.5.5.1.10.2 Function

Specifies the main display image resolution register.

13.5.5.1.10.3 Diagram**13.5.5.1.10.4 Fields**

Field	Function
31 MainStandby	Specifies standby for receiving DISPCON output in Command mode after setting all configuration. 0 = Not ready 1 = Stand by Standby should be set after configuration (resolution, reqtype, pixelform, and so on) is set for command mode. In Video mode, if this bit value is 0, data is not transferred.
30-28 —	Reserved
27-16 MainVResol	Specifies Vertical resolution (1 ~ 2047).
15-12 —	Reserved
11-0 MainHResol	Specifies Horizontal resolution (1 ~ 2047).

13.5.5.1.11 Specifies the main display Vporch register. (DSI_MVPORCH)

13.5.5.1.11.1 Offset

Register	Offset
DSI_MVPORCH	24h

13.5.5.1.11.2 Function

Specifies the main display Vporch register.

NOTE

Transfers command packets after Stable VFP area. Display controller VFP lines should be set based on sum of these values: Stable VFP, command allowing area and command masked area. Please refer to [Transfer general data in video mode](#) for more information

13.5.5.1.11.3 Diagram

13.5.5.1.11.4 Fields

Field	Function
31-28 CmdAllow	Specifies the number of horizontal lines, where command packet transmission is allowed after Stable VFP period. For more information, please see Figure 13-57 .
27 —	Reserved

Table continues on the next page...

Field	Function
26-16 StableVfp	Specifies the number of horizontal lines, where command packet transmission is not allowed after end of active region. For more information, please see Figure 13-57 . NOTE: In Command mode, these bits are ignored.
15-11 —	Reserved
10-0 MainVbp	Specifies vertical back porch width for Video mode (line count). In Command mode, these bits are ignored.

13.5.5.1.12 Specifies the main display Hporch register. (DSI_MHPORCH)

13.5.5.1.12.1 Offset

Register	Offset
DSI_MHPORCH	28h

13.5.5.1.12.2 Function

Specifies the main display Hporch register.

13.5.5.1.12.3 Diagram

13.5.5.1.12.4 Fields

Field	Function
31-16 MainHfp	Specifies the horizontal front porch width for Video mode. HFP is specified using blank packet. These bits specify the word counts for blank packet in HFP. In Command mode, these bits are ignored.
15-0 MainHbp	Specifies the horizontal back porch width for Video mode. HBP is specified using blank packet. These bits specify the word counts for blank packet in HBP. In Command mode, these bits are ignored.

13.5.5.1.13 Specifies the main display Sync Area register. (DSI_MSYNCR)

13.5.5.1.13.1 Offset

Register	Offset
DSI_MSYNCR	2Ch

13.5.5.1.13.2 Function

Specifies the main display Sync Area register.

13.5.5.1.13.3 Diagram

13.5.5.1.13.4 Fields

Field	Function
31-22 MainVsa	Specifies the vertical sync pulse width for Video mode (Line count). In command mode, these bits are ignored.
21-16 —	Reserved
15-0 MainHsa	Specifies the horizontal sync pulse width for Video mode. HSA is specified using blank packet. These bits specify word counts for blank packet in HSA. In command mode, these bits are ignored.

13.5.5.1.14 Specifies the sub display image resolution register. (DSI_SDRESOL)

13.5.5.1.14.1 Offset

Register	Offset
DSI_SDRESOL	30h

13.5.5.1.14.2 Function

Specifies the sub display image resolution register.

13.5.5.1.14.3 Diagram

13.5.5.1.14.4 Fields

Field	Function
31 SubStandby	Specifies standby for receiving DISPCON output in Command mode after setting all configuration. 0 = Not ready 1 = Standby Standby should be set after configuration (resolution, reqtype, pixelform, and so on) is set for command mode. In Video mode, this bit is ignored.
30-27 —	Reserved
26-16 SubVResol	Specifies the Vertical resolution (1 ~ 1024).
15-11	Reserved

Table continues on the next page...

Field	Function
—	
10-0 SubHResol	Specifies the Horizontal resolution (1 ~ 1024).

13.5.5.1.15 Specifies the interrupt source register. (DSI_INTSRC)

13.5.5.1.15.1 Offset

Register	Offset
DSI_INTSRC	34h

13.5.5.1.15.2 Function

This register identifies interrupt sources. Internal block error, data transmit interrupt, inter-layer (D_PHY) error, etc.

The bits are set even if they are masked off by DSI_INTMSK_REG.

Write '1' to clear the Interrupt.

13.5.5.1.15.3 Diagram

13.5.5.1.15.4 Fields

Field	Function
31 PIIStable	Indicates that D-phy PLL is stable.
30 SwRstRelease	Releases the software reset.
29 SFRPLFifoEmpty	Specifies the SFR payload FIFO empty.
28 SFRPHFifoEmpty	Specifies the SFR Packet Header FIFO empty.
27 SyncOverride	Indicates that other DSI command transfer have overridden sync timing.
26 —	Reserved
25 BusTurnOver	Indicates when bus grant turns over from DSI slave to DSI master.
24 FrameDone	Indicates when MIPI DSI transfers the whole image frame. NOTE: If Hsync is not received during two line times, internal timer is timed out and this bit is flagged.
23-22 —	Reserved
21 LpdrTout	Specifies the LP Rx timeout. Please refer to the DSI_TIMEOUT register.
20 TaTout	Turns around Acknowledge Timeout. Please refer to the DSI_TIMEOUT register.
19 —	Reserved
18 RxDatDone	Completes receiving data.
17 RxTE	Receives TE Rx trigger.
16 RxAck	Receives ACK Rx trigger.
15 ErrRxECC	Specifies the ECC multi bit error in LPDR.
14 ErrRxCRC	Specifies the CRC error in LPDR.
13 ErrEsc3	Specifies the escape mode entry error lane 3. For more information, please refer to the standard D-PHY specification.

Table continues on the next page...

Field	Function
12 ErrEsc2	Specifies the escape mode entry error lane 2. For more information, please refer to the standard D-PHY specification.
11 ErrEsc1	Specifies the escape mode entry error lane 1. For more information, please refer to the standard D-PHY specification.
10 ErrEsc0	Specifies the escape mode entry error lane 0. For more information, please refer to the standard D-PHY specification.
9 ErrSync3	Specifies the LPDT sync error lane 3. For more information, please refer to the standard D-PHY specification.
8 ErrSync2	Specifies the LPDT Sync Error lane2. For more information, refer to standard D-PHY specification.
7 ErrSync1	Specifies the LPDT Sync Error lane1. For more information, refer to standard D-PHY specification.
6 ErrSync0	Specifies the LPDT Sync Error lane0. For more information, refer to standard D-PHY specification.
5 ErrControl3	Controls Error lane3. For more information, please refer to the standard D-PHY specification.
4 ErrControl2	Controls Error lane2. For more information, please refer to the standard D-PHY specification.
3 ErrControl1	Controls Error lane1. For more information, please refer to the standard D-PHY specification.
2 ErrControl0	Controls Error lane0. For more information, please refer to the standard D-PHY specification.
1 ErrContentLP0	Specifies the LP0 Contention Error (only lane0, because BTA occurs at lane0 only). For more information, please refer to the standard D-PHY specification.
0 ErrContentLP1	Specifies the LP1 Contention Error (only lane0, because BTA occurs at lane0 only). For more information, please refer to the standard D-PHY specification.

13.5.5.1.16 Specifies the interrupt mask register. (DSI_INTMSK)

13.5.5.1.16.1 Offset

Register	Offset
DSI_INTMSK	38h

13.5.5.1.16.2 Function

This register masks interrupt sources.

13.5.5.1.16.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

13.5.5.1.16.4 Fields

Field	Function
31 MskPllStable	Indicates that D-PHY PLL is stable.
30 MskSwRstRelease	Releases software reset.
29 MskSFRPLFifoEmpty	Empties SFR payload FIFO.
28 MskSFRPHFifoEmpty	Interrupt Mask for SFR packet header FIFO empty
27 MskSyncOverride	Indicates that other DSI command transfer have overridden sync timing.
26 —	Reserved
25 MskBusTurnOver	Indicates when bus grant turns over from DSI slave to DSI master.

Table continues on the next page...

Field	Function
24 MskFrameDone	Indicates when MIPI DSI transfers whole image frame.
23-22 —	Reserved
21 MskLpdrTout	Specifies LP Rx timeout. Please refer to the DSI_TIMEOUT register.
20 MskTaTout	Specifies turnaround acknowledge timeout. Please refer to the DSI_TIMEOUT register.
19 —	Reserved
18 MskRxDatDone	Specifies completion of data receiving.
17 MskRxTE	Specifies receipt of TE Rx trigger.
16 MskRxAck	Specifies receipt of ACK Rx trigger.
15 MskRxECC	Specifies ECC multibit error in LPDR.
14 MskRxCRC	Specifies CRC error in LPDR.
13 MskEsc3	Specifies escape mode entry error in lane3. For more information, please refer to the standard D-PHY specification.
12 MskEsc2	Specifies escape mode entry error in lane2. For more information, please refer to the standard D-PHY specification.
11 MskEsc1	Specifies escape mode entry error in lane1. For more information, please refer to the standard D-PHY specification.
10 MskEsc0	Specifies escape mode entry error in lane0. For more information, please refer to the standard D-PHY specification.
9 MskSync3	Specifies LPDT sync error in lane3. For more information, refer to standard D-PHY specification.
8 MskSync2	Specifies LPDT sync error in lane2. For more information, refer to standard D-PHY specification.
7 MskSync1	Specifies LPDT sync error in lane1. For more information, refer to standard D-PHY specification.
6 MskSync0	Specifies LPDT sync error in lane0. For more information, refer to standard D-PHY specification.
5 MskControl3	Controls error in lane3. For more information, please refer to the standard D-PHY specification.
4	Controls error in lane2. For more information, please refer to the standard D-PHY specification.

Table continues on the next page...

MIPI DSI Host Controller (MIPI_DSI)

Field	Function
MskControl2	
3 MskControl1	Controls error in lane1. For more information, please refer to the standard D-PHY specification.
2 MskControl0	Controls error in lane0. For more information, please refer to the standard D-PHY specification.
1 MskContentLP0	Specifies LP0 contention error. For more information, refer to standard D-PHY specification.
0 MskContentLP1	Specifies LP1 contention error. For more information, refer to standard D-PHY specification.

13.5.5.1.17 Specifies the packet header FIFO register. (DSI_PKTHDR)

13.5.5.1.17.1 Offset

Register	Offset
DSI_PKTHDR	3Ch

13.5.5.1.17.2 Function

This register is the FIFO for packet header to send DSI packets.

13.5.5.1.17.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved								PacketHeader							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R	PacketHeader															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

13.5.5.1.17.4 Fields

Field	Function
31-24	Reserved

Table continues on the next page...

Field	Function
—	
23-0 PacketHeader	Writes the packet header of Tx packet. [7:0] = DI [15:8] = Dat0 (Word Count lower byte for long packet) [23:16] = Dat1 (Word Count upper byte for long packet)

13.5.5.1.18 Specifies the payload FIFO register. (DSI_PAYLOAD)

13.5.5.1.18.1 Offset

Register	Offset
DSI_PAYLOAD	40h

13.5.5.1.18.2 Function

This register specifies the FIFO for payload to send DSI packets.

13.5.5.1.18.3 Diagram

13.5.5.1.18.4 Fields

Field	Function
31-0 Payload	Writes the Payload of Tx packet.

13.5.5.1.19 Specifies the read FIFO register. (DSI_RXFIFO)

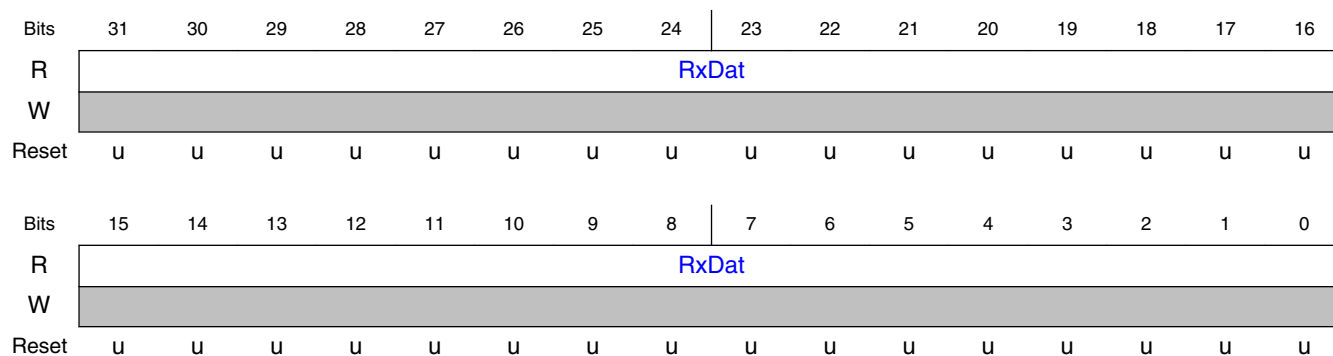

13.5.5.1.19.1 Offset

Register	Offset
DSI_RXFIFO	44h

13.5.5.1.19.2 Function

This register is the gate of FIFO read.

13.5.5.1.19.3 Diagram

13.5.5.1.19.4 Fields

Field	Function
31-0 RxDat	In the Rx mode, you can read Rx data through this register. NOTE: The CRC in packet is not stored in RxFIFO.

13.5.5.1.20 Specifies the FIFO threshold level register. (DSI_FIFOTHLD)

13.5.5.1.20.1 Offset

Register	Offset
DSI_FIFOTHLD	48h

13.5.5.1.20.2 Function

Specifies the FIFO threshold level register.

13.5.5.1.20.3 Diagram

13.5.5.1.20.4 Fields

Field	Function
31-9 —	Reserved
8-0 WfullLevelSfr	Almost full level of SFR payload FIFO

13.5.5.1.21 Specifies the FIFO status and control register. (DSI_FIFO CTRL)

13.5.5.1.21.1 Offset

Register	Offset
DSI_FIFOCtrl	4Ch

13.5.5.1.21.2 Function

Specifies the FIFO status and control register.

13.5.5.1.21.3 Diagram

13.5.5.1.21.4 Fields

Field	Function
31-26 —	Reserved
25 FullRx	Rx FIFO full
24 EmptyRx	Rx FIFO empty
23 FullHSfr	SFR packet header FIFO full
22 EmptyHSfr	SFR packet header FIFO empty
21 FullLSfr	SFR payload FIFO full
20 EmptyLSfr	SFR payload FIFO empty
19 FullHI80	S-i80 packet header FIFO full
18 EmptyHI80	S-i80 packet header FIFO empty
17 FullLI80	S-i80 payload FIFO full

Table continues on the next page...

Field	Function
16 EmptyLI80	S-i80 payload FIFO empty
15 FullHSub	Sub display packet header FIFO full
14 EmptyHSub	Sub display packet header FIFO empty
13 FullLSub	Sub display payload FIFO full
12 EmptyLSub	Sub display payload FIFO empty
11 FullHMain	Main display packet header FIFO full
10 EmptyHMain	Main display packet header FIFO empty
9 FullLMain	Main display payload FIFO full
8 EmptyLMain	Main display payload FIFO empty
7-5 —	Reserved
4 nInitRx	MD FIFO read point initialize
3 nInitSfr	SFR FIFO write point initialize
2 nInitI80	S-i80 FIFO write point initialize
1 nInitSub	SD FIFO write point initialize
0 nInitMain	MD FIFO write point initialize

13.5.5.1.22 Specifies the FIFO memory AC characteristic register. (DSI_MEMACCHR)

13.5.5.1.22.1 Offset

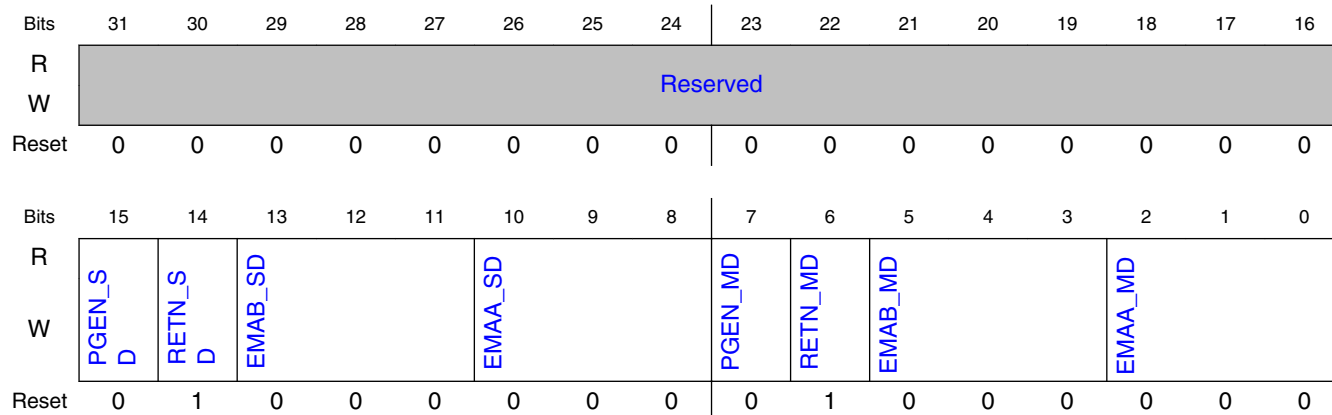

Register	Offset
DSI_MEMACCHR	50h

13.5.5.1.22.2 Function

Specifies the FIFO memory AC characteristic register.

NOTE

In the current design, these memory port controls were disabled. User can ignore the function of this register.

13.5.5.1.22.3 Diagram**13.5.5.1.22.4 Fields**

Field	Function
31-16 —	Reserved
15 PGEN_SD	Sub display FIFO memory power gating
14 RETN_SD	Sub display FIFO memory Retention
13-11 EMAB_SD	Sub display FIFO memory B port margin adjustment
10-8 EMAA_SD	Sub display FIFO memory A port margin adjustment
7 PGEN_MD	Main display FIFO memory power gating
6 RETN_MD	Main display FIFO memory Retention
5-3 EMAB_MD	Main display FIFO memory B port margin adjustment

Table continues on the next page...

Field	Function
2-0 EMAA_MD	Main display FIFO memory A port margin adjustment

13.5.5.1.23 Specifies the Multi Packet, Packet Go register. (DSI_MULTI_PKT)

13.5.5.1.23.1 Offset

Register	Offset
DSI_MULTI_PKT	78h

13.5.5.1.23.2 Function

Specifies the Multi Packet, Packet Go register.

13.5.5.1.23.3 Diagram

13.5.5.1.23.4 Fields

Field	Function
31 —	Reserved
30	Specifies the send multi command packets on single transmission.

Table continues on the next page...

Field	Function
Multi_PKT_EN	Multi command packet can transfer by only HS mode. '0' = Send single command packet. '1' = Send multi command packets.
29 PKT_Go_EN	Specifies the send command packet(s) per frame enable Packet go can transfer by only HS mode. '0' = Send command packet(s) during every VFP. '1' = Send command packet(s) during 1frame VFP.
28 PKT_Go_Rdy	Specifies the send command packet(s) on this frame VFP. If packet transferred or PKT_Go_EN is disabled, this bit goes to 1'b0.
27-16 PKT_Send_Cnt_Ref	Specifies the command packet(s) send point indicator. That value is 1H time + D-PHY LP-HS-LP latency by ByteCLK. Do not use '0'.
15-0 Multi_PKT_Cnt_Ref	Specifies the number of packets on single transmission. Do not use '0' and '1'. 0 and 1 are same as '2'

13.5.5.1.24 Specifies the 1Gbps D-PHY PLL control register. (DSI_PLLCTRL_1G)

13.5.5.1.24.1 Offset

Register	Offset
DSI_PLLCTRL_1G	90h

13.5.5.1.24.2 Function

This register configures 1Gbps D-PHY PLL control, D-PHY, clock range indication, and so on.

13.5.5.1.24.3 Diagram

13.5.5.1.24.4 Fields

Field	Function
31-16 —	Reserved
15-12 HSzeroCtl	1Gbps D-PHY HS-Zero driving timing control.
11-8 Freq_Band	1Gbps D-PHY Timing control for D-PHY global operation timing.
7 —	Reserved
6-4 PREPRCtl	1Gbps D-PHY PLL Tclk-prepare and Ths-prepare driving control.
3 —	Reserved
2-0 PRPRCtlClk	1Gbps D-PHY PLL Ths-prepare driving time control.

13.5.5.1.25 Specifies the PLL control register. (DSI_PLLCTRL)

13.5.5.1.25.1 Offset

Register	Offset
DSI_PLLCTRL	94h

13.5.5.1.25.2 Function

This register configures PLL control, D-PHY, clock range indication, and so on.

13.5.5.1.25.3 Diagram**13.5.5.1.25.4 Fields**

Field	Function
31-26 —	Reserved
25 DpDnSwap_CLK	Swaps Dp/Dn channel of clock lane. If this bit is set, Dp and Dn channel swap each other.
24 DpDnSwap_DAT	Swaps Dp/Dn channel of Data lanes. If this bit is set, Dp and Dn channel swap each other.
23 PIIEn	Enables PLL.
22-20 —	Reserved
19-1 PMS	Specifies the PLL PMS value.
0 —	Reserved

13.5.5.1.26 Specifies the PLL control register 1. (DSI_PLLCTRL1)

13.5.5.1.26.1 Offset

Register	Offset
DSI_PLLCTRL1	98h

13.5.5.1.26.2 Function

This register configures D-PHY PLL control (M_PLLCTL[31:0]).

13.5.5.1.26.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

13.5.5.1.26.4 Fields

Field	Function
31-0 M_PLLCTL0	M_PLLCTL[31:0] to D-PHY

13.5.5.1.27 Specifies the PLL control register 2. (DSI_PLLCTRL2)

13.5.5.1.27.1 Offset

Register	Offset
DSI_PLLCTRL2	9Ch

13.5.5.1.27.2 Function

This register configures D-PHY PLL control (M_PLLCTL[39:32]).

13.5.5.1.27.3 Diagram

13.5.5.1.27.4 Fields

Field	Function
31-8 —	Reserved
7-0 M_PLLCTL1	M_PLLCTL[39:32] to D-PHY

13.5.5.1.28 Specifies the PLL timer register. (DSI_PLLTMR)

13.5.5.1.28.1 Offset

Register	Offset
DSI_PLLTMR	A0h

13.5.5.1.28.2 Function

Specifies the PLL timer register.

13.5.5.1.28.3 Diagram

13.5.5.1.28.4 Fields

Field	Function
31-0	Specifies the PLL Timer for stability of the generated clock (System clock cycle base).
PIITimer	If the timer value goes to 0x00000000, the clock stable bit of status and interrupt register is set.

13.5.5.1.29 Specifies the D-PHY control register 1. (DSI_PHYCTRL_B1)

13.5.5.1.29.1 Offset

Register	Offset
DSI_PHYCTRL_B1	A4h

13.5.5.1.29.2 Function

D-PHY Master and Slave Analog block characteristics control registers (B_DPHYCTL).

13.5.5.1.29.3 Diagram

13.5.5.1.29.4 Fields

Field	Function
31-0 B_DPHYCTL0	B_DPHYCTL[31:0] to D-PHY

13.5.5.1.30 Specifies the D-PHY control register 2. (DSI_PHYCTRL_B2)

13.5.5.1.30.1 Offset

Register	Offset
DSI_PHYCTRL_B2	A8h

13.5.5.1.30.2 Function

D-PHY Master and Slave Analog block characteristics control registers (B_DPHYCTL).

13.5.5.1.30.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

13.5.5.1.30.4 Fields

Field	Function
31-0 B_DPHYCTL1	B_DPHYCTL[63:32] to D-PHY

13.5.5.1.31 Specifies the D-PHY control register 1. (DSI_PHYCTRL_M1)

13.5.5.1.31.1 Offset

Register	Offset
DSI_PHYCTRL_M1	ACh

13.5.5.1.31.2 Function

D-PHY Master Analog block characteristics control registers (M_DPHYCTL).

13.5.5.1.31.3 Diagram

13.5.5.1.31.4 Fields

Field	Function
31-0 M_DPHYCTL0	M_DPHYCTL[31:0] to D-PHY

13.5.5.1.32 Specifies the D-PHY control register 2. (DSI_PHYCTRL_M2)

13.5.5.1.32.1 Offset

Register	Offset
DSI_PHYCTRL_M2	B0h

13.5.5.1.32.2 Function

D-PHY Master Analog block characteristics control registers (M_DPHYCTL).

13.5.5.1.32.3 Diagram

13.5.5.1.32.4 Fields

Field	Function
31-0 M_DPHYCTL1	M_DPHYCTL[63:32] to D-PHY

13.5.5.1.33 Specifies the D-PHY timing register. (DSI_PHYTIMING)

13.5.5.1.33.1 Offset

Register	Offset
DSI_PHYTIMING	B4h

13.5.5.1.33.2 Function

D-PHY Master global operating timing registers.

13.5.5.1.33.3 Diagram

13.5.5.1.33.4 Fields

Field	Function
31-16 —	Reserved
15-8 M_TLPXCTL	M_TLPXCTL[7:0] to D-PHY
7-0 M_THSEXITCTL	M_THSEXITCTL[7:0] to D-PHY

13.5.5.1.34 Specifies the D-PHY timing register 1. (DSI_PHYTIMING1)

13.5.5.1.34.1 Offset

Register	Offset
DSI_PHYTIMING1	B8h

13.5.5.1.34.2 Function

D-PHY Master global operating timing registers.

13.5.5.1.34.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

13.6 MIPI D-PHY (MIPI_DPHY)

13.6.1 Overview

This chapter describes integrating the MIPI D-PHY core into the ASIC or SoC chips and testing the MIPI D-PHY core. The MIPI D-PHY core IP is a flexible, low-cost, and high-speed serial interface that connects a mobile display driver or a camera sensor to a host processor

The MIPI D-PHY has simplified functions for DSI2 Master and CSI Slave.

The functions of the Master Clock Lane of the core are:

- HS-TX

- LP-TX
- CIL-MCEN

The functions of Slave Clock Lane Module of core are:

- HS-RX
- LP-RX
- CIL-SCEN

The functions of Master Data Lane 0 Module of the core are:

- HS-TX
- LP-TX
- LP-RX
- LP-CD
- CIL-MFAA (Bi-directional Escape Mode, Bi-directional LPDT).

The functions of Master Data Lane 1/2/3 Module of core are:

- HS-TX
- LP-TX
- CIL-MFEN (forward ULPS only, no LPDT)

The functions of the Slave Data Lane 0/1/2/3 Module of the core are:

- HS-RX
- LP-RX
- CIL-SFEN (forward ULPS only)

13.6.2 Features

The maximum high-speed clock frequency of MIPI D-PHY core is 1.5 GHz.

The features of MIPI D-PHY are:

- D-PHY spec v1.2 compatible.
- Synchronous link between Master (data source) and Slave (data sink).
- All lanes support high-speed transmission in the forward direction.
- Bi-directional data transmission in Low-Power mode at the Master Data Lane 0 only.
- Uses token passing to control the communication direction of the link.
- High-Speed mode for fast data traffic and Low-Power mode for controls and low-speed data transmission.
- High-Speed mode: Differential and terminated, 200 mV swing: 80 – 1500 Mbps.
- Low-Power mode: Single-ended and non-terminated, 1.2 V swing: 10 Mbps maximum.

NOTE

Use this mode for low-speed asynchronous data communications or controls.

13.6.3 PLL and Clock Lane Connection

The following figure illustrates the PLL and Clock Lane connection.

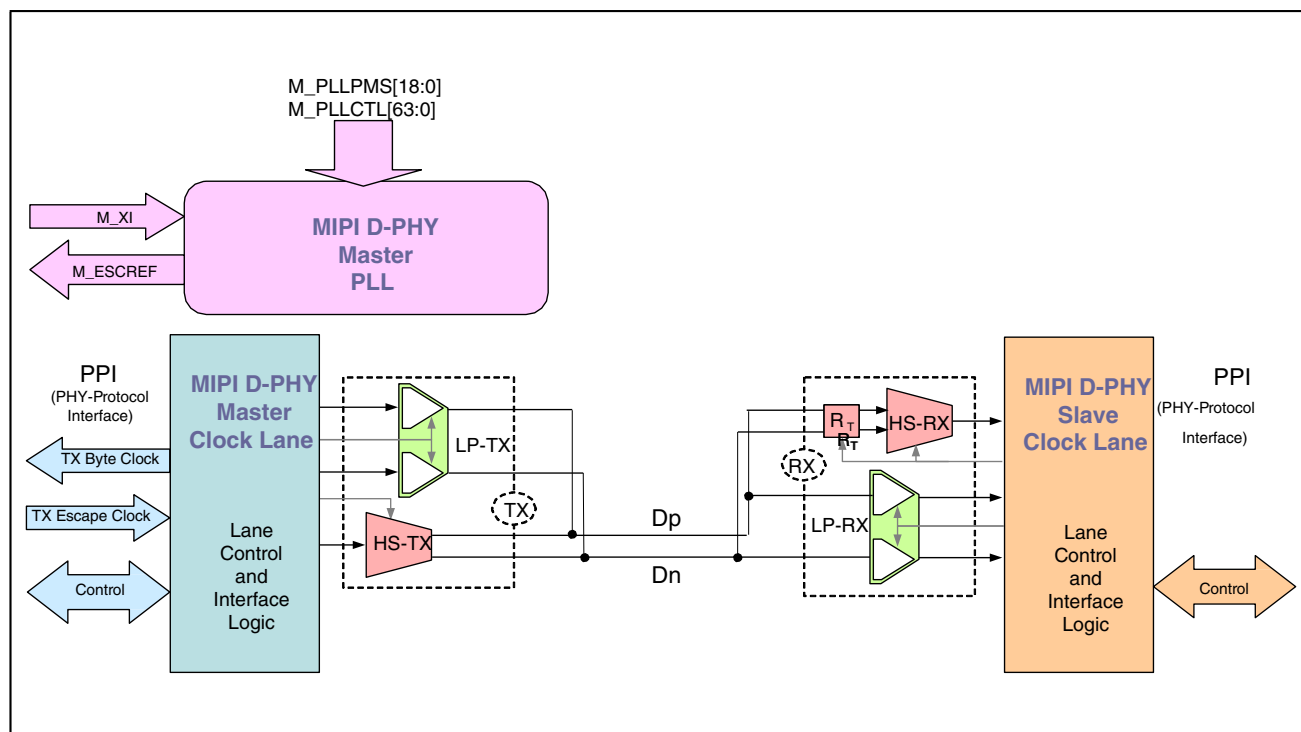

Figure 13-68. PLL and Clock Lane Connection

13.6.4 Data Lane Connection

The following figure illustrates the Data0 Lane connection between Master and the Slave.

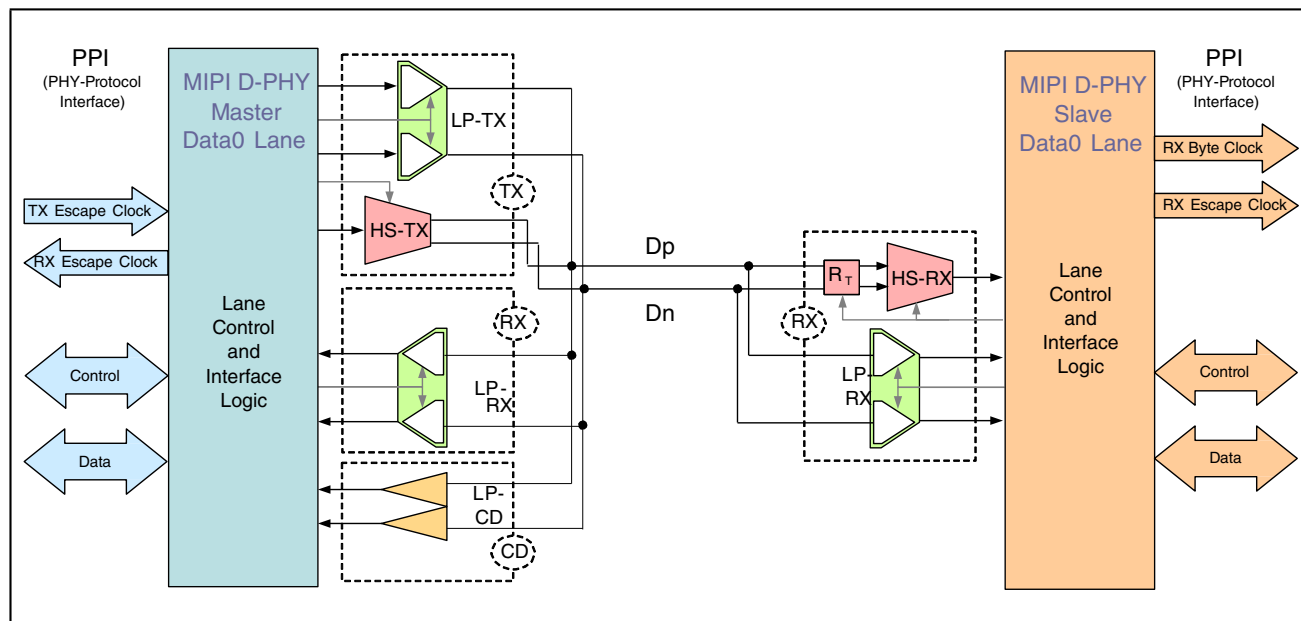

Figure 13-69. Data0 Lane Connection

The following figure illustrates the Data1 Lane connection between Master and the Slave.

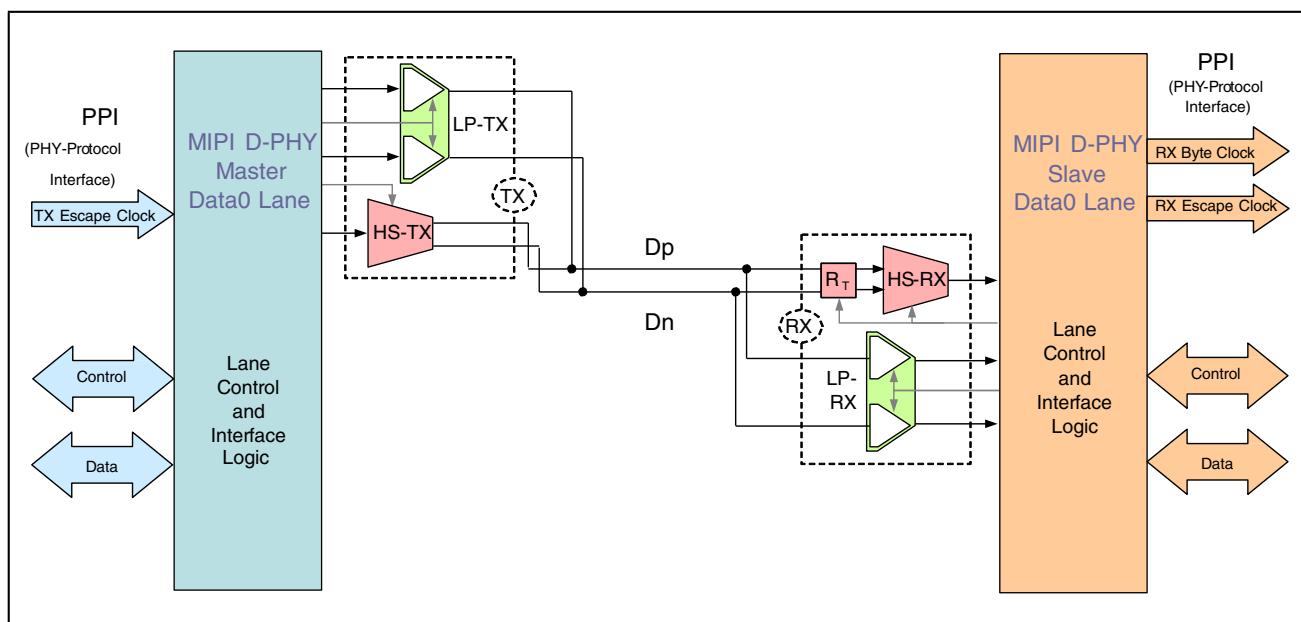

Figure 13-70. Data1 Lane Connection

The following figure illustrates the Data2 Lane connection between Master and the Slave.

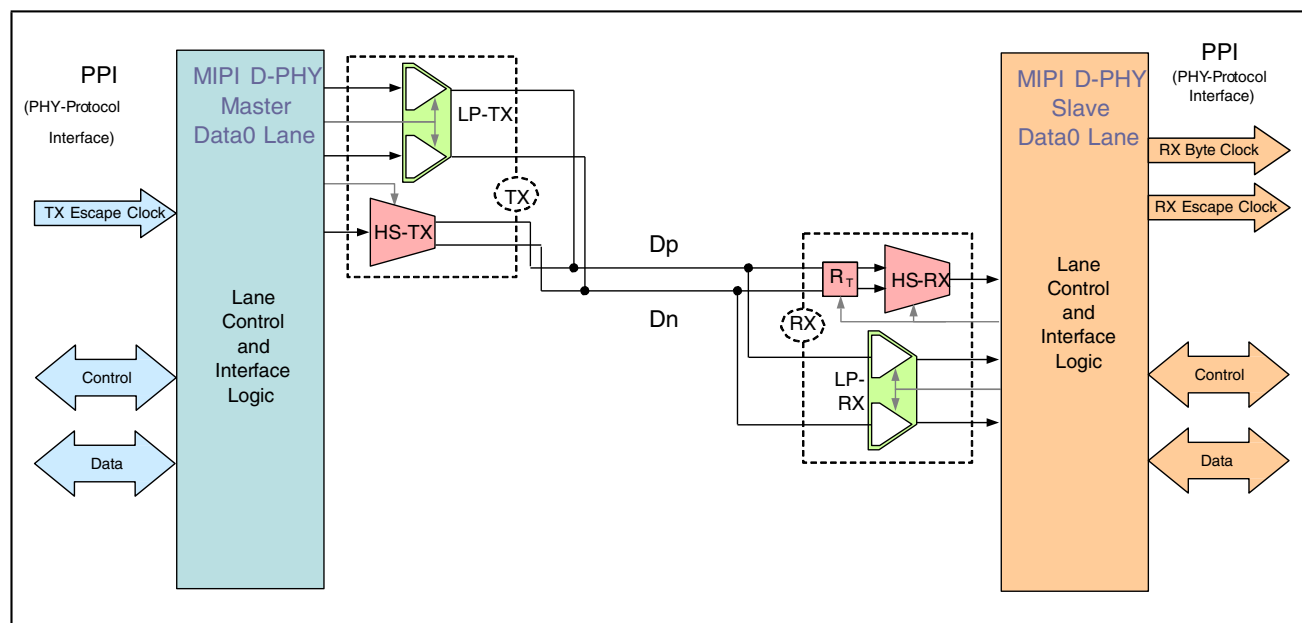

Figure 13-71. Data2 Lane Connection

The following figure illustrates the Data3 Lane connection between Master and the Slave.

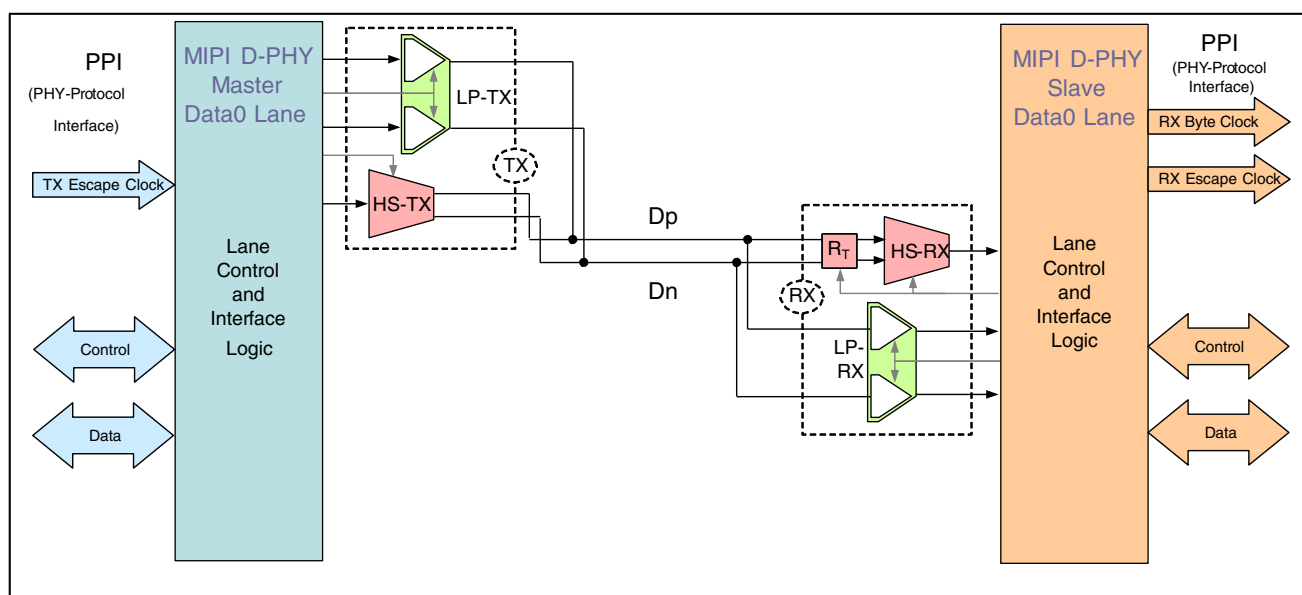

Figure 13-72. Data3 Lane Connection

13.6.5 IP Structure

The MIPI D-PHY core consists of five modules. The modules are:

- Master PLL

- Master Clock lane
- Master Data lane
- Slave Clock lane
- Slave Data lane

NOTE

It is strongly recommended to use the Master and Slave lane as a pair for loop-back test.

The following figure illustrates the IP structure.

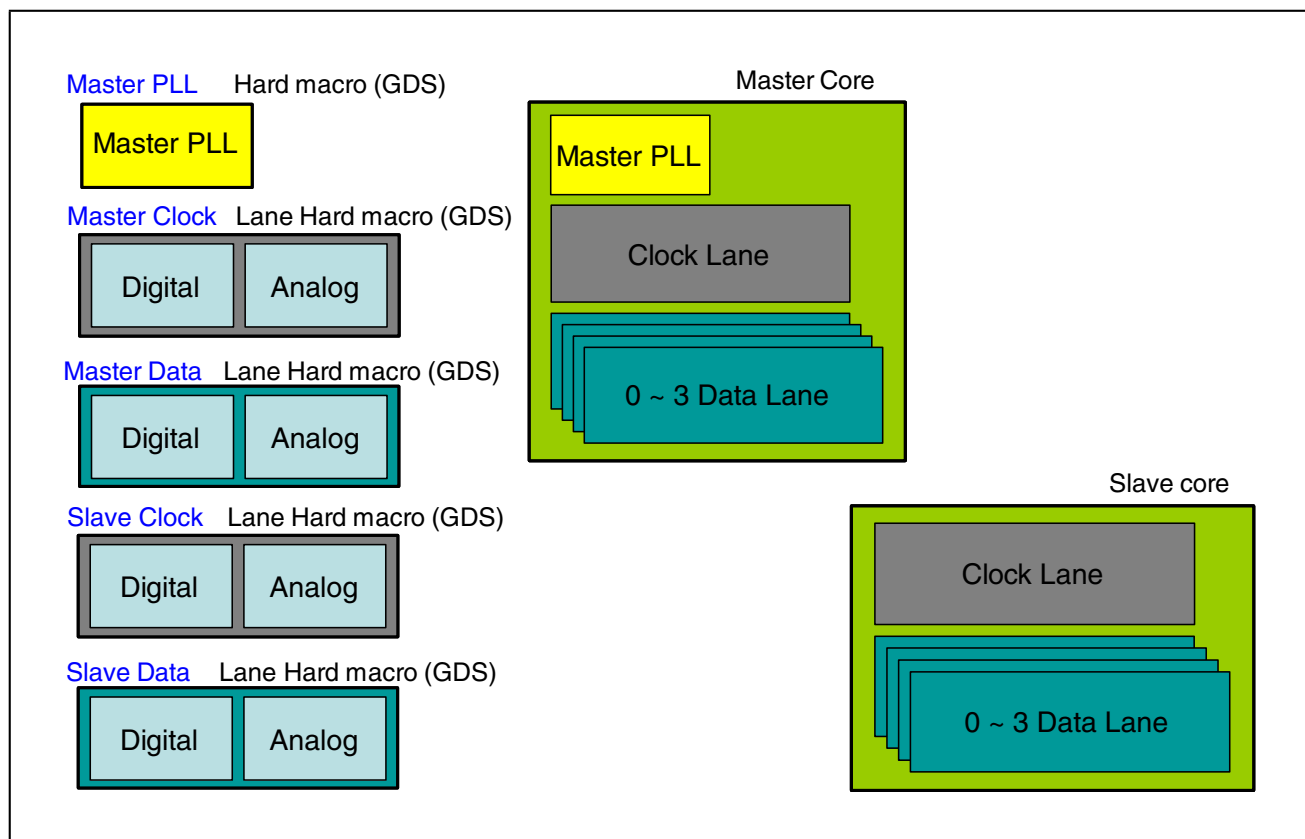

Figure 13-73. IP Structure

13.6.6 D-PHY Architecture

The 4-lane D-PHY architecture including lanes and common block is shown in the following figure.

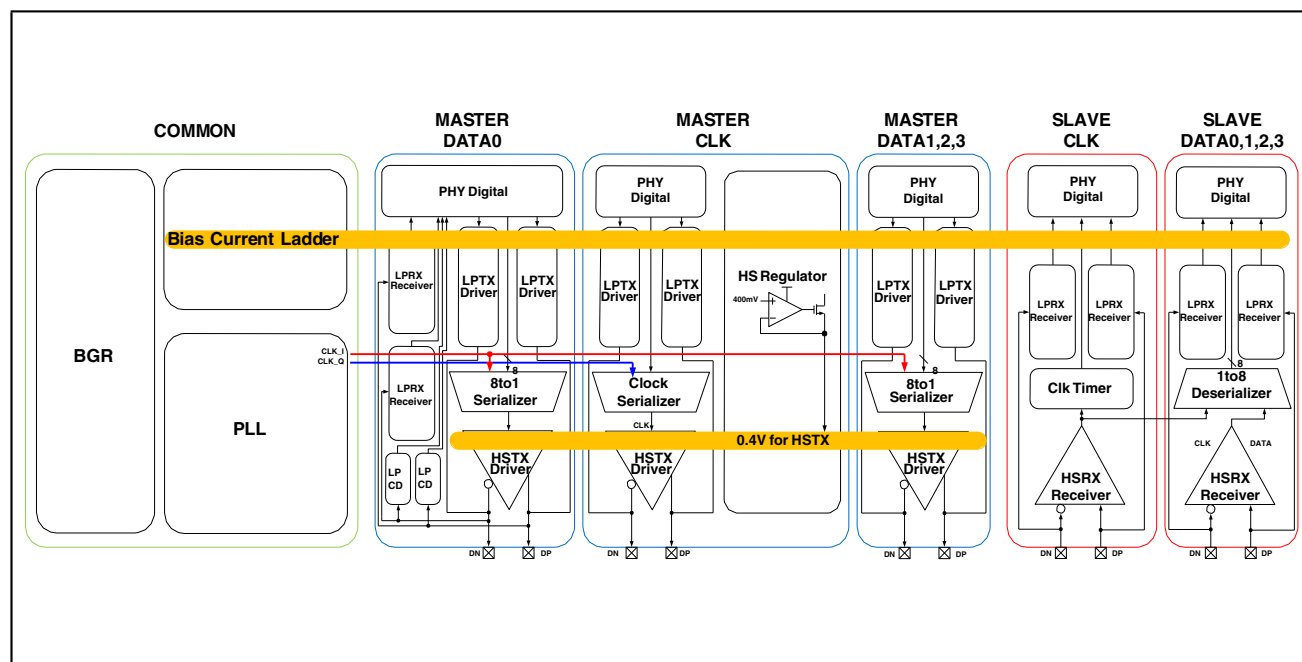

Figure 13-74. D-PHY Architecture

13.6.7 Protocol Support Summary

A summary of supported standards with corresponding data rates is listed in the below table.

Table 13-35. Supported Standards

Standard	Lane	Data Rate
MIPI D-PHY V1.2	4	80Mbps~1500Mbps

13.6.8 IP Interface

MIPI D-PHY configuration contains a Clock Lane Module and 1–4 Data Lane Modules. "0/1/2/3" in signals signify the data lane 0/1/2/3.

13.6.8.1 I/O Diagram

The following figure illustrates the 4-line D-PHY I/O diagram.

Here, [N] means the number of data lanes. The power and the ground pins described with gray box in upper side and the other signal pins described in lower side.

The MIPI D-PHY core includes the I/O pads. I/O pads are dedicated to D-PHY and you cannot share them with any other signals. You can determine the number of power pads and signal pads from the core module configurations.

The following table describes the pad signals.

Table 13-36. Pad Signals

Mode	I/O	Active Level	Description
M_VREG_0P4V	I/O	N/A	Regulator capacitor connection
M_DPCLK	O	N/A	Master CLK Lane DP
M_DNCLK	O	N/A	Master CLK Lane DN
M_DPDATA0	O	N/A	Master DATA0 Lane DP
M_DNDATA0	O	N/A	Master DATA0 Lane DN
M_DPDATA1	O	N/A	Master DATA1 Lane DP
M_DNDATA1	O	N/A	Master DATA1 Lane DN
M_DPDATA2	O	N/A	Master DATA2 Lane DP
M_DNDATA2	O	N/A	Master DATA2 Lane DN
M_DPDATA3	O	N/A	Master DATA3 Lane DP
M_DNDATA3	O	N/A	Master DATA3 Lane DN
S_DPCLK	I	N/A	Slave CLK Lane DP
S_DNCLK	I	N/A	Slave CLK Lane DN
S_DPDATA0	I	N/A	Slave DATA0 Lane DP
S_DNDATA0	I	N/A	Slave DATA0 Lane DN
S_DPDATA1	I	N/A	Slave DATA1 Lane DP
S_DNDATA1	I	N/A	Slave DATA1 Lane DN
S_DPDATA2	I	N/A	Slave DATA2 Lane DP
S_DNDATA2	I	N/A	Slave DATA2 Lane DN
S_DPDATA3	I	N/A	Slave DATA3 Lane DP
S_DNDATA3	I	N/A	Slave DATA3 Lane DN
VDD18_PLL	Supply	N/A	1.8V Power for PLL
DVDD08D_PLL	Supply	N/A	0.9V Power for PLL
MS_VDD_0P8	Supply	N/A	0.9 V Power for Internal Logic
MS_VDD18	Supply	N/A	1.8 V Power for Analog
M_VDD12	Supply	N/A	1.2 V Power for Analog
MS_VSS	GND	N/A	Ground
RTO/SNS/VB0/VB1/V18/V25	I/O	N/A	These signals are I/O pad's ring signals. If you want to get more detail information about these signals, check the datasheet of GPIO.

13.6.8.3 ESD Protection Port

The anti-parallel diode is located between the D-PHY ground and the SoC logic ground for ESD protection.

Table 13-37. ESD Protection Port

Mode	I/O	Active Level	Description
VSS_CDM	Supply	N/A	This port is connected to the SoC logic ground with wide metal. See Figure 21.

13.6.8.4 Master PLL: PHY-Protocol Interface (PPI) Signals

The following table describes the PPI signals of Master PLL.

Table 13-38. Master PLL: PPI Signals

Name	I/O	Active Level	Description
M_XI	I	N/A	PLL reference input clocks. You should shield and route the inputs shortly.
M_PLLPMS[18:0]	I	N/A	80 MHz to 2.1 GHz Frequency Control Signals from the register: PMS setting.
M_PLLCTL[63:0]	I	N/A	PLL control.
M_BITCLKHSDIV4	O	N/A	Used for Protocol Layer multiple Lanes FIFO controls (maximum 525 MHz).
M_PLEN	I	High	Initializes PLL during LOW state and enable when it is HIGH state. NOTE: You must assert to Low state during power-up sequence for a stable initialization.

13.6.8.5 Master Clock Lane: PPI Signals

The following table describes the PPI signals of Master Clock Lane.

Table 13-39. Master Clock Lane: PPI Signals

Name	I/O	Active Level	Description
M_TXBYTECLKHS	O	N/A	To Protocol Layer, PPI clock 10 MHz to 262.5 MHz Periodic Jitter: tM_TXBYTECLKHS*(+/-3%)

Table continues on the next page...

Table 13-39. Master Clock Lane: PPI Signals (continued)

Name	I/O	Active Level	Description
M_TXREQUESTHSCLK	I	High	This signal causes the Clock Lane Module to transmit a high-speed clock (M_TXBYTECLKHS , Level High).
M_TXREADYHSCLK	O	High	High-Speed Transmit Ready on clock Lane (M_TXBYTECLKHS , Level High).
M_TXCLKESCCLK	I	N/A	Escape Mode Clock (≈ 20 MHz). Used for LP mode operations.
M_TXULPCLK	I	High	Transmits Ultra Low-Power mode on clock Lane (M_TXCLKESCCLK, Level High).
M_TXULPSEXITCLK	I	High	Transmits the ULP Exit Sequence (M_TXCLKESCCLK , Level High).
M_ULPSACTIVENOTCLK	O	Low	Ultra Low Power State (not) Active (M_TXCLKESCCLK , Level Low).
M_STOPSTATECLK	O	High	Lane is in the Stop state (asynchronous, Level High).
M_ENABLECLK	I	High	Enables the Clock Lane Module (asynchronous, Level High). NOTE: You must assert to Low state during power-up sequence for a stable initialization.
M_TXSKEWCALHS	I	High	This signal causes the Master Module to begin the Skew-Calibration Mode (M_TXBYTECLKHS , Level or Pulse High).

13.6.8.6 Master Data0 Lane: PPI Signals

The following table describes the PPI signals of Master Data0 Lane.

Table 13-40. Master Data0 Lane: PPI Signals

Name	I/O	Active Level	Description
M_TXDATAHS0[7:0]	I	N/A	High-Speed Transmit Data (M_TXBYTECLKHS , captured). Transmits M_TXDATAHS [0 position bit] first.
M_TXREQUESTHS0	I	High	High-Speed Transmit Request and Data Valid (M_TXBYTECLKHS , Level High).
M_TXREADYHS0	O	High	High-Speed Transmit Ready (M_TXBYTECLKHS , Level High).
M_TXCLKESC0	I	N/A	Escape mode Clock (£ 20 MHz).
M_TXREQUESTESC0	I	High	Escape mode Transmit Request (M_TXCLKESC0 , Level High).
M_TXULPSESC0	I	High	Escape mode Transmit Ultra Low Power (M_TXCLKESC0 , Pulse High).
M_TXULPSEXITESC	I	High	Transmits ULP Exit Sequence (M_TXCLKESC0 , Pulse High).
M_TXTRIGGERESC0[3:0]	I	High	Escape mode Transmit Trigger 0-3 (M_TXCLKESC0 , Pulse High only 1-bit).
M_TXLPDTEESC0	I	High	Escape mode Transmit Low Power Data (M_TXCLKESC0 , Pulse High).
M_TXDATAESC0[7:0]	I	High	Escape mode Transmit Data (M_TXCLKESC0 , captured). Transmits M_TXDATAESC [0 position bit] first.
M_TXVALIDESC0	I	High	Escape mode Transmit Data Valid (M_TXCLKESC0 , Pulse High or Level High).
M_TXREADYESC0	O	High	Escape mode Transmit Ready (M_TXCLKESC0 , Pulse High or Level High).
M_RXCLKESC0	O	N/A	Escape mode Receive Clock (This is edge detection clock from both Dp, Dn lines).
M_RXLPDTEESC0	O	High	Escape Low Power Data Receive mode (M_RXCLKESC0 , Level High).

Table continues on the next page...

Table 13-40. Master Data0 Lane: PPI Signals (continued)

Name	I/O	Active Level	Description
M_RXULPSESC0	O	High	Escape Ultra Low Power Receive mode (M_RXCLKESC0 , Level High).
M_RXTRIGGERESC0[3:0]	O	High	Escape Receive Trigger 0–3 (M_RXCLKESC0 , Level High only 1-bit).
M_RXDATAESC0[7:0]	O	High	Escape mode Receive Data (M_RXCLKESC0 , captured) Receives M_RXDATAESC [0] first.
M_RXVALIDESC0	O	High	Escape mode Receive Data Valid (M_RXCLKESC0 , Pulse High).
M_TURNREQUEST0	I	High	Turn Around Request (M_TXCLKESC0 , Level High).
M_DIRECTION0	O	High	Transmit/Receive Direction (M_TXCLKESC0 or M_RXCLKESC0 , Level-Low: Transmit, High: Receive).
M_FORCETXSTOPMODE0	I	High	Force Lane into Transmit mode Generate Stop state (asynchronous, Level High).
M_ULPSACTIVENOT0	O	Low	Ultra Low Power State (not) Active (M_TXCLKESC0 or M_RXCLKESC0 , Level Low).
M_STOPSTATE0	O	High	Data Lane is in Stop state (asynchronous, Level High).
M_ENABLE0	I	High	Enable Data Lane Module (Asynchronous, Level High). NOTE: You must assert to Low state during power-up sequence for a stable initialization.
M_ERR0ESC	O	High	Escape Entry Error (M_RXCLKESC0 , Level High).
M_ERR0SYNCESC	O	High	Low Power Data Transmission Synchronization Error (M_RXCLKESC0 , Pulse High).
M_ERR0CONTROL	O	High	Control Error (M_RXCLKESC0 , Pulse High).
M_ERR0CONTENTIONLP0	O	High	LP0 Contention Error (M_TXCLKESC0 , Pulse High or Level High).

Table continues on the next page...

Table 13-40. Master Data0 Lane: PPI Signals (continued)

Name	I/O	Active Level	Description
M_ERR0CONTENTIONLP1	O	High	LP1 Contention Error (M_TXCLKESC0 , Pulse High or Level High).

13.6.8.7 Master Data1 Lane: PPI Signals

The following table describes the PPI signals of Master Data1 Lane.

Table 13-41. Master Data1 Lane: PPI Signals

Name	I/O	Active Level	Description
M_TXDATAHS1[7:0]	I	N/A	High-Speed Transmit Data (M_TXBYTECLKHS , captured). Transmits M_TXDATAHS [0 position bit] first.
M_TXREQUESTHS1	I	High	High-Speed Transmit Request and Data Valid (M_TXBYTECLKHS , Level High).
M_TXREADYHS1	O	High	High-Speed Transmit Ready (M_TXBYTECLKHS , Level High).
M_TXCLKESC1	I	N/A	Escape mode Clock (£ 20 MHz).
M_TXREQUESTESC1	I	High	Escape mode Transmit Request (M_TXCLKESC1 , Level High).
M_TXULPSESC1	I	High	Escape mode Transmit Ultra Low Power (M_TXCLKESC1, Pulse High).
M_TXULPSEXITESC1	I	High	Transmit ULP Exit Sequence (M_TXCLKESC1 , Pulse High).
M_FORCETXSTOPMODE1	I	High	Force Lane into Transmit mode. Generates the Stop state (asynchronous, Level High).
M_ULPSACTIVENOT1	O	Low	Ultra Low Power State is (not) Active (M_TXCLKESC1 , Level Low).
M_STOPSTATE1	O	High	Data Lane is in the Stop state (asynchronous, Level High).
M_ENABLE1	I	High	Enables Data Lane Module (Asynchronous, Level High). NOTE: You should assert to

Table 13-41. Master Data1 Lane: PPI Signals

Name	I/O	Active Level	Description
			Low state during power-up sequence for stable initialization.

13.6.8.8 Master Data2 Lane: PPI Signals

The following table describes the PPI signals of Master Data2 Lane.

Table 13-42. Master Data2 Lane: PPI Signals

Name	I/O	Active Level	Description
M_TXDATAHS2[7:0]	I	N/A	High-Speed Transmit Data (M_TXBYTECLKHS , captured). Transmits M_TXDATAHS [0 position bit] first.
M_TXREQUESTHS2	I	High	High-Speed Transmit Request and Data Valid (M_TXBYTECLKHS , Level High).
M_TXREADYHS2	O	High	High-Speed Transmit Ready (M_TXBYTECLKHS , Level High).
M_TXCLKESC2	I	N/A	Escape mode Clock (£ 20 MHz).
M_TXREQUESTESC2	I	High	Escape mode Transmit Request (M_TXCLKESC2 , Level High).
M_TXULPSESC2	I	High	Escape mode Transmit Ultra Low Power (M_TXCLKESC2, Pulse High).
M_TXULPSEXITESC2	I	High	Transmits the ULP Exit Sequence (M_TXCLKESC2 , Pulse High).
M_FORCETXSTOPMODE2	I	High	Forces the Lane into the Transmit mode. Generates the Stop state (asynchronous, Level High).
M_ULPSACTIVENOT2	O	Low	Ultra Low Power State (not) Active (M_TXCLKESC2 , Level Low).
M_STOPSTATE2	O	High	Data Lane is in the Stop state (asynchronous, Level High).
M_ENABLE2	I	High	Enables the Data Lane Module (asynchronous, Level High). NOTE: You must

Table 13-42. Master Data2 Lane: PPI Signals

Name	I/O	Active Level	Description
			assert to Low state during power-up sequence for stable initialization.

13.6.8.9 Master Data3 Lane: PPI Signals

The following table describes the PPI signals of Master Data3 Lane.

Table 13-43. Master Data3 Lane: PPI Signals

Name	I/O	Active Level	Description
M_TXDATAHS3[7:0]	I	N/A	High-Speed Transmit Data (M_TXBYTECLKHS , captured). Transmits M_TXDATAHS [0 position bit] first.
M_TXREQUESTHS3	I	High	High-Speed Transmit Request and Data Valid (M_TXBYTECLKHS , Level High).
M_TXREADYHS3	O	High	High-Speed Transmit Ready (M_TXBYTECLKHS , Level High).
M_TXCLKESC3	I	N/A	Escape mode Clock (£ 20 MHz).
M_TXREQUESTESC3	I	High	Escape mode Transmit Request (M_TXCLKESC3 , Level High).
M_TXULPSESC3	I	High	Escape mode Transmit Ultra Low Power (M_TXCLKESC3 , Pulse High).
M_TXULPSEXITESC3	I	High	Transmits the ULP Exit Sequence (M_TXCLKESC3 , Pulse High).
M_FORCETXSTOPMODE3	I	High	Force Lane into Transmit mode Generate Stop state (asynchronous, Level High).
M_ULPSACTIVENOT3	O	Low	Ultra Low Power State (not) Active (M_TXCLKESC3 , Level Low).
M_STOPSTATE3	O	High	Data Lane is in the Stop state (asynchronous, Level High).
M_ENABLE3	I	High	Enable Data Lane Module (a synchronous, Level High) NOTE: You must assert to Low state during power-up sequence for a stable initialization.

13.6.8.10 Slave Clock Lane: PPI Signals

The following table describes the PPI signals of Slave Clock Lane.

Table 13-44. Slave Clock Lane: PPI Signals

Name	I/O	Active Level	Description
S_RXCLKACTIVEHSCLK	O	High	Receiver Clock Active (asynchronous, Level High).
S_RXULPSCLKNOT	O	Low	Receive Ultra Low-Power State on Clock Lane (asynchronous, Level Low).
S_ULPSACTIVENOTCLK	O	Low	Ultra Low Power State (not) Active (asynchronous, Level Low).
S_STOPSTATECLK	O	High	Lane is in Stop state (asynchronous, Level High).
S_ENABLECLK	I	High	Enables Clock Lane Module (asynchronous, Level High). NOTE: You must assert to Low state during power-up sequence for a stable initialization.

13.6.8.11 Slave Data0 Lane: PPI Signals

The following table describes the PPI signals of Slave Data0 Lane.

Table 13-45. Slave Data0 Lane: PPI Signals

Name	I/O	Active Level	Description
S_RXBYTECLKHS0	O	N/A	"RXDDR/4" Clock. For HS Digital operation and for PPI. 10 MHz to 262.5 MHz Periodic jitter (@D-PHY): $tS_RXBYTECLKHS0 \times \pm 5.5\%$
S_RXDATAHS0[7:0]	O	N/A	High-Speed Receive Data (S_RXBYTECLKHS0 , captured). This matches accurately with M_TXDATAHS[7:0] bits order.
S_RXACTIVEHS0	O	High	High-Speed Receive Active (S_RXBYTECLKHS0 , Level High).

Table continues on the next page...

Table 13-45. Slave Data0 Lane: PPI Signals (continued)

Name	I/O	Active Level	Description
S_RXVALIDHS0	O	High	High-Speed Receive Data including garbage data during HS- RX trail period (S_RXBYTECLKHS0 , Level High).
S_RXCLKESC0	O	N/A	Escape mode Receive Clock (this is edge detection clock from both DP and DN lines).
S_RXULPSESC0	O	High	Escape Ultra Low Power Receive mode (S_RXCLKESC0 , Level High).
S_FORCERXMODE0	I	High	Force Lane into Receive mode/Wait for Stop state (asynchronous, Level High)
S_ULPSACTIVENOT0	O	Low	Ultra Low Power State (not) Active (S_TXCLKESC0 or S_RXCLKESC0 , Level Low).
S_STOPSTATE0	O	High	Data Lane is in Stop state (asynchronous, Level High).
S_ENABLE0	I	High	Enable Data Lane Module (asynchronous, Level High). NOTE: You must assert to Low state during power-up sequence for a stable initialization.
S_ERR0SOTHS	O	High	Start-of-Transmission Error (S_RXBYTECLKHS0 , Pulse High).
S_ERR0ESC	O	High	Escape Entry Error (S_RXCLKESC0 , Level High).
S_ERR0CONTROL	O	High	Control Error (S_RXCLKESC0 , Pulse High).

13.6.8.12 Slave Data1 Lane: PPI Signals

The following table describes the PPI signals of Slave Data1 Lane.

Table 13-46. Slave Data1 Lane: PPI Signals

Name	I/O	Active Level	Description
S_RXBYTECLKHS1	O	N/A	"RXDDR/4" Clock. For HS Digital operation and for PPI. 10 MHz to 262.5 MHz

Table continues on the next page...

Table 13-46. Slave Data1 Lane: PPI Signals (continued)

Name	I/O	Active Level	Description
			Periodic jitter(@D-PHY): tS_RXBYTECLKHS1 * +/-5.5%
S_RXDATAHS1[7:0]	O	N/A	High-Speed Receive Data (S_RXBYTECLKHS1 , captured). It matches accurately with M_TXDATAHS[7:0] bits order.
S_RXACTIVEHS1	O	High	High-Speed Receive Active (S_RXBYTECLKHS1 , Level High).
S_RXVALIDHS1	O	High	High-Speed Receive Data including garbage data during HS- RX trail period (S_RXBYTECLKHS1 , Level High).
S_RXCLKESC1	O	N/A	Escape mode Receive Clock (this is the edge detection clock from both DP and DN lines).
S_RXULPSESC1	O	High	Escape Ultra Low Power Receive mode (S_RXCLKESC1 , Level High).
S_FORCERXMODE1	I	High	Force Lane into Receive mode/Wait for Stop state (asynchronous, Level High).
S_ULPSACTIVENOT1	O	Low	Ultra Low Power State (not) Active (S_TXCLKESC1 or S_RXCLKESC1 , Level Low).
S_STOPSTATE1	O	High	Data Lane is in Stop state (asynchronous, Level High).
S_ENABLE1	I	High	Enable Data Lane Module (asynchronous, Level High) NOTE: You must assert to Low state during power-up sequence for a stable initialization.
S_ERR1SOTHS	O	High	Start-of-Transmission Error (S_RXBYTECLKHS1 , Pulse High).
S_ERR1ESC	O	High	Escape Entry Error (S_RXCLKESC1 , Level High).
S_ERR1CONTROL	O	High	Control Error (S_RXCLKESC1 , Pulse High).

13.6.8.13 Slave Data2 Lane: PPI Signals

The following table describes the PPI signals of Slave Data2 Lane.

Table 13-47. Slave Data2 Lane: PPI Signals

Name	I/O	Active Level	Description
S_RXBYTECLKHS2	O	N/A	"RXDDR/4" Clock. For HS Digital operation and for PPI. 10 MHz to 262.5 MHz Periodic jitter (@D-PHY): $t_{S_RXBYTECLKHS2} * \pm 5.5\%$
S_RXDATAHS2[7:0]	O	N/A	High-Speed Receive Data (S_RXBYTECLKHS2 , captured). It matches accurately with M_TXDATAHS[7:0] bits order.
S_RXACTIVEHS2	O	High	High-Speed Receive Active (S_RXBYTECLKHS2 , Level High).
S_RXVALIDHS2	O	High	High-Speed Receive Data including garbage data during HS- RX trail period (S_RXBYTECLKHS2 , Level High).
S_RXCLKESC2	O	N/A	Escape mode Receive Clock (This is edge detection clock from both DP and DN lines).
S_RXULPSESC2	O	High	Escape Ultra Low Power Receive mode (S_RXCLKESC2 , Level High).
S_FORCERXMODE2	I	High	Force Lane into Receive mode/Wait for Stop state (asynchronous, Level High).
S_ULPSACTIVENOT2	O	Low	Ultra Low Power State (not) Active (S_TXCLKESC2 or S_RXCLKESC2 , Level Low).
S_STOPSTATE2	O	High	Data Lane is in Stop state (asynchronous, Level High).
S_ENABLE2	I	High	Enable Data Lane Module (asynchronous, Level High). NOTE: You should assert to Low state during power-up sequence for stable initialization.
S_ERR2SOTHS	O	High	Start-of-Transmission Error (S_RXBYTECLKHS2 , Pulse High).
S_ERR2ESC	O	High	Escape Entry Error (S_RXCLKESC2 , Level High).

Table continues on the next page...

Table 13-47. Slave Data2 Lane: PPI Signals (continued)

Name	I/O	Active Level	Description
S_ERR2CONTROL	O	High	Control Error (S_RXCLKESC2 , Pulse High).

13.6.8.14 Slave Data3 Lane: PPI Signals

The following table describes the PPI signals of Slave Data3 Lane.

Table 13-48. Slave Data3 Lane: PPI Signals

Name	I/O	Active Level	Description
S_RXBYTECLKHS3	O	N/A	"RXDDR/4" Clock. For HS Digital operation and for PPI. 10 MHz to 262.5 MHz Periodic jitter(@D-PHY): $t_{S_RXBYTECLKHS3} * \pm 5.5\%$
S_RXDATAHS3[7:0]	O	N/A	High-Speed Receive Data (S_RXBYTECLKHS3 , captured). It matches accurately with M_TXDATAHS[7:0] bits order.
S_RXACTIVEHS3	O	High	High-Speed Receive Active (S_RXBYTECLKHS3 , Level High).
S_RXVALIDHS3	O	High	High-Speed Receive Data including garbage data during HS-RX trail period (S_RXBYTECLKHS3 , Level High).
S_RXCLKESC3	O	N/A	Escape mode Receive Clock (This is edge detection clock from both DP and DN lines).
S_RXULPSESC3	O	High	Escape Ultra Low Power Receive mode (S_RXCLKESC3 , Level High).
S_FORCERXMODE3	I	High	Force Lane into Receive mode/Wait for Stop state (asynchronous, Level High).
S_ULPSACTIVENOT3	O	Low	Ultra Low Power State (not) Active (S_TXCLKESC3 or S_RXCLKESC3 , Level Low).
S_STOPSTATE3	O	High	Data Lane is in Stop state (asynchronous, Level High).

Table continues on the next page...

Table 13-48. Slave Data3 Lane: PPI Signals (continued)

Name	I/O	Active Level	Description
S_ENABLE3	I	High	Enable Data Lane Module (asynchronous, Level High). NOTE: You must assert to Low state during power-up sequence for a stable initialization.
S_ERR3SOTHS	O	High	Start-of-Transmission Error (S_RXBYTECLKHS3 , Pulse High).

13.6.8.15 Control Register: PPI Signals

13.6.8.15.1 Timing Control Register of High-Speed Data Transmission

Before High-Speed Data Transmission, you should set these registers. For more information, see register descriptions.

The following table describes the Timing Control Registers of High-Speed Data Transmission.

Table 13-49. Timing Control Registers of High-Speed Data Transmission

Name	I/O	Active Level	Description
M_TCLKPRPRCTL[7:0]	I	N/A	Master Clock Lane Control Register for TCLK-PREPARE.
M_TCLKZEROCTL[7:0]	I	N/A	Master Clock Lane Control Register for TCLK-ZERO.
M_TCLKPOSTCTL[7:0]	I	N/A	Master Clock Lane Control Register for TCLK-POST.
M_TCLKTRAILCTL[7:0]	I	N/A	Master Clock Lane Control Register for TCLK-TRAIL.
M_THSPRPRCTL[7:0]	I	N/A	Master Data Lanes Control Register for THS-PREPARE.

13.6.8.16 PPI Requests and Timing Conditions

13.6.8.16.1 PPI Request Conditions

Following are the request conditions invoked by the D-PHY:

- The Correct request timing window is in the Stop state.
- Accepts only one request from protocol.
- D-PHY selects only one request based on the service priority when you assert two or more requests.

13.6.8.16.2 PPI Requests and D-PHY Timing

HS-TX:

- **Latency** - The minimum required FIFO depth is 128, because the HS-TX requests the HS-TX ready latency.
- **Data Lane** - D-PHY ensures $T_{HS-EXIT}$ (minimum 100 ns) timing.
- **Clock Lane** - D-PHY must guarantee the $T_{CLK-PRE}$ and $T_{CLK-POST}$ timings.

NOTE

The protocol layer need not control these timings.

- **HS-2-HS Request Interval** - Not implied.

LP:

- **LP-2-LP Request** - The LP-2_LP request wait for the 2-ESC CLK.

LP and HS:

- **LP-2-HS Request Interval** - LP-2_HS request interval wait for the 2-ESC CLK in the Stop state.
- **HS-2-LP Request Interval** - Not implied.

13.6.8.16.3 Protocol Watchdog Timers

Following are the features of the Protocol Watchdog Timers:

- **HS RX Timeout** - Protocol specific.
- The Protocol times-out when there is no EoT received within a certain period in the HS RX mode.
- **HS TX Timeout** - Protocol specific.
- The maximum transmission length in HS TX is bounded.
- **Escape Mode Timeout** - Protocol specific.
- The Escape mode timeout should be greater than the Escape mode Silence Limit of the other device.
- **Escape Mode Silence Timeout** - Protocol specific.
- A device has a bound length for LP TX-00 during Escape mode, after which the other device may timeout. For example, a display module must have an Escape Mode Silence Limit, after which the host processor can timeout.
- **Turnaround Errors**
- The Protocol times out initiates appropriate action when there is no acknowledgement observed within a certain period of time.

13.6.8.16.4 Abnormal Conditions

The abnormal conditions are:

- M_FORCETXSTOPMODE
- M_FORCERXMODE
- M (S)_ERRCONTENTIONLP0 and M (S)_ERRCONTENTIONLP1

13.6.8.17 Core Interface Timing Diagrams

13.6.8.17.1 Clock Lane: HS-TX and HS-RX Function

The following figure illustrates the HS-TX and HS-RX function of the Clock Lane.

13.6.8.17.8 Skew Calibration

The following figure illustrates the Skew Calibration sequence.

The protocol should assert the M_TXSKEWCALHS synchronized M_TXBYTECLKHS for start Skew Calibration. PHY-Protocol Interface output signals of the Slave are 1'b0 in the Skew Calibration mode.

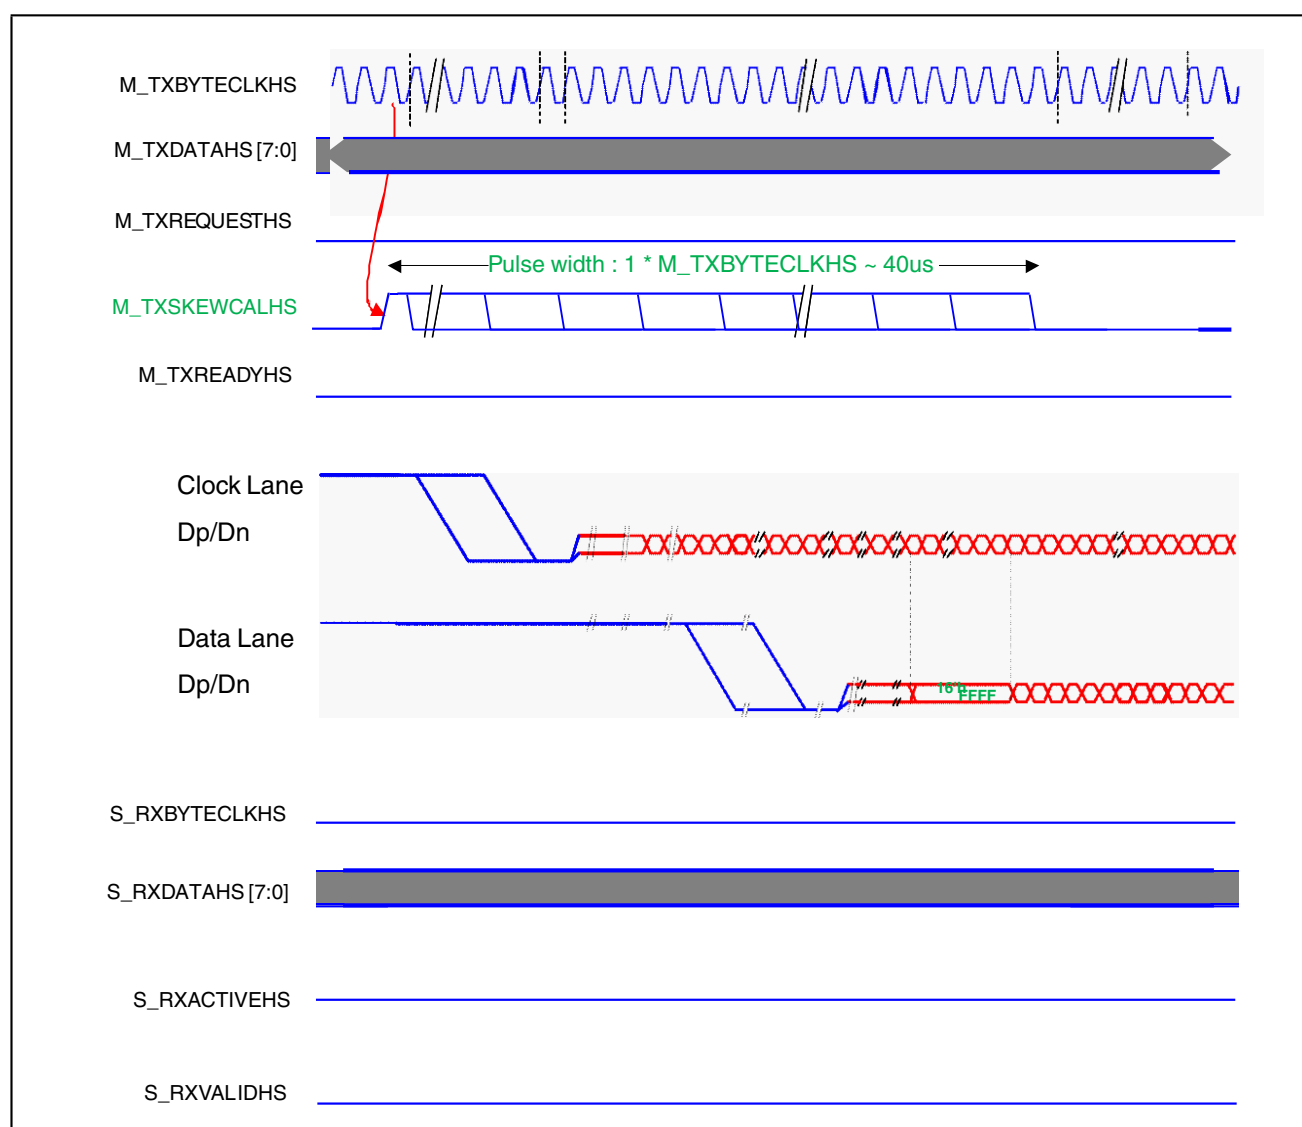

Figure 13-83. Skew Calibration

13.6.8.18 Physical Layer (PHY)

The Samsung D-PHY consists of:

- One Common block
- Master data four lane blocks
- Master clock lane block
- Slave data four lane blocks
- Slave clock lane block

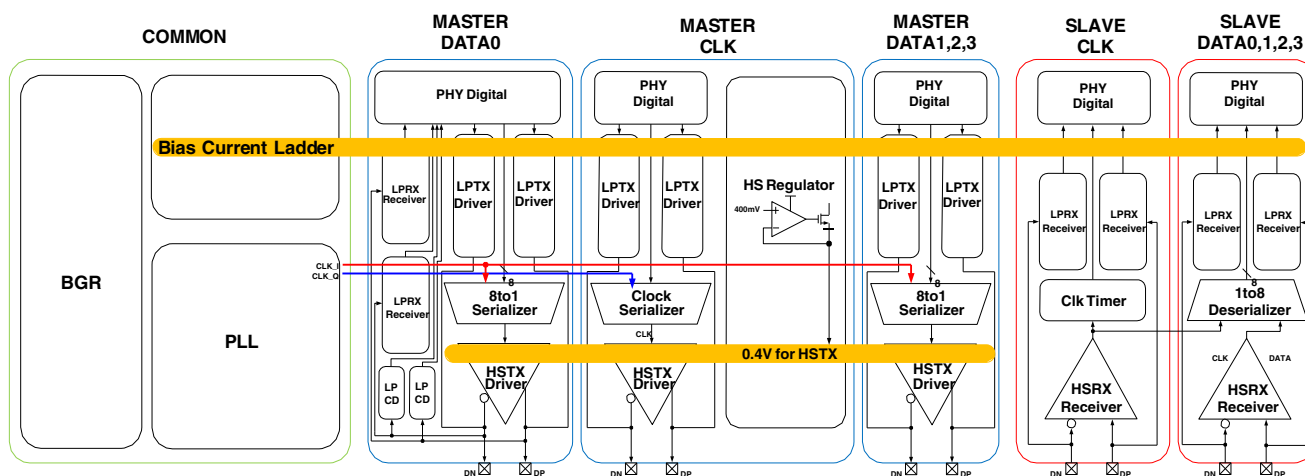

Figure 13-84. Physical Layer

The MIPI D-PHY requires one off-chip 2.2nF capacitor for Master 0.4V regulator. The LANE block consists of serializer, de-serializer, output driver block, LP-TX, and LP-RX block. The data is serialized and transmitted through DP/DN pads by voltage-mode driver. Detail operation and features of each block are described in following sections.

13.6.8.18.1 Common

The Common block consists of a band-gap reference (BGR), bias generator, and PLL. Detailed information on each block is described in the following sections.

13.6.8.18.2 BGR and bias generator

The BGR circuit generates high-accuracy reference voltage of 820mV across PVT variation. A bias generator makes internal-resistor (RMRES)-referred currents, and these currents are distributed to each block in Common and Lanes. The internal resistor-referred current is generated using internally integrated replica resistor to compensate resistance error across PVT variation.

13.6.8.18.3 Phase Locked Loop (PLL)

The PLL in the Common synthesizes high-speed clock, which is used for TX serializer from a reference clock. The nominal reference frequency is 26MHz.

In the PHY, the high frequency clock from PLL is used in the serialization of TX data. The following are the main features of the PLL:

- Supports output frequency from 80MHz to 2.1GHz clock
- Supports pre-defined and programmable divider setting for MIPI D-PHY specification
- Supports spread spectrum clocking (SSC) with sigma-delta modulated fractional divider.

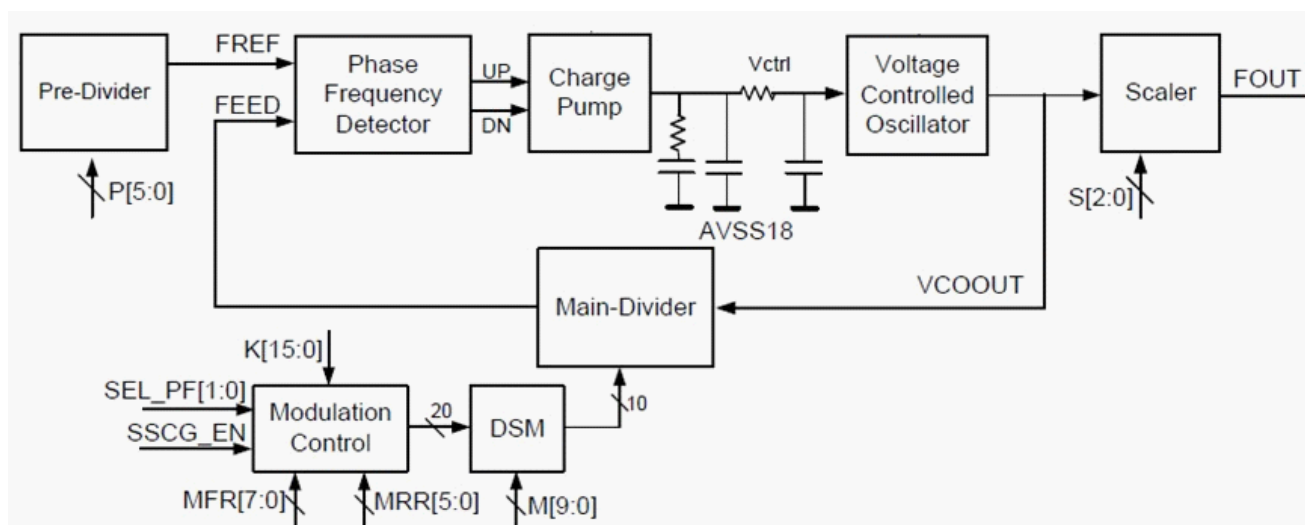

Figure 13-85. Phase Locked Loop (PLL)

13.6.8.18.4 DPHY PLL

The MIPI DSI DPHY PLL is a high performance PLL based frequency synthesizer that incorporates an independent output divider. The PLL block diagram is shown below.

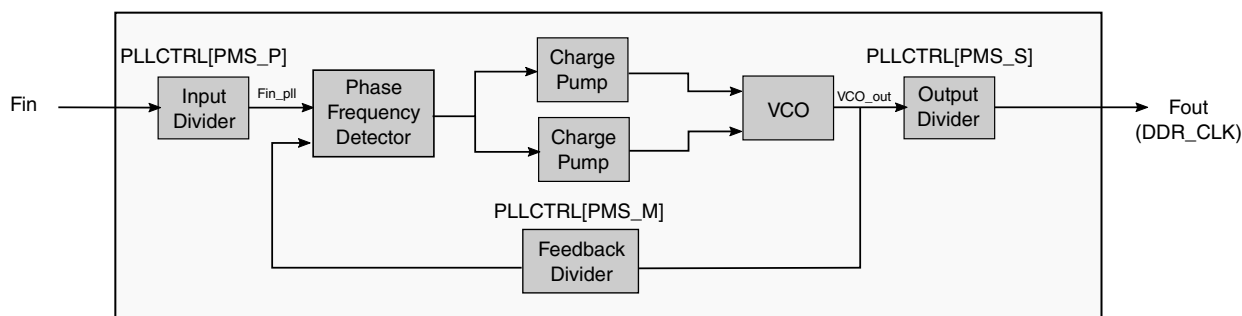

Figure 13-86. MIPI DSI DPHY PLL Block Diagram

The DPHY PLL input clock is F_{in} . The PLL output (F_{out}) multiplies the input frequency (F_{in}) by $(M / (P * 2^S))$.

NOTE

Setting P or M divider values as zero can cause malfunction of the PLL.

NOTE

The P and M divider values must be programmed to maintain VCO stability. The VCO output frequency (VCO_out) range of the MIPI PLL is from 350 MHz to 750 MHz.

Table 13-51. DPHY PLL Parameters

Parameter	Description	Frequency Range (MHz)
Fin	Input Frequency	6-200
Fin_pll	P divider frequency	6-12
VCO_out	$(M \cdot Fin) / P$	350-750
Fout	$(M \cdot Fin) / (P \cdot 2^S)$	37.5-750
P	Input Divider	1-33
M	Feedback Divider	25-125
S	Output Divider (2^S)	1,2,4,8

13.6.8.18.5 Serializer

The serializer accepts 8-bit data from the PHY digital which is synchronized to TX byte clock. The parallel data is converted to the high-speed serial data. Finally, serializer transmits the serial data through the driver.

13.6.8.18.6 HS TX Driver

The driver generates baud-rate voltage waveform on TX output pads. The driver comprises of pre-driver and main-driver. The output data of serializer are delivered to the main-driver via the pre-driver. The main driver is based on voltage-mode driver to achieve a small power consumption and voltage swing.

Figure 13-87. HS TX Driver

13.6.8.18.7 LP TX Driver

In the low power mode, LP TX driver sends the low frequency data under 10Mbps. Generally LP-11 stop state and HS enter sequence (LP-11 \diamond LP-01 \diamond LP-00) are used mostly.

Figure 13-88. LP TX Driver

13.6.8.18.8 De-Serializer

In the BIST (Built-In Self-Test) mode, the serial data from the serializer is fed back to the de-serializer. And in the real mode, the real data from HS-RX receiver is sent to the de-serializer. De-serializer converted serial data to 8-bit parallel data and transferred them into PHY digital circuit for sending data to link or checking bit error at BIST mode.

13.6.8.18.9 HS RX Receiver

The high speed data from the MIPI D-PHY master has the MIPI D-PHY electrical characteristics. HS RX receiver convert it to the TTL CMOS level and send it to de-serializer for making the low parallel data.

13.6.8.18.10 LP RX Receiver

In the low power mode, LP RX receiver make esc clock from LP signal and converts the voltage level from 1.2V level to TTL CMOS logic level. And it sends them to PHY digital for command interpretation. And LP RX receiver always watches the DP/DN signal level. If DP/DN goes to LP-11, PHY recognizes Stop-state, and enters to low power mode.

13.6.9 Unused pin and power integration guide when MIPI IP into chip is not used

13.6.9.1 Unused signal pins

On chip guide:

- The unused input pins should be connected to the ground (incase of the active high operation) or the power (incase of the active low operation).
- The unused output pins should be connected nothing.

Off chip guide:

- The unused input pins (Slave DP/DN, Slave CLKP/CLKN) are tied to ground
- The unused output pins (Master DP/DN, Master CLKP/CLKN) are connected to nothing.
- M_VREG_0P4V pin into the unused Master block are connected to nothing. The external capacitor does not need to be connected.

13.6.9.2 Power into unused block

When the entire MIPI block is unused:

- Power pins are connected to nothing.
- GND pins are tied to ground.

When power is shared, some MIPI block is unused and some MIPI block is used:

- Power pins are tied to power.
- GND pins are tied to ground.

13.6.10 MIPI PHY Memory Map/Register Definition

MIPI_DPHY memory map

13.7 Sony/Philips Digital Interface (SPDIF)

13.7.1 Overview

The Sony/Philips Digital Interface (SPDIF) audio block is a stereo transceiver that allows the processor to receive and transmit digital audio.

The SPDIF transceiver allows the handling of both SPDIF channel status (CS) and User (U) data and includes a frequency measurement block that allows the precise measurement of an incoming sampling frequency.

A recovered clock is provided to drive both internal components in the system, such as ESAI ports, and external components, such as A/Ds or D/As, with clocking control provided via related registers.

As the SPDIF internal data width is 24-bit, the eight most-significant bits of all registers return zeros.

The figure below shows a block diagram of the SPDIF transceiver data paths (receiver and transmitter) and its interface.

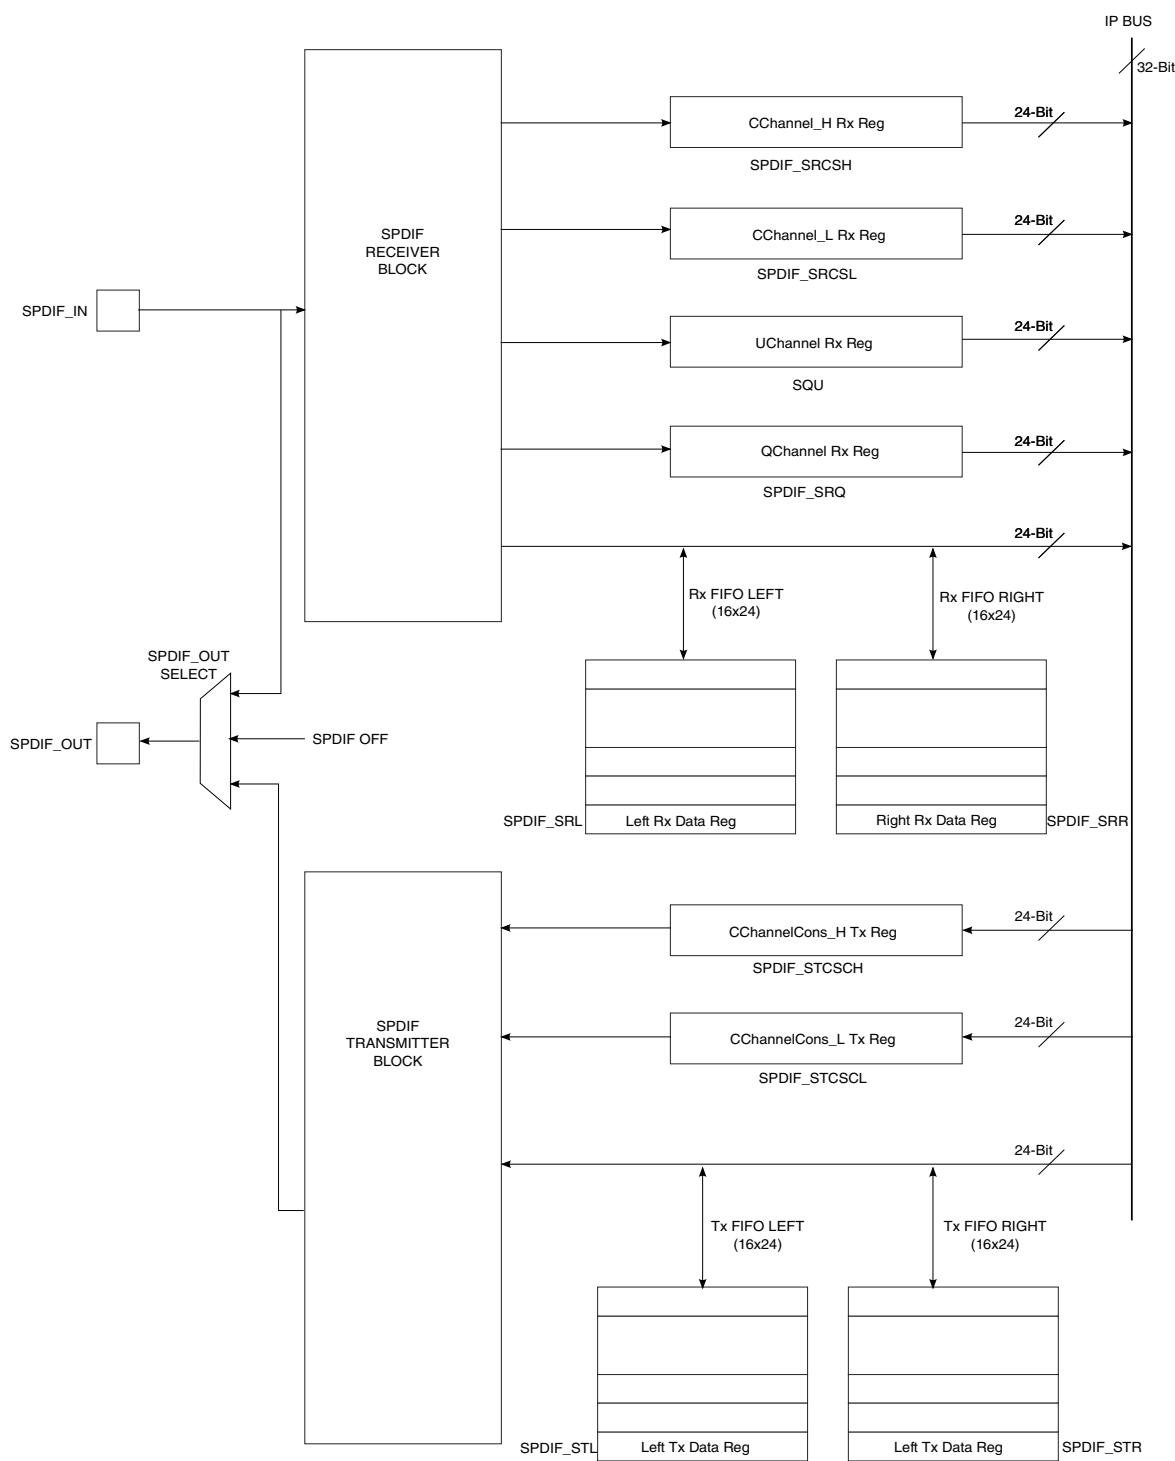

Figure 13-89. SPDIF Transceiver Data Interface Block Diagram

13.7.2 External Signals

The following table describes the external signals of SPDIF:

Table 13-52. SPDIF External Signals

Signal	Description	Direction
SPDIF_EXT_CLK	External clock signal	I
SPDIF_IN	Input line	I
SPDIF_LOCK	Lock signal	O
SPDIF_OUT	Output line signal	O
SPDIF_SR_CLK	SR clock signal	O

13.7.3 Clocks

The table found here describes the clock sources for SPDIF.

Please see clock control block for clock setting, configuration and gating information.

Table 13-53. SPDIF Clocks

Clock name	Description
gclkw_t0	Global clock
ipg_clk_s	Peripheral access clock
tx_clk	Module Tx clock

13.7.4 Functional Description

The SPDIF is composed of two parts: SPDIF Receiver and SPDIF Transmitter.

The SPDIF receiver extracts the audio data from each SPDIF frame and places the data in the SPDIF Rx left and right FIFOs. The Channel Status and User Bits are also extracted from each frame and placed in the corresponding registers. The SPDIF receiver also provides a bypass option for direct transfer of the SPDIF input signal to the SPDIF transmitter.

For the SPDIF transmitter, the audio data is provided by the processor via the SPDIFTxLeft and SPDIFTxRight registers. The Channel Status bits are also provided via the corresponding registers. The SPDIF transmitter generates a SPDIF output bitstream in the biphas mark format (IEC60958), which consists of audio data, channel status and user bits.

In the SPDIF transmitter, the IEC60958 biphas bit stream is generated on both edges of the SPDIF Transmit clock. The SPDIF Transmit clock is generated by the SPDIF internal clock generate block and the sources are from outside of the SPDIF block. For the SPDIF receiver, it can recover the SPDIF Rx clock.

The Rx clock is sent to the ASRC.

Figure 13-90 shows the clock structure of the SPDIF transceiver.

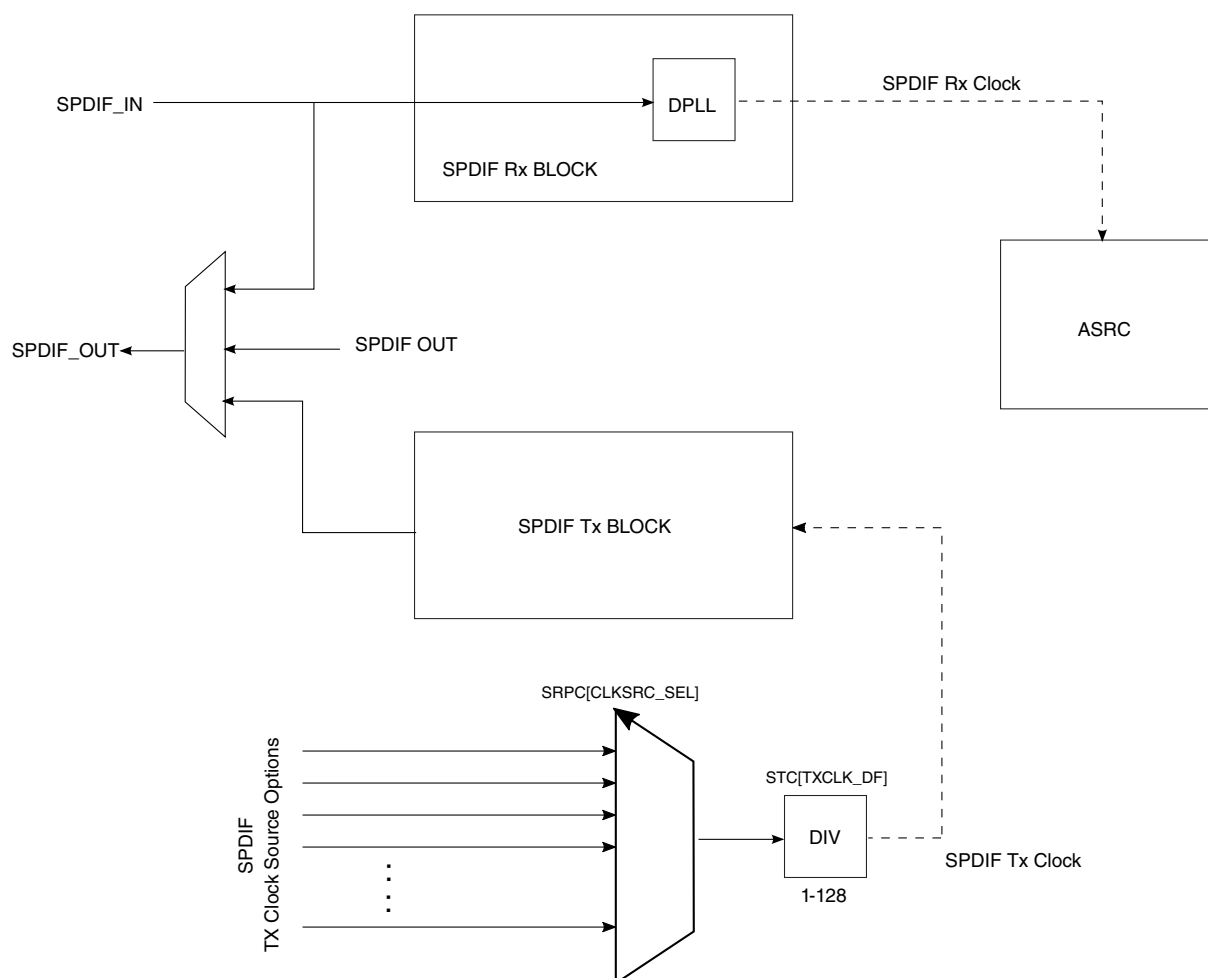

Figure 13-90. SPDIF Transceiver Clock Diagram

13.7.4.1 SPDIF Receiver

The SPDIF receiver extracts the audio data from each SPDIF frame and places the data in Rx left and right FIFOs.

The Tx left and right FIFOs are 16-deep and 24-bit-wide (equal to the audio data width). The Channel Status and User Bits are also extracted from each frame and placed in corresponding registers. The SPDIF receiver also provides a bypass option for direct transfer of the SPDIF input signal to the SPDIF transmitter.

The SPDIF receiver handles the main data audio stream and recovers the bit clock from the SPDIF input signal. The sample rate can be determined from the frequency measuring block. Additionally, the receiver supports the SPDIF C and U channels. The SPDIF C and U channel data is interfaced directly to memory-mapped registers.

All the data registers are controlled by the Interrupt Control Block and transferred to the memory-mapped IP bus.

The following functions are performed by the SPDIF receiver:

- Audio Data Reception see [Audio Data Reception](#)
- Channel Status bits Reception see [Channel Status Reception](#)
- U Channel bits Reception see [User Bit Reception](#)
- Validity Flag Reception see [Validity Flag Reception](#)
- SPDIF Receiver Exception support see [SPDIF Receiver](#)
- SPDIF Lock Detection

13.7.4.1.1 Audio Data Reception

The SPDIF Receiver block extracts the audio data from the IEC60958 stream, and outputs this via Rx left and right FIFOs to the memory-mapped registers SPDIFRxLeft and SPDIFRxRight.

Data from the SPDIF receiver is buffered in receive FIFO, and can be read by the processor from the memory-mapped registers.

- **SPDIF receiver data registers - Behavior on overrun, underrun**

The SPDIF Data Receive registers (SPDIFRxLeft and SPDIFRxRight) have individual FIFOs for left and right channel. As a result, there is always the possibility that left and right FIFOs may go out of sync due to FIFO underruns and FIFO overruns that affect only one part (left or right) of any FIFOs. To prevent this from happening, hardware has been added to the device. Two mechanisms to prevent mismatch between the FIFOs are available.

If a SPDIF Data Rx FIFO overrun occurs on e.g. the right half of the FIFO, the sample that caused the overrun is not written to the right half (due to overrun). Special hardware will make sure the next sample is not written to the left half of the FIFO. If the overrun occurs on the left half of the FIFO, the next sample is not written to the right half of the FIFO.

- **SPDIF receiver data registers - Automatic resynchronization of FIFOs**

An automatic FIFO resynchronization feature is available. It can be enabled and disabled separately for every FIFO. If it is enabled, the hardware will check to see if the left and right FIFOs are in sync. If that is not the case, it will set the filling pointer of the right FIFO to be equal to the filling pointer of the left FIFO.

Figure 13-91. FIFO Auto-resync Controller State Machine

The operation is explained from the state diagram shown above. Every FIFO auto-resync controller has a state machine with 3 states: Off, StandBy and On. In the On state, the filling of the left FIFO is compared with the filling of right, and if they are not equal, right is made equal to left, and an interrupt is generated.

The controller will stay in Off state when the feature is disabled. When not disabled, the state machine will go to Off state on any processor read or write to the FIFO. It will go from On or Off to Standby on any left sample read from SPDIF Tx FIFOs, or on any left sample write to SPDIF Rx FIFOs. The controller will go from Standby to On on any right

sample read from SPDIF Tx FIFO, or on any right sample write to SPDIF Rx FIFO. There is a control bit in the SPDIFConfig register to enable/disable the feature for the SPDIF Rx FIFO and SPDIF Tx FIFO.

13.7.4.1.1.1 Application Note

The automatic FIFO resynchronization can be switched on, and will avoid all mismatches between left and right FIFOs, if the software obeys the following rules:

1. When the left data is read or written to the left FIFO, in the same place of the program, data must be read or written to the right FIFO. Maximum time difference between left and right is 1/2 sample clock. (E.g. if sample frequency is 44 KHz, approximately 10 micro-seconds. For 88 KHz, approximately 5 micro-seconds.)
2. Write/read data to FIFOs at least 2 samples at the time. If there is a mismatch Left-Right, the resync logic may go on only 1 sample clock after last data is read/written to the FIFO. Also acceptable is polling the FIFO, if at least part of the time 2 samples will be read/written to it.
3. The first 192 frames (after DPLL lock) must be discarded.

• SPDIF receiver - Additional features

There are three exceptions associated with the SPDIF Receivers FIFOs

- full
- under/overflow
- resync

When the "full" condition is set for processor data input registers, the processor should read data from the FIFO, before overflow occurs. When "full" is set, and the FIFO contains e.g. 6 samples, it is acceptable for the software to read first 6 samples from the LEFT address, followed by 6 samples from the RIGHT address, or 6 samples from the RIGHT address, followed by 6 samples from the LEFT address, or 1 sample LEFT, followed by 1 sample RIGHT repeated 6 times. There is no order specified.

The implementation for SPDIF Rx is a double FIFO, one for left and one for right. "full" is set when both FIFOs are full. "underrun, overflow" are set when one of the FIFOs do underrun or do overflow. The resync interrupt means hardware took special action to resynchronize left and right FIFOs.

The FIFO level at which the "full" interrupt is generated, is programmable via the Full Select field in the SPDIFConfigReg register.

Rx FIFO on and Rx FIFO reset.

Two additional control fields of the SPDIF Rx FIFO are the on/off select and FIFO reset fields.

If on/off select is set to off, all-zero will be read from the FIFO, irrespective of the data received over the SPDIF interface.

If FIFO reset is set, the FIFO is blocked at "1 sample in FIFO". In this, the full interrupt will be on if FullSelect is set to "00". If FullSelect is set to any other value, interrupt will be off. The other interrupts are always off.

13.7.4.1.2 Channel Status Reception

A total of 48 channel status bits are received in two registers. No interpretation is performed by the SPDIF receiver block.

Channel Status Bits are ordered first bit left. CS-channel MSB bit "0" is located in bit position 23 in the memory-mapped register SPDIFRxCChannel_h. CS-channel bit "23" is considered the LSB bit 0 in the register. C-channel bit 24 to 47 is seen as [23:0] bits of register SPDIFRxCChannel_l.

13.7.4.1.2.1 Channel Status Interrupt

When the value of a new SPDIF "CS" channel status frame is loaded in the register, an interrupt is generated. The interrupt is cleared when the processor writes the corresponding bit in the InterruptStat register.

13.7.4.1.3 User Bit Reception

There are two modes for U Channel reception, CD and non-CD. As is decided by USyncMode (bit 1 of CDText_Control register).

- **Behavior of U Channel receive interface on incoming CD U Channel Sub-code in SPDIF receiver.**

This mode is selected if USyncMode, bit 1 in register CD Text control is set "1".

The CD sub-code stream embedded into the SPDIF U channel consists of a sequence of packets. Every packet is made up 98 "symbols". The first two symbols of every packet are "sync symbols", the other 96 symbols are "data symbols".

Any sequence found in the SPDIF U channel stream starting with a leading one, followed by 7 information bits, is recognized as a "data symbol". Subsequent data symbols are separated by "pauses". During the "pause", "zero bits" are seen on the SPDIF U channel.

Data symbols are coming in MSB first. The MSB is the leading one.

When a "long pause" is seen between 2 subsequent "data symbols", the SPDIF receiver will assume the reception of one or more "sync symbols". Table below gives details.

Table 13-54. Sync Control Bits

Number of U Channel zero bits	Corresponding number of sync symbols
0-1	Unpredictable, not allowed
2-10	0
11-22	1
23-34	2
35-46	3
>45	Unpredictable, not allowed

The recognition of the number of sync symbols derives from the fact that the U channel transmitter in the CD channel decoder will transmit one symbol on average every 12 SPDIF channel bits. On this average rate, there is a maximum tolerance of 5%.

The SPDIF receiver is tolerant of symbol errors. Due to the physical nature of the transmission of the data over the CD disc, not more than 1 out of any 5 consecutive user channel symbols may be in error. The error may cause a change in data value, which is not detected by this interface, or it may cause a data symbol to be seen as a sync symbol, or a sync symbol to be seen as a data symbol. However, not more than 1 out of any 5 consecutive user channel symbols should be affected in this way.

The SPDIF U channel circuitry recognizes the 98-symbol packet structure, and sends the 96 symbol payload to the processor application. The 96 symbol payload is transmitted to the processor via 2 registers:

- The SPDIFRxUChannel register. In this register, data is presented 3 symbols at the time to the processor. Every time 3 new valid symbols, received on the SPDIF U Channel are present, the UChannelRxFull interrupt is asserted. For one 98-symbol packet, 96 symbols are carried across SPDIFRxUChannel. To transfer all this data, 32 UChannelRxFull interrupts are generated.
- The QChannelReceive register. In this register, only the Q bit of the packet is accumulated. Operation is similar to UChannelReceive. Because only Q-bit is transferred, only 96 Q-bits are transferred for any 98-symbol packet. To transfer this data, 4 QChannelRxFull interrupts are generated. When QChannelRxFull occurs, it is coincident with UChannelRxFull. There is only one QChannelRxFull for every 8 UChannelRxFull. The convention is that most significant data is transmitted first, and is left-aligned in the registers.
- Timing regarding packet boundary is extracted by hardware. The last UChannelRxFull corresponding to a given packet should be coincident with the last QChannelRxFull. In this last U, Q channel interrupt, symbols 95-98 are received, Q channel bits 67-98. The interrupts are coincident with UQSyncFound, flagging last symbols of the current frame.

- When the start of the new packet is found before the current packet is complete (less than 98 symbols in the packet), the UQFrameError interrupt is set. The application software should read out UChannelReceive and QchannelReceive registers, discard the value, and assume the start of a new packet.
- As already said, packet sync extraction is tolerant for single-symbol errors. Packet sync detection is based on the recognition of the sequence data-sync-sync-data in the symbol stream, because this is the only syncing sequence that is not affected by single errors. If the sync symbols are not found 98 symbols after the previous occurrence, it is assumed to be destroyed by channel error, and a new sync symbols is interpolated.
- Normally, only data bytes are passed to the application software. Every databyte will have its most significant bit set. If sync symbols are passed to the application software, they are seen as all-zero symbols. Sync symbols can only end up in the data stream due to channel error.
- **Behavior of U Channel receive interface on incoming non-CD data.**

This mode is selected if UsyncMode, bit 1 in register CD Text control is set '0'.

In non-CD mode, the SPDIF U channel stream is recognized as a sequence of "data symbols". No packet recognition is done.

Any sequence found in the SPDIF U channel stream starting with a leading one, followed by 7 information bits, is recognized as a "data symbol". Subsequent data symbols are separated by "pauses". During the "pause", "zero bits" are seen on the SPDIF U channel.

3 consecutive data symbols seen in the SPDIF U Channel stream are grouped together into the SPDIFRxUChannel register. First symbol is left, last symbol is right aligned. When SPDIFRxUChannel contains 3 new data symbols, UChannelRxFull is asserted.

In this mode, the operation of QchannelRx and associated interrupt QchannelRxFull is reserved, undefined. And the operation of UQFrameError and UQSyncFound is also reserved, undefined.

The U channel is extracted, and output by the SPDIF Rx on SPDIFRxUChannel-Stream.

When incoming SPDIF data parity error or bit error is detected, and if the next SPDIF word for that channel is error-free, the SPDIF word in error is replaced with the average of the previous word and next word. When incoming SPDIF data parity error or bit error is detected, and the next SPDIF word is in error, the previous SPDIF word is repeated.

13.7.4.1.4 Validity Flag Reception

An interrupt is associated with the Validity flag. (interrupt 16 - SPDIFValNoGood). This interrupt is set every time a frame is seen on the SPDIF interface with the validity bit set to "invalid".

13.7.4.1.5 SPDIF Receiver Interrupt Exception Definition

Several SPDIF exceptions can trigger an interrupt. They are:

- Control Status channel change. Set when SPDIFRxChannel_1 register is updated. The register is updated for every new C-Channel received. The exception is reset on write to InterruptClear register.
- SPDIF Illegal Symbol. Set on reception of illegal symbol during SPDIF receive. Reset by writing register InterruptClear.¹
- SPDIF bit error. Set on reception of bit error. (Parity bit does not match). Reset on write to InterruptClear register.
- Receive data FIFO full. Set when SPDIF receive data FIFO is full.
- Receive data FIFO underrun/overflow. Set when there is a underrun/overflow on the SPDIF receive data FIFO.
- Receive data FIFO resynchronization. Set when a resynchronization event occurs on the SPDIF receive data FIFO.
- Receive U Channel buffer full. Set when next 24 bits of U channel code are available.
- Receive Q Channel buffer overflow. Set when Q channel buffer overflow.
- Receive U Channel buffer overflow. Set on U channel buffer overflow.
- Receive Q Channel buffer full. Set when next 24 bits of Q channel code are available.
- Receive UQ sync found. Set when UQ channel sync found.
- Receive UQ frame error. Set when UQ frame error found.

13.7.4.1.6 Standards Compliance

The SPDIF interface is compatible with the Tech 3250-E standard of the European Broadcasting Union, except clause 6.3.3 and the IEC60958-3 Ed2 for relevant topics.

1. The SPDIF input is a biphasemark modulated signal. The time between any two successive transitions of the SPDIF signal is always 1, 2 or 3 SPDIF symbol periods long. The SPDIF receiver will parse the stream, and split it in so-called symbols. It recognizes s1, s2 and s3 symbols, depending on the length of the symbols. Not all sequences of these symbols are allowed. To give an example, a sequence s2-s1-s1-s1-s2 cannot occur in a no-error SPDIF signal. If the receiver finds such an illegal sequence, the illegal symbol interrupt is set. No corrective action is undertaken. When the interrupt occurs, this means that(a) The SPDIF signal is destroyed by noise (b) The SPDIF frequency changed.

Supported input frequency range is 12 KHz up to 96 KHz. (fully compliant) and 96 KHz up to 176 KHz (Can interface with compliant SPDIF transmitter within same cabinet, making reasonable assumptions on jitter added due to interconnecting wire.)

Tolerated jitter on SPDIF input signals are 0.25 bit peak-peak for high frequencies. There is no jitter limit for low frequencies. The user channel extraction in CD mode is capable of coping with single-symbol errors, and still retrieve U channel frames on correct boundaries. This capability is required for reliable reception of CD-Text from some Philips CD channel decoders. This capability was deemed more important than compliance with the IEC60958 annex A.3 standard, and for this reason user channel reception is not compliant with IEC60958 annex A.3. However, the interface is capable to receive U channel inserted by a typical CD channel decoder. Also, in this case, it is more robust and tolerant for channel error than what is required by IEC60958 annex A.3.

13.7.4.1.7 SPDIF PLOCK Detection and Rxclk Output

Using the high speed system clock, the internal DPLL can extract the bit clock (advanced pulse) from the input bitstream. When this internal DPLL is locked, the LOCK bit of PhaseConfig Register will be set, and the SPDIF Lock output pin SPDIF_LOCK will be asserted.

After DPLL has locked, the pulses are generated, and the average pulse rate is 128 x the sampling frequency. (For a 44.1 KHz input sampling frequency, the average pulse rate = 128 x 44.1 KHz.) The pulse signal is used in the FreqMeas circuit to generate the frequency measurement result.

13.7.4.1.8 Measuring Frequency of SPDIF_RxClk

The internal DPLL can extract the bit clock (advanced plus) from the input bitstream. To do that, it is necessary to measure the frequency of the incoming signal in relationship with the system clock (BUS_CLK).

Associated with it are two registers, PhaseConfig and FreqMeas. The circuit will measure the frequency of the incoming clock as a function of the BUS_CLK. The circuit is a second-order filter. The output is a value represented by an unsigned number stored in the 24-bit FreqMeas register, giving the frequency of the source as a function of the BUS_CLK.

$$\text{FreqMeas}[23:0] = \text{FreqMeas_CLK} / \text{BUS_CLK} * 2^{10} * \text{GAIN}.$$

For example, if the GAIN is selected as 8*(2**10) (PhaseConfig[5:3] = 3'b011), the actual result

$$\text{FreqMeas_CLK} / \text{BUS_CLK} \text{ is equal to } \text{FreqMeas}[23:0] / 2^{23}.$$

13.7.4.2 SPDIF Transmitter

Audio data for the SPDIF transmitter is provided by processor via the SPDIFTxLeft and SPDIFTxRight registers.

Clocking for SPDIF transmitter is selected through a multiplexer from several clock sources (see register bitfield description [STC\[TxClock_Source\]](#) for transmit clock source inputs). The SPDIF transmitter clock source can be divided down as needed using Txclk_DF. The SPDIF transmitter output can be chosen from either the SPDIF transmitter block, directly from the SPDIF receiver (via the output multiplexer), or disabled.

The SPDIF transmitter generates a SPDIF output bitstream in IEC60958 biphas mark format, consisting of audio data, channel status.

13.7.4.2.1 Audio Data Transmission

Audio data for the SPDIF transmitter is provided by the processor via SPDIFTxLeft and SPDIFTxRight registers. They send audio data to Tx left and right FIFOs. The Tx left and right FIFOs are also 16-deep and 24-width (equal to the audio data width).

- **SPDIF transmitter data registers - Behavior on overrun, underrun**

The SPDIF Data Transmit registers (SPDIFTxLeft and SPDIFTxRight) have individual FIFOs for left and right channel. As a result, there is always the possibility that left and right FIFOs may go out of sync due to FIFO underruns and FIFO overruns that affect only one part (left or right) of any FIFO. To prevent this from happening, hardware has been added on the device. Two mechanisms to prevent mismatch between the FIFOs are available.

If SPDIF Tx FIFO underruns on the right half of the FIFO, no sample leaves that FIFO (because it was already empty). Special hardware will make sure that the next sample read from the left FIFO will not leave the FIFO (no read strobe is generated). If the underrun occurs on the left half of the FIFO, next read strobe to the right FIFO is blocked.

- **SPDIF transmitter data registers - Automatic resynchronization of FIFOs**

See [Audio Data Reception](#).

- **SPDIFTxLeft, SPDIFTxRight details**

With SPDIF Tx FIFOs three exceptions are associated.

- empty

- under/overflow
- resync

When the empty condition is set for processor data output registers, the processor should write data to the FIFO, before underrun occurs. When empty is set and, for instance, 6 samples need to be written, it is acceptable for the software to write first 6 samples from the LEFT address, followed by 6 samples from the RIGHT address, or 1 sample LEFT, followed by 1 sample RIGHT repeated 6 times. Left should be written before right. The implementation of all data out FIFOs is a double FIFO, one for left and one for right. Empty is set when both FIFOs are empty. Underrun, overflow are set when one of the FIFOs do underrun or do overflow. Resync is set when the hardware resynchronizes left and right FIFOs.

On receiving underrun, overflow interrupt, synchronization between Left and Right words in the FIFOs may be lost. Synchronization will not be lost when the underrun or overflow comes from the IEC60958 side of the FIFO. If the processor reads or writes more data from, for example, left than from right, synchronization will be lost. If automatic resynchronization is enabled, and if the software obeys the rules to let this work, resynchronization will be automatic.

13.7.4.2.2 Channel Status Transmission

A total of 48 Consumer channel status bits are transmitted from two registers. Channel Status Bits are ordered first bit left.

CS-channel MSB bit "0" is located in bit position 23 in the memory-mapped register SPDIFTxChannelCons_h. CS-channel bit "23" is considered bit 0 in the register. C-channel bits 24-47 are seen as MSB-LSB bits of register SPDIFTxChannelCons_l.

13.7.4.2.3 Validity Flag Transmission

The validity bit setting is performed via bit 5 of the SPDIF_SCR register.

13.8 PDM Microphone Interface (MICFIL)

13.8.1 Preface

The purpose of this document is to present the PDM Microphone Interface block specification.

13.8.1.1 Acronyms and Abbreviations

Table 13-55 contains sample acronyms and abbreviations used in this document.

Table 13-55. Acronyms and Abbreviated Terms

Term	Meaning
CPU	Central Processing Unit (core processor)
DMA	Direct Memory Access

Table continues on the next page...

Table 13-55. Acronyms and Abbreviated Terms (continued)

Term	Meaning
CIC	Cascaded Integrator Comb filter
dB	Decibels
FIFO	First In First Out storage block
FIR	Finite Impulse Response digital filter type
IIR	Infinite Impulse Response digital filter type
IP	Intellectual Property
LSB	Least Significant Bit
MAC Unit	Multiply And Accumulate Unit
MCU	Microcontroller Unit
PDM	Pulse-density Modulation
PCM	Pulse-code Modulation
HWVAD	Hardware Voice Activity Detector

13.8.2 Introduction

This document describes the requirements and architecture for the implementation of a PDM Microphone Interface block.

13.8.2.1 Overview

PDM is a popular way to deliver audio from microphones to the processor in several applications, such as mobile telephones. However, current digital-audio systems use multibit audio signal (also known as multibit PCM) to represent the signal. For this purpose a set of FIR, CIC or/and Half Band filters are usually implemented on DSPs or software. This block implements the required digital interface to provide a 16-bit audio signal from a PDM microphone bitstream in a configurable output sampling rate.

The implementation of this digital interface is based on the application of digital signal processing techniques in hardware. The PDM Microphone Interface architecture was designed to gate saving and minimal power consumption. It implements a bunch of filters to transform a 1-bit PDM bitstream to a 16-bit PCM signal in the audio band. To avoid aliasing frequencies in passband, the overall filter has 80 dB stopband attenuation and passband ripple less than 0.2dB.

The whole module is implemented to work in a multichannel mode. All channels have the same configuration but each input channel could be turned on/off independently.

Figure 13-92 shows the block diagram for the PDM Microphone Interface module. It is composed by:

- an input interface for each pair of PDM microphones.
- a decimation filter by channel.
- a FIFO by channel.
- a time generation unit.
- shared interfaces to DMA, interrupts and SoC.
- One or more Hardware Voice Activity Detectors (HWVAD).

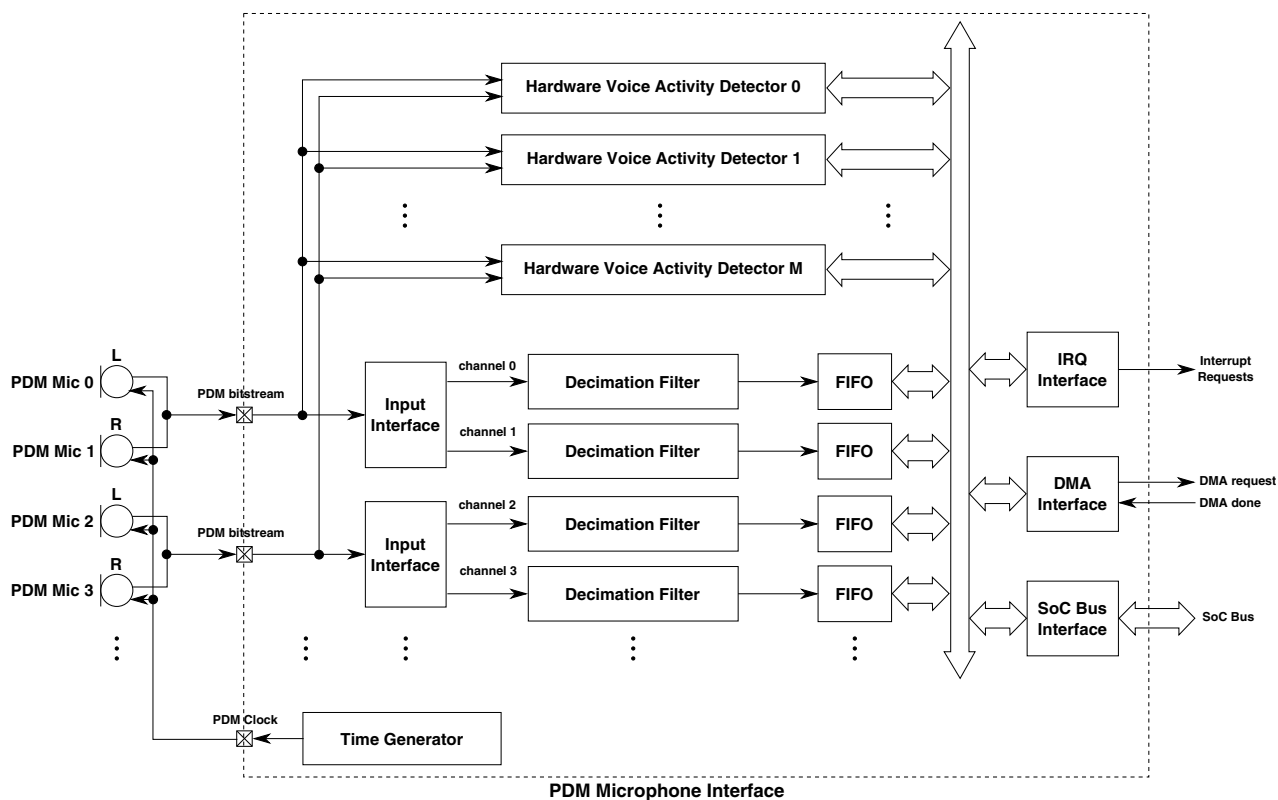

Figure 13-92. PDM Microphone Interface Block Diagram

The Time Generator unit generates a PDM clock to all microphones. All microphones must operate at the same clock frequency. Each input interface receives a time multiplexed PDM bitstream from two PDM microphones and it separates the two audio information in two channels: left (0) and right (1). Each channel is processed separately.

The Decimation Filter is composed internally by a CIC filter, a DC remover, a FIR and a Half Band filter. The Half Band and FIR filters are implemented in the traditional way. The filtering results are stored in individual FIFOs; a FIFO by channel. The FIFOs have overflow and underflow detectors to deliver an error interrupt request.

An interrupt request or DMA request could be delivered by the MICFIL. Then the filters results stored in FIFOs could be accessed by the SoC or DMA respectively via the internal bus interface.

The HWVAD takes data from the input of a selected PDM microphone to detect if there is any voice activity. When a voice activity is detected, an interrupt could be delivered to the system.

13.8.2.2 Features

This PDM Microphone Interface (MICFIL) block includes these main features:

- Fixed filtering characteristics for audio application.
- Full or partial set of channels operation with individual enable control.
- Programmable PDM clock generator.
- Programmable decimation rate.
- 16-bit signed output result.
- Overall stopband attenuation more than 80dB.
- Overall passband ripple less than 0.2dB.
- CIC filter
 - 5th order.
 - Programmable decimation rate.
- DC remover
 - First order IIR filter.
 - Programmable cut-off frequency.
- FIFOs with DMA capability.
 - Each FIFO is 8 entries length.
- Hardware Voice Activity Detector (HWVAD).
 - Interrupt capability.
 - Zero-Crossing Detection (ZCD) option.

13.8.2.3 Modes of operation

This section describes the operation modes of the MICFIL. These depends on the CPU power mode , the SoC Doze mode , the SoC Debug mode and MDIS, DBGE, DBG and DOZEN bitfields. The mode selection is summarized in [Table 13-56](#).

Table 13-56. Operation Mode Selection

Mode	MDIS	SoC Doze & DOZEN=1	CPU Power Mode	DOZEN	SoC Debug DBG	DBGE	CPU clock	MICFIL internal clock	Decimation Filter state	HWVAD[n] state	
Normal	0	0	HSRUN / RUN / VLPR	X	0	X	Enabled	Enabled	Run (Depends on PDMIEN and CHENn)	Run (Depends on PDMIEN and VADEN)	
Debug					1	1			0	Stop	Stop
Low Power			STOP/ VLPS	0	X	X	Gated (Externally)	Enabled	Run (Depends on PDMIEN and CHENn)	Run (Depends on PDMIEN and VADEN) ¹	
									LLS/VLLS	Stop	Stop
Disable/Low Leakage			STOP/ VLPS/LLS/VLLS	1					Gated		
		1	Any	X			Enabled				
	1	X					Gated (Internally)				

1. HWVAD[n] will RUN in VLLS/LLS only if it was placed on an always-on power domain in the SoC.

13.8.2.3.1 Normal mode

This is the default operational mode of the MICFIL block. In this mode the channels can be enabled and perform filtering operation. The input data are supplied by the PDM bitstreams and the PDM Clock is delivered to the PDM microphones.

13.8.2.3.2 Low Power mode

The Low Power mode is requested by the SoC only. In this mode the CPU clock is gated externally and the MICFIL is kept running. The MICFIL is in Low Power mode when the SoC is in STOP, VLPS, LLS or VLLS mode and DOZEN = 0. For more information see [Low Power Mode](#).

13.8.2.3.3 Debug mode

This mode is used to check the status of the IP when requested. In this mode the MICFIL can be stopped after the remaining data processing has finished depending on the DBGE bit value. This mode can be activated by a SoC debug request or asserting the DBG bitfield. For more information see [Debug Mode](#).

13.8.2.3.4 Disable/Low Leakage mode

The Disable/Low Leakage (DLL) mode can be requested by the SoC or by the MICFIL. In this mode the MICFIL is stopped after the remaining data processing has finished. The MICFIL is in Disable/Low Leakage (DLL) mode when:

- The SoC is in STOP, VLPS, LLS or VLLS mode and DOZEN=1.
- The SoC is in Doze and DOZEN bit is set.
- MDIS is set.

Refer to [Disable/Low Leakage mode](#) section for more details.

13.8.2.4 Quality Modes

Independently of the power mode selected, if the decimation filter is running, the MICFIL can operate in 6 different quality modes, those can be selected by the QSEL bitfield in the CTRL_2 register. The decimation and interpolation rates in internal blocks are shown in [Table 13-57](#). The quality selected can be configured dynamically when the Decimation Filter is running, the output rate is maintained in every quality selected.

The passband of the Decimation Filter depends on the quality mode, see [Overall Bandpass](#) for more information.

Table 13-57. Quality Modes

Quality Mode	QSEL bitfield	Sampler Interpolation	CIC Filter Decimation	Half Band Filter Decimation	FIR Filter Decimation	PDM Clock Rate	Passband	Relative Gain
High Quality	001	-	:(2OSR)	:2	:2	Output Rate x 8 x OSR	To ~0.5 x Output Rate	$2^{(OUTGAINn+5)}$
Medium Quality	000	-	:OSR	:2	:2	Output Rate x 4 x OSR	To ~0.5 x Output Rate	$2^{(OUTGAINn)}$
Low Quality	111	x2	:OSR	:2	:2	Output Rate x 2 x OSR	To ~0.5 x Output Rate	$2^{(OUTGAINn)}$
Very Low Quality 0	110	-	:(2OSR)	:2	-	Output Rate x 4 x OSR	To ~0.25 x Output Rate	$2^{(OUTGAINn+7)}$
Very Low Quality 1	101	-	:OSR	:2	-	Output Rate x 2 x OSR	To ~0.25 x Output Rate	$2^{(OUTGAINn+2)}$
Very Low Quality 2	100	x2	:OSR	:2	-	Output Rate x OSR	To ~0.25 x Output Rate	$2^{(OUTGAINn+2)}$

In order to maintain the same output rate in the Decimation Filter when the quality is changed, the PDM Clock rate changes depending on the quality selected. For more details about the PDM Clock see [Time Generator](#).

The Sampler and the FIR filters are whether enabled or not depending on the quality selected, achieving a low power consumption when they are disabled. The CIC filter decimation rate is also whether doubled or not depending on the quality selected. For more information about see [Decimation Filter](#).

13.8.3 External signal description

Note

The PDM Microphone Interface module does not provide metastability protection or filtering for input data. The data must be generated using the provided PDM clock.

13.8.3.1 PDM data bitstream bus

The PDM bitstream bus is the set of data bitstreams received from each PDM microphone. For more details, see [Input Interface](#).

13.8.3.2 PDM generated clock

The PDM generated clock signal is the clocking signal generated to be delivered to the PDM microphones. The generated clock frequency is configurable. For more details, see [Time Generator](#).

13.8.4 MICFIL register descriptions

This section provides the memory map and detailed description of all MICFIL registers. Any access to reserved areas can issue a slave bus error indication.

The registers allocated in this memory map are implemented for up to 4 pairs of microphones, that means 8 channels are available.

13.8.4.1 MICFIL Memory map

PDM_INTFC base address: 3008_0000h

Offset	Register	Width (In bits)	Access	Reset value
0h	MICFIL Control register 1 (CTRL_1)	32	RW	0000_0000h
4h	MICFIL Control register 2 (CTRL_2)	32	RW	0000_0000h

13.8.4.2 MICFIL Control register 1 (CTRL_1)

13.8.4.2.1 Offset

Register	Offset
CTRL_1	0h

13.8.4.2.2 Function

This MICFIL module configuration register provides configuration control bits for all sub-blocks and internal logic.

13.8.4.2.3 Diagram

13.8.4.2.4 Fields

Field	Function
31 MDIS	<p>Module Disable</p> <p>The MDIS bit puts the whole PDM Interface in Disable/Low Leakage mode. The generated PDM Clock is stopped and consequently no data is generated by the microphones. Please see more details on Disable/Low Leakage mode.</p> <p>NOTE: When MDIS=1, writes to CTRL_1 and CTRL_2 only are allowed with the exception of writes to the DBG and SRES bits. A slave bus error indication will be issued when any register except CTRL_1 and CTRL_2 is written when MDIS=1.</p> <p>0b - Normal Mode 1b - Disable/Low Leakage Mode</p>
30 DOZEN	<p>DOZE enable</p> <p>When SoC is in Doze mode and DOZEN is active the module enters in Disable/Low Leakage Mode.</p> <p>0b - DOZE enable bit is not asserted 1b - DOZE enable bit is asserted</p>
29 PDMIEN	<p>PDM Interface Enable</p> <p>The PDMIEN bit enables the operation of the filters in the module. Only the channels enabled by CHnEN starts to operate. It starts the clock generation and the overall filters operation. When it is negated, both the enabled channels and the clock generation will be stopped after finish the current filtering and only the pending data in the buffer could be processed by DMA or interrupt requests.</p> <p>NOTE: This field must be the latest to be enabled, for more information see the Initialization Procedure without HWVAD.</p> <p>0b - PDM Interface disabled 1b - PDM Interface enabled.</p>
28 DBG	<p>Debug Mode</p> <p>This bit enables the Debug mode of the PDM interface. The module could be enabled or disabled in Debug mode depending on the DBGE bit value. See Debug Mode for more details. This bit is writable only when MDIS is cleared.</p> <p>0b - PDM Interface is in Normal Mode. 1b - PDM Interface is in Debug Mode.</p>
27 SRES	Software-reset bit

Table continues on the next page...

PDM Microphone Interface (MICFIL)

Field	Function
	<p>The SRES is a self-negated bit which provides the CPU with the capability to initialize the PDM Interface module through the slave-bus interface. This bit always reads as zero, and this bit is only effective when MDIS is cleared. Refer to Soft-reset</p> <p>0b - No action 1b - Software reset</p>
26 DBGE	<p>Module Enable in Debug</p> <p>Enables/disables the PDM interface operation in Debug mode. See Debug Mode for more details.</p> <p>0b - PDM Interface is disabled in debug mode, after completing the current frame. 1b - PDM Interface is enabled in debug mode.</p>
25-24 DISEL	<p>DMA Interrupt Selection</p> <p>The DISEL field selects if the module performs DMA requests or filter interrupt requests when the number of FIFO elements surpasses the configured watermark. Note that requests are only generated from the channels whose CHnEN bits are asserted.</p> <p>NOTE: This bit mustn't change when BSY_FIL bit is asserted</p> <p>00b - DMA and interrupt requests disabled 01b - DMA requests enabled 10b - Interrupt requests enabled 11b - Reserved</p>
23 ERREN	<p>Error Interruption Enable</p> <p>The ERREN bit enables Error Interrupts in the PDM Interface. This error could be caused by an overflow or underflow in the FIFOs, an overflow or underflow in the Decimation Filter output or when the MICFIL internal clock frequency is not enough to filter data of all enabled channels. The specific error type could be checked on the FIFOOVF or FIFOUND bits, the OUTOVF or OUTUNF bits or in the LOWFREQF bit.</p> <p>NOTE: This bit mustn't change when BSY_FIL bit is asserted</p> <p>0b - Error Interrupts disabled 1b - Error Interrupts enabled</p>
22-16 —	Reserved
15-8 —	Reserved
7 CH7EN	<p>Channel 7 Enable</p> <p>The CH7EN bit enables the Channel 7 processing. Overall channel filters are enabled, DMA or interrupt request could be enabled depending of the DISEL bit. When is negated the overall channel filters and respective FIFO are disabled. It must be changed only when PDMIEN and BSY_FIL are negated. See Initialization Procedure without HWVAD for more information.</p> <p>NOTE: This bit mustn't change when BSY_FIL bit is asserted.</p> <p>0b - Channel 7 disabled 1b - Channel 7 enabled</p>
6 CH6EN	<p>Channel 6 Enable</p> <p>The CH6EN bit enables the Channel 6 processing. Overall channel filters are enabled, DMA or interrupt request could be enabled depending of the DISEL bit. When is negated the overall channel filters and respective FIFO are disabled. It must be changed only when PDMIEN and BSY_FIL are negated. See Initialization Procedure without HWVAD for more information.</p> <p>NOTE: This bit mustn't change when BSY_FIL bit is asserted.</p> <p>0b - Channel 6 disabled 1b - Channel 6 enabled</p>
5	Channel 5 Enable

Table continues on the next page...

Field	Function
CH5EN	<p>The CH5EN bit enables the Channel 5 processing. Overall channel filters are enabled, DMA or interrupt request could be enabled depending of the DISEL bit. When is negated the overall channel filters and respective FIFO are disabled. It must be changed only when PDMIEN and BSY_FIL are negated. See Initialization Procedure without HWVAD for more information.</p> <p>NOTE: This bit mustn't change when BSY_FIL bit is asserted. 0b - Channel 5 disabled 1b - Channel 5 enabled</p>
4 CH4EN	<p>Channel 4 Enable</p> <p>The CH4EN bit enables the Channel 4 processing. Overall channel filters are enabled, DMA or interrupt request could be enabled depending of the DISEL bit. When is negated the overall channel filters and respective FIFO are disabled. It must be changed only when PDMIEN and BSY_FIL are negated. See Initialization Procedure without HWVAD for more information.</p> <p>NOTE: This bit mustn't change when BSY_FIL bit is asserted. 0b - Channel 4 disabled 1b - Channel 4 enabled</p>
3 CH3EN	<p>Channel 3 Enable</p> <p>The CH3EN bit enables the Channel 3 processing. Overall channel filters are enabled, DMA or interrupt request could be enabled depending of the DISEL bit. When is negated the overall channel filters and respective FIFO are disabled. It must be changed only when PDMIEN and BSY_FIL are negated. See Initialization Procedure without HWVAD for more information.</p> <p>NOTE: This bit mustn't change when BSY_FIL bit is asserted. 0b - Channel 3 disabled 1b - Channel 3 enabled</p>
2 CH2EN	<p>Channel 2 Enable</p> <p>The CH2EN bit enables the Channel 2 processing. Overall channel filters are enabled, DMA or interrupt request could be enabled depending of the DISEL bit. When is negated the overall channel filters and respective FIFO are disabled. It must be changed only when PDMIEN and BSY_FIL are negated. See Initialization Procedure without HWVAD for more information.</p> <p>NOTE: This bit mustn't change when BSY_FIL bit is asserted. 0b - Channel 2 enabled 1b - Channel 2 disabled</p>
1 CH1EN	<p>Channel 1 Enable</p> <p>The CH1EN bit enables the Channel 1 processing. Overall channel filters are enabled, DMA or interrupt request could be enabled depending of the DISEL bit. When is negated the overall channel filters and respective FIFO are disabled. It must be changed only when PDMIEN and BSY_FIL are negated. See Initialization Procedure without HWVAD for more information.</p> <p>NOTE: This bit mustn't change when BSY_FIL bit is asserted. 0b - Channel 1 disabled 1b - Channel 1 enabled</p>
0 CH0EN	<p>Channel 0 Enable</p> <p>The CH0EN bit enables the Channel 0 processing. Overall channel filters are enabled, DMA or interrupt request could be enabled depending of the DISEL bit. When is negated the overall channel filters and respective FIFO are disabled. It must be changed only when PDMIEN and BSY_FIL are negated. See Initialization Procedure without HWVAD for more information.</p> <p>NOTE: This bit mustn't change when BSY_FIL bit is asserted. 0b - Channel 0 disabled 1b - Channel 0 enabled</p>

13.8.4.3 MICFIL Control register 2 (CTRL_2)

13.8.4.3.1 Offset

Register	Offset
CTRL_2	4h

13.8.4.3.2 Function

This MICFIL module configuration register provides configuration control bits for all sub-blocks and internal logic.

NOTE

CLKDIV=0 has the same effect than CLKDIV=1. CLKDIV=0 or 1 has the same effect than CLKDIV=2 during Medium Quality mode. CLKDIV=0 or 1 is not allowed during High Quality mode.

13.8.4.3.3 Diagram

13.8.4.3.4 Fields

Field	Function
31-28 —	Reserved
27-25 QSEL	Quality Select This bit defines the actual quality mode of the Decimation Filter. See more information in Quality Modes .

Table continues on the next page...

Field	Function
	NOTE: This bitfield mustn't change when BSY_FIL bit is asserted. 000b - Medium quality mode. 001b - High quality mode. 100b - Very low quality 2 mode. 101b - Very low quality 1 mode. 110b - Very low quality 0 mode. 111b - Low quality mode.
24-20 —	Reserved
19-16 CICOSR	CIC Oversampling Rate This bitfield defines the oversampling rate of the CIC filter. In case the Decimation Filter is in High or Very Low Quality 0 mode the oversampling rate is 2(16-CICOSR), otherwise it is (16-CICOSR). See CIC Filter for more information. NOTE: This bitfield mustn't change when BSY_FIL bit is asserted.
15-8 —	Reserved
7-0 CLKDIV	Clock Divider The CLKDIV field sets the divisor for the MICFIL internal clock. The division generates the PDM microphones clock and determines the output sampling rate of the overall filtering. See Time Generator for more information. NOTE: This bitfield mustn't change when BSY_FIL bit is asserted.

13.8.4.4 MICFIL Status register (STAT)

13.8.4.4.1 Offset

Register	Offset
STAT	8h

13.8.4.4.2 Diagram

13.8.4.4.3 Fields

Field	Function
31 BSY_FIL	Decimation Filter Busy Flag This flag signalizes when at least a Decimation Filter channel or at least a HWVAD is running and the PDM clock is being generated. See Busy Flag for more information. 0b - All Decimation Filters are stopped. 1b - At least one Decimation Filter channel is running.
30 FIR_RDY	FIR Filter Data Ready This bit indicates that all the TAPs from FIR Filter have been updated, and all data provided from now on will be reliable. After PDMIEN is set this bit field remains low for a time interval correspondent to about 68 FIR results. NOTE: When FIR is bypassed, it depends on Half Band filter. 0b - FIR Filter data not reliable. 1b - FIR Filter data reliable.
29 LOWFREQF	Low Frequency Flag This bit indicates that the CLKDIV bitfield value is not high enough to filter all enabled channels, and the FIR or Half Band filters didn't finish their operations before the next sample arrived. For more information see Minimum Required CLKDIV bitfield value . Write a logic 1 to this field to clear this flag. NOTE: The filtering results in this condition are unpredictable. 0b - CLKDIV value is OK. 1b - CLKDIV value is too low.
28-16 —	Reserved
15-8 —	Reserved
7	Channel 7 Output Data Flag

Table continues on the next page...

Field	Function
CH7F	<p>The CH7F bit flag indicates that the FIFO from this channel has surpassed its watermark value and the data is available at the DATACH7 register. This flag contributes to generate an Interrupt or DMA request if enabled by DISEL in the CTRL_1. Write a logic 1 to this field to clear this flag. If DMA request is set (DISEL = 01) the CH7F flag will be set according to watermark level and will be cleared , in the other cases (IRQ included) the CH7F flag will be set according to the watermark level and will be cleared with the w1c functionality of the bit.</p> <p>NOTE: If DMA is enabled, this flag is self-cleared when the DMA transaction is finished. 0b - Channel's FIFO did not reach the number of elements configured in watermark bit-field. 1b - Channel's FIFO reached the number of elements configured in watermark bit-field.</p>
6 CH6F	<p>Channel 6 Output Data Flag</p> <p>The CH6F bit flag indicates that the FIFO from this channel has surpassed its watermark value and the data is available at the DATACH6 register. This flag contributes to generate an Interrupt or DMA request if enabled by DISEL in the CTRL_1. Write a logic 1 to this field to clear this flag. If DMA request is set (DISEL = 01) the CH6F flag will be set according to watermark level and will be cleared , in the other cases (IRQ included) the CH6F flag will be set according to the watermark level and will be cleared with the w1c functionality of the bit.</p> <p>NOTE: If DMA is enabled, this flag is self-cleared when the DMA transaction is finished. 0b - Channel's FIFO did not reach the number of elements configured in watermark bit-field. 1b - Channel's FIFO reached the number of elements configured in watermark bit-field.</p>
5 CH5F	<p>Channel 5 Output Data Flag</p> <p>The CH5F bit flag indicates that the FIFO from this channel has surpassed its watermark value and the data is available at the DATACH5 register. This flag contributes to generate an Interrupt or DMA request if enabled by DISEL in the CTRL_1. Write a logic 1 to this field to clear this flag. If DMA request is set (DISEL = 01) the CH5F flag will be set according to watermark level and will be cleared , in the other cases (IRQ included) the CH5F flag will be set according to the watermark level and will be cleared with the w1c functionality of the bit.</p> <p>NOTE: If DMA is enabled, this flag is self-cleared when the DMA transaction is finished. 0b - Channel's FIFO did not reach the number of elements configured in watermark bit-field. 1b - Channel's FIFO reached the number of elements configured in watermark bit-field.</p>
4 CH4F	<p>Channel 4 Output Data Flag</p> <p>The CH4F bit flag indicates that the FIFO from this channel has surpassed its watermark value and the data is available at the DATACH4 register. This flag contributes to generate an Interrupt or DMA request if enabled by DISEL in the CTRL_1. Write a logic 1 to this field to clear this flag. If DMA request is set (DISEL = 01) the CH4F flag will be set according to watermark level and will be cleared , in the other cases (IRQ included) the CH4F flag will be set according to the watermark level and will be cleared with the w1c functionality of the bit.</p> <p>NOTE: If DMA is enabled, this flag is self-cleared when the DMA transaction is finished. 0b - Channel's FIFO did not reach the number of elements configured in watermark bit-field. 1b - Channel's FIFO reached the number of elements configured in watermark bit-field.</p>
3 CH3F	<p>Channel 3 Output Data Flag</p> <p>The CH3F bit flag indicates that the FIFO from this channel has surpassed its watermark value and the data is available at the DATACH3 register. This flag contributes to generate an Interrupt or DMA request if enabled by DISEL in the CTRL_1. Write a logic 1 to this field to clear this flag. If DMA request is set (DISEL = 01) the CH3F flag will be set according to watermark level and will be cleared , in the other cases (IRQ included) the CH3F flag will be set according to the watermark level and will be cleared with the w1c functionality of the bit.</p> <p>NOTE: If DMA is enabled, this flag is self-cleared when the DMA transaction is finished. 0b - Channel's FIFO did not reach the number of elements configured in watermark bit-field. 1b - Channel's FIFO reached the number of elements configured in watermark bit-field.</p>
2	Channel 2 Output Data Flag

Table continues on the next page...

Field	Function
CH2F	<p>The CH2F bit flag indicates that the FIFO from this channel has surpassed its watermark value and the data is available at the DATACH2 register. This flag contributes to generate an Interrupt or DMA request if enabled by DISEL in the CTRL_1. Write a logic 1 to this field to clear this flag. If DMA request is set (DISEL = 01) the CH2F flag will be set according to watermark level and will be cleared , in the other cases (IRQ included) the CH2F flag will be set according to the watermark level and will be cleared with the w1c functionality of the bit.</p> <p>NOTE: If DMA is enabled, this flag is self-cleared when the DMA transaction is finished. 0b - Channel's FIFO did not reach the number of elements configured in watermark bit-field. 1b - Channel's FIFO reached the number of elements configured in watermark bit-field.</p>
1 CH1F	<p>Channel 1 Output Data Flag</p> <p>The CH1F bit flag indicates that the FIFO from this channel has surpassed its watermark value and the data is available at the DATACH1 register. This flag contributes to generate an Interrupt or DMA request if enabled by DISEL in the CTRL_1. Write a logic 1 to this field to clear this flag. If DMA request is set (DISEL = 01) the CH1F flag will be set according to watermark level and will be cleared , in the other cases (IRQ included) the CH1F flag will be set according to the watermark level and will be cleared with the w1c functionality of the bit.</p> <p>NOTE: If DMA is enabled, this flag is self-cleared when the DMA transaction is finished. 0b - Channel's FIFO did not reach the number of elements configured in watermark bit-field. 1b - Channel's FIFO reached the number of elements configured in watermark bit-field.</p>
0 CH0F	<p>Channel 0 Output Data Flag</p> <p>The CH0F bit flag indicates that the FIFO from this channel has surpassed its watermark value and the data is available at the DATACH0 register. This flag contributes to generate an Interrupt or DMA request if enabled by DISEL in the CTRL_1. Write a logic 1 to this field to clear this flag. If DMA request is set (DISEL = 01) the CH0F flag will be set according to watermark level and will be cleared , in the other cases (IRQ included) the CH0F flag will be set according to the watermark level and will be cleared with the w1c functionality of the bit.</p> <p>NOTE: If DMA is enabled, this flag is self-cleared when the DMA transaction is finished. 0b - Chanel's FIFO did not reach the number of elements configured in watermark bit-field. 1b - Channel's FIFO reached the number of elements configured in watermark bit-field.</p>

13.8.4.5 MICFIL FIFO Control register (FIFO_CTRL)

13.8.4.5.1 Offset

Register	Offset
FIFO_CTRL	10h

15 FIFOFOUND7	FIFO Underflow Exception flag for channel 7 The FIFOFOUND bit indicates an exceptional underflow condition in the FIFO. If the FIFO is empty and a read operation is requested then this flag is set. Write a logic 1 to this field to clear this flag. 0b - No exception by FIFO Underflow 1b - Exception by FIFO underflow
14 FIFOFOUND6	FIFO Underflow Exception flag for channel 6 The FIFOFOUND bit indicates an exceptional underflow condition in the FIFO. If the FIFO is empty and a read operation is requested then this flag is set. Write a logic 1 to this field to clear this flag. 0b - No exception by FIFO Underflow 1b - Exception by FIFO underflow
13 FIFOFOUND5	FIFO Underflow Exception flag for channel 5 The FIFOFOUND bit indicates an exceptional underflow condition in the FIFO. If the FIFO is empty and a read operation is requested then this flag is set. Write a logic 1 to this field to clear this flag. 0b - No exception by FIFO Underflow 1b - Exception by FIFO underflow
12 FIFOFOUND4	FIFO Underflow Exception flag for channel 4 The FIFOFOUND bit indicates an exceptional underflow condition in the FIFO. If the FIFO is empty and a read operation is requested then this flag is set. Write a logic 1 to this field to clear this flag. 0b - No exception by FIFO Underflow 1b - Exception by FIFO underflow
11 FIFOFOUND3	FIFO Underflow Exception flag for channel 3 The FIFOFOUND bit indicates an exceptional underflow condition in the FIFO. If the FIFO is empty and a read operation is requested then this flag is set. Write a logic 1 to this field to clear this flag. 0b - No exception by FIFO Underflow 1b - Exception by FIFO underflow

Table continues on the next page...

Field	Function
10 FIFOUND2	FIFO Underflow Exception flag for channel 2 The FIFOUND bit indicates an exceptional underflow condition in the FIFO. If the FIFO is empty and a read operation is requested then this flag is set. Write a logic 1 to this field to clear this flag. 0b - No exception by FIFO Underflow 1b - Exception by FIFO underflow
9 FIFOUND1	FIFO Underflow Exception flag for channel 1 The FIFOUND bit indicates an exceptional underflow condition in the FIFO. If the FIFO is empty and a read operation is requested then this flag is set. Write a logic 1 to this field to clear this flag. 0b - No exception by FIFO Underflow 1b - Exception by FIFO underflow
8 FIFOUND0	FIFO Underflow Exception flag for channel 0 The FIFOUND bit indicates an exceptional underflow condition in the FIFO. If the FIFO is empty and a read operation is requested then this flag is set. Write a logic 1 to this field to clear this flag. 0b - No exception by FIFO Underflow 1b - Exception by FIFO underflow
7 FIFOOVF7	FIFO Overflow Exception flag for channel 7 The FIFOOVF bit indicates an exceptional overflow condition in the FIFO. If the FIFO is full and an additional result is received to be written then this flag is set. Write a logic 1 to this field to clear this flag. 0b - No exception by FIFO overflow 1b - Exception by FIFO overflow
6 FIFOOVF6	FIFO Overflow Exception flag for channel 6 The FIFOOVF bit indicates an exceptional overflow condition in the FIFO. If the FIFO is full and an additional result is received to be written then this flag is set. Write a logic 1 to this field to clear this flag. 0b - No exception by FIFO overflow 1b - Exception by FIFO overflow
5 FIFOOVF5	FIFO Overflow Exception flag for channel 5 The FIFOOVF bit indicates an exceptional overflow condition in the FIFO. If the FIFO is full and an additional result is received to be written then this flag is set. Write a logic 1 to this field to clear this flag. 0b - No exception by FIFO overflow 1b - Exception by FIFO overflow
4 FIFOOVF4	FIFO Overflow Exception flag for channel 4 The FIFOOVF bit indicates an exceptional overflow condition in the FIFO. If the FIFO is full and an additional result is received to be written then this flag is set. Write a logic 1 to this field to clear this flag. 0b - No exception by FIFO overflow 1b - Exception by FIFO overflow
3 FIFOOVF3	FIFO Overflow Exception flag for channel 3 The FIFOOVF bit indicates an exceptional overflow condition in the FIFO. If the FIFO is full and an additional result is received to be written then this flag is set. Write a logic 1 to this field to clear this flag. 0b - No exception by FIFO overflow 1b - Exception by FIFO overflow
2 FIFOOVF2	FIFO Overflow Exception flag for channel 2 The FIFOOVF bit indicates an exceptional overflow condition in the FIFO. If the FIFO is full and an additional result is received to be written then this flag is set. Write a logic 1 to this field to clear this flag. 0b - No exception by FIFO overflow 1b - Exception by FIFO overflow
1 FIFOOVF1	FIFO Overflow Exception flag for channel 1 The FIFOOVF bit indicates an exceptional overflow condition in the FIFO. If the FIFO is full and an additional result is received to be written then this flag is set. Write a logic 1 to this field to clear this flag.

Table continues on the next page...

Field	Function
	0b - No exception by FIFO overflow 1b - Exception by FIFO overflow
0 FIFOOVF0	FIFO Overflow Exception flag for channel 0 The FIFOOVF bit indicates an exceptional overflow condition in the FIFO. If the FIFO is full and an additional result is received to be written then this flag is set. Write a logic 1 to this field to clear this flag. 0b - No exception by FIFO overflow 1b - Exception by FIFO overflow

13.8.4.7 MICFIL Output Result Register (DATACH0 - DATACH7)

13.8.4.7.1 Offset

Field	Function
31-24 —	Reserved
23 OUTUNF7	Channel 7 Output Underflow Flag The OUTUNF bit indicates an exceptional underflow condition in the output. 0b - No exception by output underflow. 1b - Exception by output underflow.
22 OUTUNF6	Channel 6 Output Underflow Flag The OUTUNF bit indicates an exceptional underflow condition in the output. 0b - No exception by output underflow. 1b - Exception by output underflow.
21 OUTUNF5	Channel 5 Output Underflow Flag The OUTUNF bit indicates an exceptional underflow condition in the output. 0b - No exception by output underflow. 1b - Exception by output underflow.
20 OUTUNF4	Channel 4 Output Underflow Flag The OUTUNF bit indicates an exceptional underflow condition in the output. 0b - No exception by output underflow. 1b - Exception by output underflow.
19 OUTUNF3	Channel 3 Output Underflow Flag The OUTUNF bit indicates an exceptional underflow condition in the output. 0b - No exception by output underflow. 1b - Exception by output underflow.
18 OUTUNF2	Channel 2 Output Underflow Flag The OUTUNF bit indicates an exceptional underflow condition in the output. 0b - No exception by output underflow. 1b - Exception by output underflow.
17 OUTUNF1	Channel 1 Output Underflow Flag The OUTUNF bit indicates an exceptional underflow condition in the output. 0b - No exception by output underflow. 1b - Exception by output underflow.
16 OUTUNF0	Channel 0 Output Underflow Flag The OUTUNF bit indicates an exceptional underflow condition in the output. 0b - No exception by output underflow. 1b - Exception by output underflow.
15-8 —	Reserved
7 OUTOVF7	Channel 7 Output Overflow Flag The OUTOVF bit indicates an exceptional overflow condition in the output. 0b - No exception by output overflow. 1b - Exception by output overflow.
6 OUTOVF6	Channel 6 Output Overflow Flag The OUTOVF bit indicates an exceptional overflow condition in the output. 0b - No exception by output overflow. 1b - Exception by output overflow.

Table continues on the next page...

Field	Function
5 OUTOVF5	Channel 5 Output Overflow Flag The OUTOVF bit indicates an exceptional overflow condition in the output. 0b - No exception by output overflow. 1b - Exception by output overflow.
4 OUTOVF4	Channel 4 Output Overflow Flag The OUTOVF bit indicates an exceptional overflow condition in the output. 0b - No exception by output overflow. 1b - Exception by output overflow.
3 OUTOVF3	Channel 3 Output Overflow Flag The OUTOVF bit indicates an exceptional overflow condition in the output. 0b - No exception by output overflow. 1b - Exception by output overflow.
2 OUTOVF2	Channel 2 Output Overflow Flag The OUTOVF bit indicates an exceptional overflow condition in the output. 0b - No exception by output overflow. 1b - Exception by output overflow.
1 OUTOVF1	Channel 1 Output Overflow Flag The OUTOVF bit indicates an exceptional overflow condition in the output. 0b - No exception by output overflow. 1b - Exception by output overflow.
0 OUTOVF0	Channel 0 Output Overflow Flag The OUTOVF bit indicates an exceptional overflow condition in the output. 0b - No exception by output overflow. 1b - Exception by output overflow.

13.8.4.11 Voice Activity Detector 0 Control register (VAD0_CTRL_1)

13.8.4.11.1 Offset

Register	Offset
VAD0_CTRL_1	90h

13.8.4.11.2 Diagram

13.8.4.11.3 Fields

Field	Function
31-27 —	Reserved
26-24 VADCHSEL	Voice Activity Detector Channel Selector Selects the number of channel which the hardware voice activity detector will work. NOTE: This bitfield mustn't change when BSY_FIL is asserted.
23-22 —	Reserved
21-20 —	Reserved
19-16 VADCICOSR	Voice Activity Detector CIC Oversampling Rate This bitfield defines the oversampling rate of the CIC filter. The oversampling rate is (16-CICOSR). NOTE: This bitfield mustn't change when BSY_FIL is asserted.
15-13 —	Reserved
12-8 VADINITT	Voice Activity Detector Initialization Time Selects the number of frames to be used to initialize the voice detection. During this period the output of the voice activity detector is forced to inactive. For more information see Initialization Time . NOTE: The initialization time will be the time taken by [VADINITT+1] frames. NOTE: This bitfield mustn't change when BSY_FIL is asserted.
7-5 —	Reserved
4 VADST10	Voice Activity Detector Internal Filters Initialization Initializes the signal and noise filter with pre-filter value.

Table continues on the next page...

PDM Microphone Interface (MICFIL)

Field	Function
	NOTE: If the use of this bit is required, it should be stay pulsed by more than 2 cycles of system clock. NOTE: There is not voice activity detection when VADST10 is asserted. 0b - Normal operation. 1b - Filters are initialized.
3 VADERIE	Voice Activity Detector Error Interruption Enable The VADERIE bit enables Error Interrupts in the PDM Interface. This error could be caused by an overflow in the input of the HWVAD and it is signalized by the VADINSATF flag. 0b - HWVAD Error Interrupts disabled 1b - HWVAD Error Interrupts enabled
2 VADIE	Voice Activity Detector Interruption Enable This bit enables interrupts in the PDM Interface when voice activity event has been detected by the Hardware Voice Activity Detector (HWVAD). See the VADIF for more information. 0b - HWVAD Interrupts disabled 1b - HWVAD Interrupts enabled
1 VADRST	Voice Activity Detector Reset The VADRST is a self-negated bit which provides the CPU with the capability to initialize the VAD through the slave-bus interface. This bit always reads as zero. Refer to VAD Soft-reset .
0 VADEN	Voice Activity Detector Enable Enables the use of the Hardware Voice Activity Detector. NOTE: This bitfield mustn't change when BSY_FIL is asserted. 0b - The HWVAD is disabled. 1b - The HWVAD is enabled.

13.8.4.17.4 Fields

Field	Function
31-26 —	Reserved
25-16 VADZCDTH	Zero-Crossing Detector Threshold This bit-field is the initial value taken to estimate the ZCD threshold when it is estimated automatically (VADZCDAUTO = 1), otherwise (VADZCDAUTO = 0) this bit-field is the static value of the ZCD threshold.
15-12 —	Reserved
11-8 VADZCDADJ	Zero-Crossing Detector Adjustment Selects the adjustment value of the threshold estimator. For more information see Zero-Crossing Detector .
7-5 —	Reserved
4 VADZCDAND	Zero-Crossing Detector AND Behavior Selects whether the Zero-Crossing detector results will be AND'ed or OR'ed with the energy-based detection to form the voice activity detection event. 0b - The ZCD result is OR'ed with the energy-based detection. 1b - The ZCD result is AND'ed with the energy-based detection.
3 —	Reserved
2 VADZCDAUTO	Zero-Crossing Detector Automatic Threshold Enables the automatic estimation of the ZCD threshold. 0b - The ZCD threshold is not estimated automatically, 1b - The ZCD threshold is estimated automatically.
1 —	Reserved
0 VADZCDEN	Zero-Crossing Detector Enable Enables the Zero-Crossing Detector (ZCD) in the Hardware Voice Activity Detector (HWVAD). 0b - The ZCD is disabled. 1b - The ZCD is enabled.

13.8.5 Functional Description

13.8.5.1 Overview

Figure 13-92 shows the block diagram of the PDM Microphone Interface (MICFIL) block. Basically this module is composed by a Decimation Filter and a FIFO by channel, an Input Interface for each pair of microphones, a shared Time Generator unit, a shared bus interface, a shared DMA interface and a shared interrupt interface.

The Decimation Filter implements a low-pass filter in the audio band (20Hz-22.5KHz @48KHz output sampling rate by default) with a configurable decimation rate. It is implemented using an arrange of a CIC, a Half Band, a FIR and a DC remover filter.

The Time Generator unit generates the PDM clock to the microphones. This clock is the same for all the PDM microphones and it is active for all the microphones, i.e. there is not possibility to turn off the PDM clock for one microphone only.

Finally, the output of each Decimation Filter is stored in a FIFO buffer. Each FIFO is mapped in the DATACHn registers. It is possible to generate either an interrupt or a DMA request when, in each FIFO of all enabled channels, the number of data stored surpasses a configured watermark.

13.8.5.2 Time Generator

The Time Generator is the responsible to generate the PDM clock to the external PDM microphones.

The PDM Clock rate depends on the desired output rate (fout), the quality mode (defined by QSEL bitfield) and the CIC's OSR (defined by CICOSR bitfield) as is shown in Table 13-57.

To the MICFIL work properly, the CLKDIV bitfield must be configured depending on the desired Output rate, the internal MICFIL clock frequency and the OSR value (see CIC Filter) as shown in Equation 1 on page 4215. Once calculated the CLKDIV value, the generated PDM clock rate can be estimated as shown in Equation 2 on page 4215, where the K factor value depends on the quality mode (see Table 13-59).

$$CLKDIV = \frac{\text{MICFIL Clock rate}}{8(\text{OSR})(\text{Output Rate})}$$

Equation 1. CLKDIV bitfield value

$$\text{PDM clock rate} = \frac{\text{MICFIL Clock rate}}{2 \cdot \text{floor}(K \cdot CLKDIV)}$$

Equation 2. PDM clock rate

NOTE

The Time Generator is affected by soft-reset. The PDM Clock starts with a rising edge after a soft reset is issued.

13.8.5.2.1 Busy Flag

If a least one Decimation Filter channel is running and HWVAD is stopped (in Normal mode, Debug mode when DBGE is 1 or Low Power mode) and then all channels are stopped (by clearing PDMIEN bit, changing to Debug when DBGE=0 or changing to Disable/Low Leakage modes), the MICFIL waits for filter completion, then BSY_FIL is cleared.

If only HWVAD are running and then are stopped, BSY_FIL is cleared immediately.

This bit can also be used as a confirmation that all Decimation Filters are stopped in a transition to Debug (when DBGE=0) or Disable/Low Leakage modes.

13.8.5.3 Input Interface

The Input Interface block splits up the 1-bit bitstream incoming from the PDM microphone in two signals, one by channel, as is shown in [Figure 13-92](#). The left microphone (L) will be directed to the lower channel and the right microphone (R) will be directed to the upper channel.

13.8.5.3.1 Input Interface Signals

The timing diagram of the input interface signals is shown in [Figure 13-93](#). The data generated in the first half (Right microphone) of the PDM clock is directed to the Channel 1 and the data generated during the last half (Left microphone) is directed to the Channel 0.

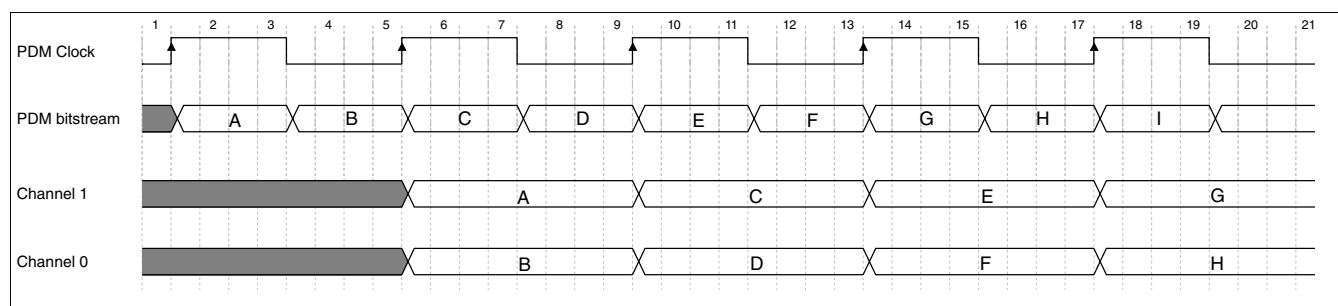

Figure 13-93. Input Interface signals

13.8.5.3.2 Input/Output Timing Requirements

The PDM microphones must meet the setup and hold timing requirements shown in [Table 13-58](#) and [Figure 13-94](#). The "k" factor value in [Table 13-58](#) depends on the selected quality mode as shown in [Table 13-59](#).

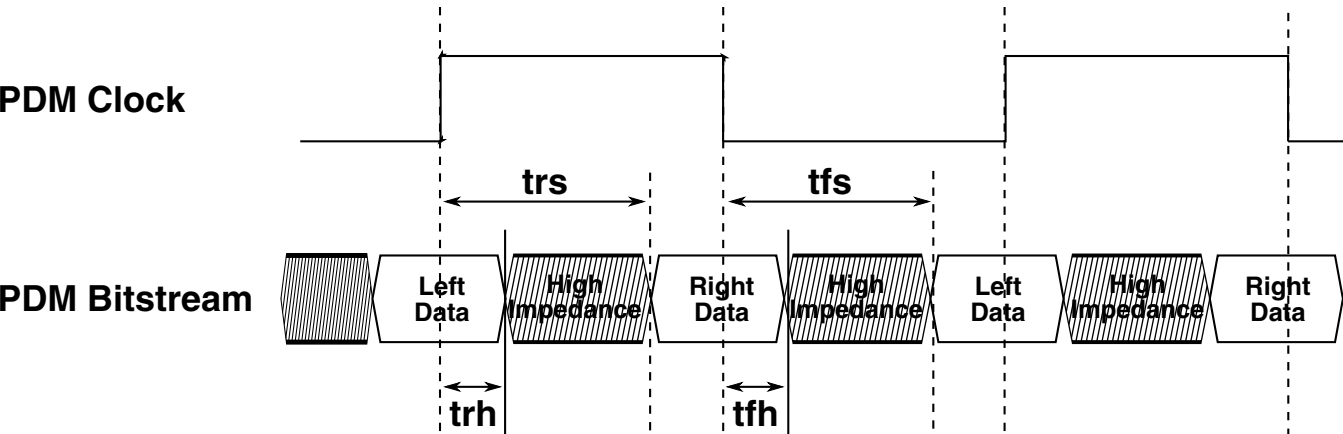

Figure 13-94. Input/Output Timing Requirements

Table 13-58. Timing parameters

Parameter	Value
trs, tfs	$\leq \frac{\text{floor}(K \times CLKDIV) - 1}{MICFIL \text{ Clock rate}}$ 1
trh, tfh	≥ 0

1. Depending on K value, the user must make sure floor(K x CLKDIV) > 1 to avoid timing problems.

Table 13-59. K factor value

Quality mode	K factor
High Quality	1/2
Medium Quality, Very Low Quality 0	1
Low Quality, Very Low Quality 1	2
Very Low Quality 2	4

13.8.5.4 Decimation Filter

[Figure 13-95](#) shows the block diagram of the Decimation Filter. This block is composed by a CIC filter, a DC remover, a FIR filter and a Half Band filter for each channel.

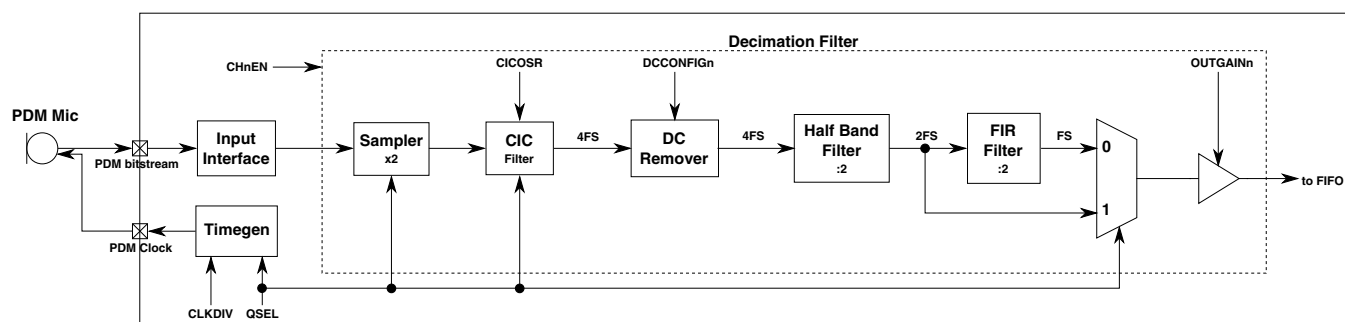

Figure 13-95. Decimation Filter Block Diagram

The Sampler block is activated depending on the quality mode selected (QSEL bitfield). This one samples twice the PDM data incoming from the Input Interface.

The CIC filter (Cascaded Integrator Comb filter) is a low pass filter commonly used to filter the sigma-delta modulator output signal. Its implementation is very simple without multipliers. It is composed by 5 cascable unit sections of Integrator plus Differentiator units. Each section implements a low pass Sinc filter to improve the attenuation in the high frequencies range. It has a configurable decimation rate. This filter does not introduce phase distortions to the input signal, however the frequency amplitude response is not flat.

The DC remover is a high pass filter used to remove the DC component of the processed signal. It is a first order IIR filter of Chebichev type-I and it's implemented in the Direct Form-II. Its cut-off frequency is configurable.

The Half Band filter block implements a 19-tap low pass digital FIR filter with decimation by 2. It's used to compensate the high CIC drop in passband and helps the FIR filter block to flat the overall passband response.

The FIR filter block implements a 125-tap low pass digital FIR filter with decimation by 2 designed to achieve an overall filter passband ripple less than 0.2dB and a stopband attenuation more than 80dB. Such as the Half Band filter, it is also used to compensate the high CIC drop and to achieve a little passband ripple.

The Decimation Filter output depends on the quality mode selected by the QSEL bitfield, so it can come from the Half Band filter output directly or the FIR filter output.

Each Decimation Filter output can be adjusted by shifting right or left the filtered result. In case the adjusted output overflows or underflows the signed 16-bits, an error interrupt can be generated and the value is saturated to the maximum or minimum value respectively. Finally, each Decimation Filter result is sent to a FIFO.

13.8.5.4.1 CIC Filter

The CIC filter itself is an optimized implementation of the low pass Sinc filter with multiple stages. It is widely used because it requires just adders and subtractors to be implemented. The CIC filter is composed by sub-blocks called: integrator and comb. The architecture of the CIC filter is presented in [Figure 13-96](#) and it consists of 5 integrator sections, and then followed by 5 comb sections downsampled.

The decimation rate of the CIC filters is defined by the CICOSR bitfield and by the quality selected (see [Quality Modes](#)). When the MICFIL is running in High and Very Low Quality 0 modes the decimation rate is 2OSR (where $OSR = 16 - CICOSR$), otherwise the decimation rate is OSR only.

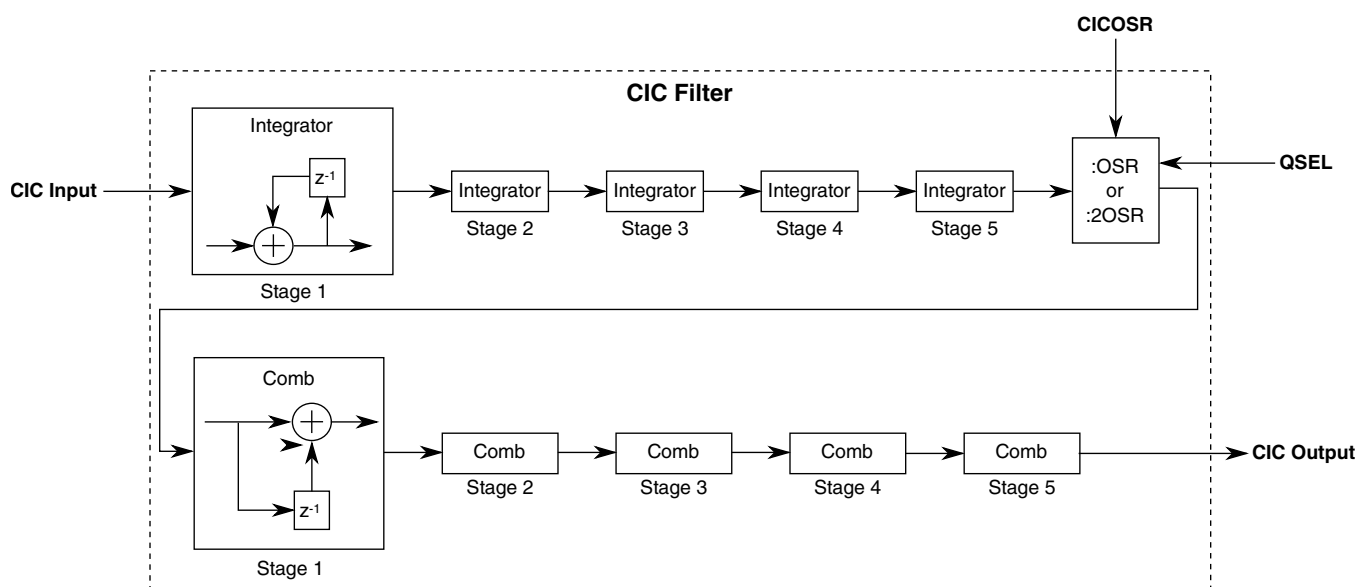

Figure 13-96. CIC Filter Block Diagram

13.8.5.4.2 DC Remover

The purpose of the DC Remover block is to remove the DC level component of the signal using a high-pass filter with a very low cut-off frequency selected by the DCCONFIGn bitfield. This filter can be bypassed when DCCONFIGn=11.

13.8.5.4.3 Half Band Filter

The use of half band filters is very attractive because it divides the base-band of the signal into two equal subbands and the half of the coefficients are zero-valued. The calculated filter has 19 coefficients (8 zero-valued) and its structure is shown in [Figure 13-97](#).

Figure 13-97. Half band filter structure

13.8.5.4.4 FIR Filter

The FIR block implements a fixed low-pass digital FIR filter. The calculated filter has 125 coefficients and its classical structure is shown in [Figure 13-98](#).

Figure 13-98. FIR filter structure

13.8.5.4.5 Decimated Output

The Decimation Filter's output depends on the quality mode selected by QSEL bitfield. It can be selected between the incoming signal from whether the Half Band filter or the FIR filter.

At the end, the selected output can be adjusted by a gain determined by the OUTGAINn bitfield for each channel ([Figure 13-99](#)), then the adjusted output is sent to its respective FIFO. The adjusted output is saturated when it is greater than the maximum 16-bits signed positive value or lower than the 16-bits signed negative value. In both cases overflow (OUTOVFn) or underflow (OUTUNFn) flags are set respectively and an error interrupt is generated if ERREN bitfield value was previously enabled.

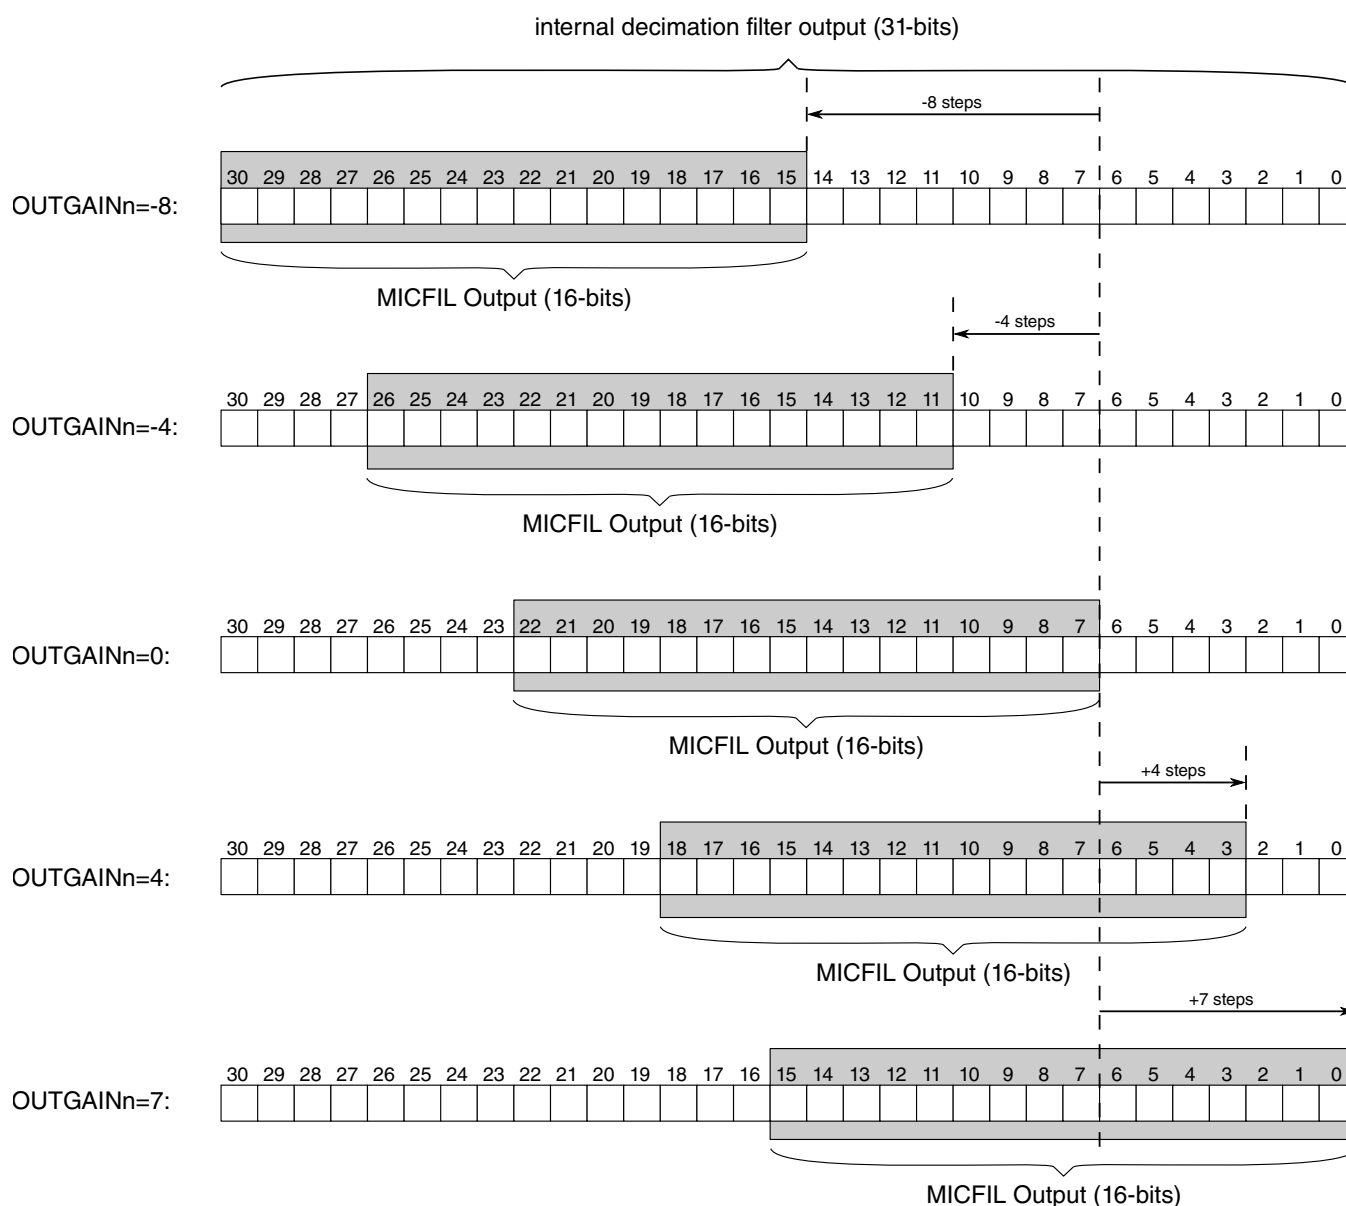

Figure 13-99. Output Gain

13.8.5.4.6 Minimum Required CLKDIV bitfield value

To work properly the CLKDIV bitfield value must have a minimum value according to the quality mode configured (see [Quality Modes](#)), the number of enabled channels (EC), OSR value (see [CIC Filter](#)) and K factor (see [Input/Output Timing Requirements](#)). When this condition is not met the LOWFREQF bit is asserted and an error interrupt can be issued (in case ERREN=1).

The equation to estimate the minimum required CLKDIV bitfield value in Medium, High and Low Quality modes is shown in [Equation 3 on page 4221](#).

$$\text{floor}(K \times \text{CLKDIV}) \geq K \times \frac{10 + 125EC}{8 \times \text{OSR}}$$

Equation 3. Minimum required CLKDIV value in Medium, High and Low Quality modes

The equation to estimate the minimum required CLKDIV bitfield value in Very Low Quality modes is shown in [Equation 4 on page 4222](#).

$$\text{floor}(K \times \text{CLKDIV}) \geq K \times \frac{10 + 19EC}{8 \times \text{OSR}}$$

Equation 4. Minimum required CLKDIV value in Very Low Quality modes

13.8.5.4.7 Overall Bandpass

The bandpass of the Decimation Filter depends on the quality mode and the output rate. For instance, the overall filter passband for different output data rates when the MICFIL is in High, Medium and Low Quality modes is shown in [Table 13-60](#). The passband is about the half of the output rate because the FIR filter is enabled.

Table 13-60. Filter Passband in High, Medium and Low Quality modes (DCCONFIGn=00)

Output Data Rate (KHz)	Overall Filter Passband
16	7Hz - 7.5KHz
24	10.5Hz - 11.25KHz
32	14Hz - 15KHz
48	21Hz - 22.5KHz

The overall filter passband for different output data rates when the MICFIL is in Very Low Quality modes is shown in [Table 13-61](#).

Table 13-61. Filter Passband in Very Low Quality modes (DCCONFIGn=00)

Output Data Rate (KHz)	Overall Filter Passband
16	3.5Hz - 3.75KHz
24	5.25Hz - 5.63KHz
32	7Hz - 7.5KHz
48	10.5Hz - 11.25KHz
96	21Hz - 22.5KHz

13.8.5.5 Hardware Voice Activity Detector

The Hardware Voice Activity Detector (HWVAD) is a block responsible for detect voice activity in a channel selected by the user as shown in the [Figure 13-100](#) and [Figure 13-101](#). It can be configured in Envelope-based or Energy-based mode and it should be configured as described in [Procedures](#).

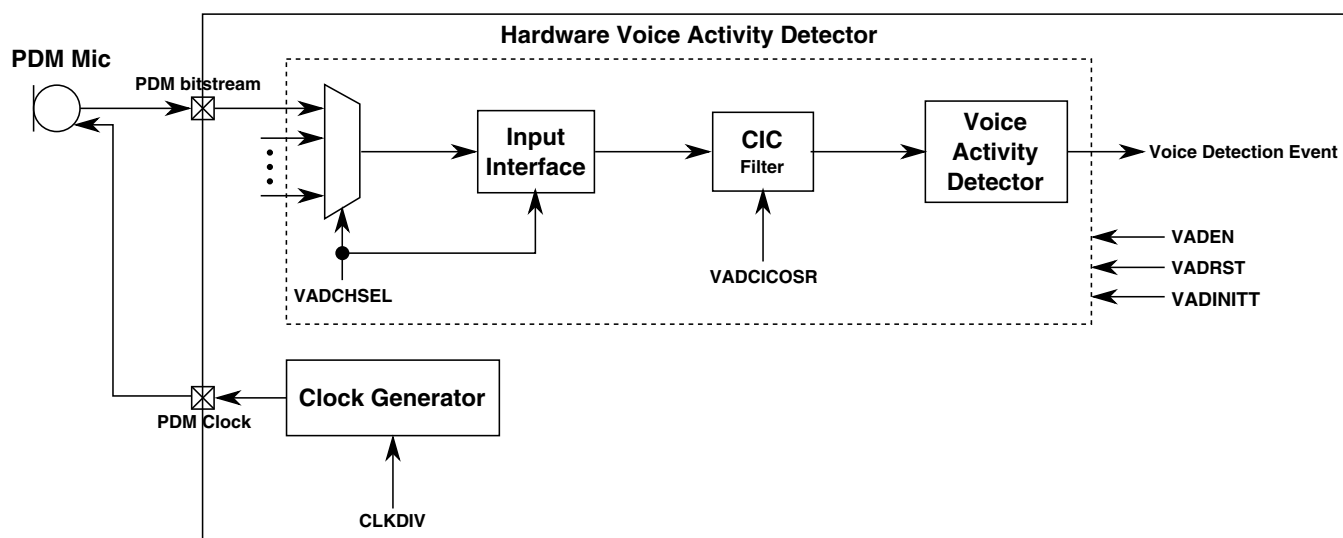

Figure 13-100. HWVAD Block Diagram

The HWVAD can divide the incoming PCM signal from its internal CIC in frames, the frame energy is used to estimate the background noise. Both frame energy and noise energy are examined, a voice activity is detected when a specific delta between them is detected, then a interrupt will be issued. Optionally a Zero-Crossing Detection block (ZCD) could be enabled to avoid low energy voiced speech be missed, improving the voice detection performance.

The HWVAD detector can be enabled by the VADEN bit (VAD_CTRL_1 register) and could be reset by software through the VADRST bit (VAD_CTRL_1 register) . It is important to remark that the HWVAD detector could be enabled and/or reset only when the MICFIL isn't running i.e. when the BSY_FIL bit in STAT register is cleared.

To perform voice detection a Noise Filter and Signal Filter are used as shown [Figure 13-101](#). In addition, a minimum block in the output of the Noise Filter and a maximum block in the output of the Signal Filter can be used. The result of both blocks can be scaled by gain blocks. Finally, the signal and noise estimated are compared, voice is detected when signal is greater than noise.

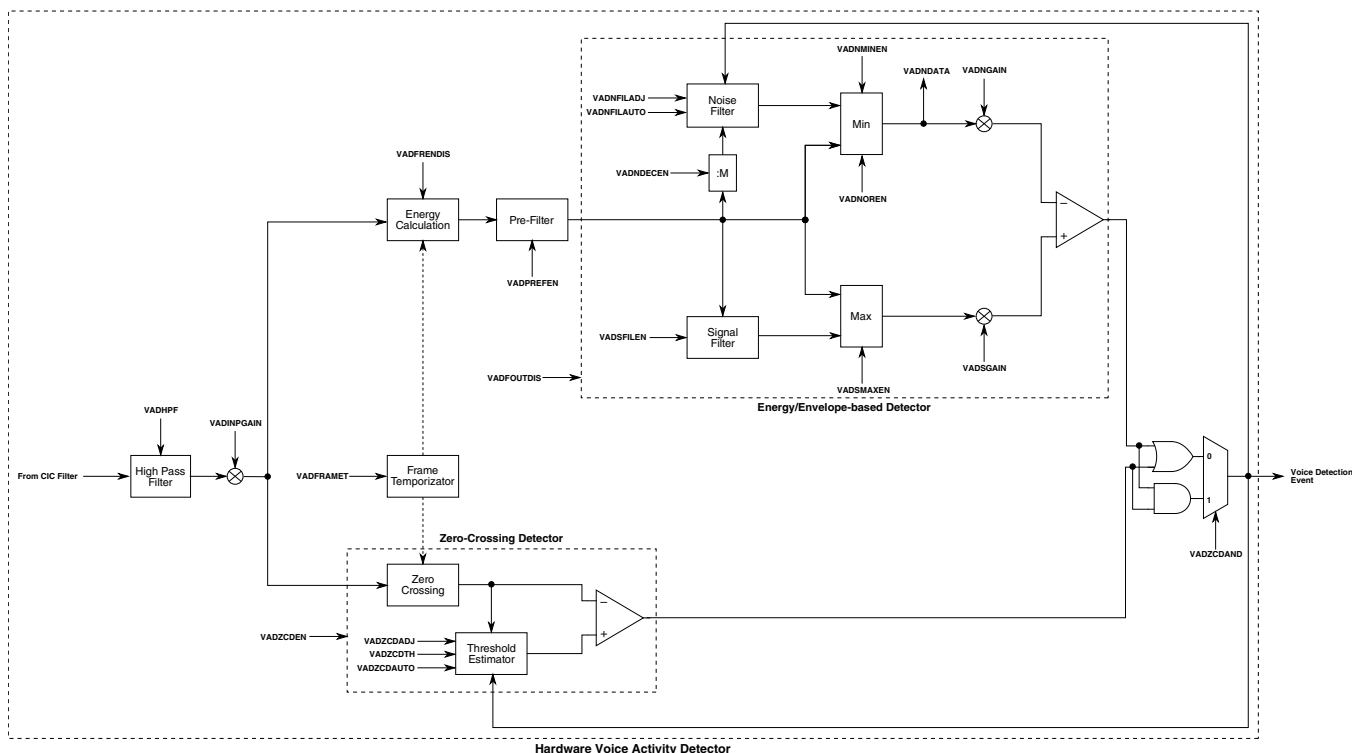

Figure 13-101. HWVAD Block Diagram (cont.)

13.8.5.5.1 High-Pass Filter

The purpose of the High-Pass Filter is to remove the low frequency components. The cut-off frequency is selected by the VADHPF bitfield. This filter is bypassed when VADHPF=00.

13.8.5.5.2 Input Setting

The HWVAD input has internally a user configurable High-Pass filter (see VADHPF bit description) and a user configurable gain (see VADINPGAIN). Both controls could be used to configure the module based on external noise conditions.

13.8.5.5.3 Frame Time Setting

In order to perform voice detection the signal frames incoming from the CIC filter can be divided in frames whose duration can be configured. The frame time will depend on the CIC output rate, the value of the VADFRAME bitfield and a constant as is defined in [Equation 5 on page 4224](#).

$$frame\ time = \frac{VADFRAME \times 192}{CIC\ output\ rate}$$

Equation 5. Frame Time

For instance, in the typical case of the CIC filter output rate would be 192KHz, the frame time would be 10ms when VADFRAMET is 10.

13.8.5.5.4 Initialization Time

An initialization time can be configured by the VADINITT bitfield. During this initialization time no voice detection event is issued, Zero-Crossing and Energy/Envelope-based detectors are kept disabled.

$$\text{initialization time} = (\text{VADINITT} + 1) \times \text{frame time}$$

Equation 6. Initialization Time

13.8.5.5.5 Energy Calculation

In case VADFRENDIS = 0, the sum of the absolute values of all the samples of each frame are used to detect voice. Otherwise, if VADFRENDIS=1, the absolute value of the samples are used to detect voice i.e. the data incoming from CIC is not divided in frames.

13.8.5.5.6 Pre-Filter

The Pre-Filter block is a low-pass filter which can be enabled when VADPREFEN=1.

13.8.5.5.7 Energy/Envelope-based Detector

To perform voice detection a Noise Filter and Signal Filter are used as shown in the HWVAD Block Diagram in the HWVAD Overview. In addition, a minimum block in the output of the Noise Filter and a maximum block in the output of the Signal Filter can be used. The result of both blocks can be scaled by gain blocks. Finally, the signal and noise estimated are compared, voice is detected when signal is greater than noise.

13.8.5.5.8 Noise Filter

The Noise Filter is a low-pass filter . This filter could be adjusted by the VADNFILADJ bitfield . In case VADNFILAUTO=1 the noise filter is enabled only when voice is not detected, when voice is detected the filter output does not change. In case VADNFILAUTO=0 the filter is always enabled.

A decimation stage in the input of the Noise Filter can be enabled by the VADNDECEN bitfield.

13.8.5.5.9 Minimum Noise

In order to estimate the noise, a block which calculates the minimum value between the input and output of the noise filter can be used. This block can be enabled by VADNMINEN, otherwise the output of the noise filter is passed directly.

The estimated noise of the output of this block is stored in the VADNDATA register for post-processing via software.

13.8.5.5.10 Signal Filter

The Signal Filter is a low-pass filter . This filter will be enabled when VADSFLEN=1, otherwise the filter will be bypassed.

13.8.5.5.11 Maximum Signal

In order to estimate the signal, a block which calculates the maximum value between the input and output of the signal filter can be used. This block can be enabled by VADSMAXEN, otherwise the output of the signal filter is passed directly.

13.8.5.5.12 Filter Result Gain Setting

There are two gain adjustment controls, one for the estimated noise (VADNGAIN) and another for signal estimated (VADSGAIN). Both gain adjustments outputs are compared, the comparison result determines whether or not there is voice in the channel.

13.8.5.5.13 Zero-Crossing Detector

Optionally, the HWVAD performance can be increased by the use of a Zero-Crossing Detection (ZCD) circuit. It is enabled by a VADZCDEN bit.

The threshold of the ZCD could be static or calculated dynamically depending on the VADZCDAUTO bit. When it is dynamically determined (VADZCDAUTO = 1) the threshold is calculated automatically taking the VADZCDTH bit-field as initial value, otherwise (VADZCDAUTO=0) the threshold is static in the VADZCDTH user configurable value.

The ZCD result can be AND'ed or OR'ed with the energy-based or envelope-based detection, it is selected by the VADZCDAND bit. The filter coefficient is equal to $(VADZCDADJ+1)*2^{(-4)}$.

13.8.5.5.14 Interrupt

The HWVAD issues an interrupt when voice activity is detected and the VADIE bit in the VAD_CTRL_1 register is enabled. The voice activity event also will set the VADIF flag in the VAD_STAT register, this bit will be cleared when it is written 1.

13.8.5.5.15 Extended Operation

The VADIF bit could be used for a HWVAD extended operation i.e. using the VADNDATA bitfield value to determine a more accurate voice detection event by software. The procedure to follow will be:

1. An interrupt is issued by the HWVAD, the VADIF is set.
2. Leave the VADIF asserted while software is processing the VADNDATA bitfield content.
3. When software finishes to process the VADNDATA and detects voice activity:
 - If Envelope-based Detection is used, pulse VADST10 by more than 2-cycles and clear VADIF flag.
 - If Energy-based Detection is used, clear VADIF flag.

13.8.5.5.16 VAD Soft-reset

The VAD soft-reset is requested by writing 1 to the VADRST bit. It resets the following blocks and/or registers:

- VADIF, VADINSATF bitfields.
- All internal VAD buffers.

13.8.5.6 Bus Interface

The Bus Interface manages the Direct Memory Access (DMA) transactions, the interrupt requests and the user register interface with the SoC.

13.8.5.6.1 FIFO

The FIFO is a First-In, First-Out buffer that saves the overall filtering results. Each FIFO is 8 entries length. There is one FIFO for each channel. A push writes data into the FIFO, and a read pops data from FIFO. The push and pop operations from FIFO are in different clock domains, the push operation is made using the MICFIL clock while the pop operation uses the CPU clock. The FIFO has a configurable watermark FIFOWMK in the FIFO_CTRL register. When the amount of data in all the FIFOs of the enabled channels is greater than the watermark value (FIFO_CTRL[FIFOWMK]) a DMA/IRQ is requested depending on the DISEL field in the CTRL_1 register. After the filters are enabled by PDMIEN, the initial FIR results are discarded and not written into the FIFOs.

About 68 initial FIR results are not stored on FIFOs (FIR_RDY=0). After the STAT[FIR_RDY] register is set the data generated by the filter is valid and starts to push the results in FIFO.

A new filtered result is discarded (not stored) when the FIFO is full and overflow flag FIFOOVFn rises. Similarly, when trying a pop and FIFO is empty no valid data is read and underflow flag rises. In both cases, when overflow or underflow occurs they are flagged in the FIFO_STAT register to the respective channel, and an error interrupt is generated if the ERREN in the CTRL_1 register is asserted.

When the FIFO is reset by asserting the SRES soft-reset bit, zero values fills all FIFO positions, as well as push and pop pointers are set to initial position.

13.8.5.6.2 DMA

If DISEL=01 the FIFO stored samples will be read through DMA transactions. Then if there is at least one enabled channel and all FIFOs of all enabled channels reach their watermark the output interface makes a request for DMA transaction. When the PDMIEN is set and the filters start to operate, there is a period to wait the filter results to stabilize and no filter results are stored on the FIFOs. Therefore the first DMA request takes longer to occur than the following ones.

The CHnF flags in the STAT register are cleared when a DMA transaction is finished.

When the MICFIL is in Low Power mode and the watermark level is surpassed an asynchronous DMA request is delivered to the system, then the system wakes up the CPU clock, returning to Normal mode, to read FIFOs data.

13.8.5.6.3 Interrupt Requests

If DISEL=10 then an interrupt request is used to indicate that filtering results are stored in the FIFOs to be read by CPU. Also in this case the data can be read in the DATAChn registers and the flag CHnF of the STAT register are asserted for the enabled channels when the CHn FIFO surpasses the watermark level.

When the module is in Low Power mode the CPU clock is disabled, but the MICFIL clock remains enabled. In this case, an asynchronous interrupt is delivered to the system, it wakes up the CPU clock, returning to Normal mode. The system could read the FIFOs data and after should clear the CHnF flags to get a new interrupt request.

An error interrupt request can be generated also when an exceptional condition happens, such as a overflow or underflow in any channel output, an overflow or underflow of any FIFO, or the MICFIL clock rate is not the minimum value required to the MICFIL working (see [Minimum Required CLKDIV bitfield value](#)). This one is enabled by the

ERREN bit and the type of error is signaled by its respective status flag: OUTOVFn and OUTUNFn for channel outputs errors, FIFOOVF and FIFOUND flags for FIFO errors, and LOWFREQF for MICFIL clock rate.

13.8.5.7 Low Power Mode

In Low Power mode the MICFIL is able to filter the PDM microphone data and perform voice detection such as in Normal mode and can generate a wake up event through asynchronous DMA/IRQ requests depending on CHENn, VADEN and PDMIEN values.

In case the CPU is on a STOP/VLPS entry , PDMIEN is asserted and either CHENn or VADEN are asserted, then the CPU clock is gated.

In case the CPU is on a VLLS/LLS entry , VADEN is asserted and PDMIEN is asserted, then the CPU clock is gated.

In case the CPU is on a VLLS/LLS entry and either PDMIEN or VADEN are cleared, then the mode will be acknowledged when the last sample is processed.

The DMA and IRQ requests can be generated asynchronously to wake up the CPU. Then the system wakes up the CPU clock, and get back the MICFIL to Normal mode to read FIFOs data if required.

NOTE

The asynchronous DMA or interrupt requests are generated only in this mode.

13.8.5.8 Debug Mode

In case DBGE=0, if a debug request is received or DBG is asserted while the MICFIL is running with at least a channel enabled, the PDM generated clock and the MICFIL will be stopped after finish to process remaining data. Otherwise, in case DBGE=1, the module will continue processing, it will not stop.

The PDM Interface cannot enter Debug mode once in Disable/Low Leakage or Low Power mode.

The Debug mode request affects all channels in the MICFIL. Access to output buffers remain operational, as well as their related flags.

NOTE

Once a debug request is issued, it can not be aborted.

13.8.5.9 Disable/Low Leakage mode

When Disable/Low Leakage (DLL) mode is requested while the MICFIL is running with at least a channel enabled, the PDM generated clock and the MICFIL will be stopped after finish to process remaining data, then CPU clock and MICFIL clock are gated. In case this mode is requested via SoC Doze when DOZEN=1 the MICFIL clock is gated but the CPU clock remains running.

After the MICFIL clock is stopped, the BSY_FIL bit is self-cleared and the mode is acknowledged .

Writes only to CTRL_1 and CTRL_2 registers are allowed with the exception of writes to the DBG and SRES bits, which are ignored, but read is still available for these bits.

NOTE

It can take up to 1020 MICFIL clock cycles from the request to the stop of the processing.

13.8.5.10 Soft-reset

The soft-reset is used to clear all the data in the filters. It is requested by writing 1 to the SRES bit. It reset the following blocks and/or registers:

- All internal buffers in Decimation Filters and Voice Activity Detectors.
- All FIFOs.
- All CHnF flags and LOWFREQF flag on the STAT register, and the FIFO_STAT register.
- Time Generator.

13.8.6 Procedures

Following are some simple initialization steps to be done before using the MICFIL block.

13.8.6.1 Initialization Procedure without HWVAD

The sequence of steps for the block initialization without enabling voice activity detector, i.e. using decimation filters only, is as follows:

1. Program the bit-fields as desired for your application (CLKDIV, CHnEN, FIFOWMK, DIESEL, ERREN etc.). For more details see [Application Clock and CLKDIV calculation example](#).
2. Start the overall module asserting the PDMIEN bit.
3. The module is ready to receive data from the input ports of the enabled channels.

13.8.6.2 Initialization Procedure with HWVAD

In this section is described the initialization procedures to initialize MICFIL with the voice activity detector.

The voice activity detector can work in two modes: Energy-based mode or Envelope-based mode. Optionally, a Zero-Crossing Detector can be enabled to improve the voice detection.

13.8.6.2.1 HWVAD in Energy-based mode

The sequence of steps to initialize the voice activity detector in Energy-based mode is as follows:

1. Program the control bitfields as desired for your application (CLKDIV, CHnEN, FIFOWMK, DIESEL, ERREN etc.). For more details see [Application Clock and CLKDIV calculation example](#).
2. Configure general HWVAD parameters:
 - a. CIC oversampling rate (VADCICOSR bitfield).
 - b. Configure the voice source channel (VADCHSEL bitfield).
 - c. Configure the internal initialization timer (VADINITT bitfield) if required. More details in [Initialization Time](#).
 - d. Assert VADEN bitfield.
3. Configure input, noise and signal gains according to the environmental noise conditions:
 - a. Configure the input gain (VADINPGAIN bitfield).
 - b. Configure the signal gain (VADSGAIN bitfield).
 - c. Configure the noise gain (VADNGAIN bitfield).
4. Enable the high-pass filter if required (VADHPF bitfield).
5. Configure the VADNFILADJ bitfield according to environmental noise conditions (VADNFILADJ = 16 is recommended).
6. Put HWVAD in energy-based mode (default values):
 - a. Keep the VADFRENDIS bitfield cleared.
 - b. Keep the VADPREFEN bitfield cleared.
 - c. Keep the VADSFLEN bitfield cleared.

- d. Keep the VADSMAXEN bitfield cleared.
- e. Keep the VADNFILAUTO bitfield asserted.
- f. Keep the VADNMINEN bitfield cleared.
- g. Keep the VADNDECEN bitfield cleared.
- h. Keep the VADNOREN bitfield cleared.
7. Initialize the Zero-Crossing Detector ([Zero-Crossing Detector Initialization](#)) if required.
8. Enable interrupts if required (VADIE and VADERIE bitfields).
9. Start the overall module asserting the PDMIEN bit.
10. The module is ready to receive data from the input ports of the enabled channels and to trigger interrupts when voice is detected.

Figure 13-102. Energy-based initialization sequence

13.8.6.2.2 HWVAD in Envelope-based mode

The sequence of steps to initialize MICIL with the voice activity detector in Envelope-based mode is as follows:

1. Program the control bitfields as desired for your application (CLKDIV, CHnEN, FIFOWMK, DIESEL, ERREN etc.). For more details see [Application Clock and CLKDIV calculation example](#).
2. Configure general HWVAD parameters:
 - a. CIC oversampling rate (VADCICOSR bitfield).
 - b. Configure the voice source channel (VADCHSEL bitfield).
 - c. Configure the internal initialization timer (VADINITT bitfield) if required. More details in [Initialization Time](#).
 - d. Assert VADEN bitfield.
3. Configure input, noise and signal gains according the environment noise conditions:
 - a. Configure the input gain (VADINPGAIN bitfield).
 - b. Configure the signal gain (VADSGAIN bitfield).
 - c. Configure the noise gain (VADNGAIN bitfield).

4. Enable the high-pass filter if required (VADHPF bitfield).
5. Put HWVAD in envelope-based mode:
 - a. Keep VADNFILADJ bitfield cleared.
 - b. Assert the VADFRENDIS bitfield.
 - c. Assert the VADPREFEN bitfield.
 - d. Assert the VADSFLEN bitfield.
 - e. Assert the VADSMAXEN bitfield.
 - f. Clear the VADNFILAUTO bitfield.
 - g. Assert the VADNMINEN bitfield.
 - h. Assert the VADNDECEN bitfield.
 - i. Assert the VADNOREN bitfield.
6. Initialize the Zero-Crossing Detector ([Zero-Crossing Detector Initialization](#)) if required.
7. Start the overall module asserting the PDMIEN bit.
8. Wait for VADINITF to be cleared.
9. Write VADST10 bitfield three times.
10. Enable interrupts if required (VADIE and VADERIE bitfields).
11. The module is ready to receive data from the input ports of the enabled channels and to trigger interrupts when voice is detected.

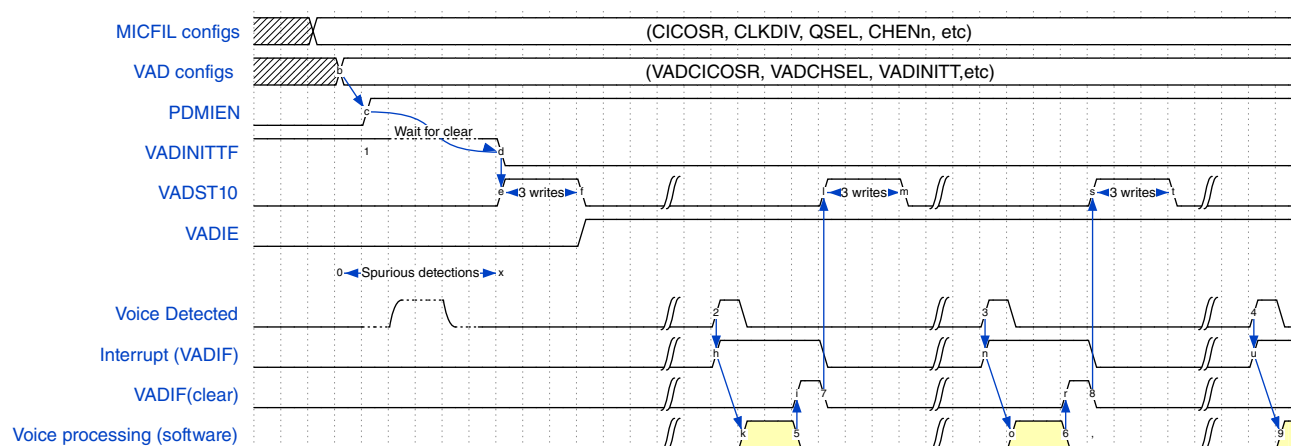

Figure 13-103. Envelope-based initialization sequence

13.8.6.2.3 Zero-Crossing Detector Initialization

The sequence of steps to initialize the Zero-Crossing Detector in Automatic mode is as follows:

1. Configure VADZCDADJ bitfield.
2. Configure an initial threshold in VADZCDTH according to the environmental noise conditions if required.
3. Configure VADZCDAND bitfield.

4. Keep VADZCDAUTO bitfield asserted.
5. Assert VADZCDEN.

The sequence of steps to initialize the Zero-Crossing Detector in Manual mode is as follows:

1. Configure a threshold in VADZCDTH according to the environmental noise conditions if required.
2. Configure VADZCDAND bitfield.
3. Clear VADZCDAUTO bitfield.
4. Assert VADZCDEN.

13.8.6.3 Reconfiguration Procedure

The sequence of steps for the block reconfiguration is as follows:

1. Deassert PDMIEN bit.
2. Wait to BSY_FIL to be cleared.
3. Run a soft-reset cycle.
4. Run a initialization procedure as described in [Initialization Procedure without HWVAD](#) or [Initialization Procedure with HWVAD](#).

13.8.6.4 Application Clock and CLKDIV calculation example

Assume that it is required to work at High Quality mode, CIC decimation by 16 (OSR = 16), 4 channels enabled (EC=4) and an output rate equal to 48KHz:

1. Check the PDM rate for High Quality mode in [Table 13-57](#). PDM rate = 48KHz x 8 x 16 = 6.144MHz. (It is assumed that the PDM microphone part can work at this frequency; if not, quality mode need to be changed or CIC decimation need to be decreased.)
2. Check the K factor value for High Quality mode in [Table 13-59](#). K factor is 1/2.
3. Calculate minimum CLKDIV value (see [Equation 3 on page 4221](#)): $\text{floor}(K \times \text{CLKDIV}) \geq K \times (10 + 125EC)/(8 \times \text{OSR})$ then $\text{floor}(K \times \text{CLKDIV}) \geq 1.9922$, Finally, $\text{CLKDIV} \geq 4$.
4. Calculate minimum MICFIL application clock (see [Equation 1 on page 4215](#)). MICFIL clock rate = 8 x OSR x CLKDIV x (Output rate). From step 3: MICFIL clock rate $\geq 8 \times 16 \times 4 \times 48\text{KHz}$. Finally, MICFIL clock rate $\geq 24.58\text{MHz}$.

13.9 Synchronous Audio Interface (SAI)

13.9.1 Introduction

The I²S (or I2S) module provides a synchronous audio interface (SAI) that supports full-duplex serial interfaces with frame synchronization such as I²S, AC97, TDM, and codec/DSP interfaces.

13.9.1.1 Features

Note that some of the features are not supported across all SAI instances; see the chip-specific information in the first section of this chapter.

- Transmitter with independent bit clock and frame sync supporting 2 data lines
- Receiver with independent bit clock and frame sync supporting 2 data lines
- Each data line can support a maximum Frame size of 32 words
- Word size of between 8-bits and 32-bits
- Word size configured separately for first word and remaining words in frame
- Asynchronous 128 x 32-bit FIFO for each transmit and receive data line
- Supports graceful restart after FIFO error
- Supports automatic restart after FIFO error without software intervention
- Supports packing of 8-bit and 16-bit data into each 32-bit FIFO word
- Supports combining multiple data line FIFOs into single data line FIFO
- Independent 32-bit timestamp counters and bit counters for monitoring transmit and receive progress

13.9.1.2 Block diagram

The following block diagram also shows the module clocks.

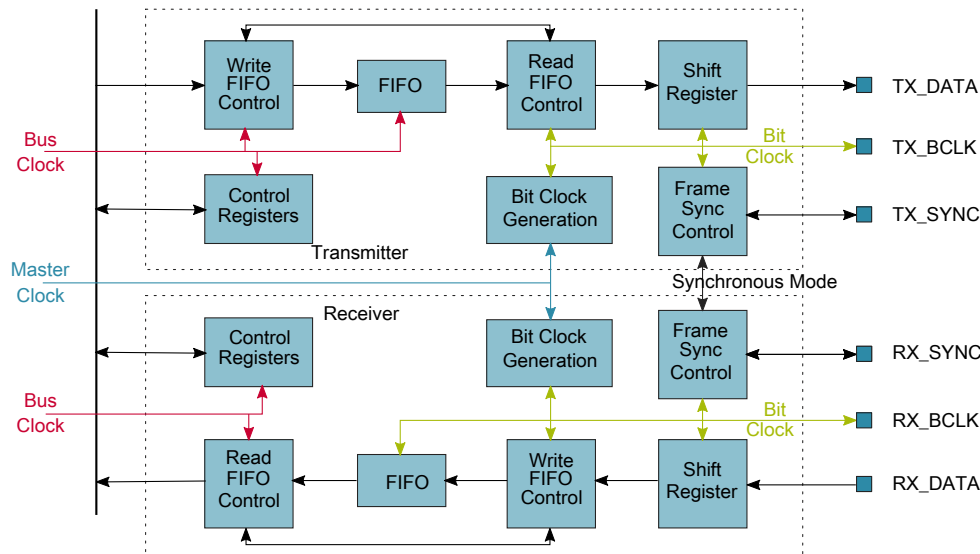

Figure 13-104. I²S/SAI block diagram

13.9.1.3 Modes of operation

Module power modes include Run mode, and Debug mode.

13.9.1.3.1 Run mode

In Run mode, the SAI transmitter and receiver operate normally.

13.9.1.3.2 Debug mode

In Debug mode, the SAI transmitter and/or receiver can continue operating provided the Debug Enable bit is set. When TCSR[DBGE] or RCSR[DBGE] bit is clear and Debug mode is entered, the SAI is disabled after completing the current transmit or receive frame. The transmitter and receiver bit clocks are not affected by Debug mode.

13.9.2 External signals

Name	Function	I/O
TX_BCLK	Transmit Bit Clock. The bit clock is an input when externally generated and an output when internally generated.	I/O

Table continues on the next page...

Name	Function	I/O
TX_SYNC	Transmit Frame Sync. The frame sync is an input sampled synchronously by the bit clock when externally generated and an output generated synchronously by the bit clock when internally generated.	I/O
TX_DATA[1:0]	Transmit Data. The transmit data is generated synchronously by the bit clock and is tristated whenever not transmitting a word.	O
RX_BCLK	Receive Bit Clock. The bit clock is an input when externally generated and an output when internally generated.	I/O
RX_SYNC	Receive Frame Sync. The frame sync is an input sampled synchronously by the bit clock when externally generated and an output generated synchronously by the bit clock when internally generated.	I/O
RX_DATA[1:0]	Receive Data. The receive data is sampled synchronously by the bit clock.	I
MCLK	Audio Master Clock. The audio master clock is an input when externally generated and an output when internally generated.	I/O

13.9.3 Functional description

This section provides a complete functional description of the block.

13.9.3.1 SAI clocking

The SAI clocks include:

- The audio master clock
- The bit clock
- The bus clock

13.9.3.1.1 Audio master clock

The audio master clock is used to generate the bit clock when the receiver or transmitter is configured for an internally generated bit clock. The transmitter and receiver can independently select between the bus clock and up to three audio master clocks to generate the bit clock.

The SAI peripheral controls the pin direction and post-divider of an audio master clock. The post-divide can be used to divide down the clock output on the MCLK signal pin, without affecting the audio master clock used by the transmitter and receiver.

The audio master clock generation and selection is chip-specific. Refer to chip-specific clocking information about how the audio master clocks are generated.

13.9.3.1.2 Bit clock

The SAI transmitter and receiver support asynchronous free-running bit clocks that can be generated internally from an audio master clock or supplied externally. There is also the option for synchronous bit clock and frame sync operation between the receiver and transmitter or between multiple SAI peripherals.

- If both transmitter and receiver are configured for asynchronous operation, then the transmitter and receiver will each use *their own* bit clock and frame sync.
- If the *transmitter* is configured for asynchronous mode and the receiver is configured for synchronous mode, then both transmitter and receiver will use the *transmitter* bit clock and frame sync.
- If the *receiver* is configured for asynchronous mode and the transmitter is configured for synchronous mode, then both transmitter and receiver will use the *receiver* bit clock and frame sync.

Note that the software configures synchronous or asynchronous mode, and that choice selects the bit clock/frame sync used.

Externally generated bit clocks must be:

- Enabled before the SAI transmitter or receiver is enabled
- Disabled after the SAI transmitter or receiver is disabled and completes its current frames

If the SAI transmitter or receiver is using an externally generated bit clock in asynchronous mode and that bit clock is generated by an SAI that is disabled in stop mode, then the transmitter or receiver should be disabled by software before entering stop mode. This issue does not apply when the transmitter or receiver is in a synchronous mode because all synchronous SAIs are enabled and disabled simultaneously.

13.9.3.1.3 Bus clock

The bus clock is used by the control and configuration registers and to generate synchronous interrupts and DMA requests.

NOTE

Although there is no specific minimum bus clock frequency specified, the bus clock frequency must be fast enough (relative

to the bit clock frequency) to ensure that the FIFOs can be serviced, without generating either a transmitter FIFO underrun or receiver FIFO overflow condition.

13.9.3.2 SAI resets

The SAI is asynchronously reset on system reset. The SAI has a software reset and a FIFO reset.

13.9.3.2.1 Software reset

The SAI transmitter includes a software reset that resets all transmitter internal logic, including the bit clock generation, status flags, and FIFO pointers. It does not reset the configuration registers. The software reset remains asserted until cleared by software.

The SAI receiver includes a software reset that resets all receiver internal logic, including the bit clock generation, status flags and FIFO pointers. It does not reset the configuration registers. The software reset remains asserted until cleared by software.

13.9.3.2.2 FIFO reset

The SAI transmitter includes a FIFO reset that synchronizes the FIFO write pointer to the same value as the FIFO read pointer. This empties the FIFO contents and is to be used after TCSR[FEF] is set, and before the FIFO is re-initialized and TCSR[FEF] is cleared. The FIFO reset is asserted for one cycle only.

The SAI transmitter can also reset the FIFO of individual data channels by setting the appropriate TCR3[CFR] bit. This should only be done when the corresponding TCR3[TCE] bit is clear.

The SAI receiver includes a FIFO reset that synchronizes the FIFO read pointer to the same value as the FIFO write pointer. This empties the FIFO contents and is to be used after the RCSR[FEF] is set and any remaining data has been read from the FIFO, and before the RCSR[FEF] is cleared. The FIFO reset is asserted for one cycle only.

The SAI receiver can also reset the FIFO of individual data channels by setting the appropriate RCR3[CFR] bit. This should only be done when the corresponding RCR3[RCE] bit is clear.

13.9.3.3 Synchronous modes

The SAI transmitter and receiver can operate synchronously to each other.

13.9.3.3.1 Synchronous mode

The SAI transmitter and receiver can be configured to operate with synchronous bit clock and frame sync.

If the transmitter bit clock and frame sync are to be used by both the transmitter and receiver:

- The transmitter must be configured for asynchronous operation and the receiver for synchronous operation.
- In synchronous mode, the receiver is enabled only when both the transmitter and receiver are enabled.
- It is recommended that the transmitter is the last enabled and the first disabled.

If the receiver bit clock and frame sync are to be used by both the transmitter and receiver:

- The receiver must be configured for asynchronous operation and the transmitter for synchronous operation.
- In synchronous mode, the transmitter is enabled only when both the receiver and transmitter are both enabled.
- It is recommended that the receiver is the last enabled and the first disabled.

When operating in synchronous mode, only the bit clock, frame sync, and transmitter/receiver enable are shared. The transmitter and receiver otherwise operate independently, although configuration registers must be configured consistently across both the transmitter and receiver.

13.9.3.4 Frame sync configuration

When enabled, the SAI continuously transmits and/or receives frames of data. Each frame consists of a fixed number of words and each word consists of a fixed number of bits. Within each frame, any given word can be masked causing the receiver to ignore that word and the transmitter to tri-state for the duration of that word.

The frame sync signal is used to indicate the start of each frame. A valid frame sync requires a rising edge (if active high) or falling edge (if active low) to be detected and the transmitter or receiver cannot be busy with a previous frame. A valid frame sync is also ignored (slave mode) or not generated (master mode) for the first four bit clock cycles after enabling the transmitter or receiver.

The transmitter and receiver frame sync can be configured independently with any of the following options:

- Externally generated or internally generated
- Active high or active low
- Assert with the first bit in frame or asserts one bit early
- Assert for a duration between 1 bit clock and the first word length
- Frame length from 1 to 32 words per frame
- Word length to support 8 to 32 bits per word
 - First word length and remaining word lengths can be configured separately
- Words can be configured to transmit/receive MSB first or LSB first

These configuration options cannot be changed after the SAI transmitter or receiver is enabled.

13.9.3.5 Data FIFO

Each transmit and receive channel includes a FIFO of size 128 x 32-bit. The FIFO data is accessed using the SAI Transmit/Receive Data Registers.

13.9.3.5.1 Data alignment

Data in the FIFO can be aligned anywhere within the 32-bit wide register through the use of the First Bit Shifted configuration field, which selects the bit index (between 31 and 0) of the first bit shifted.

Examples of supported data alignment and the required First Bit Shifted configuration are illustrated in [Figure 13-105](#) for LSB First configurations and [Figure 13-106](#) for MSB First configurations.

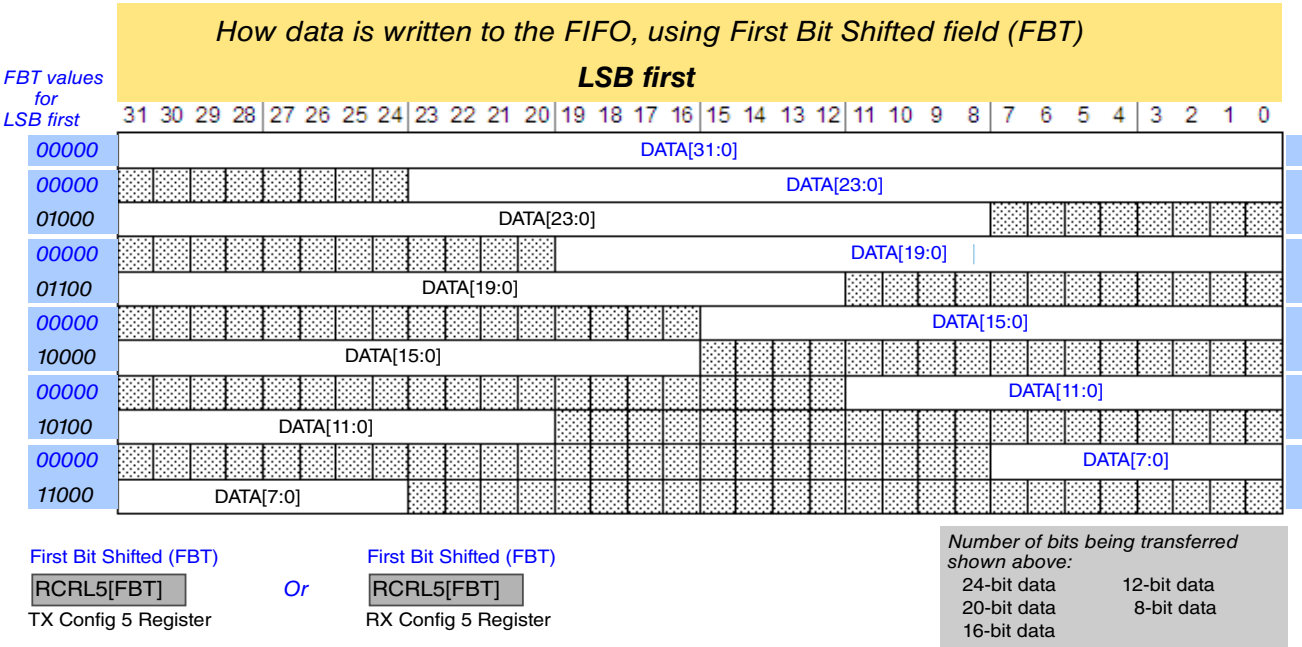

Figure 13-105. SAI first bit shifted, LSB first

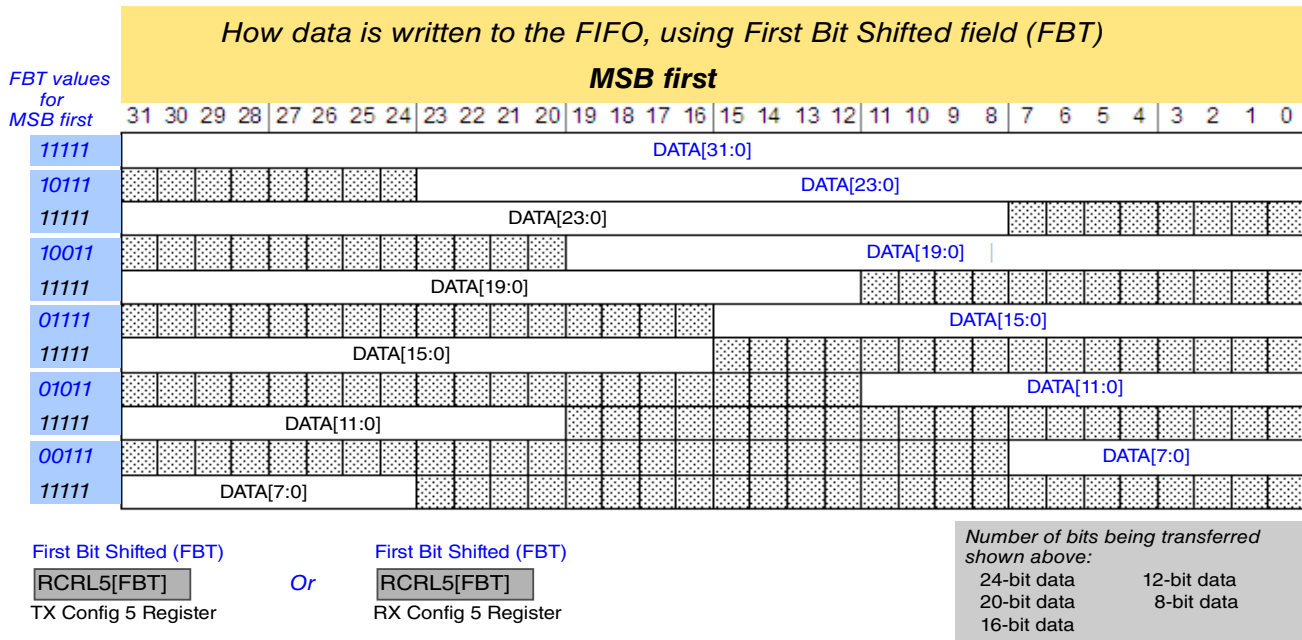

Figure 13-106. SAI first bit shifted, MSB first

13.9.3.5.2 FIFO pointers

When writing to a Transmit Data Register (TDR_n), the Write FIFO Pointer (WFP) of the corresponding Transmit FIFO Register (TFR_n) increments after each valid write. The SAI supports 8-bit, 16-bit and 32-bit writes to the Transmit Data Register and the FIFO pointer will increment after each individual write. Note that 8-bit writes should only be used when transmitting up to 8-bit data; 16-bit writes should only be used when transmitting up to 16-bit data.

- If the Transmit FIFO is full, then writes to a Transmit Data Register are ignored.
- If the Transmit FIFO is empty, then to avoid a FIFO underrun, the Transmit Data Register must be written at least 3 bit clocks before the start of the next unmasked word. Before enabling the transmitter, the Transmit FIFO should be initialized with data (since after the transmitter is enabled, the transmitter will start a new frame, and if no data is in the FIFO, then the transmitter will immediately give an error).

When reading a Receive Data Register (RDR_n), the Read FIFO Pointer (RFP) of the corresponding Receive FIFO Register (RFR_n) increments after each valid read. The SAI supports 8-bit, 16-bit and 32-bit reads from the RDR and the FIFO pointer will increment after each individual read. Note that 8-bit reads should only be used when receiving up to 8-bit data; 16-bit reads should only be used when receiving up to 16-bit data.

- If the Receive FIFO is empty, then reads from a Receive Data Register are ignored.
- If the Receive FIFO is full, then to avoid a FIFO overrun, the Receive Data Register must be read at least 3 bit clocks before the end of an unmasked word.

13.9.3.5.3 FIFO packing

FIFO packing supports storing multiple 8-bit or 16-bit data words in one 32-bit FIFO word for the transmitter and/or receiver. While this can be emulated by adjusting the number of bits per word and number of words per frame (for example, one 32-bit word per frame versus two 16-bit words per frame), FIFO packing does not require even multiples of words per frame and fully supports word masking. When FIFO packing is enabled, the FIFO pointers only increment when the full 32-bit FIFO word has been written (transmit) or read (receive) by software, supporting scenarios where different words within each frame are loaded/stored in different areas of memory.

When 16-bit FIFO packing is enabled for transmit, the transmit shift register is loaded at the start of each frame and after every second unmasked transmit word. The first word transmitted is taken from 16-bit word at byte offset \$0 (first bit is selected by $TCFG5[FBT]$ must be configured within this 16-bit word) and the second word transmitted is taken from the 16-bit word at byte offset \$2 (first bit is selected by $TCSR5[FBT][3:0]$). The transmitter will transmit logic zero until the start of the next word once the 16-bit word has been transmitted.

When 16-bit FIFO packing is enabled for receive, the receive shift register is stored after every second unmasked received word, and at the end of each frame if there is an odd number of unmasked received words in each frame. The first word received is stored in the 16-bit word at byte offset \$0 (first bit is selected by RCFG5[FBT] and must be configured within this 16-bit word) and the second word received is stored in the 16-bit word at byte offset \$2 (first bit is selected by RCSR5[FBT][3:0]). The receiver will ignore received data until the start of the next word once the 16-bit word has been received.

The 8-bit FIFO packing is similar to 16-bit packing except four words are loaded or stored into each 32-bit FIFO word. The first word is loaded/stored in byte offset \$0, second word in byte offset \$1, third word in byte offset \$2 and fourth word in byte offset \$3. The TCFG5[FBT] and/or RCFG5[FBT] must be configured within byte offset \$0.

13.9.3.5.4 FIFO Combine

FIFO combining mode allows the separate FIFOs for multiple data channels to be used as a single FIFO for either software accesses or a single data channel or both. Note that the enabled data channels must be contiguous and data channel 0 must be enabled when FIFO Combine mode is enabled.

Combining FIFOs for software access (writing transmit FIFO registers, reading receive FIFO registers) allows a DMA controller or software to read or write multiple FIFOs without incrementing the address that is accessed. Once enabled, the first software access to a FIFO register will access the first enabled channel FIFO, while the second access to a FIFO register will access the second enabled channel FIFO. This continues until software accesses the last enabled channel FIFO and the pointer resets back to the first enabled channel FIFO. To reset the pointer manually, software can reset the FIFOs or disable the FIFO combining on software accesses.

Combining FIFOs for transmit data channels allows one data channel to use the FIFOs of all enabled channel FIFOs, with identical data output on each enabled data channel. The transmit shift registers for all enabled data channels are loaded at the start of each frame and every N unmasked words (where N is the number of enabled data channels). The first word transmitted is loaded from the first enabled channel FIFO, while the second word transmitted is loaded from the second enabled channel FIFO, and so on until the end of the frame. Since the first word in each frame is always loaded from the first enabled data channel, it is recommended that the number of unmasked words in each frame is evenly divisible by the number of enabled data channels.

Combining FIFOs for receive data channels allows one data channel to use the FIFOs of all enabled channel FIFOs, with received data from channel 0 stored into each enabled data channel. The receive shift register for all enabled data channels are stored after every

N unmasked words (where N is the number of enabled data channels). The first word received is stored to the first enabled channel FIFO, while the second word received is stored to the second enabled channel FIFO, and so on until the end of the frame. Since the first word in each frame is always stored to the first enabled data channel, it is recommended that the number of unmasked words in each frame is evenly divisible by the number of enabled data channels.

Note that combining FIFOs for data channels will load or store each channel FIFO at the same time. This means that FIFO error conditions are only checked every N words (where N is the number of enabled data channels) and that the FIFO warning and request flags will assert if any of the enabled data channel meets the warning flag or request flag conditions.

13.9.3.6 Word mask register

The SAI transmitter and receiver each contain a word mask register, namely TMR and RMR, that can be used to mask any word in the frame. Because the word mask register is double buffered, software can update it before the end of each frame to mask a particular word in the next frame.

The TMR causes the Transmit Data pin to be tri-stated for the length of each selected word and the transmit FIFO is not read for masked words.

The RMR causes the received data for each selected word to be discarded and not written to the receive FIFO.

13.9.3.7 Timestamp Counter

The transmitter and receiver implement separate timestamp counters and bit counters. The bit counter increments at the end of each bit in a frame whenever the transmitter or receiver is enabled. The bit counter continues to increment if a word is masked or a FIFO underrun or overrun condition occurs, but does not increment if an external frame sync is configured and no frame sync is detected. The bit counter can be reset by software, due to synchronization delays it can take up to 3 bit clock cycles for the bit clock counter to continue incrementing after a bit counter reset.

The timestamp counter increments on the bus interface clock whenever it is enabled, but can be configured to synchronize to the bit counter by waiting for the bit counter to increment first (if configured, this synchronization is performed whenever the time counter is reset). The current value of the timestamp counter is latched whenever the bit counter increments. Reading the bit counter register will cause the latched timestamp

value to be saved in the bit counter timestamp register. The timestamp counter can be reset by software, this also resets the latched timestamp value and the bit counter timestamp register.

The timestamp counter and bit counter can be used by software to track the progress of the transmitter and receiver. It can also be used to calculate the relative frequency of the bit clock against the bus interface clock.

13.9.3.8 Interrupts and DMA requests

The SAI transmitter and receiver generate separate interrupts and separate DMA requests, but support the same status flags.

13.9.3.8.1 FIFO request flag

The FIFO request flag is set based on the number of entries in the FIFO and the FIFO watermark configuration.

The transmit FIFO request flag is set when the number of entries in any of the enabled transmit FIFOs is less than or equal to the transmit FIFO watermark configuration and is cleared when the number of entries in each enabled transmit FIFO is greater than the transmit FIFO watermark configuration.

The receive FIFO request flag is set when the number of entries in any of the enabled receive FIFOs is greater than the receive FIFO watermark configuration and is cleared when the number of entries in each enabled receive FIFO is less than or equal to the receive FIFO watermark configuration.

The FIFO request flag can generate an interrupt or a DMA request.

13.9.3.8.2 FIFO warning flag

The FIFO warning flag is set based on the number of entries in the FIFO.

The transmit warning flag is set when the number of entries in any of the enabled transmit FIFOs is empty and is cleared when the number of entries in each enabled transmit FIFO is not empty.

The receive warning flag is set when the number of entries in any of the enabled receive FIFOs is full and is cleared when the number of entries in each enabled receive FIFO is not full.

The FIFO warning flag can generate an Interrupt or a DMA request.

13.9.3.8.3 FIFO error flag

The transmit FIFO error flag is set when the any of the enabled transmit FIFOs underflow. After it is set, all enabled transmit channels will transmit zero data before TCSR[FEF] is cleared.

When TCR4[FCONT] is set, the FIFO will continue transmitting data following an underflow without software intervention. To ensure that data is transmitted in the correct order, the transmitter will continue from the same word number in the frame that caused the FIFO to underflow, but only after new data has been written to the transmit FIFO. Software should still clear the TCSR[FEF] flag, but without reinitializing the transmit FIFOs.

RCSR[FEF] is set when the any of the enabled receive FIFOs overflow. After it is set, all enabled receive channels discard received data until RCSR[FEF] is cleared and the next next receive frame starts. All enabled receive FIFOs should be emptied before RCSR[FEF] is cleared.

When RCR4[FCONT] is set, the FIFO will continue receiving data following an overflow without software intervention. To ensure that data is received in the correct order, the receiver will continue from the same word number in the frame that caused the FIFO to overflow, but only after data has been read from the receive FIFO. Software should still clear the RCSR[FEF] flag, but without emptying the receive FIFOs.

The FIFO error flag can generate only an interrupt.

13.9.3.8.4 Sync error flag

The sync error flag, TCSR[SEF] or RCSR[SEF], is set when configured for an externally generated frame sync and the external frame sync asserts when the transmitter or receiver is busy with the previous frame. The external frame sync assertion is ignored and the sync error flag is set. When the sync error flag is set, the transmitter or receiver continues checking for frame sync assertion when idle or at the end of each frame.

The sync error flag can generate an interrupt only.

13.9.3.8.5 Word start flag

The word start flag is set at the start of the second bit clock for the selected word, as configured by the Word Flag register field.

The word start flag can generate an interrupt only.

13.9.4 Memory map and register definition

A read or write access to an address from offset 0x108 and above will result in a bus error.

13.9.4.1.4.3 Fields

Field	Function
31 TE	Transmitter Enable

Table continues on the next page...

Synchronous Audio Interface (SAI)

Field	Function
	Enables/disables the transmitter. When software clears this field, the transmitter remains enabled, and this bit remains set, until the end of the current frame. 0b - Transmitter is disabled. 1b - Transmitter is enabled, or transmitter has been disabled and has not yet reached end of frame.
30 —	Reserved Software should only write zero to this reserved bit.
29 DBGE	Debug Enable Enables/disables transmitter operation in Debug mode. The transmit bit clock is not affected by debug mode. 0b - Transmitter is disabled in Debug mode, after completing the current frame. 1b - Transmitter is enabled in Debug mode.
28 BCE	Bit Clock Enable Enables the transmit bit clock, separately from the TE. This field is automatically set whenever TE is set. When software clears this field, the transmit bit clock remains enabled, and this bit remains set, until the end of the current frame. 0b - Transmit bit clock is disabled. 1b - Transmit bit clock is enabled.
27-26 —	Reserved
25 FR	FIFO Reset Empties the FIFO, and sets the FIFO read and write pointers to the same value, which may or may not be zero. Reading this field will always return zero. FIFO pointers should only be reset when the transmitter is disabled or the FIFO error flag is set. 0b - No effect. 1b - FIFO reset.
24 SR	Software Reset When set, resets the internal transmitter logic including the FIFO read and write pointers. Software-visible registers are not affected, except for the status registers. 0b - No effect. 1b - Software reset.
23-21 —	Reserved
20 WSF	Word Start Flag Indicates that the start of the configured word has been detected. Write a logic 1 to this field to clear this flag. 0b - Start of word not detected. 1b - Start of word detected.
19 SEF	Sync Error Flag Indicates that an error in the externally-generated frame sync has been detected. Write a logic 1 to this field to clear this flag. 0b - Sync error not detected. 1b - Frame sync error detected.
18 FEF	FIFO Error Flag Indicates that an enabled transmit FIFO has underrun. Write a logic 1 to this field to clear this flag. 0b - Transmit underrun not detected. 1b - Transmit underrun detected.
17	FIFO Warning Flag

Table continues on the next page...

Field	Function
FWF	Indicates that an enabled transmit FIFO is empty. 0b - No enabled transmit FIFO is empty. 1b - Enabled transmit FIFO is empty.
16 FRF	FIFO Request Flag Indicates that the number of words in an enabled transmit channel FIFO is less than or equal to the transmit FIFO watermark. 0b - Transmit FIFO watermark has not been reached. 1b - Transmit FIFO watermark has been reached.
15-13 —	Reserved
12 WSIE	Word Start Interrupt Enable Enables/disables word start interrupts. 0b - Disables interrupt. 1b - Enables interrupt.
11 SEIE	Sync Error Interrupt Enable Enables/disables sync error interrupts. 0b - Disables interrupt. 1b - Enables interrupt.
10 FEIE	FIFO Error Interrupt Enable Enables/disables FIFO error interrupts. 0b - Disables the interrupt. 1b - Enables the interrupt.
9 FWIE	FIFO Warning Interrupt Enable Enables/disables FIFO warning interrupts. 0b - Disables the interrupt. 1b - Enables the interrupt.
8 FRIE	FIFO Request Interrupt Enable Enables/disables FIFO request interrupts. 0b - Disables the interrupt. 1b - Enables the interrupt.
7-5 —	Reserved
4-2 —	Reserved
1 FWDE	FIFO Warning DMA Enable Enables/disables DMA requests. 0b - Disables the DMA request. 1b - Enables the DMA request.
0 FRDE	FIFO Request DMA Enable Enables/disables DMA requests. 0b - Disables the DMA request. 1b - Enables the DMA request.

13.9.4.1.6.4 Fields

Field	Function
31-30 SYNC	<p>Synchronous Mode</p> <p>Configures between asynchronous and synchronous modes of operation. When configured for a synchronous mode of operation, the receiver must be configured for asynchronous operation.</p> <p>00b - Asynchronous mode. 01b - Synchronous with receiver. 10b - Reserved. 11b - Reserved.</p>
29 BCS	<p>Bit Clock Swap</p> <p>This field swaps the bit clock used by the transmitter. When the transmitter is configured in asynchronous mode and this bit is set, the transmitter is clocked by the receiver bit clock (RX_BCLK). This allows the transmitter and receiver to share the same bit clock, but the transmitter continues to use the transmit frame sync (TX_SYNC).</p> <p>When the transmitter is configured in synchronous mode, the transmitter BCS field and receiver BCS field must be set to the same value. When both are set, the transmitter and receiver are both clocked by the transmitter bit clock (TX_BCLK) but use the receiver frame sync (RX_SYNC).</p> <p>0b - Use the normal bit clock source. 1b - Swap the bit clock source.</p>
28 BCI	<p>Bit Clock Input</p> <p>When this field is set and using an internally generated bit clock in either synchronous or asynchronous mode, the bit clock actually used by the transmitter is delayed by the pad output delay (the transmitter is clocked by the pad input as if the clock was externally generated). This has the effect of decreasing the data input setup time, but increasing the data output valid time.</p> <p>The slave mode timing from the datasheet should be used for the transmitter when this bit is set. In synchronous mode, this bit allows the transmitter to use the slave mode timing from the datasheet, while the receiver uses the master mode timing. This field has no effect when configured for an externally generated bit clock .</p> <p>0b - No effect. 1b - Internal logic is clocked as if bit clock was externally generated.</p>
27-26 MSEL	MCLK Select

Table continues on the next page...

Synchronous Audio Interface (SAI)

Field	Function
	Selects the audio Master Clock option used to generate an internally generated bit clock. This field has no effect when configured for an externally generated bit clock. NOTE: Depending on the device, some Master Clock options might not be available. See the chip-specific information for the meaning of each option. 00b - Bus Clock selected. 01b - Master Clock (MCLK) 1 option selected. 10b - Master Clock (MCLK) 2 option selected. 11b - Master Clock (MCLK) 3 option selected.
25 BCP	Bit Clock Polarity Configures the polarity of the bit clock. 0b - Bit clock is active high with drive outputs on rising edge and sample inputs on falling edge. 1b - Bit clock is active low with drive outputs on falling edge and sample inputs on rising edge.
24 BCD	Bit Clock Direction Configures the direction of the bit clock. 0b - Bit clock is generated externally in Slave mode. 1b - Bit clock is generated internally in Master mode.
23 BYP	Bit Clock Bypass Bypasses the bit clock divider, internal bit clock is divide by 1 of the audio master clock. 0b - Internal bit clock is generated from bit clock divider. 1b - Internal bit clock is divide by one of the audio master clock.
22-8 —	Reserved
7-0 DIV	Bit Clock Divide Divides down the audio master clock to generate the bit clock when configured for an internal bit clock. The division value is $(DIV + 1) * 2$.

13.9.4.1.8.4 Fields

Field	Function
31-29 —	Reserved
28 FCONT	FIFO Continue on Error Configures when the SAI will continue transmitting after a FIFO error has been detected. 0b - On FIFO error, the SAI will continue from the start of the next frame after the FIFO error flag has been cleared. 1b - On FIFO error, the SAI will continue from the same word that caused the FIFO error to set after the FIFO warning flag has been cleared.
27-26 FCOMB	FIFO Combine Mode

Table continues on the next page...

Field	Function
	<p>When FIFO combine mode is enabled for FIFO writes, software writing to any FIFO data register will alternate the write among the enabled data channel FIFOs. For example, if two data channels are enabled then the first write will be performed to the first enabled data channel FIFO and the second write will be performed to the second enabled data channel FIFO. Resetting the FIFO or disabling FIFO combine mode for FIFO writes will reset the pointer back to the first enabled data channel.</p> <p>When FIFO combine mode is enabled for FIFO reads from the transmit shift registers, the transmit data channel output will alternate between the enabled data channel FIFOs. For example, if two data channels are enabled then the first unmasked word will be transmitted from the first enabled data channel FIFO and the second unmasked word will be transmitted from the second enabled data channel FIFO. Since the first word of the frame is always transmitted from the first enabled data channel FIFO, it is recommended that the number of unmasked words per frame is evenly divisible by the number of enabled data channels.</p> <p>00b - FIFO combine mode disabled. 01b - FIFO combine mode enabled on FIFO reads (from transmit shift registers). 10b - FIFO combine mode enabled on FIFO writes (by software). 11b - FIFO combine mode enabled on FIFO reads (from transmit shift registers) and writes (by software).</p>
25-24 FPAK	<p>FIFO Packing Mode</p> <p>Enables packing of 8-bit data or 16-bit data into each 32-bit FIFO word. If the word size is greater than 8-bit or 16-bit then only the first 8-bit or 16-bits are loaded from the FIFO. The first word in each frame always starts with a new 32-bit FIFO word and the first bit shifted must be configured within the first packed word. When FIFO packing is enabled, the FIFO write pointer will only increment when the full 32-bit FIFO word has been written by software.</p> <p>00b - FIFO packing is disabled 01b - Reserved 10b - 8-bit FIFO packing is enabled 11b - 16-bit FIFO packing is enabled</p>
23-21 —	Reserved
20-16 FRSZ	<p>Frame size</p> <p>Configures the number of words in each frame. The value written must be one less than the number of words in the frame. For example, write 0 for one word per frame. The maximum supported frame size is 32 words.</p>
15-13 —	Reserved
12-8 SYWD	<p>Sync Width</p> <p>Configures the length of the frame sync in number of bit clocks. The value written must be one less than the number of bit clocks. For example, write 0 for the frame sync to assert for one bit clock only. The sync width cannot be configured longer than the first word of the frame.</p>
7-6 —	Reserved
5 CHMOD	<p>Channel Mode</p> <p>Configures if transmit data pins are configured for TDM mode or Output mode.</p> <p>0b - TDM mode, transmit data pins are tri-stated when slots are masked or channels are disabled. 1b - Output mode, transmit data pins are never tri-stated and will output zero when slots are masked or channels are disabled.</p>
4 MF	<p>MSB First</p> <p>Configures whether the LSB or the MSB is transmitted first.</p> <p>0b - LSB is transmitted first.</p>

Table continues on the next page...

Synchronous Audio Interface (SAI)

Field	Function
	1b - MSB is transmitted first.
3 FSE	Frame Sync Early 0b - Frame sync asserts with the first bit of the frame. 1b - Frame sync asserts one bit before the first bit of the frame.
2 ONDEM	On Demand Mode When set, and the frame sync is generated internally, a frame sync is only generated when the FIFO warning flag is clear. 0b - Internal frame sync is generated continuously. 1b - Internal frame sync is generated when the FIFO warning flag is clear.
1 FSP	Frame Sync Polarity Configures the polarity of the frame sync. 0b - Frame sync is active high. 1b - Frame sync is active low.
0 FSD	Frame Sync Direction Configures the direction of the frame sync. 0b - Frame sync is generated externally in Slave mode. 1b - Frame sync is generated internally in Master mode.

13.9.4.1.9.4 Fields

Field	Function
31-29 —	Reserved
28-24 WNW	Word N Width Configures the number of bits in each word, for each word except the first in the frame. The value written must be one less than the number of bits per word. Word width of less than 8 bits is not supported.
23-21 —	Reserved
20-16 W0W	Word 0 Width Configures the number of bits in the first word in each frame. The value written must be one less than the number of bits in the first word. Word width of less than 8 bits is not supported if there is only one word per frame.
15-13 —	Reserved
12-8 FBT	First Bit Shifted Configures the bit index for the first bit transmitted for each word in the frame. If configured for MSB First, the index of the next bit transmitted is one less than the current bit transmitted. If configured for LSB First, the index of the next bit transmitted is one more than the current bit transmitted. The value written must be greater than or equal to the word width when configured for MSB First. The value written must be less than or equal to 31-word width when configured for LSB First.
7-0 —	Reserved

13.9.4.1.10 SAI Transmit Data Register (TDR0 - TDR1)

13.9.4.1.10.1 Offset

Register	Offset
TDR0	20h
TDR1	24h

13.9.4.1.10.2 Diagram

13.9.4.1.10.3 Fields

Field	Function
31-0	Transmit Data Register
TDR	Writes to this register when the transmit FIFO is not full will push the data written into the transmit data FIFO. Writes to this register when the transmit FIFO is full are ignored.

13.9.4.1.11 SAI Transmit FIFO Register (TFR0 - TFR1)

13.9.4.1.11.1 Offset

Register	Offset
TFR0	40h
TFR1	44h

13.9.4.1.11.2 Function

The MSB of the read and write pointers is used to distinguish between FIFO full and empty conditions. If the read and write pointers are identical, then the FIFO is empty. If the read and write pointers are identical except for the MSB, then the FIFO is full.

13.9.4.1.11.3 Diagram

13.9.4.1.11.4 Fields

Field	Function
31 WCP	Write Channel Pointer When FIFO Combine mode is enabled for writes, indicates that this data channel is the next FIFO to be written. 0b - No effect. 1b - FIFO combine is enabled for FIFO writes and this FIFO will be written on the next FIFO write.
30-24 —	Reserved
23-16 WFP	Write FIFO Pointer FIFO write pointer for transmit data channel.
15-8 —	Reserved
7-0 RFP	Read FIFO Pointer FIFO read pointer for transmit data channel.

13.9.4.1.12 SAI Transmit Mask Register (TMR)

13.9.4.1.12.1 Offset

Register	Offset
TMR	60h

13.9.4.1.12.2 Function

This register is double-buffered and updates:

1. When TCSR[TE] is first set
2. At the end of each frame.

This allows the masked words in each frame to change from frame to frame.

13.9.4.1.12.3 Diagram

13.9.4.1.12.4 Fields

Field	Function
31-0	Transmit Word Mask
TWM	<p>Configures whether the transmit word is masked (transmit data pins are tri-stated or drive zero and transmit data not read from FIFO) for the corresponding word in the frame.</p> <p>00000000000000000000000000000000b - Word N is enabled.</p> <p>00000000000000000000000000000001b - Word N is masked. The transmit data pins are tri-stated or drive zero when masked.</p>

13.9.4.1.13 SAI Transmit Timestamp Control Register (TTCR)

13.9.4.1.13.1 Offset

Register	Offset
TTCR	70h

13.9.4.1.13.2 Function

This register controls the transmit timestamp counter and bit clock counter.

13.9.4.1.13.3 Diagram

13.9.4.1.13.4 Fields

Field	Function
31-10 —	Reserved
9 RBC	Reset Bit Counter Reset the bit counter. 0b - Bit counter is not reset. 1b - Bit counter is reset.
8 RTSC	Reset Timestamp Counter Reset the timestamp counter. 0b - Timestamp counter is not reset. 1b - Timestamp counter is reset.
7-2 —	Reserved
1 TSINC	Timestamp Increment Configures when the timestamp counter starts to increment. 0b - Timestamp counter starts to increment when enabled and the bit counter has incremented. 1b - Timestamp counter starts to increment when enabled.
0 TSEN	Timestamp Enable Enables the timestamp counter to increment on the bus interface clock. 0b - Timestamp counter is disabled. 1b - Timestamp counter is enabled.

13.9.4.1.14 SAI Transmit Timestamp Register (TTSR)

13.9.4.1.14.1 Offset

Register	Offset
TTSR	74h

13.9.4.1.14.2 Function

This register returns the current value of the transmit timestamp counter.

13.9.4.1.14.3 Diagram**13.9.4.1.14.4 Fields**

Field	Function
31-0	Timestamp Counter
TSC	Current value of the timestamp counter.

13.9.4.1.15 SAI Transmit Bit Count Register (TBCR)**13.9.4.1.15.1 Offset**

Register	Offset
TBCR	78h

13.9.4.1.15.2 Function

This register returns the current value of the transmit bit counter. The bit counter increments for each bit in a frame when the SAI transmitter is enabled. Reading this

register causes the Bit Count Timestamp Register to update with the value of the timestamp counter that corresponds to the bit count register value.

13.9.4.1.15.3 Diagram

13.9.4.1.15.4 Fields

Field	Function
31-0	Bit Counter
BCNT	Returns the current value of the bit counter.

13.9.4.1.16 SAI Transmit Bit Count Timestamp Register (TBCTR)

13.9.4.1.16.1 Offset

Register	Offset
TBCTR	7Ch

13.9.4.1.16.2 Function

Returns the value of the timestamp register that corresponds to the value last read from the bit count register.

13.9.4.1.16.3 Diagram

13.9.4.1.16.4 Fields

Field	Function
31-0	Bit Timestamp
BCTS	Returns the timestamp counter value that matches the last read of the bit count register.

13.9.4.1.17 SAI Receive Control Register (RCSR)

13.9.4.1.17.1 Offset

Register	Offset
RCSR	88h

13.9.4.1.17.2 Diagram

13.9.4.1.17.3 Fields

Field	Function
31 RE	Receiver Enable Enables/disables the receiver. When software clears this field, the receiver remains enabled, and this bit remains set, until the end of the current frame. 0b - Receiver is disabled. 1b - Receiver is enabled, or receiver has been disabled and has not yet reached end of frame.
30 —	Reserved Software should only write zero to this reserved bit.
29 DBGE	Debug Enable Enables/disables receiver operation in Debug mode. The receive bit clock is not affected by Debug mode. 0b - Receiver is disabled in Debug mode, after completing the current frame. 1b - Receiver is enabled in Debug mode.
28 BCE	Bit Clock Enable Enables the receive bit clock, separately from RE. This field is automatically set whenever RE is set. When software clears this field, the receive bit clock remains enabled, and this field remains set, until the end of the current frame. 0b - Receive bit clock is disabled. 1b - Receive bit clock is enabled.
27-26 —	Reserved
25 FR	FIFO Reset Empties the FIFO, and sets the FIFO read and write pointers to the same value, which may or may not be zero. Reading this field will always return zero. FIFO pointers should only be reset when the receiver is disabled or the FIFO error flag is set. 0b - No effect. 1b - FIFO reset.
24 SR	Software Reset Resets the internal receiver logic including the FIFO pointers. Software-visible registers are not affected, except for the status registers. 0b - No effect. 1b - Software reset.
23-21 —	Reserved
20 WSF	Word Start Flag Indicates that the start of the configured word has been detected. Write a logic 1 to this field to clear this flag. 0b - Start of word not detected. 1b - Start of word detected.
19 SEF	Sync Error Flag Indicates that an error in the externally-generated frame sync has been detected. Write a logic 1 to this field to clear this flag. 0b - Sync error not detected. 1b - Frame sync error detected.
18 FEF	FIFO Error Flag Indicates that an enabled receive FIFO has overflowed. Write a logic 1 to this field to clear this flag.

Table continues on the next page...

Synchronous Audio Interface (SAI)

Field	Function
	0b - Receive overflow not detected. 1b - Receive overflow detected.
17 FWF	FIFO Warning Flag Indicates that an enabled receive FIFO is full. 0b - No enabled receive FIFO is full. 1b - Enabled receive FIFO is full.
16 FRF	FIFO Request Flag Indicates that the number of words in an enabled receive channel FIFO is greater than the receive FIFO watermark. 0b - Receive FIFO watermark not reached. 1b - Receive FIFO watermark has been reached.
15-13 —	Reserved
12 WSIE	Word Start Interrupt Enable Enables/disables word start interrupts. 0b - Disables interrupt. 1b - Enables interrupt.
11 SEIE	Sync Error Interrupt Enable Enables/disables sync error interrupts. 0b - Disables interrupt. 1b - Enables interrupt.
10 FEIE	FIFO Error Interrupt Enable Enables/disables FIFO error interrupts. 0b - Disables the interrupt. 1b - Enables the interrupt.
9 FWIE	FIFO Warning Interrupt Enable Enables/disables FIFO warning interrupts. 0b - Disables the interrupt. 1b - Enables the interrupt.
8 FRIE	FIFO Request Interrupt Enable Enables/disables FIFO request interrupts. 0b - Disables the interrupt. 1b - Enables the interrupt.
7-5 —	Reserved
4-2 —	Reserved
1 FWDE	FIFO Warning DMA Enable Enables/disables DMA requests. 0b - Disables the DMA request. 1b - Enables the DMA request.
0 FRDE	FIFO Request DMA Enable Enables/disables DMA requests. 0b - Disables the DMA request. 1b - Enables the DMA request.

13.9.4.1.19.4 Fields

Field	Function
31-30 SYNC	<p>Synchronous Mode</p> <p>Configures between asynchronous and synchronous modes of operation. When configured for a synchronous mode of operation, the transmitter must be configured for asynchronous operation.</p> <p>00b - Asynchronous mode. 01b - Synchronous with transmitter. 10b - Reserved. 11b - Reserved.</p>
29 BCS	<p>Bit Clock Swap</p> <p>This field swaps the bit clock used by the receiver. When the receiver is configured in asynchronous mode and this bit is set, the receiver is clocked by the transmitter bit clock (TX_BCLK). This allows the transmitter and receiver to share the same bit clock, but the receiver continues to use the receiver frame sync (RX_SYNC).</p> <p>When the receiver is configured in synchronous mode, the transmitter BCS field and receiver BCS field must be set to the same value. When both are set, the transmitter and receiver are both clocked by the receiver bit clock (RX_BCLK) but use the transmitter frame sync (TX_SYNC).</p> <p>0b - Use the normal bit clock source. 1b - Swap the bit clock source.</p>
28 BCI	<p>Bit Clock Input</p> <p>When this field is set and using an internally generated bit clock in either synchronous or asynchronous mode, the bit clock actually used by the receiver is delayed by the pad output delay (the receiver is clocked by the pad input as if the clock was externally generated). This has the effect of decreasing the data input setup time, but increasing the data output valid time.</p> <p>The slave mode timing from the datasheet should be used for the receiver when this bit is set. In synchronous mode, this bit allows the receiver to use the slave mode timing from the datasheet, while the transmitter uses the master mode timing. This field has no effect when configured for an externally generated bit clock .</p> <p>0b - No effect.</p>

Table continues on the next page...

Field	Function
	1b - Internal logic is clocked as if bit clock was externally generated.
27-26 MSEL	<p>MCLK Select</p> <p>Selects the audio Master Clock option used to generate an internally generated bit clock. This field has no effect when configured for an externally generated bit clock.</p> <p>NOTE: Depending on the device, some Master Clock options might not be available. See the chip-specific information for the availability and chip-specific meaning of each option.</p> <p>00b - Bus Clock selected. 01b - Master Clock (MCLK) 1 option selected. 10b - Master Clock (MCLK) 2 option selected. 11b - Master Clock (MCLK) 3 option selected.</p>
25 BCP	<p>Bit Clock Polarity</p> <p>Configures the polarity of the bit clock.</p> <p>0b - Bit Clock is active high with drive outputs on rising edge and sample inputs on falling edge. 1b - Bit Clock is active low with drive outputs on falling edge and sample inputs on rising edge.</p>
24 BCD	<p>Bit Clock Direction</p> <p>Configures the direction of the bit clock.</p> <p>0b - Bit clock is generated externally in Slave mode. 1b - Bit clock is generated internally in Master mode.</p>
23 BYP	<p>Bit Clock Bypass</p> <p>Bypasses the bit clock divider, internal bit clock is divide by 1 of the audio master clock.</p> <p>0b - Internal bit clock is generated from bit clock divider. 1b - Internal bit clock is divide by one of the audio master clock.</p>
22-8 —	Reserved
7-0 DIV	<p>Bit Clock Divide</p> <p>Divides down the audio master clock to generate the bit clock when configured for an internal bit clock. The division value is $(DIV + 1) * 2$.</p>

13.9.4.1.21.4 Fields

Field	Function
31-29 —	Reserved
28 FCONT	FIFO Continue on Error Configures when the SAI will continue receiving after a FIFO error has been detected. 0b - On FIFO error, the SAI will continue from the start of the next frame after the FIFO error flag has been cleared. 1b - On FIFO error, the SAI will continue from the same word that caused the FIFO error to set after the FIFO warning flag has been cleared.
27-26 FCOMB	FIFO Combine Mode

Table continues on the next page...

Field	Function
	<p>When FIFO combine mode is enabled for FIFO reads, software reading any FIFO data register will alternate the read among the enabled data channel FIFOs. For example, if two data channels are enabled then the first read will be performed to the first enabled data channel FIFO and the second read will be performed to the second enabled data channel FIFO. Resetting the FIFO or disabling FIFO combine mode for FIFO reads will reset the pointer back to the first enabled data channel.</p> <p>When FIFO combine mode is enabled for FIFO writes from the receive shift registers, the first enabled data channel input will alternate between the enabled data channel FIFOs. For example, if two data channels are enabled then the first unmasked received word will be stored in the first enabled data channel FIFO and the second unmasked received word will be stored in the second enabled data channel FIFO. Since the first word of the frame is always stored in the first enabled data channel FIFO, it is recommended that the number of unmasked words per frame is evenly divisible by the number of enabled data channels.</p> <p>00b - FIFO combine mode disabled. 01b - FIFO combine mode enabled on FIFO writes (from receive shift registers). 10b - FIFO combine mode enabled on FIFO reads (by software). 11b - FIFO combine mode enabled on FIFO writes (from receive shift registers) and reads (by software).</p>
25-24 FPACK	<p>FIFO Packing Mode</p> <p>Enables packing of 8-bit data or 16-bit data into each 32-bit FIFO word. If the word size is greater than 8-bit or 16-bit then only the first 8-bit or 16-bits are stored to the FIFO. The first word in each frame always starts with a new 32-bit FIFO word and the first bit shifted must be configured within the first packed word. When FIFO packing is enabled, the FIFO read pointer will only increment when the full 32-bit FIFO word has been read by software.</p> <p>00b - FIFO packing is disabled 01b - Reserved. 10b - 8-bit FIFO packing is enabled 11b - 16-bit FIFO packing is enabled</p>
23-21 —	Reserved
20-16 FRSZ	<p>Frame Size</p> <p>Configures the number of words in each frame. The value written must be one less than the number of words in the frame. For example, write 0 for one word per frame. The maximum supported frame size is 32 words.</p>
15-13 —	Reserved
12-8 SYWD	<p>Sync Width</p> <p>Configures the length of the frame sync in number of bit clocks. The value written must be one less than the number of bit clocks. For example, write 0 for the frame sync to assert for one bit clock only. The sync width cannot be configured longer than the first word of the frame.</p>
7-6 —	Reserved
5 —	Reserved Software should only write zero to this bit.
4 MF	<p>MSB First</p> <p>Configures whether the LSB or the MSB is received first.</p> <p>0b - LSB is received first. 1b - MSB is received first.</p>
3	Frame Sync Early

Table continues on the next page...

Field	Function
FSE	0b - Frame sync asserts with the first bit of the frame. 1b - Frame sync asserts one bit before the first bit of the frame.
2 ONDEM	On Demand Mode When set, and the frame sync is generated internally, a frame sync is only generated when the FIFO warning flag is clear. 0b - Internal frame sync is generated continuously. 1b - Internal frame sync is generated when the FIFO warning flag is clear.
1 FSP	Frame Sync Polarity Configures the polarity of the frame sync. 0b - Frame sync is active high. 1b - Frame sync is active low.
0 FSD	Frame Sync Direction Configures the direction of the frame sync. 0b - Frame Sync is generated externally in Slave mode. 1b - Frame Sync is generated internally in Master mode.

13.9.4.1.22.4 Fields

Field	Function
31-29 —	Reserved
28-24 WNW	Word N Width Configures the number of bits in each word, for each word except the first in the frame. The value written must be one less than the number of bits per word. Word width of less than 8 bits is not supported.
23-21 —	Reserved
20-16 W0W	Word 0 Width Configures the number of bits in the first word in each frame. The value written must be one less than the number of bits in the first word. Word width of less than 8 bits is not supported if there is only one word per frame.
15-13 —	Reserved
12-8 FBT	First Bit Shifted Configures the bit index for the first bit received for each word in the frame. If configured for MSB First, the index of the next bit received is one less than the current bit received. If configured for LSB First, the index of the next bit received is one more than the current bit received. The value written must be greater than or equal to the word width when configured for MSB First. The value written must be less than or equal to 31-word width when configured for LSB First.
7-0 —	Reserved

13.9.4.1.23 SAI Receive Data Register (RDR0 - RDR1)**13.9.4.1.23.1 Offset**

Register	Offset
RDR0	A0h
RDR1	A4h

13.9.4.1.23.2 Function

Reading this register introduces one additional peripheral clock wait state on each read.

13.9.4.1.23.3 Diagram

13.9.4.1.23.4 Fields

Field	Function
31-0	Receive Data Register
RDR	Reads from this register when the receive FIFO is not empty will return the data from the top of the receive FIFO. Reads from this register when the receive FIFO is empty are ignored.

13.9.4.1.24 SAI Receive FIFO Register (RFR0 - RFR1)

13.9.4.1.24.1 Offset

Register	Offset
RFR0	C0h
RFR1	C4h

13.9.4.1.24.2 Function

The MSB of the read and write pointers is used to distinguish between FIFO full and empty conditions. If the read and write pointers are identical, then the FIFO is empty. If the read and write pointers are identical except for the MSB, then the FIFO is full.

13.9.4.1.24.3 Diagram

13.9.4.1.24.4 Fields

Field	Function
31-24 —	Reserved
23-16 WFP	Write FIFO Pointer FIFO write pointer for receive data channel.
15 RCP	Receive Channel Pointer When FIFO Combine mode is enabled for reads, indicates that this data channel is the next FIFO to be read. 0b - No effect. 1b - FIFO combine is enabled for FIFO reads and this FIFO will be read on the next FIFO read.
14-8 —	Reserved
7-0 RFP	Read FIFO Pointer FIFO read pointer for receive data channel.

13.9.4.1.25 SAI Receive Mask Register (RMR)

13.9.4.1.25.1 Offset

Register	Offset
RMR	E0h

13.9.4.1.25.2 Function

This register is double-buffered and updates:

1. When RCSR[RE] is first set
2. At the end of each frame

This allows the masked words in each frame to change from frame to frame.

13.9.4.1.25.3 Diagram

13.9.4.1.25.4 Fields

Field	Function
31-0	Receive Word Mask
RWM	Configures whether the receive word is masked (received data ignored and not written to receive FIFO) for the corresponding word in the frame. 0000000000000000000000000000000b - Word N is enabled. 0000000000000000000000000000001b - Word N is masked.

13.9.4.1.26 SAI Receive Timestamp Control Register (RTCR)

13.9.4.1.26.1 Offset

Register	Offset
RTCR	F0h

13.9.4.1.26.2 Function

This register controls the receive timestamp counter and bit clock counter.

13.9.4.1.26.3 Diagram

13.9.4.1.26.4 Fields

Field	Function
31-10 —	Reserved
9 RBC	Reset Bit Counter Reset the receive bit counter. 0b - Bit counter is not reset. 1b - Bit counter is reset.
8 RTSC	Reset Timestamp Counter Reset the receive timestamp counter. 0b - Timestamp counter is not reset. 1b - Timestamp counter is reset.
7-2 —	Reserved
1 TSINC	Timestamp Increment Configures when the timestamp counter starts to increment. 0b - Timestamp counter starts to increment when enabled and the bit counter has incremented. 1b - Timestamp counter starts to increment when enabled.
0 TSEN	Timestamp Enable Enables the timestamp counter to increment on the bus interface clock. 0b - Timestamp counter is disabled. 1b - Timestamp counter is enabled.

13.9.4.1.27 SAI Receive Timestamp Register (RTSR)

13.9.4.1.27.1 Offset

Register	Offset
RTSR	F4h

13.9.4.1.27.2 Function

This register returns the current value of the receive timestamp counter.

13.9.4.1.27.3 Diagram

13.9.4.1.27.4 Fields

Field	Function
31-0	Timestamp Counter
TSC	Current value of the timestamp counter.

13.9.4.1.28 SAI Receive Bit Count Register (RBCR)

13.9.4.1.28.1 Offset

Register	Offset
RBCR	F8h

13.9.4.1.28.2 Function

This register returns the current value of the receive bit counter. The bit counter increments for each bit in a frame when the SAI receiver is enabled. Reading this register

causes the Bit Count Timestamp Register to update with the value of the timestamp counter that corresponds to the bit count register value.

22-8 —	Reserved
7-0 DIV	MCLK Post Divide Post-divide for the audio master clock that only divides the output to the MCLK signal pin. The division value is $(DIV + 1) * 2$.

Chapter 14

Graphics Processing Unit (GPU)

14.1 GPU Overview

14.1.1 Overview

This section provides a high-level overview of the Graphics Processing Unit (GPU) Subsystem in the chip. This chip uses two GPU cores, one for 3D processing and the other to provide 2D/3D acceleration.

14.1.1.1 Block Diagram

The high level block diagram is shown as below:

Figure 14-1. High Level Diagram

The 3D GPU and 2D GPU are designed in such a way that if only one core is required, the other can be gated off.

14.1.2 Features

The key features of the GPUs are described below:

- 3D GPU Core:
 - Support OpenGL ES 1.1, 2.0
 - Support OpenVG 1.1
 - TrustZone support using a local MMU to manage secure regions
- 2D GPU Core:
 - Support multi-source composition
 - Support one-pass filter

14.2 2D Graphics Processing Unit (GPU2D)

14.2.1 Overview

This Graphics Processing Unit defines a high-performance, multi-pipe 2D raster graphics core that accelerates the 2D graphics display on a variety of consumer devices and provides advanced compression capabilities.

It supports the following graphic APIs:

- DirectFB (on Linux / Linux Embedded)
- GDI/DirectDraw (on Windows Embedded Compact 7 / Embedded CE 6)
- Android

14.2.1.1 Block Diagram

The block diagram and a description of the functional blocks of the complete graphics pipeline is given below.

- Host Interface - Allows the core to communicate with external memory and the CPU through the AXI or the AHB bus. In this block, data crosses clock domain boundaries.
- Memory Controller - Internal memory management unit that controls the block-to-host memory requests.
- Graphics Pipeline Front End - Inserts high level primitives and commands into the graphics pipeline.

- 2D Drawing and Scaling Engine - Draws 2D graphics primitives and rasterizes 2D images.
- Pixel Engine - Pixel manipulation and filtering on rendered images. The GPU has four pixel pipes.

Figure 14-2. GPU Block Diagram

14.2.2 GPU Features

The features of the GPU include:

- 2D GPU Unit:
 - Bit Blit
 - Stretch Blit
 - Rectangle fill and clear
 - Line drawing
 - Filter Blit
 - Mono expansion for text rendering
 - ROP2, ROP3 and ROP4
 - Alpha blending, including Java 2 Porter-Duff compositing blending rules
 - 32K x 32K coordinate system
 - 90 / 180 / 270 degree rotation

- Transparency by monochrome mask, chroma key, or pattern mask
- Support 2x2 in 4x4 tile format
- A8 output with rotation in filter Blit and bit Blit
- Src/Dest color key full bypass support
- Multi Source Blending:
 - Full support for Multi source blending with variable block size to improve BW and reduce SW overhead
 - Up to 8 sources are supported
 - Programmable block size guarantees cache efficiency so each source is read once and each destination is written once
 - Supports 90, 180, 270 degree rotation with different block size for higher cache efficiency
- YUV Support:
 - Full Multi destination support for converting non-planar YUV formats to planar YUV. It is used in extracting various components from input color into different destination planes
 - YUV422 output with alpha blending supported
- Clock disabling:
 - The core clock enters the frequency scaling block, and a clock with missing pulses is output, buffered, and sent to clock gating logic. The clock gate output will be used by the 2D GPU blocks. The core clock can be shut down through software by setting the proper register bits
- AXI Bus:
 - AXI 4-bit ID, such that all Read and Write transactions have a unique AXI ID
 - AXI out of order read return supported
- Additional Enhancements:
 - Full functional MMU with variable page size support
- Rotation:
 - 90° / 180° / 270° / Mirror rotation is supported for all primitives
 - Independent source rotation
- Transparency Mode:
 - For Monochrome Expansion:
 - Opaque
 - Conditional transparency - Transparent if the current pixel matches the specified value
 - For blits:
 - Opaque
 - Masked transparency - Transparent if the mask for the current pixel or pattern is zero

- Source Conditional transparency - Transparent if the source pixel is within the specified value range
- Destination Conditional transparency - Transparent if the destination pixel is not within the specified value range
- Clipping:
 - One clipping rectangle is supported for all bit blit primitives

14.2.2.1 GPU Host and Memory Interface Features

Table 14-1. Host and memory interface features

Feature	GPU Support
AHB interface	32-bit
Interface for External memory access	one 128-bit AXI
Virtual memory support	Yes
Out of order return support	Yes, supports out of order return for different clients
Code and data memory location restrictions	Unrestricted; arbitrary memory reads and writes
System address space	256 Kbytes (64K 32-bit words); however, the range of addresses used is only 4 Kbytes
Physical address	32 bits
Resource locks with CPU	Semaphore lock
Read write request size support	Memory controller supports 16, 32, 64, 128 byte read and write requests
MMU with variable page size support	MMU supports variable page sizes (4KB, 64KB, 1MB, 16MB)
GPU Cache Flush	Auto-flush at programmable intervals

14.2.2.2 GPU Power Management Features

Table 14-2. Power management features

Feature	Support
Low power CMOS technology compatible	Yes
Dynamic clock scaling	Yes
Automatic clock gating of flip flops and rams	Yes
Global clock gating of unused macro blocks	Yes
Active(ON), Idle, Standby and Sleep(OFF) Programmable Power Modes	Yes

14.2.2.3 Composition and 2D Hardware Features

This topic highlights the hardware features of the dedicated 2D GPU.

Table 14-3. Composition and 2D Hardware Features

Feature	Support

Table 14-3. Composition and 2D Hardware Features (continued)

Feature	Support
Alpha blending modes	Java2 Porter-Duff, Chroma Key, Pattern Mask
Alpha blending during filter blit	Not supported
Transparency	Supported by monochrome mask, chroma key or pattern mask
Dithering	2D dither support
Image scaling	Filter Blit FIR resampling filter with up to 9 taps, One Pass Filter with 3/5 taps
Rotation	90 / 180 / 270 degrees with mirror
Clipping	one clipping rectangle supported for all bit blit primitives.
Text rendering	Monochrome expansion
Rendering size	32k x 32k raster 2D coordinate system
Compression	Lossless, tiled compression support

14.2.2.4 Composition and 2D Operations and Features

14.2.2.4.1 Line

The LINE operation draws a line. The coordinates for two points are given - start point and end point and the end point is not drawn.

Lines are rendered using the Bresenham algorithm. The Bresenham algorithm has the advantage of using integer arithmetic and has no accumulation of rounding errors.

In the case of line, only ROP2 and ROP4 are supported. It operates on pattern and destination. The pattern should have a transparency mask in order to use ROP4.

Clipping is supported for lines on a per pixel basis.

the figure below shows the operation in more detail.

**Figure 14-3. Line**

14.2.2.4.2 Rectangle Fill and Clear

Rectangle fill suffuses a rectangle area with a given color. Essentially rectangle fill is a pattern fill, where an 8x8 pattern is initialized with the specified color. It supports ROP2 and ROP4 with the pattern and destination as its inputs. If ROP4 is used, the pattern should have a transparency mask.

Clear is similar to rectangle fill except that it does not use a pattern. A 32-bit clear value with 4-bit byte mask is used to fill the entire rectangle area.

Both rectangle fill and clear support clipping, which is performed on a per primitive basis.

14.2.2.4.3 Bit Blit

Bit blit transfers data from one area of a memory (source) to another area of the memory (destination). The source and destination can be from the same or from different memory locations. Both source and destination must be described by a rectangular area. The source and destination rectangles can be the same size (most bit blits are of this nature) or they can be different sizes, in which case the operation becomes a stretch or shrink blit.

Bit blit supports ROP2, ROP3, and ROP4 which includes source, destination and pattern, and an optional transparency color.

Clipping can be performed on a primitive basis.

Figure 14-4. Bit Blit

14.2.2.4.4 Stretch Blit

The stretch blit primitive performs a bit blit operation with stretch or shrink. The modified Bresenham algorithm is used to generate corresponding coordinates for fast stretching. The stretch factor is specified in a 15.0 fixed-point format. Stretch blit is not

allowed to overlap, that is, no part of source and destination can share any piece of memory. Non-stretch blits can overlap. For stretch blit clipping is performed on a per pixel basis.

14.2.2.4.5 Monochrome Expansion and Mask Blit

Monochrome expansion and mask blit are different operations, although both use the bit stream from the command buffer. And both can be the source for ROP4 source selection. This means that each output pixel can be a combination of source, pattern, monochrome mask (for masked blits) and destination.

Monochrome expansion

For monochrome expansion, the bit from the stream is used to switch on/off a solid color that is defined in a register. This mechanism enables the use of just one bit per pixel to represent colors. In effect, the MONO EXPANSION primitive increases color representation from one bit per pixel to multiple bits per pixel. A typical application for mono color is font drawing.

Monochrome expansion does not support overlapping of the source and destination. It is the responsibility of the driver to make sure that the command will never be executed on overlapping source and destination.

Mask Blit

For mask blit, the bit from the stream is used to toggle on/off a color in the source frame buffer. Mask blit takes its color source from memory and its monochrome mask from the command stream. Clipping is supported and is performed on a per pixel basis.

14.2.2.4.6 YUV Output for 2D Operations

YUV output is available for packed or planar YUV input formats per the following table.

Table 14-4. YUV Output Support for Packed or Planar YUV Source per 2D Operation

2D Operation	Destination
Bit blit	Packed YUV
One Pass Filter	Packed YUV
Multi-source	Packed YUV (no scaling)
Multi-destination	Planar YUV
Stretch blit	NO
Two Pass Filter	NO

14.2.2.4.7 ARGB Data Conversion

The pixels read from source or destination will be expanded into A8R8G8B8 format to maintain lossless pixel operations. The resulting pixels will be converted into the destination format.

14.2.2.4.8 YUV to RGB Conversion

YUV data can be converted into 8-bit per component RGB format at the output of the cache only. Once converted, there is no way back to YUV format. GPU supports BT.601 and BT.709 YUV to RGB color conversion standards.

In BT.601, the YUV to RGB conversion is done using the following approximation:

$$\begin{aligned}
 16 &\leq Y \leq 235 \\
 16 &\leq U \leq 240 \\
 16 &\leq V \leq 240 \\
 A &= Y - 16 \quad B = U - 128 \quad C = V - 128 \\
 R &= \text{clip}((298*A + 410*C + 128) \gg 8) \\
 G &= \text{clip}((298*A - 101*B - 209*C + 128) \gg 8) \\
 B &= \text{clip}((298*A + 519*B + 128) \gg 8)
 \end{aligned}$$

The Y, U and V components are clamped prior to the conversion. Y is clamped between 16 and 235, inclusively. U and V are clamped between 16 and 240, inclusively.

In BT.709, the R, G, B equations are slightly changed to:

$$\begin{aligned}
 R &= \text{clip}((298*A + 461*C + 128) \gg 8) \\
 G &= \text{clip}((298*A - 55*B - 137*C + 128) \gg 8) \\
 B &= \text{clip}((298*A + 543*B + 128) \gg 8)
 \end{aligned}$$

14.2.2.4.9 Color Index Input Conversion Support

Color index is supported for source data only. A look-up table with 256 entries is provided for indexing the data. The table is fully programmable. The conversion is done when pixels are read out of the cache.

14.2.2.4.10 Source/Destination Pre-multiply Support

The GPU supports pre-multiply source alpha or global alpha, or source global color for global colorizing.

On destination, the GPU supports destination pre-multiply and destination alpha.

On destination, the GPU supports destination pre-multiply destination alpha, destination de-multiply alpha.

Table 14-5. Pre-multiplied modes

Microsoft Alpha Blending	Equation
S:Fix Alpha	$D.C = A * S.C + (1-A) * D.C$
	$D.A = A * S.A + (1-A) * D.A$
S:Per-Pixel	$D.C = S.C + (1-S.A) * D.C$
	$D.A = S.A + (1-S.A) * D.A$
S:Fix+Per-Pixel	$D.C = A * S.C + (1-S.A) * D.C$
	$D.A = A * S.A + (1-S.A) * D.A$
S:Per-Pixel	$D.C = S.A * S.C + (1-S.A) * D.C$
	$D.A = S.A + (1-S.A) * D.A$
S:Fix+Per-Pixel	$D.C = A * S.A * S.C + (1-S.A) * D.C$
	$D.A = A * S.A + (1-S.A) * D.A$

NOTE

D: Destination

S: Source

A: Alpha

C: Color

14.2.2.4.11 Source/Destination Pre-multiply Support

The GPU supports alpha blending together with ROP. Alpha blending function is performed on ROP function result source.

The general alpha blending equations are:

$$Cd = Fs * Cs' + Fd * Cd'$$

$$Ad = Fs * As'' + Fd * Ad''$$

Where, Cs' is the source color component (adjusted for NPM if necessary)

Cd' is the destination color component (adjusted for NPM if necessary)

As'' is the modified source alpha component

Ad'' is the modified destination alpha component

Fs is fraction of the source that contributes to the final value

Fd is fraction of the destination that contributes to the final value

The blending is done in four logical stages:

1. Transparent/opaque conversion - In this stage, the incoming alpha (source or destination independently) can be inverted if needed to match the internal alpha rule. Internally, an alpha of 0 means transparent, while an alpha of “0xFF” means opaque. External content might follow the opposite rule. The output of the block is either A_s (A_d for destination) or $1-A_s$ ($1-A_d$ for destination).
2. Global value substitution - A global alpha value from a register can be used to substitute or scaled the incoming alpha. An incoming alpha A_s can pass-through, be directly substituted by A_g (global alpha) or scaled by the global alpha value ($A_s * A_g$). The source and destination have distinct global alpha values.
3. Blending factor generation - At this stages, the blending factors are generated (refer to table below). Each alpha can take the values 0, 1, A or 1-A depending on the blending mode.
4. Final blending - This is the final stage which implements the operations described by equations.
- 5.

The stages are shown in the figure below:

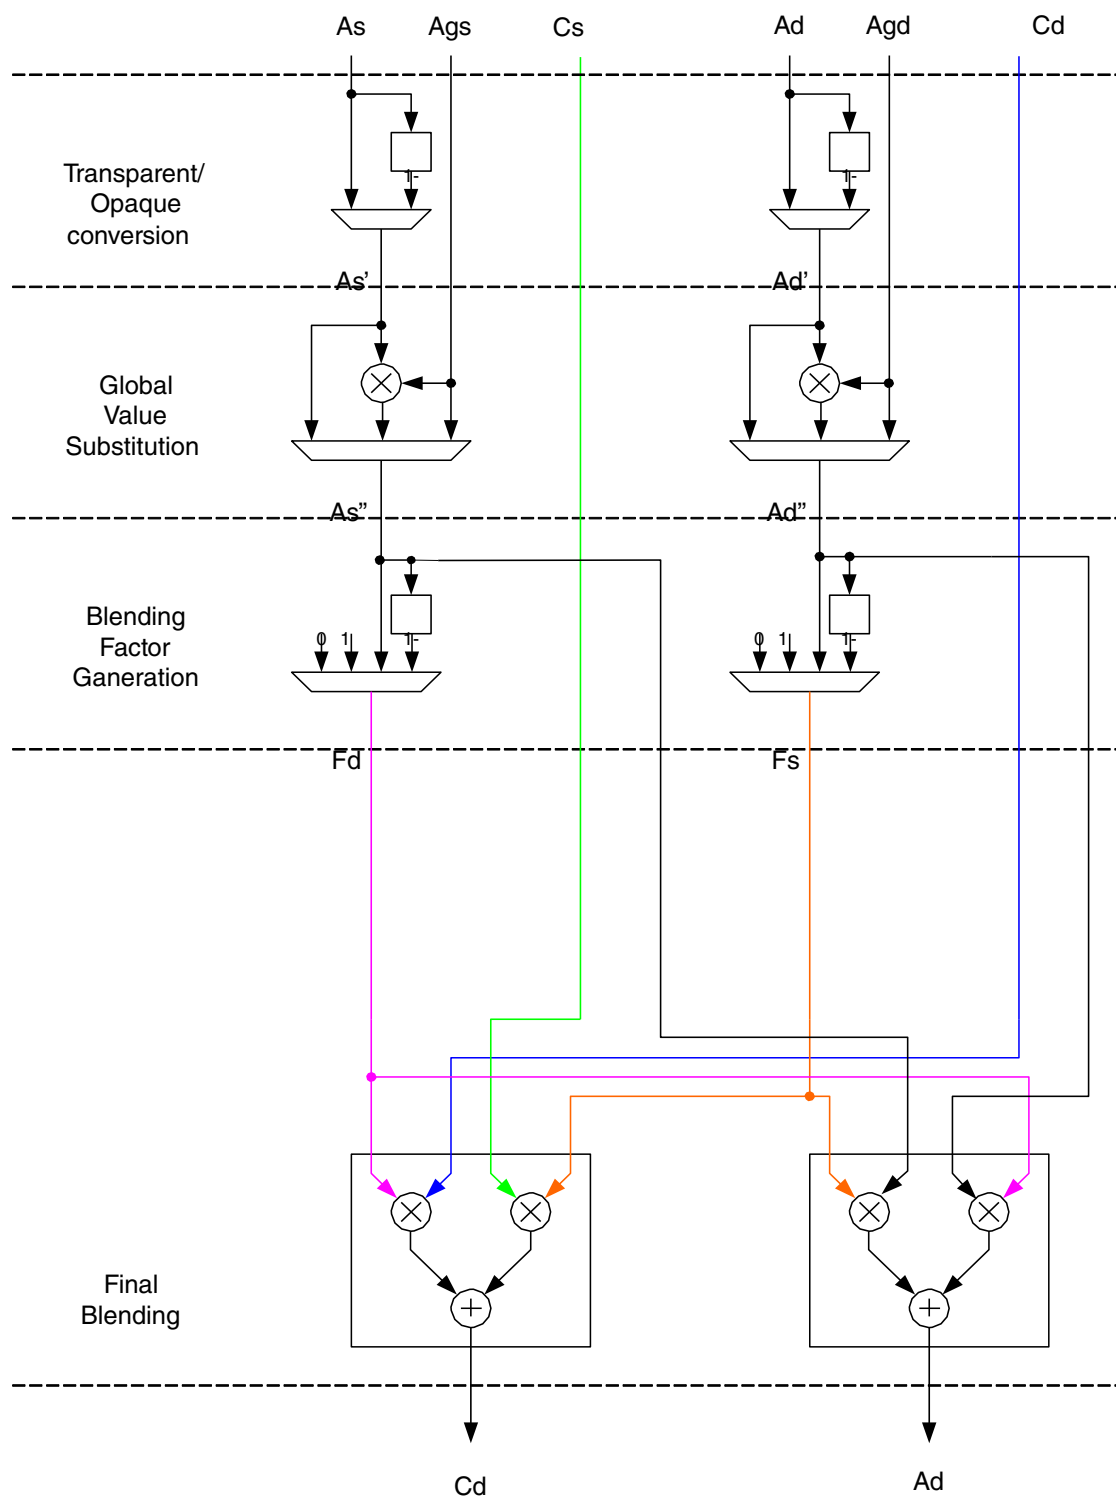

Figure 14-5. Alpha Blender for One Pixel

The fractions take the values described in the following table, depending on the blending mode:

Table 14-6. Blending Modes Fractions Description

Blending Mode	Fs	Fd
Clear	0	0
SRC	1	0
DST	0	1
SRC_OVER	1	$1 - A_s''$
DST_OVER	$1 - A_d''$	1
SRC_IN	A_d''	0
DST_IN	0	A_s''
SRC_OUT	$1 - A_d''$	0
DST_OUT	0	$1 - A_s''$
SRC_ATOP	A_d''	$1 - A_s''$
DST_ATOP	$1 - A_d''$	A_s''
XOR	$1 - A_d''$	$1 - A_s''$

14.2.2.4.12 Dither

Color intensity at any point of an image can be thought of as a real number between 0.0 and 1.0 at each location. However, in reality only a discrete number of intensity levels can be represented. This discretization leads to a total error in the color intensities of an image equal to the square root of the sum of the squares from each point.

This error results in contouring. In an image where intensities change slowly, this will cause noticeable jumps. Dithering can be used to diffuse the intensity across neighboring pixels.

In dithering mode pixels are scanned in order, and errors in calculating a pixel's intensity are distributed (i.e., diffused) to neighboring pixels to keep the overall intensity of the image closer to the input intensity.

Dithering is supported for 16-bit color destination formats. The dither table is programmable by software.

14.2.2.4.13 Multi-Source Blending

Up to 8 sources are supported. Programmable block size guarantees cache efficiency so each source is read once and each destination is written once. It supports 90, 180, 270 degree destination and source rotation and mirror with different block size to have high

cache efficiency. It also supports ROP2, ROP3, and ROP4 which includes source, destination and pattern, and an optional transparency color. Alpha blending between every source is supported.

14.2.2.4.14 GPU Cache Management

SW cache flush is supported to flush the GPU cache to memory. Auto-flush of GPU cache is also supported. SW sets up the auto-flush interval, and HW will do the cache flush automatically at programmable intervals.

14.3 3D Graphics Processing Unit (GPU3D)

14.3.1 Overview

The graphics processing unit (GPU) provides high performance, high quality graphics, low power consumption, and the smallest silicon footprint for its class. The dynamic power consumption is minimized by extensive use of multi-level hierarchical clock gating.

An optimized software stack, complete software development tools, and a growing application ecosystem are supported by a robust graphics pipeline designed for industry-standard APIs, and with full support for Android, Linux, and Windows embedded development platforms. The GPU supports the following graphics APIs:

- OpenGL ES 2.0/1.1
- EGL 1.4
- OpenGL 2.1
- OpenVG 1.1

14.3.1.1 Block Diagram

A block diagram and a description of the functional blocks of the complete graphics pipeline is given below.

- Host Interface - Allows GCCORE to communicate with external memory and the CPU through AXI or AHB bus. In this block data crosses clock domain boundaries.
- Memory Controller - Internal memory management unit that controls the block-to-host memory request interface.
- Graphics Pipeline Front End - Inserts high level primitives and commands into the graphics pipeline.

- Ultra-threaded Unified Shader - SIMD processor that performs as both vertex shader and fragment shader. When used as a vertex shader it performs geometry transformations and lighting computations. When used as a fragment shader it applies texture data and computes color values for each pixel. The GPU has one (1) such vec4 shader.
- 3D Rendering Engine - Converts triangles and lines into pixels. Computes slopes of color attributes and texture coordinates. Performs clipping.
- Texture Engine - Retrieves texture information from memory upon request by the fragment shader. Performs interpolation and filtering, and transfers the computed value to the fragment shader or the vertex shader. This GCCORE texture unit can process one pixel or one vertex /cycle.
- Pixel Engine/Resolve - Pixel engine does alpha blending and visible surface determination. Resolve does tiling and de-tiling. This GCCORE Pixel Engine can process one pixel/cycle.

Figure 14-6. GPU Block Diagram

14.3.2 GPU Features

The features of the GPU 3D unit include:

- OpenGL ES 2.0 / 1.1 compliance, including extensions; OpenVG 1.1
- IEEE 32-bit floating-point pipeline
- Ultra-threaded, unified vertex and fragment (pixel) shaders
- Low bandwidth at both high and low data rates
- Low CPU loading
- Up to 12 programmable elements per vertex
- Dependent texture operation with high-performance
- Alpha blending
- Depth and stencil compare
- Point sampling, bi-linear sampling, tri-linear filtering, and cubic textures
- Resolve and fast clear
- 8k x 8k texture size and 8k x 8k rendering target
- 4 Vertex DMA streams
- MMU functionality supported

The following table describes API support and select architectural features of the GPU:

Table 14-7. GPU Architecture Features

Feature	GPU Support
Primary API	OpenGL ES 2.0 / 1.1
Additional APIs	OpenVG 1.1 DirectX 11 (9_3) OpenGL 2.1
Other graphics support	EGL 1.4
Drivers	OpenGL ES 2.0 / 1.1 OpenVG 1.1 EGL 1.4 DirectX 11 (9_3) OpenGL 2.1
Operating systems	Windows Embedded Compact 7, Embedded CE 6 Embedded Linux Android 5.x / 4.x / 3.x
Z (depth)	Early Z support included
Stencil	Early stencil support included
GLSL ES Shader languages	1.0
Shader model compatibility	SM3.0
Shader types and execution units	One programmable Scalable Ultra-threaded Unified Shader (SIMD4: ctl-flow,tx-load) one instruction issue per shader per clock; IEEE 32-bit floating-point pipeline supports long shader instructions
FSAA anti-aliasing mechanisms	High quality MSAA 4x

14.3.2.1 GPU Host and Memory Interface Features

Table 14-8. GPU host and memory interface features

Feature	GPU Support
AHB interface	32-bit
AXI interface	1 64-bit AXI interface for external memory access
Virtual memory support	Yes
Code and data memory location restrictions	Unrestricted; arbitrary memory reads and writes
Physical address	32 bits
Resource locks with CPU	Semaphore lock
TLB	4 cache lines per requestor

14.3.2.2 GPU Power Management Features

Table 14-9. Power management features

Feature	GPU Support
Low power CMOS technology compatible	Yes
Automatic clock gating of flip flops and rams	Yes
Global clock gating of unused macro blocks	Yes
Software controlled effective clock frequency without changing the PLL	Yes

14.3.2.3 GPU Command Processor Features

Table 14-10. GPU command processor features

Feature	GPU Support
Counters	Variety of hardware counters for performance profiling

14.3.2.4 Texture processing

Table 14-11. Texture Processing Features

Feature	GPU Support
Fixed-point input texture formats	A8, L8, I8, A8L8, ARGB4, XRGB4, ARGB8, XRGB8, ABGR8, XBGR8, R5G6B5, A1RGB5, X1RGB5, YUY2, UYVY, D16, D24X8, A8_OES, DXT1, DXT2, DXT3, DXT4, DXT5, ETC1. All fixed-point formats are filtered.

	32	XRGB8888	X	8	8	8
	32	ABGR8888	8	8	8	8

14.3.3 Usage Mode

The GPU should be programmed through the NXP provided driver. NXP does not provide support for software that directly programs the GPU registers. APIs for programming the GPU through the software driver are described in separate driver documentation.

Chapter 15

Video Processing Unit (VPU)

15.1 VPU G1 (VPU_G1)

15.1.1 Overview

This block details the VPU G1 hardware based decoders and API. The decoders are able to decode H.264, VP8. The decoders conform to the H.264 Baseline, Main and High profile, and VP8 Main Profile

NOTE

The overall performance and capabilities of the decoders is system dependent. Formats and features that are presented depend on the chip configuration.

15.1.2 Features (G1)

The API is implemented on top of the VPU G1 decoder H.264 and VP8. The features of the decoders are noted in the following sections.

15.1.2.1 Decoder Features

The VPU G1 decoder has the following features:

- H.264 baseline profile, levels 1-4.1 decoding
 - Byte stream input
 - NAL unit input
- VP8 decoding
- Video post-processing features
 - Frame rotation 90 degrees left/right
 - Frame mirroring horizontally/vertically
 - Frame cropping

- Frame conversion from YCbCr formats to 16-bit or 32-bit RGB formats
- Frame scaling with maximum up-scaling factor of 3
- Two rectangular or alpha blending masks for output frame

The post-processing features can be used in pipeline with the decoder. The post-processing features can also be used as stand-alone, without performing any decoding.

- H.264 main and high profile, levels 1-4.1 decoding
- VP8 decoding

15.1.3 Video Frame Storage Format

This chapter describes the different input and output picture storage formats supported by the decoder and post-processor. Notice that some of the formats are only used for input or output.

15.1.3.1 YCbCr 4:2:0 Planar Format

In the planar format each video sample component forms one memory plane. The luminance and both chrominance planes must be stored in a linear and contiguous memory block as shown in Figure 3. The luminance samples are stored in raster-scan order (Y0Y1Y2Y3Y4...). The chrominance samples are stored in two planes also in raster scan order (Cb0Cb1Cb2Cb3... and Cr0Cr1Cr2Cr3...).

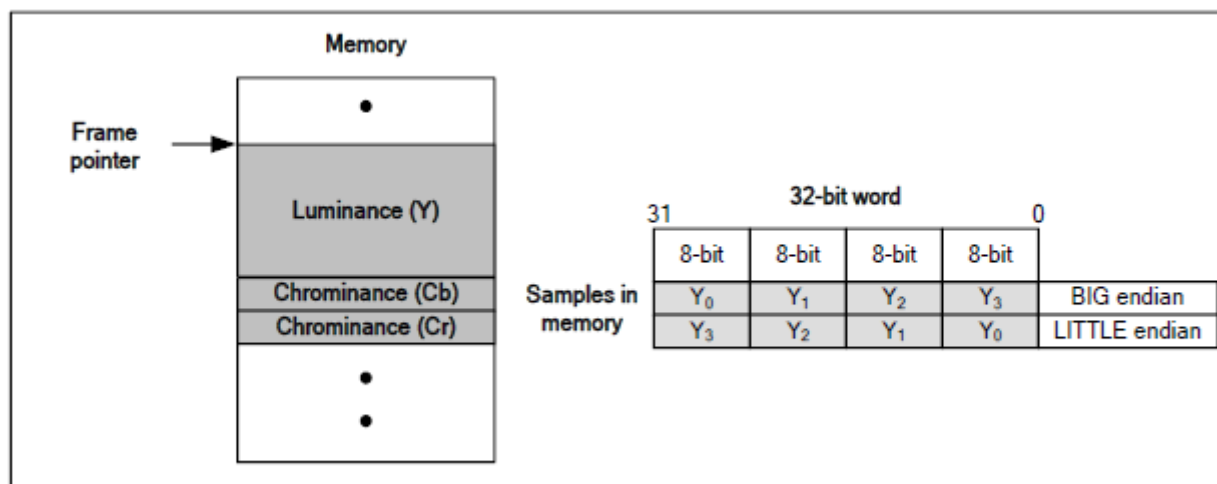

Figure 15-1. YCbCr 4:2:0 Planar Format External Memory Usage

The YCbCr 4:2:0 planar format is supported only as an input format for the postprocessor. In this format each pixel takes 12 bits of memory.

15.1.3.2 YCbCr 4:2:0 Semi-Planar Format

In semi-planar YCbCr 4:2:0 format the luminance samples form one plane in memory, and chrominance samples form another. The luminance and chrominance planes must be stored in a linear and contiguous memory block as presented in the following figure. The luminance pixels are stored in raster-scan order $Y_0Y_1Y_2Y_3Y_4\dots$. The interleaved chrominance CbCr samples are stored in raster-scan order in memory as $Cb_0Cr_0Cb_1Cr_1Cb_2Cr_2Cb_3\dots$.

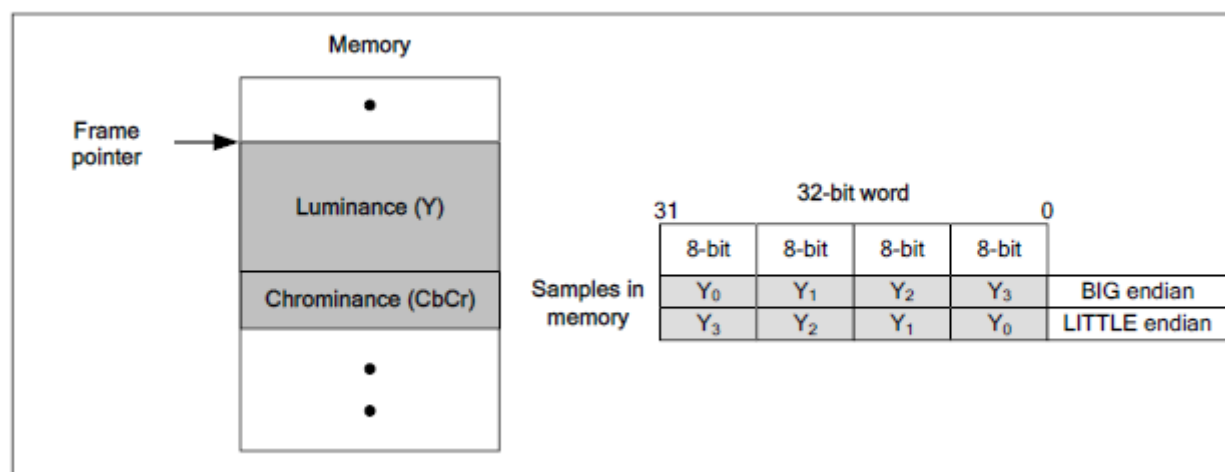

Figure 15-2. YCBCR 4:2:0 Planar Format External Memory Usage

The YCbCr 4:2:0 semi-planar format is supported both as an input and as an output format for the post-processor. In this format each pixel takes 12 bits of memory. As the chrominance components are interleaved, the bus load caused by this format can be slightly lower than with the planar format due to the reduced amount of non-sequential memory addressing.

15.1.3.3 YCbCr 4:2:2 Interleaved Format

In the interleaved YCbCr 4:2:2 format the pixel samples form a single plane in which the data has to be stored linearly and contiguously as shown in Figure 5. The pixel data is in raster scan order and the chrominance samples are interleaved between the luminance samples as $Y_0Cb_0Y_1Cr_0Y_2Cb_1Y_3Cr_1\dots$.

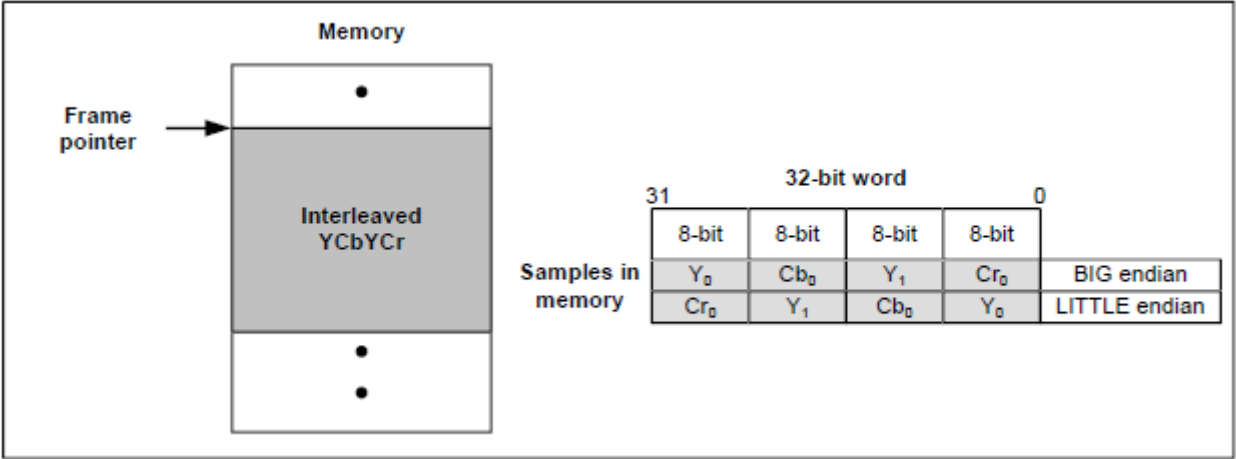

Figure 15-3. YCbCr 4:2:2 Interleaved Format External Memory Usage

The YCbCr 4:2:2 interleaved format is supported both as an input and as an output format for the post-processor. In this format each pixel takes 16 bits of memory. Although there is more data to be transferred than in the 4:2:0 formats, the interleaved format is bus effective as there are no non-sequential memory accesses caused by the plane changes.

15.1.3.4 G2 Decoder Tiled 4x4 Format

The output picture of the decoder is in semi-planar YCbCr 4:2:0 4x4 tiled format, i.e. luminance data forms one plane in memory, and chrominance data forms another. The distinction from raster scan format is that the output picture is grouped into tiles, which are then stored linearly and contiguously in the memory. The chrominance tiles have to be stored right after the luminance tiles in external memory as shown in Figure 6.

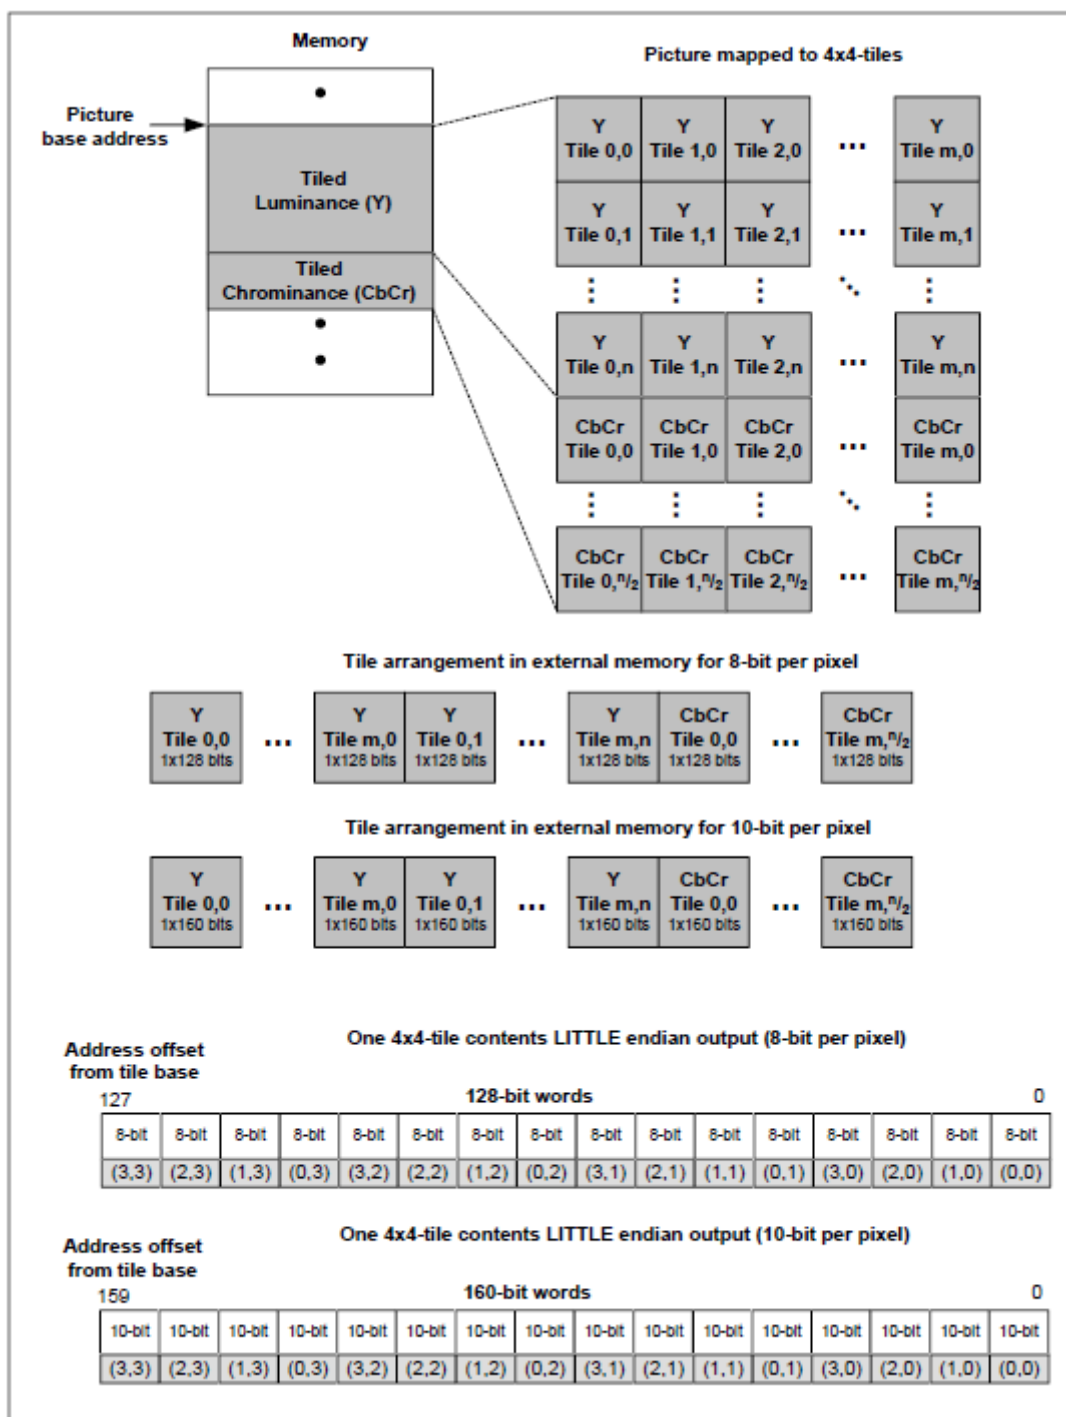

Figure 15-4. Tiled 4x4 Format External Memory Usage

15.1.3.5 RGB 16bpp Format

In this format each pixel is represented by 16 or less bits containing the red, blue and green samples. There are several 16bpp formats which use different number of bits for each sample. For example the RGB 5-5-5 format uses 5 bits for each sample and 1 bit is left unused or can represent a transparency flag, where RGB 5-6-5 uses 6 bits for the G sample and 5 bits for R and B samples. Common for all 16bpp types is that two pixels fit into one 32-bit space.

The data has to be stored linearly and contiguously in the memory as shown in Figure 7. The order of the sample bytes is always defined with a 16 bit word which will define the byte order in the memory. The pixel samples are stored in raster-scan order.

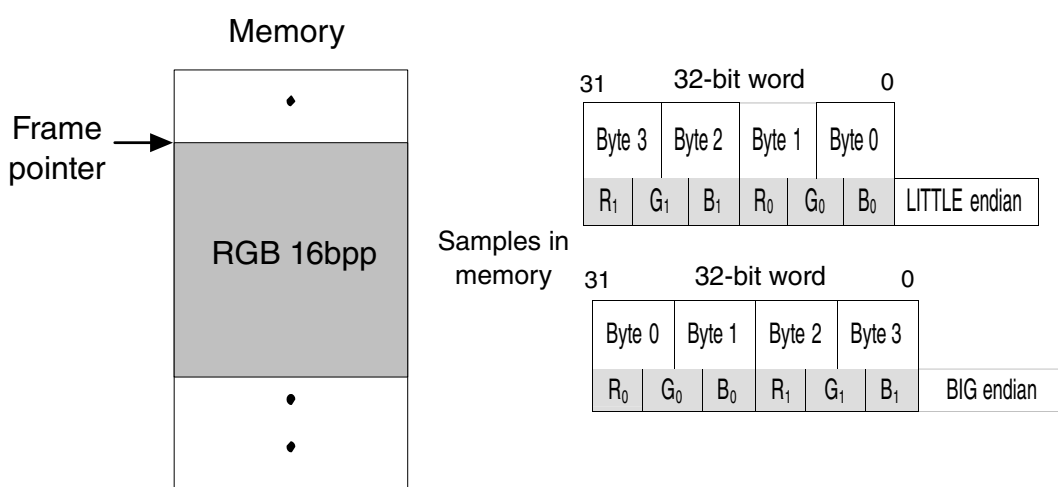

Figure 15-5. RGB 16bpp Format External Memory Usage

The RGB 16bpp formats are supported only as post-processor output formats.

15.1.3.6 RGB 32bpp Format

Any RGB format that has its pixels represented by more than 16 bits each is considered to be of 32bpp type. Typically in this format each pixel is represented by three bytes containing a red, blue and green sample and a 4th byte which can be empty or hold an alpha blending value. Common for all 32bpp types is that only one pixel fit into one 32-bit space.

The data has to be stored linearly and contiguously in the memory as shown in Figure 8. The order of the sample bytes is always defined on a 32 bit word and that will define the byte order in the memory (for example, ARGB order means that on a little endian system

the B sample will be stored in the lowest offset byte followed by the G, R and A samples. In a big endian system the A sample will be on the lowest offset byte). The pixel samples are stored in raster-scan order.

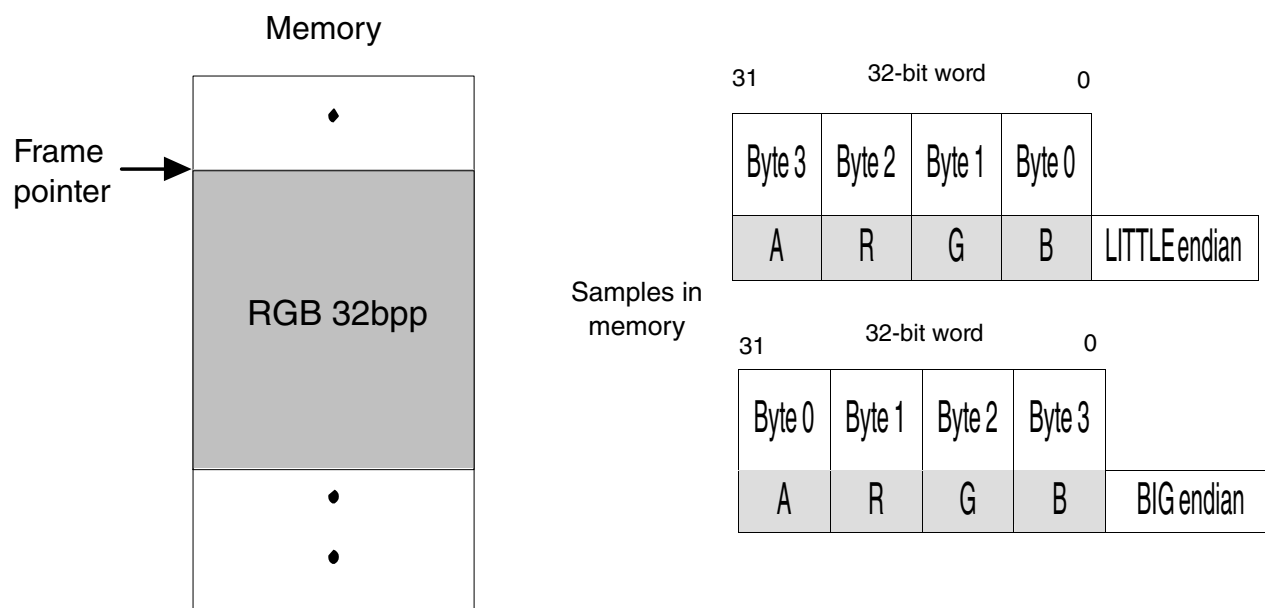

Figure 15-6. RGB 32bpp Format External Memory Usage

15.1.5 VPU G1 Memory Map/Register Definition

15.1.5.1 VPU_G1 common registers descriptions

15.1.5.1.1 VPU_G1 common registers memory map

VPU_G1 base address: 3830_0000h

Offset	Register	Width (In bits)	Access	Reset value
4h	Interrupt register decoder (SWREG1)	32	RW	0000_0000h
8h	Device configuration register decoder (SWREG2)	32	RW	0000_0000h

Table continues on the next page...

Offset	Register	Width (In bits)	Access	Reset value
Ch	Decoder control register 0 (decmode,picture type etc) (SWREG3)	32	RW	0000_0000h
30h	Base address for RLC data (RLC) / stream start address/decoded end addr register (VLC) (SWREG12)	32	RW	0000_0000h
34h	Base address for decoded picture (SWREG13)	32	RW	0000_0000h
A0h	Base address for standard dependent tables (SWREG40)	32	RW	0000_0000h
A4h	Base address for direct mode motion vectors (SWREG41)	32	RW	0000_0000h
C0h	Error concealment register (SWREG48)	32	RW	0000_0000h
C4h	Prediction filter tap register for H264 (SWREG49)	32	RW	0000_0000h
C8h	Synthesis configuration register decoder 0 (SWREG50)	32	RO	Table 15-
CCh	Reference picture buffer control register (SWREG51)	32	RW	0000_0000h
D0h	Reference picture buffer information register 1 (SWREG52)	32	RO	0000_0000h
D4h	Reference picture buffer information register 2 (SWREG53)	32	RO	0000_0000h
D8h	Synthesis configuration register decoder 1 (SWREG54)	32	RO	0000_0000h
DCh	Reference picture buffer 2 / Advanced prefetch control register (SWREG55)	32	RW	0000_0000h
E0h	Reference buffer information register 3 (SWREG56)	32	RO	0000_0000h
E4h	Decoder fuse register (SWREG57)	32	RO	Table 15-
E8h	Device configuration register decoder 2 + Multi core control register (SWREG58)	32	RW	0000_0000h
ECh	H264 Chrominance 8 pixel interleaved data base (SWREG59)	32	RW	0000_0000h
F0h	Interrupt register post-processor (SWREG60)	32	RW	0000_0000h
F4h	Device configuration register post-processor (SWREG61)	32	RW	0000_0100h
F8h	Deinterlace control register (SWREG62)	32	RW	0000_0000h
FCh	Base address for reading post-processing input picture luminance (top field/frame) (SWREG63)	32	RW	0000_0000h
100h	Base address for reading post-processing input picture Cb/Ch (top field/frame) (SWREG64)	32	RW	0000_0000h
104h	Base address for reading post-processing input picture Cr (SWREG65)	32	RW	0000_0000h
108h	Base address for writing post-processed picture luminance/RGB (SWREG66)	32	RW	0000_0000h
10Ch	Base address for writing post-processed picture Ch (SWREG67)	32	RW	0000_0000h
110h	Register for contrast adjusting (SWREG68)	32	RW	0000_0000h
114h	Register for colour conversion and contrast adjusting/YUYV 422 channel orders (SWREG69)	32	RW	0000_0000h
118h	Register for colour conversion 0 (SWREG70)	32	RW	0000_0000h
11Ch	Register for colour conversion 1 + rotation mode (SWREG71)	32	RW	0000_0000h
120h	PP input size and -cropping register (SWREG72)	32	RW	0000_0000h
124h	PP input picture base address for Y bottom field (SWREG73)	32	RW	0000_0000h
128h	PP input picture base for Ch bottom field (SWREG74)	32	RW	0000_0000h
13Ch	Scaling register 0 ratio and padding for R and G (SWREG79)	32	RW	0000_0000h
140h	Scaling ratio register 1 and padding for B (SWREG80)	32	RW	0000_0000h

Table continues on the next page...

Offset	Register	Width (In bits)	Access	Reset value
144h	Scaling ratio register 2 (SWREG81)	32	RW	0000_0000h
148h	Rmask register (SWREG82)	32	RW	0000_0000h
14Ch	Gmask register (SWREG83)	32	RW	0000_0000h
150h	Bmask register (SWREG84)	32	RW	0000_0000h
154h	Post-processor control register (SWREG85)	32	RW	0000_0000h
158h	Mask 1 start coordinate register (SWREG86)	32	RW	0000_0000h
15Ch	Mask 2 start coordinate register + Mask extensions (SWREG87)	32	RW	0000_0000h
160h	Mask 1 size and PP original width register (SWREG88)	32	RW	0000_0000h
164h	Mask 2 size register + mask extensions (SWREG89)	32	RW	0000_0000h
168h	PiP register 0 (SWREG90)	32	RW	0000_0000h
16Ch	PiP register 1 and dithering control (SWREG91)	32	RW	0000_0000h
170h	Display width and PP input size extension register (SWREG92)	32	RW	0000_0000h
174h	Base address for alpha blend 1 gui component (SWREG93)	32	RW	0000_0000h
178h	Base address for alpha blend 2 gui component (SWREG94)	32	RW	0000_0000h
17Ch	Alpha blend input cropping register (scanline for cropping) (SWREG95)	32	RW	0000_0000h
18Ch	PP fuse register (SWREG99)	32	RO	Table 15-
190h	Synthesis configuration register post-processor (SWREG100)	32	RO	Table 15-
198h	Base address for H264 decoded chroma picture (SWREG102)	32	RW	0000_0000h
19Ch	Base address for reference chroma picture index 0 (SWREG103)	32	RW	0000_0000h
1A0h	Base address for reference chroma picture index 1 (SWREG104)	32	RW	0000_0000h
1A4h	Base address for reference chroma picture index 2 (SWREG105)	32	RW	0000_0000h
1A8h	Base address for reference chroma picture index 3 (SWREG106)	32	RW	0000_0000h
1ACh	Base address for reference chroma picture index 4 (SWREG107)	32	RW	0000_0000h
1B0h	Base address for reference chroma picture index 5 (SWREG108)	32	RW	0000_0000h
1B4h	Base address for reference chroma picture index 6 (SWREG109)	32	RW	0000_0000h
1B8h	Base address for reference chroma picture index 7 (SWREG110)	32	RW	0000_0000h
1BCh	Base address for reference chroma picture index 8 (SWREG111)	32	RW	0000_0000h
1C0h	Base address for reference chroma picture index 9 (SWREG112)	32	RW	0000_0000h
1C4h	Base address for reference chroma picture index 10 (SWREG113)	32	RW	0000_0000h
1C8h	Base address for reference chroma picture index 11 (SWREG114)	32	RW	0000_0000h

1D0h	Base address for reference chroma picture index 13 (SWREG116)	32	RW	0000_0000h
1D4h	Base address for reference chroma picture index 14 (SWREG117)	32	RW	0000_0000h
1D8h	Base address for reference chroma picture index 15 (SWREG118)	32	RW	0000_0000h

15.1.5.1.2 Interrupt register decoder (SWREG1)

15.1.5.1.2.1 Offset

Register	Offset
SWREG1	4h

15.1.5.1.2.2 Diagram

15.1.5.1.2.3 Fields

Field	Function
31-25 —	Reserved.
24 SW_DEC_PIC_INF	B slice detected. This signal is driven high during picture ready interrupt if B-type slice is found. This bit does not launch interrupt but is used to inform SW about h264 tools.
23-19 —	Reserved.
18 SW_DEC_TIMEOUT	Interrupt status bit decoder timeout. When high the decoder has been idling for too long. HW will self reset. Possible only if timeout interrupt is enabled

Table continues on the next page...

Field	Function
17 SW_DEC_SLICE_INT	Interrupt status bit dec_slice_decoded. When high SW must set new base addresses for sw_dec_out_base and sw_jpg_ch_out_base before resetting this status bit. Used for VP8 web-p modes
16 SW_DEC_ERROR_INT	Interrupt status bit input stream error. When high, an error is found in input data stream decoding. HW will self reset.
15 SW_DEC_ASO_INT	H264: Interrupt status bit ASO (Arbitrary Slice Ordering) detected. When high, ASO detected in input data stream decoding. HW will self reset. VP8: Error detected in Residual data. HW returns MB number in error concealment register for MB it detected it
14 SW_DEC_BUFFER_INT	Interrupt status bit input buffer empty. When high, input stream buffer is empty but picture is not ready. HW will not self reset.
13 SW_DEC_BUS_INT	Interrupt status bit bus. Error response from bus.
12 SW_DEC_RDY_INT	Interrupt status bit decoder. When this bit is high decoder has decoded a picture. HW will self reset.
11-9 —	Reserved.
8 SW_DEC_IRQ	Decoder IRQ. When high, decoder requests an interrupt. SW will reset this after interrupt is handled.
7-6 —	Reserved.
5 SW_DEC_ABORT_E	Abort decoding enable. Setting this bit high will cause HW to abort decoding and safely to reset itself down. After abort is complete the corresponding interrupt status is set and this bit is set low as well as the decoder enable.
4 SW_DEC_IRQ_DIS	Decoder IRQ disable. When high, there are no interrupts concerning decoder from HW. Polling must be used to see the interrupt statuses.
3-1 —	Reserved.
0 SW_DEC_E	Decoder enable. Setting this bit high will start the decoding operation. HW will reset this when picture is processed or ASO or stream error is detected or bus error or timeout interrupt is given.

15.1.5.1.3 Device configuration register decoder (SWREG2)

15.1.5.1.3.1 Offset

Register	Offset
SWREG2	8h

15.1.5.1.3.2 Diagram

15.1.5.1.3.3 Fields

Field	Function
31-24 SW_DEC_AXI_RD_ID	Read ID used for decoder reading services in AXI bus (if connected to AXI).
23 SW_DEC_TIMEOUT_E	Timeout interrupt enable. If enabled HW may return timeout interrupt in case HW gets stuck while decoding picture.
22 SW_DEC_STRSWAP32_E	Decoder input 32bit data swap for stream data (may be used for 64 bit environment): 0b - no swapping of 32 bit words 1b - 32 bit data words are swapped (needed in 64 bit environment to achieve 7-6-5-4-3-2-1-0 byte order(also little endian should be enabled))
21 SW_DEC_STRENDIAN_E	Decoder input endian mode for stream data: 0b - Big endian (0-1-2-3 order) 1b - Little endian (3-2-1-0 order)
20	Decoder input 32bit data swap for other than stream data (may be used for 64 bit environment): 0b - no swapping of 32 bit words

Table continues on the next page...

VPU G1 Memory Map/Register Definition

Field	Function
SW_DEC_INSW AP32_E	1b - 32 bit data words are swapped (needed in 64 bit environment to achieve 7-6-5-4-3-2-1-0 byte order(also little endian should be enabled))
19 SW_DEC_OUT SWAP32_E	Decoder output 32bit data swap (may be used for 64 bit environment): 0b - no swapping of 32 bit words 1b - 32 bit data words are swapped (needed in 64 bit environment to achieve 7-6-5-4-3-2-1-0 byte order(also little endian should be enabled))
18 SW_DEC_DAT A_DISC_E	Data discard enable. Precise burst lengths are used with reading services. Extra data is discarded internally. Note. If AHB maxburst 17 is used data discard cannot be enabled (causes conflict)
17 SW_TILED_MO DE_MSB	Tiled mode msb. Concatenated to Tiled mode lsb which form 2 bit tiled mode. 0b - Tiled mode not enabled 1b - Tiled mode enabled for 8x4 tile size
16-11 SW_DEC_LATE NCY	Decoder master interface additional latency. Can be used to slow down decoder HW between services in steps of 8 clock cycles: 0 = no latency 1 = minimum 8 cycles of IDLE between services 2 = minimum 16 cycles of IDLE between services . . . 63 = minimum latency of 504 cycles of IDLE between services
10 SW_DEC_CLK_ GATE_E	Decoder dynamic clock gating enable: 0b - Clock is running for all structures 1b - Clock is gated for decoder structures that are not used. Note: Clock gating value can be changed only when decoder is disabled.
9 SW_DEC_IN_E NDIAN	Decoder input endian mode for other than stream data: 0b - Big endian (0-1-2-3 order) 1b - Little endian (3-2-1-0 order)
8 SW_DEC_OUT_ ENDIAN	Decoder output endian mode: 0b - Big endian (0-1-2-3 order) 1b - Little endian (3-2-1-0 order)
7 SW_TILED_MO DE_LSB	Tiled mode lsb. Concatenated to Tiled mode msb which form 2 bit tiled mode. Defined in tiled_mode_msb
6 SW_DEC_ADV_ PRE_DIS	Advanced PREFETCH mode disable (advanced reference picture reading mode for video)
5 SW_DEC_SCM D_DIS	9170 decoder and later->: AXI Single Command Multiple Data disable. 9170 axi wrapper supports this mode by default (where only the first addresses of the burst are given from address generator). This bit is used to disable the feature (possible SW workaround if something is not working correctly)
4-0 SW_DEC_MAX_ BURST	Maximum burst length for decoder bus transactions. Valid values: AHB: 1, 4, 8, 16 and 17. Other values will result in INCR type (undefined length) for all transfers. INCR used for lengths 2 and 3.

Field	Function
	17 = fixed bursts are used when possible. INCR bursts are used for lengths 2, 3, 5, 6, 7, 9, 10, 11, 12, 13, 14 and 15. OCP: 16-31 AXI: 1-16

15.1.5.1.4 Decoder control register 0 (decmode,picture type etc) (SWREG3)

15.1.5.1.4.1 Offset

Register	Offset
SWREG3	Ch

15.1.5.1.4.2 Diagram

15.1.5.1.4.3 Fields

Field	Function
31-28 SW_DEC_MODE	Decoding mode: 0000b - H.264 0001b - Reserved 0010b - Reserved 0011b - Reserved 0100b - Reserved 0101b - Reserved 0110b - Reserved 0111b - Reserved 1000b - Reserved 1001b - Reserved 1010b - VP8 1011b - Reserved 1100b - Reserved 1101b - Reserved 1110b - Reserved 1111b - Reserved
27 SW_RLC_MODE	RLC mode enable: 0b - HW decodes video from bit stream (VLC mode) + side information 1b - HW decodes video from RLC input data + side information (Differential MV's, separate DC coeffs, Intra 4x4 modes, MB control). Valid only for H.264 Baseline.
26 SW_SKIP_MODE	VP8: <ul style="list-style-type: none"> 0 : HW decodes mb_coeff_skip -flag 1 : HW does not decode mb_coeff_skip -flag
25 —	Reserved.
24 —	Reserved.
23 SW_PIC_INTERLACE	Coding mode of the current picture: 0b - progressive 1b - interlaced
22 SW_PIC_FIELD_MODE	Structure of the current picture (residual structure) 0b - Frame structure. For H264, this means MBAFF structured picture for interlaced sequence 1b - Field structure
21 SW_PIC_B	B picture enable for current picture: 0b - picture type is I or P depending on sw_pic_inter_e 1b - picture type is B depending on sw_pic_inter_e (not valid for H264 since it is slice based information)
20 SW_PIC_INTER	Picture type. Please also see SW_PIC_B. 0b - Intra type (I) 1b - Inter type (P)
19 SW_PIC_TOPFIELD	If field structure is enabled, this bit informs which one of the fields is being decoded: 0b - bottom field 1b - top field
18 SW_FWD_INTERLACE	Coding mode of forward reference picture NOTE: For backward reference picture, the coding mode is always the same as for current picture. 0b - progressive

Table continues on the next page...

Field	Function
	1b - interlaced
17 —	Reserved.
16 SW_REF_TOPFIELD_E	Indicates which field should be used as reference if sw_ref_frames = '0': 0b - bottom field 1b - top field
15 SW_DEC_OUT_DIS	Disable decoder output picture writing: 0b - Decoder output picture is written to external memory 1b - Decoder output picture is not written to external memory
14 SW_FILTERING_DIS	De-block filtering disable: 0b - filtering is enabled for current picture 1b - filtering is disabled for current picture
13 SW_WEBP_E	SW_WEBP_E: Webp enable for VP8: <ul style="list-style-type: none"> '0' = Normal VP8 '1' = WEBP picture SW_MVC_E: Multi View Coding enable. Possible for H264 only.
12 SW_WRITE_MVS_E	Direct mode motion vector write enable for current picture / VPX motion vector write enable for error concealment purposes: 0b - Writing disabled for current picture 1b - The direct mode motion vectors are written to external memory. H264 direct mode motion vectors are written to DPB aside with the corresponding reference picture. Other decoding mode dir mode mvs are written to external memory starting from sw_dir_mv_base.
11 SW_REFTOPFIRST_E	Indicates which FWD reference field has been decoded first. 0b - FWD reference bottom field 1b - FWD reference top field
10 SW_SEQ_MBAFF_E	Sequence includes MBAFF coded pictures
9 SW_PICORDER_COUNT_E	h264_high config: Picture order count table read enable. If enabled HW will read picture order counts from memory in the beginning of picture
8 SW_DEC_AHB_HLOCK_E	AHB master HLOCK enable. When high the service is locked to decoder as long as it needs the bus (whenever decoder requests the bus it will be granted)
7-0 SW_DEC_AXI_WR_ID	Write ID used for decoder writing services in AXI bus (if connected to AXI)

15.1.5.1.5 Base address for RLC data (RLC) / stream start address/ decoded end addr register (VLC) (SWREG12)

15.1.5.1.5.1 Offset

Register	Offset
SWREG12	30h

15.1.5.1.5.2 Diagram

15.1.5.1.5.3 Fields

Field	Function
31-0	RLC mode: Base address for RLC data (swreg3.sw_rlc_mode_e = 1).
SW_RLC_VLC_BASE	VLC mode: Stream start address / end address with byte precision (swreg4.rlc_mode_en = 0), start bit number in swreg5.stream_start_bit. When sw_dec_buffer_int is high or sw_dec_e is low this register contains HW return value of last_byte_address where stream has been read (and used) in accuracy of byte. For debug purposes the last_byte_address is also written when stream error/ASO is detected even though it may not be accurate. VP8: This base address is used as sw_dct_strm0_base including DCT stream for MB rows 0,2n.

15.1.5.1.6 Base address for decoded picture (SWREG13)

15.1.5.1.6.1 Offset

Register	Offset
SWREG13	34h

15.1.5.1.6.2 Diagram

15.1.5.1.6.3 Fields

Field	Function
31-2 SW_DEC_OUT_BASE	Video: Base address for decoder output picture. Points directly to start of decoder output picture or field.
1 SW_DPB_ILACE_MODE	DPB ilaced mode: '0' : DPB consist of ilaced/progressive frames '1' : DPB consist of progressive frames / separate fields. This mode requires config support from HW
0 —	Reserved.

15.1.5.1.7 Base address for standard dependent tables (SWREG40)

15.1.5.1.7.1 Offset

Register	Offset
SWREG40	A0h

15.1.5.1.7.2 Diagram

15.1.5.1.7.3 Fields

Field	Function
31-2	Base address for standard dependent tables:
SW_QTABLE_BASE	H.264: base address for various tables VP8: base address for stream decoding tables
1-0	Reserved.
—	

15.1.5.1.8 Base address for direct mode motion vectors (SWREG41)

15.1.5.1.8.1 Offset

Register	Offset
SWREG41	A4h

15.1.5.1.8.2 Diagram

15.1.5.1.8.3 Fields

Field	Function
31-2 SW_DIR_MV_BASE	Direct mode motion vector write/read base address. For H264 this is used only for direct mode motion vector write base. VP8: Motion vectors are written for error concealment purposes if sw_write_mvs is high. In error concealment mode motion vectors are read from this base address
1-0 —	Reserved.

15.1.5.1.9 Error concealment register (SWREG48)

15.1.5.1.9.1 Offset

Register	Offset
SWREG48	C0h

15.1.5.1.9.2 Diagram

15.1.5.1.9.3 Fields

Field	Function
31-23 SW_STARTMB_X	Start MB from SW for X dimension. Used in error concealment case as HW return value if HW finds an error or in HW init mb for error concealment if SW enables error concealment
22-14 SW_STARTMB_Y	Start MB from SW for Y dimension. Used in error concealment case as HW return value if HW finds an error or in HW init mb for error concealment if SW enables error concealment
13-12 SW_ERROR_CONC_MODE	Error concealment mode: 00b - disabled (normal decoding mode) 01b - enabled for direct mode MV usage starting from MB defined by sw_startmb_x, sw_startmb_y
11-0 —	Reserved.

15.1.5.1.10 Prediction filter tap register for H264 (SWREG49)

15.1.5.1.10.1 Offset

Register	Offset

15.1.5.1.19 Device configuration register decoder 2 + Multi core control register (SWREG58)

15.1.5.1.19.1 Offset

Register	Offset
SWREG58	E8h

15.1.5.1.19.2 Diagram

15.1.5.1.19.3 Fields

Field	Function
31 SW_SERV_MERGE_DIS	Decoder service merge disable: 0b - HW merges simultaneous sub-block requests internally if they are same type (read or write). 1b - decoder serves one sub-block per service and merging is disabled.
30 SW_DEC_MULTICORE_E	Decoder multi core enable: 0b - Multi core disabled or only one core exists in design. 1b - Multi core enable. Each reference picture status must be verified from external memory status field before usage. 128 bits status word exists after each reference picture and include picture proceeding coordinates Y and X.
29 SW_DEC_WRITE_STAT_E	Decoder write statusword enable. Must be high if multi core decoding enabled. HW writes output picture data proceeding to external memory after picture data (and after H264 direct mode MVS if they exist)
28-27 SW_DEC_MC_POLLMODE	Decoder multicore status reading mode: 00b - HW internal status polling mechanism is used. Status of reference picture is read only when required coordinate for the reference picture is not big enough. If the status is still not big enough after reading it the HW waits N clock cycles per pixel from the coordinate difference. The N is defined by the sw_dec_mc_polltime (range 0...4). 01b - Dummy status polling mechanism is used for all reference pictures. HW reads status of all reference pictures at frequency defined by sw_dec_mc_polltime.
26-17 SW_DEC_MC_POLLTIME	sw_dec_mc_polltime definition depends on sw_dec_mc_mode. if mode is 0 (HW internal mechanism) the sw_dec_mc_polltime: <ul style="list-style-type: none"> 0 = 1/4 cycles per pixel 1 = wait 1/2 cycles per pixel 2 = wait one cycle per pixel 3 = wait 2 cycles per pixel 4=wait 4 cycles per pixel

Table continues on the next page...

Field	Function
	For dummy polling mechanism the sw_dec_mc_polltime defines the amount cycles between status reads x1024: <ul style="list-style-type: none"> • 0 = wait 1024 cycles between status reading • 1 = wait 2048 cycles between status reading • 2 = wait 3072 cycles between status reading • N = wait (N+1)x1024 cycles
16-0 —	Reserved.

15.1.5.1.20 H264 Chrominance 8 pixel interleaved data base (SWREG59)

15.1.5.1.20.1 Offset

Register	Offset
SWREG59	ECh

15.1.5.1.20.2 Diagram

15.1.5.1.20.3 Fields

Field	Function
31-2	Base address for additional chrominance data format where chrominance is interleaved in group of 8 pixels. The usage is enabled by sw_ch_8pix_ileav_e

Table continues on the next page...

Field	Function
SW_DEC_CH8 PIX_BASE	
1-0 —	Reserved.

15.1.5.1.21 Interrupt register post-processor (SWREG60)

15.1.5.1.21.1 Offset

Register	Offset
SWREG60	F0h

15.1.5.1.21.2 Diagram

15.1.5.1.21.3 Fields

Field	Function
31-14 —	Reserved.
13 SW_PP_BUS_INT	Interrupt status bit bus. Error response from bus. In pipeline mode this bit is not used

Table continues on the next page...

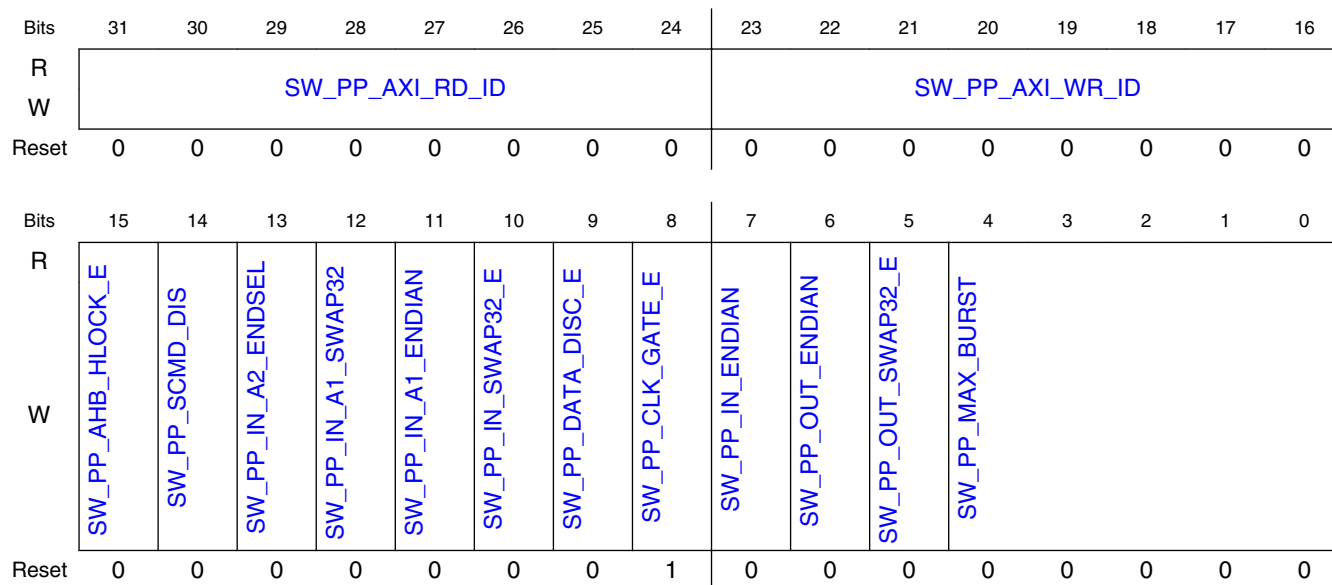

Field	Function
12 SW_PP_RDY_I NT	Interrupt status bit pp. When this bit is high post processor has processed a picture in external mode. In pipeline mode this bit is not used.
11-9 —	Reserved.
8 SW_PP_IRQ	Post-processor IRQ. SW will reset this after interrupt is handled. HINTpp is not used for pp if IRQ disable pp is high (sw_pp_irq_n_e = 1). In pipeline mode this bit is not used
7-5 —	Reserved.
4 SW_PP_IRQ_DI S	Post-processor IRQ disable. When high, there are no interrupts from HW concerning post processing. Polling must be used to see the interrupt
3-2 —	Reserved.
1 SW_PP_PIPELI NE_E	Decoder – post-processing pipeline enable: 0b - Post-processing is processing different picture than decoder or is disabled 1b - Post-processing is performed in pipeline with decoder
0 SW_PP_E	External mode post-processing enable. This bit will start the post-processing operation. Not to be used if PP is in pipeline with decoder (sw_pp_pipeline_e = 1). HW will reset this when picture is post-processed.

15.1.5.1.22 Device configuration register post-processor (SWREG61)

15.1.5.1.22.1 Offset

Register	Offset
SWREG61	F4h

15.1.5.1.22.2 Diagram

15.1.5.1.22.3 Fields

Field	Function
31-24 SW_PP_AXI_RD_ID	Read ID used for AXI PP read services (if connected to AXI)
23-16 SW_PP_AXI_WR_ID	Write ID used for AXI PP write services (if connected to AXI)
15 SW_PP_AHB_HLOCK_E	AHB master HLOCK enable. When high the service is locked to pp as long as it needs the bus (whenever pp requests the bus it will be granted)
14 SW_PP_SCMD_DIS	9170 decoder: AXI Single Command Multiple Data disable. 9170 axi wrapper supports this mode by default (where only the first addresses of the burst are given from address generator). This bit is used to disable the feature (possible SW workaround if something is not working correctly)
13 SW_PP_IN_A2_ENDSEL	Endian/swap select for Alpha blend input source 2: 0b - Use PP in endian/swap definitions (sw_pp_in_endian, sw_pp_in_swap) 1b - Use Alpha blend source 1 endian/swap definitions (sw_pp_in_a1_endian, sw_pp_in_a1_swap)
12 SW_PP_IN_A1_SWAP32	Alpha blend source 1 input 32bit data swap (may be used for 64 bit environment): 0b - no swapping of 32 bit words 1b - 32 bit data words are swapped (needed in 64 bit environment to achieve 7-6-5-4-3-2-1-0 byte order(also little endian should be enabled))
11 SW_PP_IN_A1_ENDIAN	Alpha blend source 1 input data byte endian mode. 0b - Big endian (0-1-2-3 order) 1b - Little endian (3-2-1-0 order)
10	PP input 32bit data swap (may be used for 64 bit environment):

Table continues on the next page...

Field	Function
SW_PP_IN_SW AP32_E	0b - no swapping of 32 bit words 1b - 32 bit data words are swapped (needed in 64 bit environment to achieve 7-6-5-4-3-2-1-0 byte order(also little endian should be enabled))
9 SW_PP_DATA_ DISC_E	PP data discard enable. Precise burst lengths are used with reading services. Extra data is discarded internally. Note. If AHB maxburst 17 is used data discard cannot be enabled (causes conflict)
8 SW_PP_CLK_G ATE_E	PP dynamic clock gating enable. NOTE: Clock gating value can be changed only when PP is not enabled. 0b - Clock is running for all PP structures 1b - Clock is gated from PP structures that are not used
7 SW_PP_IN_EN DIAN	PP input picture byte endian mode. Used only if PP is in standalone mode. If PP is running pipelined with the decoder, this bit has no effect. 0b - Big endian (0-1-2-3 order) 1b - Little endian (3-2-1-0 order)
6 SW_PP_OUT_E NDIAN	PP output picture endian mode for YCbCr data or for any data if config value SW_PP_OEN_VERSION = 1. NOTE: For SW_PP_OEN_VERSION=0, 16 bit RGB data, this bit works as pixel swapping bit. For 32 bit RGB, this bit has no meaning. 0b - Big endian (0-1-2-3 order) 1b - Little endian (3-2-1-0 order)
5 SW_PP_OUT_S WAP32_E	PP output data word swap (may be used for 64 bit environment): 0b - no swapping of 32 bit words 1b - 32 bit data words are swapped (needed in 64 bit environment to achieve 7-6-5-4-3-2-1-0 byte order (also little endian should be enabled))
4-0 SW_PP_MAX_B URST	Maximum burst length for PP bus transactions. Valid values: AHB: 1, 4, 8, 16 and 17. Other values will result in INCR type (undefined length) transfers. 17 = fixed bursts are used when possible. INCR bursts for others. OCP: 16-31 AXI: 1-16

15.1.5.1.23 Deinterlace control register (SWREG62)

15.1.5.1.23.1 Offset

Register	Offset
SWREG62	F8h

15.1.5.1.23.2 Diagram

15.1.5.1.23.3 Fields

Field	Function
31 SW_DEINT_E	De-interface enable. Input data is in interlaced format and deinterlacing needs to be performed
30 —	Reserved.
29-16 SW_DEINT_TH RESHOLD	Threshold value used in deinterlacing
15 SW_DEINT_BL END_E	Blend enable for de-interlacing
14-0 SW_DEINT_ED GE_DET	Edge detect value used for deinterlacing

15.1.5.1.24 Base address for reading post-processing input picture luminance (top field/frame) (SWREG63)

1-0 —	Reserved.

15.1.5.1.27 Base address for writing post-processed picture luminance/RGB (SWREG66)

15.1.5.1.27.1 Offset

Register	Offset
SWREG66	108h

15.1.5.1.27.2 Diagram

15.1.5.1.27.3 Fields

Field	Function
31-0 SW_PP_OUT_L U_BASE	Base address for post-processing output picture (luminance/YUYV/RGB). NOTE: Bits 2:0 are used to adjust the post-processor output to start from zertain byte (1:0 for 32 bit bus). These bits can be other than zero only if Pixel Accurate PP output configuration is enabled

15.1.5.1.28 Base address for writing post-processed picture Ch (SWRE G67)

15.1.5.1.28.1 Offset

Register	Offset
SWREG67	10Ch

15.1.5.1.28.2 Diagram

15.1.5.1.28.3 Fields

Field	Function
31-0 SW_PP_OUT_C H_BASE	Base address for post-processing output chrominance picture (interleaved chrominance). NOTE: Bits 2:0 are used to adjust the post-processor output to start from certain byte (1:0 for 32 bit bus). These bits can be other than zero only if Pixel Accurate PP output configuration is enabled

15.1.5.1.29 Register for contrast adjusting (SWREG68)

15.1.5.1.29.1 Offset

Register	Offset
SWREG68	110h

15.1.5.1.29.2 Diagram

15.1.5.1.29.3 Fields

Field	Function
31-24 SW_CONTRAS T_THR1	Threshold value 1, used with contrast adjusting

Table continues on the next page...

VPU G1 Memory Map/Register Definition

Field	Function
23-20 —	Reserved.
19-10 SW_CONTRAS T_OFF2	Offset value 2, used with contrast adjusting
9-0 SW_CONTRAS T_OFF1	Offset value 1, used with contrast adjusting

15.1.5.1.30 Register for colour conversion and contrast adjusting/YUYV 422 channel orders (SWREG69)

15.1.5.1.30.1 Offset

Register	Offset
SWREG69	114h

15.1.5.1.30.2 Diagram

15.1.5.1.30.3 Fields

Field	Function
31 SW_PP_IN_ST ART_CH	For YUYV 422 input format. Enable for start_with_chrominance. 0b - the order is Y0CbY0Cr or Y0CrY0Cb 1b - the order is CbY0CrY0 or CrY0CbY0
30 SW_PP_IN_CR _FIRST	For YUYV 422 input format. Enable for Cr first (before Cb). 0b - the order is Y0CbY0Cr or CbY0CrY0 (if 420 semiplanar chrominance: CbCrCbCr) 1b - the order is Y0CrY0Cb or CrY0CbY0 (if 420 semiplanar chrominance: CrCbCrCb)
29 SW_PP_OUT_S TART_CH	For YUYV 422 output format. Enable for start_with_chrominance. 0b - the order is Y0CbY0Cr or Y0CrY0Cb 1b - the order is CbY0CrY0 or CrY0CbY0
28 SW_PP_OUT_C R_FIRST	For YUYV 422 output format. Enable for Cr first (before Cb). 0b - the order is Y0CbY0Cr or CbY0CrY0 1b - the order is Y0CrY0Cb or CrY0CbY0
27-18 SW_COLOR_C OEFFA2	Coefficient a2, used with Y pixel to calculate all color components
17-8 SW_COLOR_C OEFFA1	Coefficient a1, used with Y pixel to calculate all color components
7-0 SW_CONTRAS T_THR2	Threshold value 2, used with contrast adjusting

15.1.5.1.31 Register for colour conversion 0 (SWREG70)

Field	Function
31-29 SW_PP_IN_FORMAT	PP input picture data format 000b - YUYV 4:2:2 interleaved (supported only in external mode) 001b - YCbCr 4:2:0 Semi-planar in linear raster-scan format 010b - YCbCr 4:2:0 planar (supported only in external mode) 011b - YCbCr 4:0:0 (supported only in pipelined mode) 100b - YCbCr 4:2:2 Semi-planar (supported only in pipelined mode) 101b - YCbCr 4:2:0 Semi-planar in tiled format (supported only in external mode (8170 decoder only)) 110b - Reserved 111b - Escape pp input data format. Defined in swreg86.
28-26 SW_PP_OUT_FORMAT	PP output picture data format: 000b - RGB 001b - YCbCr 4:2:0 planar (Not supported) 010b - YCbCr 4:2:2 planar (Not supported) 011b - YUYV 4:2:2 interleaved 100b - YCbCr 4:4:4 planar (Not supported) 101b - YCh 4:2:0 chrominance interleaved 110b - YCh 4:2:2 (Not supported) 111b - YCh 4:4:4 (Not supported)

Table continues on the next page...

VPU G1 Memory Map/Register Definition

Field	Function
25-15 SW_PP_OUT_HEIGHT	Scaled picture height in pixels (Must be dividable by 2 or by any if Pixel Accurate PP output configuration is enabled) Max scaled picture height is 1920 pixels or maximum three times the input source height minus 8 pixels
14-4 SW_PP_OUT_WIDTH	Scaled picture width in pixels. Must be dividable by 8 or by any if Pixel Accurate PP output configuration is enabled. Max scaled picture width is 1920 pixels or maximum three times the input source width minus 8 pixels
3 SW_PP_OUT_TILED_E	Tiled mode enable for PP output. Can be used only for YCbYCr 422 output format. Can be used only if corresponding configuration supports this feature. Tile size is 4x4 pixels.
2 SW_PP_OUT_SWAP16_E	PP output swap 16, swaps 16 bit half inside of 32 bit word. Can be used for 16 bit RGB to change pixel orders but is valid also for any output format. NOTE: requires that configuration of SW_PPD_OEN_VERSION=1
1 SW_PP_CROP8_R_E	PP input picture width is not 16 pixels multiple. Only 8 pixels of the most right MB of the unrotated input picture is used for PP input.
0 SW_PP_CROP8_D_E	PP input picture height is not 16 pixels multiple. Only 8 pixel rows of the most down MB of the unrotated input picture is used for PP input.

15.1.5.1.43 Mask 1 start coordinate register (SWREG86)

15.1.5.1.46.3 Fields

Field	Function
31 —	Reserved.
30-29 SW_MASK1_E NDX_EXT	Extended coordinate upto 4k resolution
28-27 SW_MASK1_E NDY_EXT	Extended coordinate upto 4k resolution
26-25 SW_MASK2_E NDX_EXT	Extended coordinate upto 4k resolution
24-23 SW_MASK2_E NDY_EXT	Extended coordinate upto 4k resolution
22 SW_MASK2_E	Mask 2 enable. If mask 1 is used this bit is high
21-11 SW_MASK2_E NDY	Mask 2 end coordinate y in pixels (inside of PP output picture). Range must be between [Mask2StartCoordinateY, ScaledHeight].
10-0 SW_MASK2_E NDX	Mask 2 end coordinate x in pixels (inside of PP output picture). Range must be between [Mask2StartCoordinateX, ScaledWidth].

15.1.5.1.47 PiP register 0 (SWREG90)

15.1.5.1.47.1 Offset

Register	Offset
SWREG90	168h

15.1.5.1.47.2 Diagram

15.1.5.1.47.3 Fields

Field	Function
31-30 —	Reserved.
29 SW_RIGHT_CROSS_E	Right side overcross enable. 0b - No right side overcross 1b - Right side overcross
28 SW_LEFT_CROSS_E	Left side overcross enable. 0b - No left side overcross 1b - Left side overcross
27 SW_UP_CROSS_S_E	Upward overcross enable. 0b - No upward overcross 1b - Upward overcross
26 SW_DOWN_CROSS_E	Downward overcross enable. 0b - No downward overcross 1b - Downward overcross
25-15 SW_UP_CROSS_S	Amount of upward overcross (vertical pixels outside of display from the upper side). Range must be between [0, ScaledHeight].

Table continues on the next page...

Field	Function
14-13 —	Reserved.
12-11 SW_DOWN_CR OSS_EXT	Extended coordinate for 4k resolution
10-0 SW_DOWN_CR OSS	Amount of downward overcross (vertical pixels outside of display from the down side). Range must be between [0, ScaledHeight].

15.1.5.1.48 PiP register 1 and dithering control (SWREG91)

Register	Offset
SWREG91	16Ch

15.1.5.1.48.2 Diagram

15.1.5.1.48.3 Fields

Field	Function
31-30	Dithering control for R channel: 00b - dithering disabled

Table continues on the next page...

VPU G1 Memory Map/Register Definition

Field	Function
SW_DITHER_SELECT_R	01b - use four-bit dither matrix 10b - use five-bit dither matrix 11b - use six-bit dither matrix
29-28 SW_DITHER_SELECT_G	Dithering control for G channel: 00b - dithering disabled 01b - use four-bit dither matrix 10b - use five-bit dither matrix 11b - use six-bit dither matrix
27-26 SW_DITHER_SELECT_B	Dithering control for B channel: 00b - dithering disabled 01b - use four-bit dither matrix 10b - use five-bit dither matrix 11b - use six-bit dither matrix
25-24 —	Reserved.
23-22 SW_PP_TILED_MODE	Input data is in tiled mode (at the moment valid only for YCbCr 420 data, pipeline or external mode): 00b - Tiled mode not used 01b - Tiled mode enabled for 8x4 sized tiles
21-11 SW_RIGHT_CROSS	Amount of right side overcross (Horizontal pixels outside of display from the right side). Range must be between [0, ScaledWidth].
10-0 SW_LEFT_CROSS	Amount of left side overcross (Horizontal pixels outside of display from the left side). Range must be between [0, ScaledWidth].

15.1.5.1.49 Display width and PP input size extension register (SWREG92)

15.1.5.1.49.1 Offset

Register	Offset
SWREG92	170h

15.1.5.1.49.2 Diagram

15.1.5.1.49.3 Fields

Field	Function
31-29 SW_PP_IN_H_EXT	Extended PP input height. Used with WEBP
28-26 SW_PP_IN_W_EXT	Extended PP input width. Used with WEBP
25-23 SW_CROP_ST ARTY_EXT	Extended PP input crop start coordinate x. Used with WEBP
22-20 SW_CROP_ST ARTX_EXT	Extended PP input crop start coordinate y. Used with WEBP
19-18 SW_RIGHT_CR OSS_EXT	Extended coordinate for 4k resolution
17-16 SW_LEFT_CRO SS_EXT	Extended coordinate for 4k resolution

Table continues on the next page...

Field	Function
15-14 SW_UP_CROSS_EXT	Extended coordinate for 4k resolution
13 —	Reserved.
12-0 SW_DISPLAY_WIDTH	Width of the display in pixels. Max 4k (depends on HW config support)

15.1.5.1.50 Base address for alpha blend 1 gui component (SWREG93)

31 FUSE_PP_PP	1 = PP enabled
30 FUSE_PP_DEINT	1 = Deinterlacing enabled
29 FUSE_PP_ABL END	1 = Alpha Blending enabled
28-17 —	Reserved.
16 FUSE_PP_MAX W_4K	1 = Max PP output width up to 4096 pixels enabled. Priority coded with priority 1
15 FUSE_PP_MAX W_1920	1 = Max PP output width up to 1920 pixels enabled. Priority coded with priority 2

Table continues on the next page...

VPU G1 Memory Map/Register Definition

Field	Function
14 FUSE_PP_MAX W_1280	1 = Max PP output width up to 1280 pixels enabled. Priority coded with priority 3
13 FUSE_PP_MAX W_720	1 = Max PP output width up to 720 pixels enabled. Priority coded with priority 4
12 FUSE_PP_MAX W_352	1 = Max PP output width up to 352 pixels enabled. Priority coded with priority 5
11-0 —	Reserved.

15.1.5.1.54 Synthesis configuration register post-processor (SWREG100)

15.1.5.1.54.1 Offset

Register	Offset
SWREG100	190h

15.1.5.1.54.2 Diagram

15.1.5.1.54.3 Fields

Field	Function
31 SW_ABLEND_CROP_E	Alpha blending support for input cropping: 0b - Not supported. External memory must include the exact image of the area being alpha blended. 1b - Supported. External memory can include a picture from blended area can be cropped. Requires usage of swreg95.
30 SW_PPD_PIXAC_E	Pixel Accurate PP output mode exists: 0b - PIP, Scaling and masks can be adjusted by steps of 8 pixels (width) or 2 pixels (height) 1b - PIP, Scaling and masks can be adjusted by steps of 1 pixel for RGB and 2 pixels for subsampled chroma formats (by using bus specific write strobe functionality)
29 SW_PPD_TILE_D_EXIS	PP output YCbYCr 422 tiled support (4x4 pixel tiles) 0b - Not supported 1b - Supported
28 SW_PPD_DITH_EXIS	Dithering exists: 0b - No 1b - Yes
27-26	Scaling support:

Table continues on the next page...

VPU G1 Memory Map/Register Definition

Field	Function
SW_PPD_SCAL E_LEVEL	00b - No scaling 01b - Scaling with lo performance architecture 10b - Scaling with high performance architecture 11b - Scaling with high performance architecture + fast downscaling enabled
25 SW_PPD_DEIN T_EXIST	De-interlacing exists: 0b - No 1b - Yes
24 SW_PPD_BLEN D_EXIST	Alpha blending exists: 0b - No 1b - Yes
23 SW_PPD_IBUF F_LEVEL	PP input buffering level: 0b - 1 MB input buffering is used 1b - 4 MB input buffering is used
22-19 —	Reserved.
18 SW_PPD_OEN _VERSION	PP output endian version: 0b - Endian mode supported for other than RGB 1b - Endian mode supported for any output format
17 SW_PPD_OBU FF_LEVEL	PP output buffering level: 0b - 1 unit output buffering is used 1b - 4 unit output buffering is used
16 SW_PPD_PP_E XIST	PPD exists: 0b - No 1b - Yes
15-14 SW_PPD_IN_TI LED_L	PPD input tiled mode support level 00b - not supported 01b - 8x4 tile size supported
13 —	Reserved.
12-0 SW_PPD_MAX _OWIDTH	Max supported PP output width in pixels

15.1.5.1.55 Base address for H264 decoded chroma picture (SWREG102)

15.1.5.1.55.1 Offset

Register	Offset
SWREG102	198h

15.1.5.1.55.2 Diagram

15.1.5.1.55.3 Fields

Field	Function
31-2 SW_DEC_CH_BASE	Valid only if chroma address separate mode is enabled. H264: Base address for decoder output chroma picture. Points directly to start of decoder output chroma picture or field.
1 —	Reserved.
0 SW_CH_BASE_E	chroma address separate mode enable: 0b - HW outputs decoded chroma picture to the end of decoded luma picture. HW calculates the chroma picture address according to sw_dec_base and luma data length. 1b - HW outputs decoded chroma picture to independent memory address

8Ch	Reference picture numbers for index 10 and 11 (H264 VLC) / VC1, VPx prediction filter taps (SWREG35)	32	RW	0000_0000h
90h	Reference picture numbers for index 12 and 13 (H264 VLC) / VC1, VPx prediction filter taps (SWREG36)	32	RW	0000_0000h
94h	Reference picture numbers for index 14 and 15 (H264 VLC) / VPx prediction filter taps (SWREG37)	32	RW	0000_0000h
98h	Reference picture long term flags (H264 VLC) / VPx prediction filter taps (SWREG38)	32	RW	0000_0000h
9Ch	Reference picture valid flags (H264 VLC) / VPx prediction filter taps (SWREG39)	32	RW	0000_0000h
A8h	bi_dir initial ref pic list register (0-2) / VP6 prediction filter taps / Progressive JPEG Cb ACDC coefficient base (SWREG42_H264)	32	RW	0000_0000h
ACh	bi-dir initial ref pic list register (3-5) / VP6 prediction filter taps / Progressive JPEG Cr ACDC coefficient base (SWREG43_H264)	32	RW	0000_0000h
B0h	bi-dir initial ref pic list register (6-8) / VP6 prediction filter taps (SWREG44_H264)	32	RW	0000_0000h
B4h	bi-dir initial ref pic list register (9-11) / VP6 prediction filter taps (SWREG45)	32	RW	0000_0000h
B8h	bi-dir initial ref pic list register (12-14) / VP7,VP8 quantization values (SWREG46)	32	RW	0000_0000h
BCh	bi-dir and P fwd initial ref pic list register (15 and P 0-3) / VP7,VP8 quantization values (SWREG47)	32	RW	0000_0000h

15.1.5.2.2 Decoder control register 1 (picture parameters) (SWREG4)

15.1.5.2.2.1 Offset

Register	Offset
SWREG4	10h

15.1.5.2.2.2 Diagram

15.1.5.2.2.3 Fields

Field	Function
31-23 SW_PIC_MB_WIDTH	Picture width in macroblocks = ((width in pixels + 15) / 16)
22-19 SW_MB_WIDTH_OFF	The amount of meaningful horizontal pixels in last MB (width offset) 0 if exactly 16 pixels multiple picture and all the horizontal pixels in last MB are meaningful
18-11	Picture height in macroblocks = ((height in pixels + 15) / 16). Picture height is informed as size of the (progressive) frame also for single field (of interlaced content) is being decoded

Table continues on the next page...

Field	Function
SW_PIC_MB_H EIGHT_P	
10-7 SW_MB_HEIGHT T_OFF	The amount of meaningful vertical pixels in last MB (height offset 0 if exactly 16 pixels multiple picture and all the vertical pixels in last MB are meaningfull
6 SW_ALT_SCAN _E	indicates alternative vertical scan method used for interlaced frames
5 —	Reserved.
4-0 SW_REF_FRAMES	H.264: num_ref_frames, maximum number of short and long term reference frames in decoded picture buffer VC-1: num_ref semantics

15.1.5.2.3 Decoder control register 2 (stream decoding table selects) (SWREG5)

15.1.5.2.3.1 Offset

Register	Offset
SWREG5	14h

15.1.5.2.3.2 Diagram

15.1.5.2.3.3 Fields

Field	Function
31-26 SW_STRM_START_BIT	Exact bit of stream start word where decoding can be started (associates with sw_rlc_vlc_base)
25 SW_SYNC_MARKER_E	Sync markers enable For progressive JPEG, this indicates that there are restart markers in the stream after restart interval steps. 0b - synch markers are not used 1b - synch markers are used.
24 SW_TYPE1_QUANT_E	MPEG4: Type 1 quantization enable <ul style="list-style-type: none"> '0' = type 2 inverse Q method '1' = type 1 inverse Q method (Q-tables used) H264 (h264_high config): scaling matrix enable <ul style="list-style-type: none"> '0' = normal transform '1' = use scaling matrix for transform (read from external memory)
23-19 SW_CH_QP_OFFSET	Chroma Qp filter offset. (For H.264 this offset concerns Cb only)
18-14	Chroma Qp filter offset for cr type

Table continues on the next page...

Field	Function
SW_CH_QP_OFFSET2	
13-1 —	Reserved.
0 SW_FIELDPIC_FLAG_E	Flag for streamd that field_pic_flag exists in stream

15.1.5.2.4 Decoder control register 3 (stream buffer information) (SWREG6)

15.1.5.2.4.1 Offset

Register	Offset
SWREG6	18h

15.1.5.2.4.2 Diagram

15.1.5.2.4.3 Fields

Field	Function
31	Bit for indicating stream start code existence: 0b - stream doesn't contain start codes

Table continues on the next page...

VPU G1 Memory Map/Register Definition

Field	Function
SW_START_C ODE_E	1b - stream contains start codes
30-25 SW_INIT_QP	Initial value for quantization parameter (picture quantizer).
24 SW_CH_8PIX_I LEAV_E	Enable for additional chrominance data format writing where decoder writes chrominance in group of 8 pixels of Cb and then corresponding 8 pixels of Cr. Data is written to sw_dec_ch8pix_base. Cannot be used if tiled mode is enabled
23-0 SW_STREAM_L EN	Amount of stream data bytes in input buffer. If the given buffer size is not enough for finishing the picture the corresponding interrupt is given and new stream buffer base address and stream buffer size information should be given (associates with sw_rlc_vlc_base). For VC-1/VP6 the buffer must include data for one picture/slice of the picture For H264/MPEG4/H263/MPEG2/MPEG1 the buffer must include at least data for one slice/VP of the picture For JPEG the buffer size must be a multiple of 256 bytes or the amount of data for one picture.

15.1.5.2.5 Decoder control register 4 (H264, VC-1, VP6 and progressive JPEG control) (SWREG7)

15.1.5.2.5.1 Offset

Register	Offset
SWREG7	1Ch

15.1.5.2.5.2 Diagram

15.1.5.2.5.3 Fields

Field	Function
31 SW_CABAC_E	CABAC enable
30 SW_BLACKWHI TE_E	0b - 4:2:0 sampling format 1b - 4:0:0 sampling format (H264 monochroma)
29 SW_DIR_8X8_I NFER_E	Specifies the method to use to derive luma motion vectors in B_skip, B_Direct_16x16 and B_direct_8x8_inference_flag (see direct_8x8_inference flag)
28 SW_WEIGHT_P RED_E	Weighted prediction enable for P slices
27-26 SW_WEIGHT_B IPR_IDC	weighted prediction specification for B slices: 00b - default weighted prediction is applied to B slices 01b - explicit weighted prediction shall be applied to B slices 10b - implicit weighted prediction shall be applied to B slices
25 SW_AVS_H264 _H_EXT	Resolution extension to support 4k resolution for AVS/H264. Used as MSB of sw_pic_mb_height
24-21 —	Reserved.
20-16 SW_FRAMENU M_LEN	H.264: Bit length of frame_num in data stream RV: frame size length. Informs how many bits in stream are used for frame size (HW discards these bits)
15-0 SW_FRAMENU M	current frame_num, used to identify short-term reference frames. Used in reference picture reordering

15.1.5.2.6 Decoder control register 5 (H264, VC-1, VP6, Progressive JPEG and RV control) (SWREG8)

15.1.5.2.6.1 Offset

Register	Offset
SWREG8	20h

15.1.5.2.6.2 Diagram

15.1.5.2.6.3 Fields

Field	Function
31 SW_CONST_INTRA_E	constrained_intra_pred_flag equal to 1 specifies that intra prediction uses only neighbouring intra macroblocks in prediction. When equal to 0 also neighbouring inter macroblocks are used in intra prediction process.
30 SW_FILT_CTRL_PRE_S	deblocking_filter_control_present_flag indicates whether extra variables controlling characteristics of the deblocking filter are present in the slice header.
29 SW_RDPIC_CNT_PRE_S	redundant_pic_cnt_present_flag specifies whether redundant_pic_cnt syntax elements are present in the slice header.
28 SW_8X8TRANS_FLAG_E	8x8 transform flag enable for stream decoding
27-17 SW_REFPIC_MK_LEN	Length of decoded reference picture marking bits
16 SW_IDR_PIC_E	IDR (instantaneous decoding refresh) picture flag.
15-0 SW_IDR_PIC_ID	idr_pic_id, identifies IDR (instantaneous decoding refresh) picture

15.1.5.2.7 Decoder control register 6 / base address for MB-control (RLC) / VC-1 intensity control 0/ VP6,VP7,VP8 ctrl-stream length/ RV pic slice amount (SWREG9)

15.1.5.2.7.1 Offset

Register	Offset
SWREG9	24h

15.1.5.2.7.2 Diagram

15.1.5.2.7.3 Fields

Field	Function
31-24 SW_PPS_ID	pic_parameter_set_id, identifies the picture parameter set that is referred to in the slice header.
23-19 SW_REFIDX1_ACTIVE	Specifies the maximum reference index that can be used while decoding inter predicted macro blocks.

Table continues on the next page...

VPU G1 Memory Map/Register Definition

Field	Function
18-14 SW_REFIDX0_ACTIVE	Specifies the maximum reference index that can be used while decoding inter predicted macro blocks. This is same as in previous decoders (width increased with q bit)
13-8 —	Reserved.
7-0 SW_POC_LENGTH	Length of picture order count field in stream

15.1.5.2.8 Base address for differential motion vector base address (RLC-mode) /H264 P initial fwd ref pic list register (4-9)/ VC-1 intensity control 1/ VP7 and VP8 segmentation base register (SWREG10)

15.1.5.2.8.1 Offset

Register	Offset
SWREG10	28h

15.1.5.2.8.2 Diagram

15.1.5.2.8.3 Fields

Field	Function
31-30 —	Reserved.
29-25 SW_PINIT_RLI ST_F9	Initial reference picture list for P forward picid 9
24-20 SW_PINIT_RLI ST_F8	Initial reference picture list for P forward picid 8
19-15 SW_PINIT_RLI ST_F7	Initial reference picture list for P forward picid 7
14-10 SW_PINIT_RLI ST_F6	Initial reference picture list for P forward picid 6
9-5 SW_PINIT_RLI ST_F5	Initial reference picture list for P forward picid 5
4-0 SW_PINIT_RLI ST_F4	Initial reference picture list for P forward picid 4

15.1.5.2.9 Decoder control register 7 (VLC) / base address for H.264 intra prediction 4x4 / base address for MPEG-4 DC component (RLC) / H264 P initial fwd ref pic list register (10-15) / VC-1 intensity control 2 (SWREG11)

15.1.5.2.9.1 Offset

Register	Offset
SWREG11	2Ch

15.1.5.2.9.2 Diagram

15.1.5.2.9.3 Fields

Field	Function
31-30 —	Reserved.
29-25 SW_PINIT_RLIST_F15	Initial reference picture list for P forward picid 15
24-20 SW_PINIT_RLIST_F14	Initial reference picture list for P forward picid 14
19-15 SW_PINIT_RLIST_F13	Initial reference picture list for P forward picid 13
14-10 SW_PINIT_RLIST_F12	Initial reference picture list for P forward picid 12
9-5 SW_PINIT_RLIST_F11	Initial reference picture list for P forward picid 11
4-0	Initial reference picture list for P forward picid 10

Field	Function
SW_PINIT_RLI ST_F10	

15.1.5.2.10 Base address for reference picture index 0 / base address for JPEG decoder output chrominance picture (SWREG14)

15.1.5.2.10.1 Offset

Register	Offset
SWREG14	38h

15.1.5.2.10.2 Diagram

15.1.5.2.10.3 Fields

Field	Function
31-2 SW_REFERO_B ASE	Base address for reference picture index 0. See picture index definition from toplevel_sp
1 SW_REFERO_F IELD_E	Refer picture consist of single fields or frame: 0b - reference picture consists of frame 1b - reference picture consists of fields
0	Which field of reference picture is closer to current picture:

Field	Function
SW_REFER0_T OPC_E	0b - Bottom field is closer to current picture 1b - Top field is closer to current picture

15.1.5.2.11 Base address for reference picture index 1 / JPEG control (SWREG15)

15.1.5.4.2 Decoder control register 1 (picture parameters) (SWREG4_JPEG_VP7_VP8)

15.1.5.4.2.1 Offset

Register	Offset
SWREG4_JPEG_VP7_VP8	10h

15.1.5.4.2.2 Diagram

15.1.5.4.2.3 Fields

Field	Function
31-23 SW_PIC_MB_W IDTH_JPEG_VP 7_VP6	Picture width in macroblocks = ((width in pixels + 15) / 16)
22-19	The amount of meaningful horizontal pixels in last MB (width offset) 0 if exactly 16 pixels multiple picture and all the horizontal pixels in last MB are meaningful

Table continues on the next page...

Field	Function
SW_MB_WIDTH _OFF_JPEG_V P7_VP6	
18-11 SW_PIC_MB_H EIGHT_P_JPEG _VP7_VP6	Picture height in macroblocks = ((height in pixels+15)/16). Picture height is informed as size of the (progressive) frame also for single field (of interlaced content) is being decoded
10-7 SW_MB_HEIGHT _OFF_JPEG_V P7_VP6	The amount of meaningful vertical pixels in last MB (height offset 0 if exactly 16 pixels multiple picture and all the vertical pixels in last MB are meaningfull
6 SW_ALT_SCAN _E_JPEG_VP7_VP6	indicates alternative vertical scan method used for interlaced frames
5-3 SW_PIC_MB_W _EXT_JPEG_V P7_VP6	Picture mb width extension. If sw_pic_mb_width does not fit to 9 bits then these bits are used to increase the range upto 11 bits (used as 3 msb)
2-0 SW_PIC_MB_H _EXT_JPEG_V P7_VP6	Picture mb height extension. If sw_pic_mb_height_p does not fit to 9 bits then these bits are used to increase the range upto 11 bits (used as 3 msb). For 4k video one bit is used for extension (bit 0)

15.1.5.4.3 Decoder control register 2 (stream decoding table selects) (SWREG5_VP7_VP8)

15.1.5.4.3.1 Offset

Register	Offset
SWREG5_VP7_VP8	14h

15.1.5.4.3.2 Diagram

15.1.5.4.3.3 Fields

Field	Function
31-26 SW_STRM_START_BIT_VP7_VP8	Exact bit of stream start word where decoding can be started (associates with sw_rlc_vlc_base)
25-24 —	Reserved.
23-18 SW_STRM1_START_BIT_VP7_VP8	Start bit for ctrl-stream (needed if multistream is enabled, associates with sw_bitpl_ctrl_base)
17-16 —	Reserved.
15-8 SW_BOOLEAN_VALUE_VP7_VP8	Initial value for boolean dec
7-0 SW_BOOLEAN_RANGE_VP7_VP8	Initial range for boolean dec

15.1.5.4.4 Decoder control register 3 (stream buffer information) (SWRE G6_VP7_VP8)

15.1.5.4.4.1 Offset

Register	Offset
SWREG6_VP7_VP8	18h

15.1.5.4.4.2 Diagram

15.1.5.4.4.3 Fields

Field	Function
31-24 SW_STREAM_LEN_EXT_VP7_VP8	Extended stream length for WEBP/VP8
23-0 SW_STREAM_LEN_VP7_VP8	Amount of stream data bytes in input buffer. If the given buffer size is not enough for finishing the picture the corresponding interrupt is given and new stream buffer base address and stream buffer size information should be given (associates with sw_rlc_vlc_base). For VC-1/VP6 the buffer must include data for one picture/slice of the picture For H264/MPEG4/H263/MPEG2/MPEG1 the buffer must include at least data for one slice/VP of the picture For JPEG the buffer size must be a multiple of 256 bytes or the amount of data for one picture.

15.1.5.4.5 Decoder control register 4 (H264, VC-1, VP6 and progressive JPEG control) (SWREG7_VP7_VP8)

15.1.5.4.5.1 Offset

15.2 VPU G2 (VPU_G2)

15.2.1 Overview

This block details the G2 hardware-based decoder and API. The decoder is able to decode HEVC standard Main/Main 10 profile compatible video streams, and Google's VP9 Profile 0 compatible video streams. The G2 decoder conforms to the HEVC Main/Main 10 profiles and can decode streams up to level 5.1.

15.2.2 Video Frame Storage Format

The HW decoder may support two storage formats for frames, raster-scan, tiled without being compressed and compressed output. The application using the decoder may specify upon initialization which format is preferred, depending on HW support. The tiled format generally speaking offers better bus utilization and performance, however the decoder output must be converted back to raster-scan format prior to displaying it, except that GPU supports tiled format displaying. This postprocessing is beyond the scope of G2 decoder.

15.2.2.1 Raster-scan format

The output picture of the decoder is in semi-planar YCbCr 4:2:0 format, i.e. luminance data forms one plane in memory, and chrominance data forms the other. The output picture has to be stored linearly and contiguously in the memory. The interleaved

chrominance block has to be stored right after the luminance block in external memory as shown in Figure . The number of bytes in one luminance row must be divisible by 16, which means there will be padded 0 in the right edge when necessary.

The interleaved chrominance is stored raster-scanned in memory in Cb0Cr0Cb1Cr1Cb2Cr2Cb3... format.

The decoder output picture for interlaced sequence is always stored as an interlaced frame where even lines belongs to top field and odd lines belongs to bottom field of the frame.

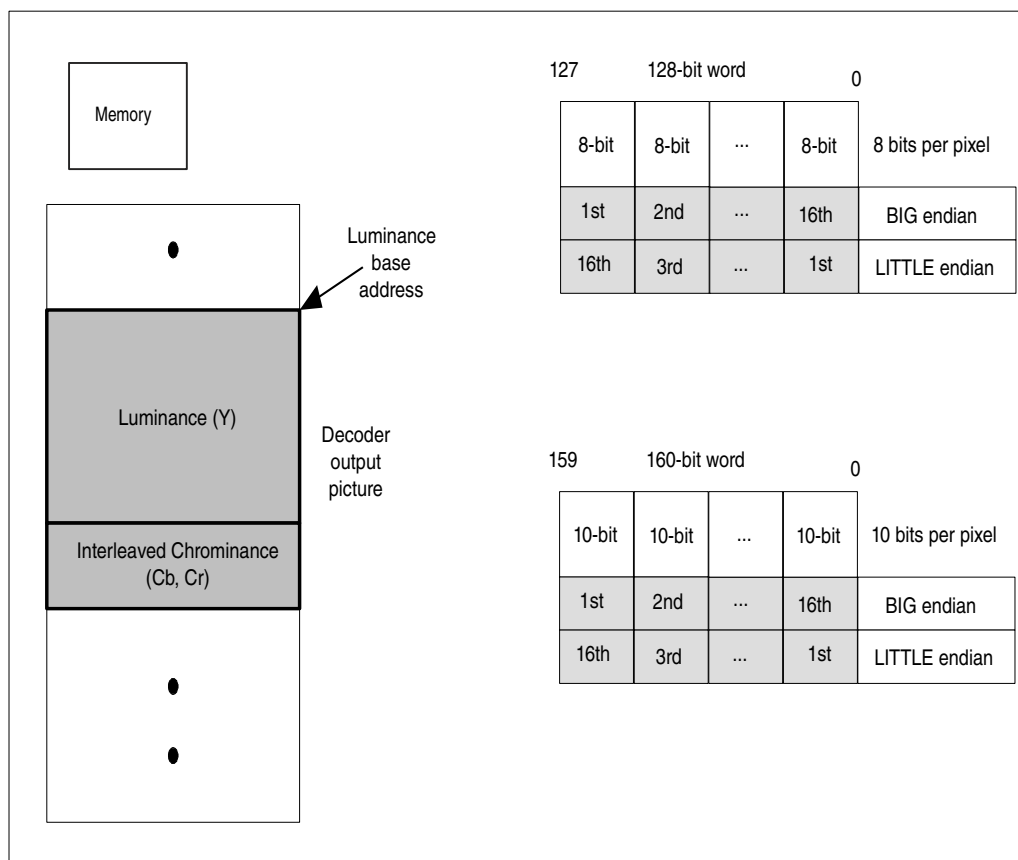

Figure 15-7. External Memory Usage

As an example the luminance pixels of a QCIF sized (176 x 144) frame with each pixel in 8 bits are numbered as presented in Table 1. Table 2 shows the storage of the luminance pixel data of the QCIF sized video frame in raster-scan order (in little endian mode).

Table 15-1. Pixel numbers of the luminance data of the QCIF video frame

0	1	2	3	4	5	6	7	...	172	173	174	175
176	177	178	179	180	181	182	183	...	348	349	350	351

25200	25201	25202	25203	25204	25205	25206	25207	...	25340	25341	25342	25343

The storage of the luminance pixel data of a QCIF video frame in raster-scan order. All pixels of a pixel row are stored in consecutive memory locations.

Table 15-2. Pixel Memory Locations

Address offset (decimal)	128-bit words(Pixel data of the luminance component. Each byte contains data for one pixel. Number in table are pixel numbers)			
0	15	...	1	0
16	31	...	17	16
32	47	...	33	32
48	63	...	49	48
64	79	...	65	64
:	:			
25296	25311	...	25297	25296
25312	25327	...	25313	25312
25328	25343	...	25329	25328

15.2.2.2 Tiled format

The output picture of the decoder is in semi-planar YCbCr 4:2:0 4x4 tiled format, i.e. luminance data forms one plane in memory, and chrominance data forms another. The distinction from raster scan format is that the output picture is grouped into tiles, which are then stored linearly and contiguously in the memory. The chrominance tiles have to be stored right after the luminance tiles in external memory as shown in Figure . The number of luminance pixels in one row must be divisible by 16.

The chrominance is stored into tiles in interleaved Cb0Cr0Cb1Cr1Cb2Cr2Cb3... format.

Figure contains example external memory usage when using 4x4 tiles, which is used in G2 decoder.

Below is an example code of converting tiled YCbCr 4:2:0 output picture back to raster scan format. The code is in generalized form, i.e. can function on arbitrary tile sizes as long as the picture dimensions are multiple of tile sizes. In the example, chrominance data is interleaved into 4x4 tile so that one 4x4 tile contains one 2x4 block of Cb and Cr each. Output is YCbCr 4:2:0 semiplanar.

```
void ConvertTiledToRaster( DecPicture decPicture, u32 tileWidth,
    u32 tileHeight, u8 *pOutput )
{
    u32 i, j;
    u32 k, l;
    u32 s, t;
    u8 *pIn;
    pIn = decPicture.pOutputPicture;
    /* loop all tile rows for luminance */
    for( i = 0 ; i < decPicture.frameHeight ; i += tileHeight )
```

```

{
t = 0;
s = 0;
/* loop all tiles in one row */
for( j = 0 ; j < decPicture.frameWidth ; j += tileWidth )
{
/* copy one tile */
for( k = 0 ; k < tileHeight ; ++k )
{
for( l = 0 ; l < tileWidth ; ++l )
{
pOutput[ k*decPicture.frameWidth + l + s ] = pIn[t++];
}
}
/* move to next horizontal tile */
s += tileWidth;
}
/* move to next tile row */
pOutput += decPicture.frameWidth * tileHeight;
pIn += decPicture.frameWidth * tileHeight;
}
/* setup pointers to chrominance data */
pIn = decPicture.pOutputPicture +
decPicture.frameWidth * decPicture.frameHeight;
/* loop all tile rows for chrominance */
for( i = 0 ; i < decPicture.frameHeight/2 ; i += tileHeight )
{
t = 0;
s = 0;
/* loop all tiles in one row */
for( j = 0 ; j < decPicture.frameWidth ; j += tileWidth )
{
/* copy one tile */
for( k = 0 ; k < tileHeight ; ++k )
{
for( l = 0 ; l < tileWidth ; ++l )
{
pOutput[ k*decPicture.frameWidth + l + s ] = pIn[t++];
}
}
/* move to next horizontal tile */
s += tileWidth;
}
/* move to next tile row */
pOutput += decPicture.frameWidth * tileHeight;
pIn += decPicture.frameWidth * tileHeight;
}
}

```

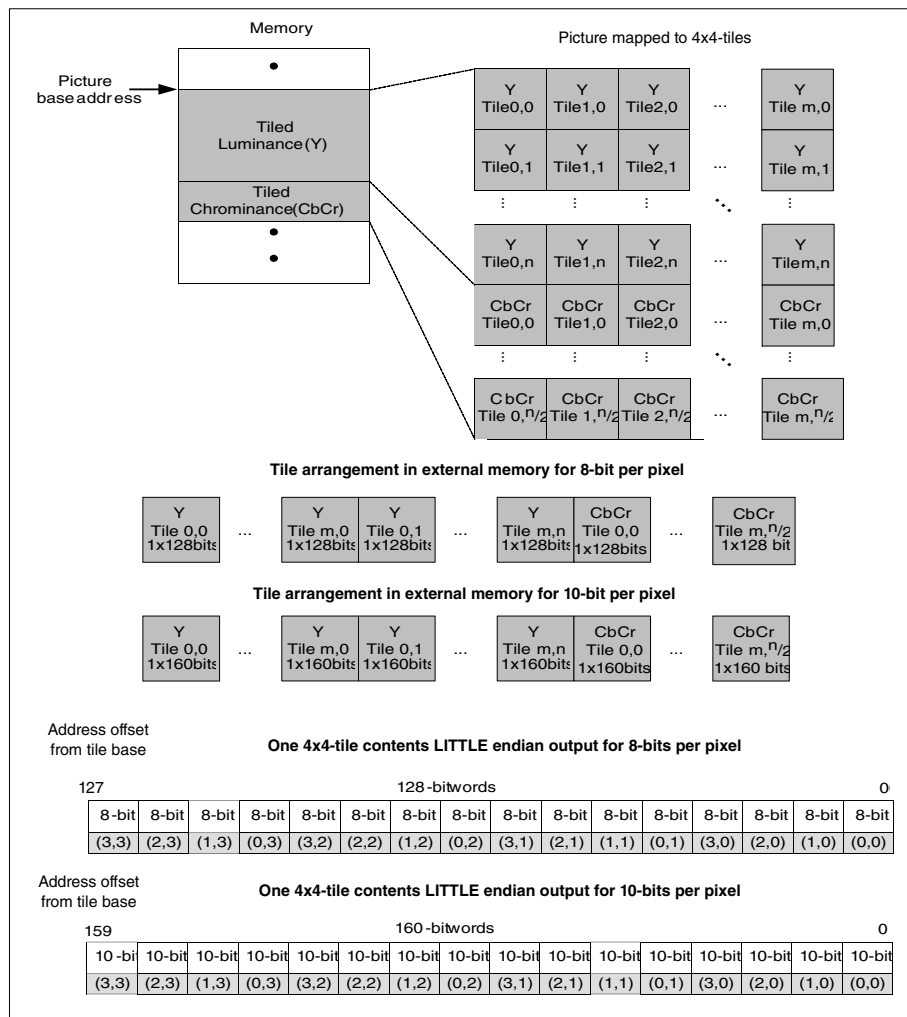

Figure 15-8. External Memory Usage in 4x4 Tiled Reference Picture Mode

15.2.2.3 Compressed format

G2 decoder supports compressed tiled output, when reference buffer compression (RFC) is enabled when synthesis, and user allows compressed reference frame output directly.

Reference frame compression is a feature added in G2 decoder to compress frame buffer so that the bandwidth of storing/loading reference frame can be reduced, especially when the resolution of decoded stream is of high definition.

When compression is enabled, the picture is divided into CBS rows, which is further divided into continuous CBS groups. Each CBS group is composed of 16 CBS. The luminance CBS is composed of 1 8x8 coded block (CB), which one chrominance CBS is composed of two 8x4 coded blocks, with cb CB first then cr CB following. The compression is performed to each CB in the CBS. The first CB's compressed data is

saved from the same offset of that CBS in raster scan buffer. And the compressed output of following CBs in the CBS row is saved continuously. That means there may be gaps between the compressed data of each CBS row.

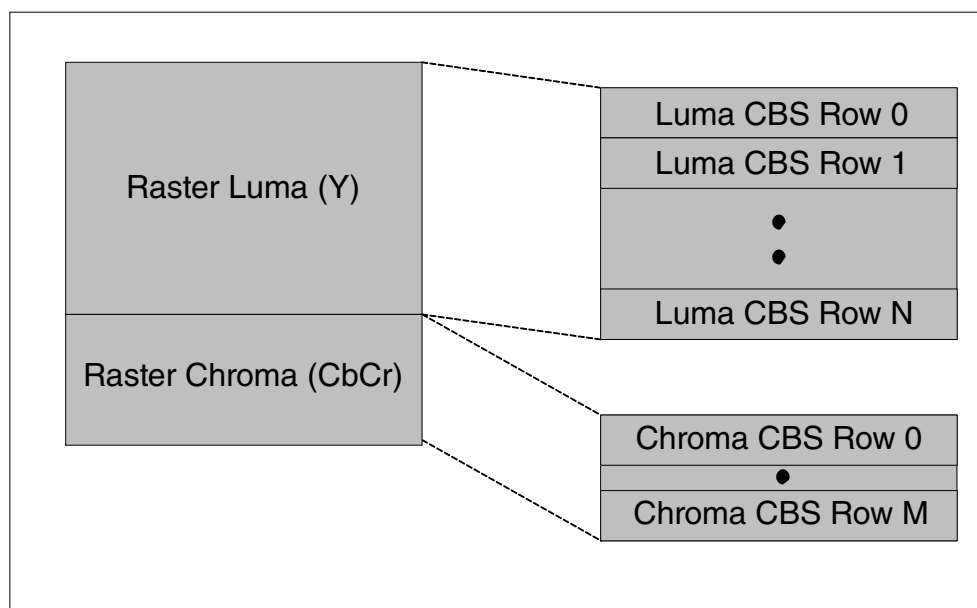

Figure 15-9. Raster scan picture mapped to CBS rows

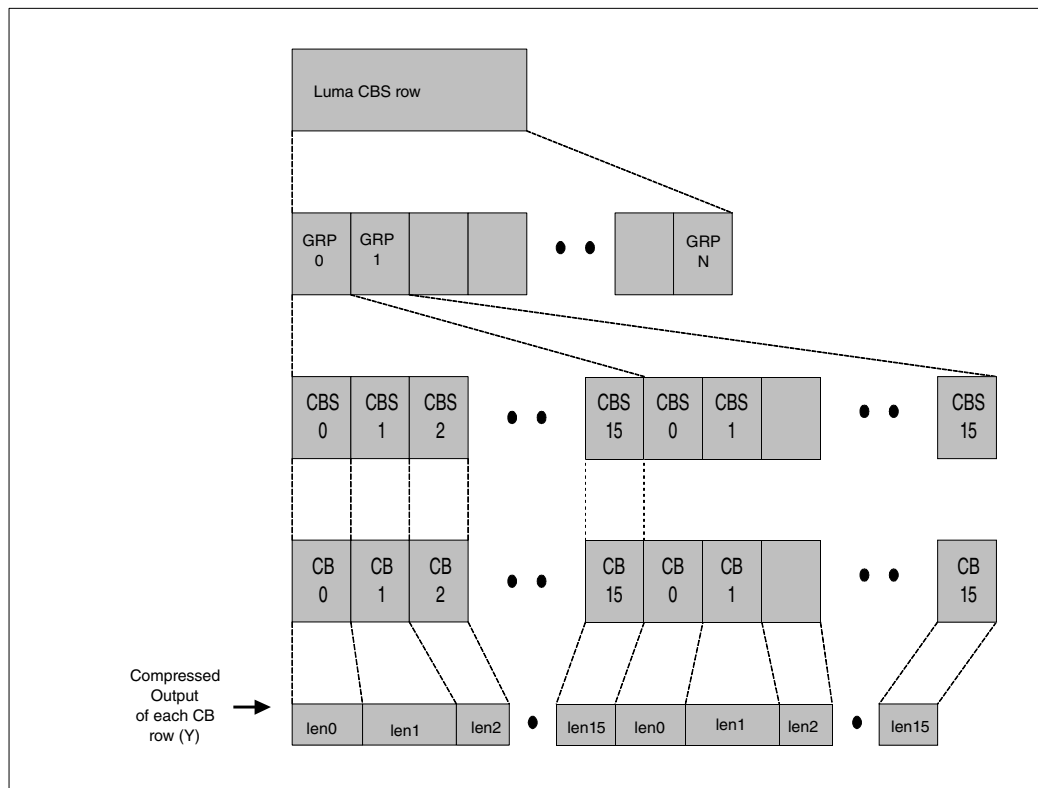

Figure 15-10. Compression performed to each Luma CBS row

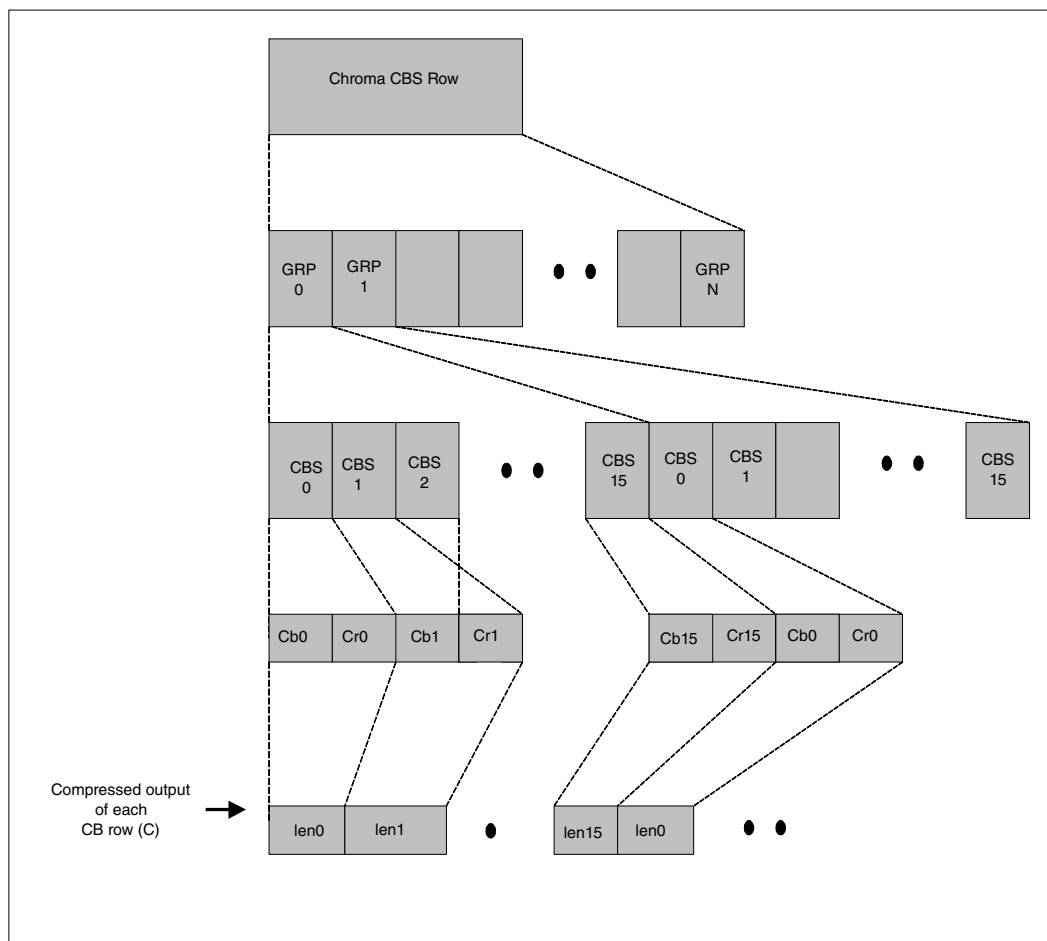

Figure 15-11. Compression performed to each Chroma CBS row

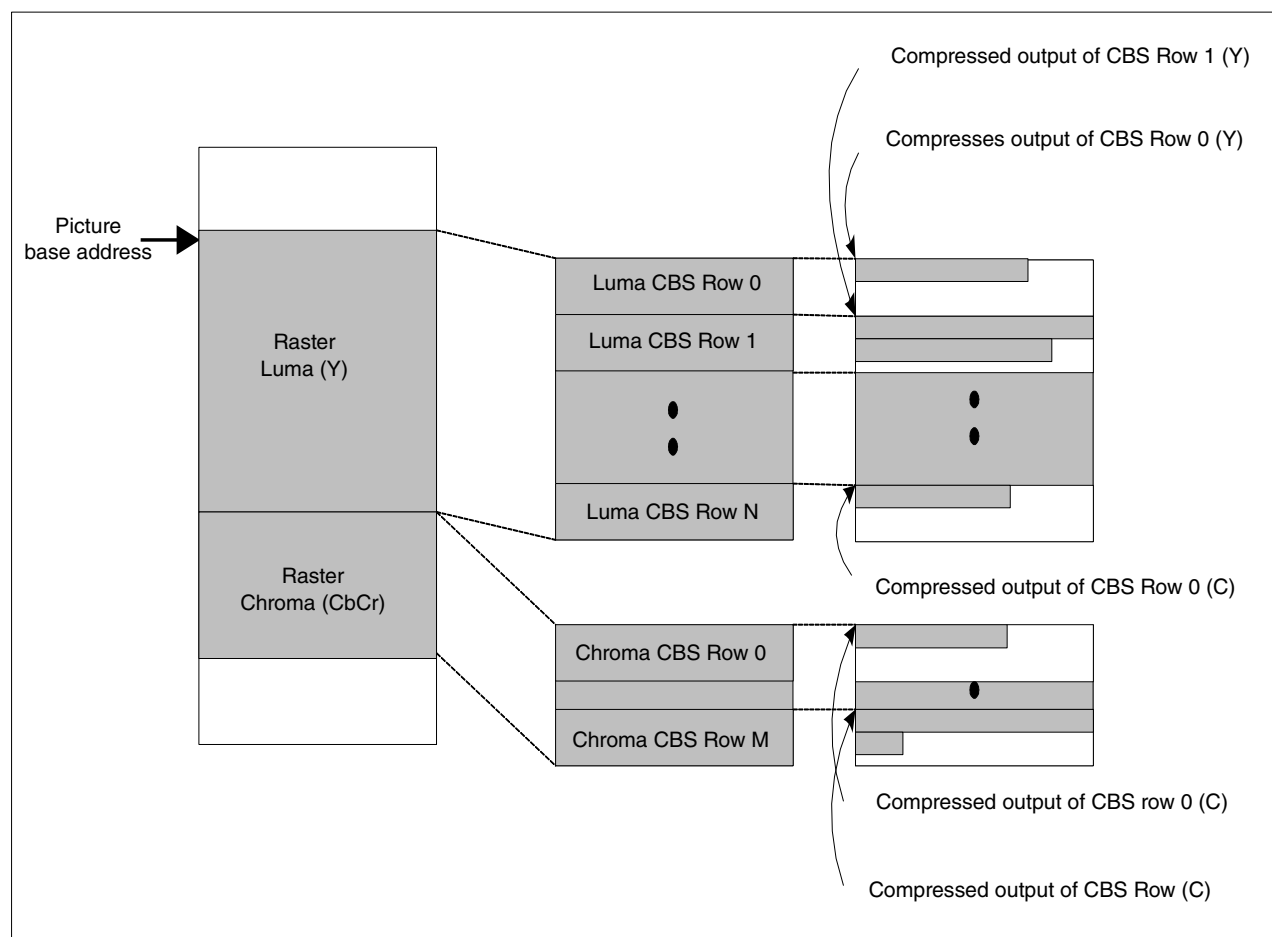

Figure 15-12. Map of external memory in RFC output buffer

Corresponding to each CBS group the starting offset of first compressed CBS output is saved in two bytes in CBS table, followed by the length of each CBS compress output, which is saved in 7 bits. So the table length of each CBS group information is $2 + 7 \times 16/8 = 16$ bytes.

This 16 bytes for each CBS group in compression table is mapped as shown in the following table. Here, X[n] means the bit-n of the length of CBS X in CBS group.

Table 15-3. Storage of the compression cache table for each CBS group

Byte	Bit7	Bit6	Bit5	Bit4	Bit 3	Bit 2	Bit 1	Bit 0
0	Offset[7:0]							
1	Offset[15:8]							
2	1[0]	0[6]	0[5]	0[4]	0[3]	0[2]	0[1]	0[0]
3	2[1]	2[0]	1[6]	1[5]	1[4]	1[3]	1[2]	1[1]

15.2.3 Interface Functions

This chapter describes the API declared in `decapi.h`, the definition of API in “software\source\common\decapi.c” of the release package.

Common numeric data types are declared in `basetype.h` as follows:

- **u8** – unsigned 8 bits integer value
- **i8** – signed 8 bits integer value
- **u16** – unsigned 16 bits integer value
- **i16** – signed 16 bits integer value
- **u32** – unsigned 32 bits value
- **i32** – signed 32 bits value

15.2.3.1 DecGetBuild

Syntax

```
struct DecSwHwBuild DecGetBuild(void)
```

Purpose

Returns the hardware and software build information of the decoder. Does not require the creation of a decoder instance.

Parameters

None.

Return value

DecSwHwBuild -- A structure containing the build information of the decoder.

```

struct DecSwHwBuild {
    u32 sw_build;                /* Software build ID */
    u32 hw_build;                /* Hardware build ID */
    struct DecHwConfig hw_config; /* Hardware configuration */
};

```

Function	Description
sw_build	The internal release version of the Hantro HW HEVC software.
hw_build	The internal release version of the Hantro HW hardware.

DecHwConfig -- A structure containing the hardware-supported configuration.

```

struct DecHwConfig {
    u32 mpeg4_support;
    u32 custom_mpeg4_support;
    u32 h264_support;
    u32 vc1_support;
    u32 mpeg2_support;
    u32 jpeg_support;
    u32 jpeg_prog_support;
    u32 max_dec_pic_width;
    u32 max_dec_pic_height;
    u32 pp_support;
    u32 pp_config;
    u32 max_pp_out_pic_width;
    u32 sorenson_spark_support;
    u32 ref_buf_support;
    u32 tiled_mode_support;
    u32 vp6_support;
    u32 vp7_support;
    u32 vp8_support;
    u32 vp9_support;
    u32 avs_support;
    u32 jpeg_esupport;
    u32 rv_support;
    u32 mvc_support;
    u32 webp_support;
    u32 ec_support;
    u32 stride_support;
    u32 field_dpb_support;
    u32 hevc_support;
    u32 double_buffer_support;
    u32 hevc_main10_support;
    u32 vp9_10bit_support;
    u32 ds_support;
    u32 rfc_support;
    u32 ring_buffer_support;
};

```

Function	Description
mpeg4_support	Hardware support for MPEG-4 decoding. Possible values: <ul style="list-style-type: none"> • MPEG4_NOT_SUPPORTED – decoding not supported • MPEG4_SIMPLE_PROFILE – simple profile decoder • MPEG4_ADVANCED_SIMPLE_PROFILE – advanced simple profile decoder (includes simple profile)
custom_mpeg4_support	Hardware support for DivX® decoding. Possible values:

Table continues on the next page...

Function	Description
	<ul style="list-style-type: none"> • MPEG4_CUSTOM_NOT_SUPPORTED – decoding not supported • MPEG4_CUSTOM - DivX Home Theater Profile Qualified™ decoder available
h264_support	<p>Hardware support for H.264 decoding. Possible values:</p> <ul style="list-style-type: none"> • H264_NOT_SUPPORTED – decoding not supported • H264_BASELINE_PROFILE – baseline profile decoder • H264_MAIN_PROFILE – main profile decoder (includes baseline profile) • H264_HIGH_PROFILE – high profile decoder (includes baseline and main profile)
vc1_support	<p>Hardware support for VC-1 decoding. Possible values:</p> <ul style="list-style-type: none"> • VC1_NOT_SUPPORTED – decoding not supported. • VC1_SIMPLE_PROFILE – simple profile decoder • VC1_MAIN_PROFILE – main profile decoder (includes simple profile) • VC1_ADVANCED_PROFILE – advanced profile decoder (includes main profile)
mpeg2_support	<p>Hardware support for MPEG-2 (includes MPEG-1) decoding. Possible values:</p> <ul style="list-style-type: none"> • MPEG2_NOT_SUPPORTED – decoding not supported • MPEG2_MAIN_PROFILE – main profile decoder
jpeg_support	<p>Hardware support for JPEG decoding. Possible values:</p> <ul style="list-style-type: none"> • JPEG_NOT_SUPPORTED – decoding not supported • JPEG_BASELINE – baseline decoder
jpeg_prog_support	<p>Hardware support for progressive JPEG decoding. Possible values:</p> <ul style="list-style-type: none"> • JPEG_NOT_SUPPORTED – decoding not supported • JPEG_PROGRESSIVE – progressive decoder available
max_dec_pic_width	Maximum decoded picture's width for video decoders. The value is given in pixel units.
max_dec_pic_height	Maximum decoded picture's height for video decoders. The value is given in pixel units.
pp_support	<p>Hardware support for video post-processing. Possible values:</p> <ul style="list-style-type: none"> • PP_NOT_SUPPORTED – post-processing not supported. • PP_SUPPORTED – post-processing supported in hardware.
pp_config	<p>Post-processing functions available. This is a bitwise list of the following values:</p> <ul style="list-style-type: none"> • PP_DITHERING, PP_SCALING, PP_DEINTERLACING, and • PP_ALPHA_BLENDING. The availability of all these post-processor functions is dependent on the hardware build.
max_pp_out_pic_width	Maximum output picture's width for the post-processor. The value is given in pixel units.

Table continues on the next page...

Function	Description
sorenson_spark_support	Hardware support for Sorenson Spark decoding. Possible values: <ul style="list-style-type: none"> • SORENSON_SPARK_NOT_SUPPORTED – decoding not supported • SORENSON_SPARK_SUPPORTED – decoder available
ref_buf_support	Hardware includes reference buffer handling speedup logic. Possible values: <ul style="list-style-type: none"> • REF_BUF_NOT_SUPPORTED – logic not available • REF_BUF_SUPPORTED – logic available for progressive pictures (flag) • REF_BUF_INTERLACED – logic available for interlaced pictures (flag) • REF_BUF_DOUBLE – logic available for buffering two reference pictures (flag) • Multiple values are possible using bitwise OR operation of valid flags.
tiled_mode_support	Hardware includes support for handling reference pictures in tiled mode to optimize bus utilization. Possible values: <ul style="list-style-type: none"> • TILED_NOT_SUPPORTED – tiled reference picture support not available • TILED_8x4_SUPPORTED – tiled reference picture support for 8x4 tiles available • TILED_8x4_ILACED_SUPPORTED – tiled reference picture support for 8x4 tiles • available also for interlaced pictures.
vp6_support	Hardware support for VP6 decoding. Possible values: <ul style="list-style-type: none"> • VP6_NOT_SUPPORTED – decoding not supported • VP6_SUPPORTED – decoder available
vp7_support	Hardware support for VP7 decoding. Possible values: <ul style="list-style-type: none"> • VP7_NOT_SUPPORTED – decoding not supported • VP7_SUPPORTED – decoder available
vp8_support	Hardware support for VP8 decoding. Possible values: <ul style="list-style-type: none"> • VP8_NOT_SUPPORTED – decoding not supported • VP8_SUPPORTED – decoder available

15.2.3.2 Declnit

Syntax

```
enum DecRet Declnit(enum DecCodec codec,
                   DecInst* decoder,
                   struct DecConfig config,
                   struct DecClientHandle callbacks)
```

Purpose

Declnit initializes a new decoder instance based on the given codec type. If parameter noOutputReordering is set to a non-zero value the decoder will not provide output pictures in display order but in decoding order (unless decoding order and display order is the same). Outputting pictures in decode order will lower the memory consumption of the decoder in case the number of reference frames used by the stream is less than the maximum number allowed by the profile and level of the stream.

Parameters

```
enum DecCodec codec
    Codec type to be initialized.
    enum DecCodec {
        DEC_VP9,
        DEC_HEVC
    };
DecInst * decoder
    Pointer to the location where Declnit returns a decoder instance. This
instance is later
    passed to other decoder API functions.
struct DecConfig config
    Decoder initialization parameters.
    struct DecConfig {
        u32 disable_picture_reordering;
        enum DecPictureFormat output_format;
        struct DWL dwl;
        const void* dwl_inst;
        u32 max_num_pics_to_decode;
        enum DecErrorConcealment concealment_mode;
        struct DecDownscaleCfg dscale_cfg;
        u32 use_video_compressor;
        u32 use_ringbuffer;
        u32 use_8bits_output;
    }
u32 disable_picture_reordering
    Flag to disable the reordering of output frames. When set to a non-zero
value the
    decoder will not provide output pictures in display order but in decoding
order (unless
    decoding order and display order is the same).
enum DecPictureFormat output_format
    Format of the output picture.
```

```

enum DecPictureFormat {
    DEC_OUT_FRM_TILED_4X4 = 0,
    DEC_OUT_FRM_RASTER_SCAN = 1,
    DEC_OUT_FRM_PLANAR_420 = 2
};
DEC_OUT_FRM_TILED_4X4 - Tiled 4x4 format
DEC_OUT_FRM_RASTER_SCAN - raster scan format (a.k.a semi-planar)
DEC_OUT_FRM_PLANAR_420 - planar format
struct DWL dwl
    Decoder wrapper layer functionality.
const void* dwl_inst
    Pointer to a DWL instance, which should be instantiated by calling DWLInit
in
    advance.
u32 max_num_pics_to_decode
    Limits the maximum pictures number to be decoded, 0 for unlimited.
enum DecErrorConcealment concealment_mode
    Flag to determine which error concealment method to use. When set to
    DEC_INTRA_FREEZE the decoder will conceal every frame after an error has
been
    detected in the bitstream, until the next IDR (key frame) frame is
decoded. When set to
    DEC_PICTURE_FREEZE, the decoder will conceal only the frames having errors
in the
    bitstream.

enum DecErrorConcealment {
    DEC_PICTURE_FREEZE = 0,
    DEC_INTRA_FREEZE = 1
};
struct DecDownscaleCfg dscale_cfg
    Down scale parameters.
    struct DecDownscaleCfg {
        u32 down_scale_x;
        u32 down_scale_y;
    };
u32 down_scale_x
    Down scale ratio in horizontal direction. Possible value: 2, 4, 8.
Available
    value:2, 4, 8, which means down scaled to 1/2, 1/4 or 1/8
respectively. 1
    means no scaling.
u32 down_scale_y
    Down scale ratio in vertical direction. Possible value: 2, 4, 8.
Available value:2,
    4, 8, which means down scaled to 1/2, 1/4 or 1/8 respectively. 1 means
no
    scaling.

```

NOTE

If the down scale ratio in one direction is set to 1, no matter what the value is in the other direction, no down scale will be performed in both directions.

```

u32 use_video_compressor
    Flag to enable reference buffer compression. Set 0 to bypass reference
buffer
    compression, or when reference buffer compression is not supported. When
set to 1,
    the decoded reference buffer will be saved in compressed format.
u32 use_ringbuffer
    Flag to indicate decoder use ring buffer or not. Set 1 to enable ring
buffer. When set to
    0, ring buffer will be disabled.
frame
    Stream ring buffer mode is an alternative storage for stream. In this mode,

```

stream data usually doesn't start from buffer head but follow a previous frame stream data. When stream data goes to stream buffer end, it must turnaround to buffer head to save left stream data. It requires a whole frame stream data saved in stream buffer and stream data start address is byte-aligned. Below figure shows how stream data is stored in stream buffer if ring buffer mode.

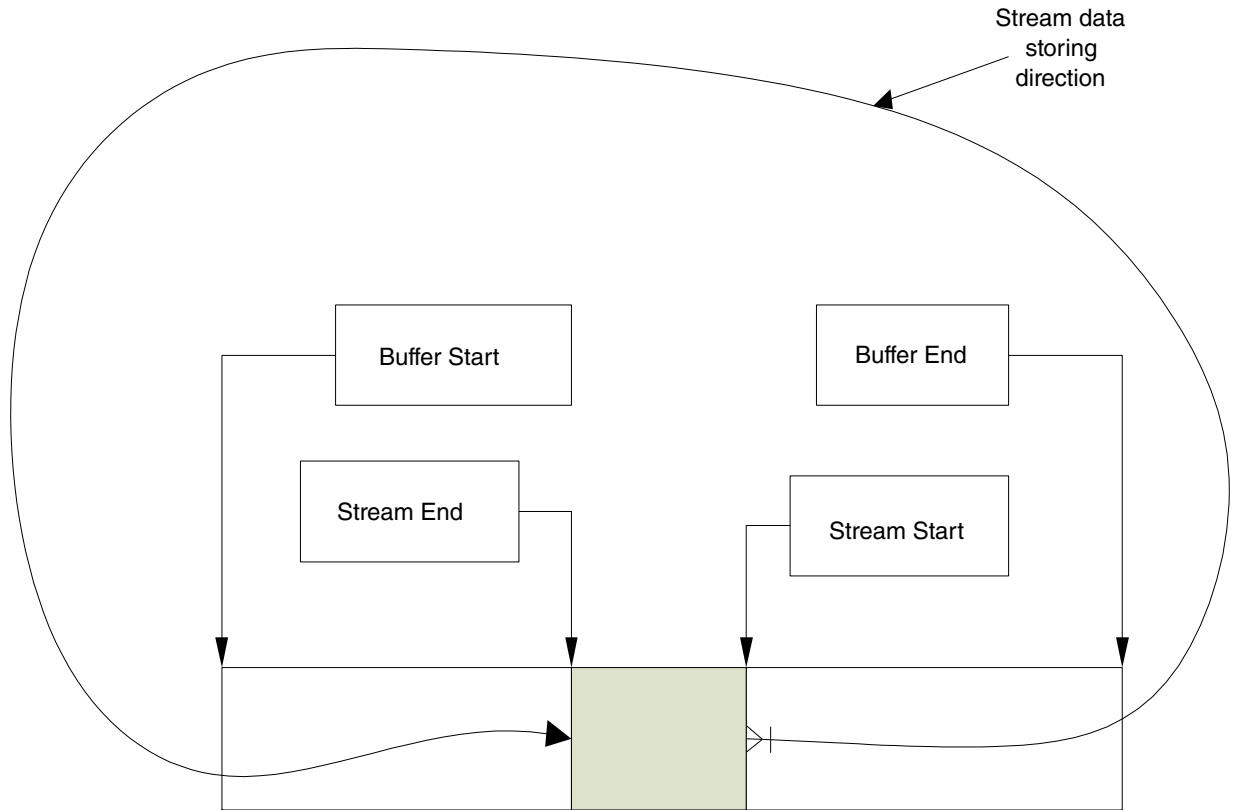

Figure 15-13. Data storage in Stream buffer in Ring Buffer Mode

```
u32 use_8bits_output
    Flag to force 8 bit per pixel output when it's a stream with higher bit
depth, e.g., HEVC
    Main10 profile stream. The conversion is based on following rule:
```

Table 15-4. Rule for conversion

Bit depth of original pixel	Original pixel	8bit output
9	XXXXXXXX0	XXXXXXXX
	XXXXXXXX1	XXXXXXXX+1
10	XXXXXXXX00	XXXXXXXX
	XXXXXXXX01	XXXXXXXX
	XXXXXXXX10	XXXXXXXX+1
	XXXXXXXX11	XXXXXXXX+1

```
struct DecClientHandle callbacks
    Callback interfaces that client should provide to facilitate the decoder
```

to inform the client that there is any events or state changing in decoder.

```

struct DecClientHandle {
    ClientInst client;
    ClientInitialized* Initialized;
    ClientHeadersDecoded* HeadersDecoded;
    ClientBufferDecoded* BufferDecoded;
    ClientPictureReady* PictureReady;
    ClientEndOfStream* EndOfStream;
    ClientReleased* Released;
    ClientNotifyError* NotifyError;
};
typedef const void* ClientInst;
    Opaque pointer to the client.
typedef void ClientInitialized(ClientInst inst);
    Function to notify the client that decoder has successfully
initialized.
    typedef void ClientHeadersDecoded(ClientInst inst,
        struct DecSequenceInfo sequence_info);
        Function to notify about successful decoding of the stream
parameters. Decoder
    expects client to provide needed buffers through
DecSetPictureBuffers function to
    continue decoding the actual stream.
    typedef void ClientBufferDecoded(ClientInst inst,
        struct DecInput* input);
        Function to notify client that a buffer has been consumed by the
decoder and it can be
        handled freely by the client.
    typedef void ClientPictureReady(ClientInst inst,
        struct DecPicture picture);
        Function to notify about picture that is ready to be outputted.
Client is expected to notify
    the decoder when it has finished processing the picture, so
decoder can reuse the
    picture buffer for another picture.
    typedef void ClientEndOfStream(ClientInst inst);
        Function to notify the client that all the pending pictures
have been outputted and
        decoder can be safely shut down.
    typedef void ClientReleased(ClientInst inst);
        Function to notify the client that decoder has shut down.
    typedef void ClientNotifyError(ClientInst inst,
        u32 pic_id,
        enum DecRet rv);
        Function to notify client about error in the decoding process.

```

Return

DEC_OK
API function returned successfully.

DEC_PARAM_ERROR
Bad input parameters.

DEC_MEMFAIL
The decoder was not able to allocate memory.

DEC_FORMAT_NOT_SUPPORTED
Format is not supported in hardware. See DecGetBuild.

15.2.3.3 DecDecode

Syntax

```
enum DecRet DecDecode(DecInst decInst,
                     DecInput *pInput)
```

Purpose

This function will push a COMMAND_DECODE command to the decoding thread, along with the input stream parameters, which will inform the decoding thread to decode one or more NAL units from the current stream for HEVC or element stream for VP9.

The input buffer should contain one of the following:

1. Exactly one NAL unit and nothing else.
2. One or more NAL units in byte stream format, as defined in Annex B of the standard [1].
3. Or for VP9 at least one whole frame bit stream data.

The decoder automatically detects the format of the stream data and decodes NAL units until the whole buffer is processed or decoding of a picture is finished for HEVC. For VP9 if there is not enough bit stream data in input buffer, HW decoder will return TIMEOUT error.

Parameters

DecInst*decInst* - A decoder instance created earlier with an DecInit call.

DecInput **pInput* - Pointer to the decoder input structure.

```
struct DecInput {
    struct DWLLinearMem buffer; /* Pointer to the input buffer. */
    u32 data_len;
};
```

struct DWLLinearMem buffer -- Linear buffer descriptor.

```
struct DWLLinearMem {
    u32 *virtual_address;
    u32 bus_address;
    u32 size;
    u32 logical_size;
};
```

Function	Description
*virtual_address	Pointer to the virtual address of stream linear buffer.
bus_address	Bus address of the linear buffer. NOTE: The start of the stream buffer must be in a 128-bit aligned position or accessible for reading from the previous 128-bit aligned position.
size	Physical size of the linear buffer, which is rounded to page multiple.
logical_size	Physical size of the linear buffer, which is rounded to page multiple.

Table continues on the next page...

Function	Description
datalen	Number of bytes contained in the buffer stream buffer. The length can be represented on maximum 32 bits. Valid range: [0, (2 ³² -1)]

Return value

DEC_OK - The COMMAND_DECODE is successfully pushed to decoder thread's input queue.

DEC_PARAM_ERROR - Error in calling parameters.

DEC_NOT_INITIALIZED - Decoder instance is not initialized. Stream decoding is not started. DecInit must be called before decoding can be started.

15.2.3.4 DecSetPictureBuffers

Syntax

```
enum DecRet DecSetPictureBuffers(DecInst dec_inst,
                                const struct DWLLinearMem* buffers,
                                u32 num_of_buffers)
```

Purpose

DecSetPictureBuffers assigns picture buffers for the decoder. When decoder has finished decoding the stream headers and knows which types of buffers and how many of them it will need, it will inform that through the HeadersDecoded callback. Buffers must not be written into until client has successfully called DecRelease or decoder has requested new set of buffers through HeadersDecoded callback.

Parameters

DecInst*decInst* - A decoder instance created earlier with an DecInit call.

const struct DWLLinearMem* *buffers* - Linear buffer to be assigned to the decoder.

u32 *num_of_buffers* - Number of buffers to be assigned to the decoder.

Return value

DEC_OK - Successfully set picture buffers.

DEC_PARAM_ERROR - Error in calling parameters.

15.2.3.5 DecPictureConsumed

Syntax

```
enum DecRet DecPictureConsumed(DecInst decInst,
                               struct DecPicture picture)
```

Purpose

DecPictureConsumed informs the decoder that the client has finished processing a specific picture, which was previously sent to client through the PictureReady callback.

Parameters

DecInst*decInst* - A decoder instance.

DecPicture *pOutput - Pointer to the location used to return the picture parameters. The picture parameters are valid only when the return value indicates that an output picture is available.

```
struct DecPicture {
    struct DecSequenceInfo sequence_info;
    struct DWLLinearMem luma;
    struct DWLLinearMem chroma;
    struct DecPictureInfo picture_info;
    struct DWLLinearMem dscale_luma;
    struct DWLLinearMem dscale_chroma;
    u32 dscale_width;
    u32 dscale_height;
    u32 dscale_stride;
};
struct DecSequenceInfo sequence_info {
    struct DecSequenceInfo {
        u32 pic_width;
        u32 pic_height;
        u32 sar_width;
        u32 sar_height;
        struct DecCropParams crop_params;
        enum DecVideoRange video_range;
        u32 matrix_coefficients;
        u32 is_mono_chrome;
        u32 is_interlaced;
        u32 num_of_ref_frames;
        u32 bit_depth_luma;
        u32 bit_depth_chroma;
        u32 pic_stride;
    };
};
```

Function	Description
picture_width	Decoded picture width in pixels.
picture_height	Decoded picture height in pixels.
sar_width	Horizontal size of the sample aspect ratio.
sar_height	Vertical size of the sample aspect ratio.
struct DecCropParams crop_param	Cropping parameters for the picture.

Table continues on the next page...

Function	Description
	<pre>struct DecCropParams { u32 crop_left_offset; u32 crop_out_width; u32 crop_top_offset; u32 crop_out_height; };</pre>
crop_left_offset	Left offset for cropping process, i.e. number of luminance samples removed from the left edge of the picture (always a multiple of 2).
crop_out_width	Width of the picture in luminance samples after cropping is performed.
crop_top_offset	Top offset for cropping process, i.e. number of luminance samples removed from the top edge of the picture (always a multiple of 2).
crop_out_height	Height of the picture in luminance samples after cropping is performed.
Enum DecVideoRange video_range	YUV sample video range. Possible value: <ul style="list-style-type: none"> • DEC_VIDEO_RANGE_NORMAL - sample range [16, 235] • DEC_VIDEO_RANGE_FULL - sample range [0, 255]
matrix_coefficients	Matrix coefficients RGB->YUV conversion.
is_mono_chrome	Flag to indicate whether sequence is of monochrome.
is_interlaced	Flag to indicate whether sequence is interlaced.
num_of_ref_frames	Maximum number of reference frames.
bit_depth_luma	Bit depth of stored pixels for luma plane.
bit_depth_chroma	Bit depth of stored pixels for chroma plane.
pic_stride	Stride of the picture as stored in memory in bytes.
struct DWLLinearMem luma	Linear buffer for luma pixels.
struct DWLLinearMem chroma	Linear buffer for chroma pixels.
struct DecPictureInfo picture_info	Picture specific information. <pre>struct DecPictureInfo { enum DecPicCodingType pic_coding_type; u32 is_corrupted; enum DecPictureFormat format; u32 cycles_per_mb; u32 pic_id; };</pre>
enum DecPicCodingType pic_coding_type	Picture coding type. Possible value: <ul style="list-style-type: none"> • DEC_PIC_TYPE_I - key frame • DEC_PIC_TYPE_P - P frame • DEC_PIC_TYPE_B - B frame
is_corrupted	Flag indicates whether picture is corrupted.
enum DecPictureFormat format	Color format of the picture. Refer to DecPictureFormat in 4.2.
cycles_per_mb	Average decoding time in cycles per mb.

Table continues on the next page...

Function	Description
pic_id	Identifier for the picture to be decoded.
struct DWLLinearMem dscale_luma	Linear buffer for luma pixels in down scaled output.
struct DWLLinearMem dscale_chroma	Linear buffer for chroma pixels in down scaled output.
dscale_width	Width of down scaled output in pixels.
dscale_height	Height of down scaled output in pixels.
dscale_stride	Stride of a pixel line in down scaled output in bytes.

Return value

DEC_OK - No pictures available for display.

DEC_PARAM_ERROR - Error in calling parameters.

DEC_NOT_INITIALIZED - Decoder instance is not initialized. DecInit must be called before decoding can be started.

15.2.3.6 DecEndOfStream

Syntax

```
enum DecRet DecEndOfStream (DecInst decInst)
```

Purpose

DecEndOfStream sends a COMMAND_END_OF_STREAM command to the decoder thread to inform the decoder that it should not be expecting any more input stream and finish decoding and outputting all the buffers that are currently pending in the component. Once decoder has finished outputting the pending pictures it will notify the client about it by calling the EndOfStream callback.

Parameters

DecInst*decInst* - A decoder instance.

Return value

DEC_OK - API function returned successfully

DEC_PARAM_ERROR - Error in calling parameters.

DEC_INITFAIL - Decoder instance is not initialized.

15.2.3.7 DecRelease

Syntax

```
void DecRelease (DecInst decInst)
```

Purpose

DecRelease sends a COMMAND_RELEASE command to decoder thread, which will finally close the decoder instance decInst and releases all internally allocated resources. This function must not be called twice for the same instance.

Parameters

DecInst*decInst* - A decoder instance to be released.

Return value

None.

15.2.4 Decoder Application Examples

Purpose

The purpose of the following examples is to show how to implement client's callback functions, as long as using G2 decoder API to implement a simple decoder with demuxer to decode both HEVC and VP9 streams. InitializedCb, HeadersDecodedCb, BufferDecodedCb, PictureReadyCb, EndOfStreamCb, ReleasedCb, and NotifyErrorCb are the system/application dependent callback functions, which are provided by client to the decoder wrapper.

The examples are simplified, e.g. they do not take errors into consideration.

NOTE

Program code in the examples should be considered as pseudo code and may not compile as such.

```
void SetupDefaultParams(struct TestParams* params);
int ParseParams(int argc, char* argv[], struct TestParams* params);
void* CreateDemuxer(struct Client* client);
void ReleaseDemuxer(struct Client* client);
void PostProcessPicture(struct Client* client, struct DecPicture* picture);

static void DispatchBufferForDecoding(struct Client* client, struct DecInput*
buffer)
{
    enum DecRet rv;
    i32 size = buffer->buffer.size;
    memset(buffer->buffer.virtual_address, 0, size);
    i32 len = client->demuxer.ReadPacket(client->demuxer.inst, (u8*)buffer-
>buffer.virtual_address, &size);
    if (len <= 0) { /* EOS or error. */
```

```

    /* If reading was due to insufficient buffer size, try to realloc with
sufficient size. */
    if (size > buffer->buffer.size) {
        i32 i;
        for (i = 0; i < GetStreamBufferCount(client); i++) {

40Ch	input stream buffer start offset (SWREG259)	32	RW	0000_0000h

15.2.5.1.2 ID register (read only) (SWREG0)

15.2.5.1.2.1 Offset

Register	Offset
SWREG0	0h

15.2.5.1.2.2 Diagram

15.2.5.1.2.3 Fields

Field	Function
31-16 SW_PRODUCT_NUMBER	Product number (g2)
15-12 SW_MAJOR_VERSION	Major version
11-4 SW_MINOR_VERSION	Minor version
3 SW_PRODUCT_ID_EN	ASCII type product ID enable
2-0 SW_BUILD_VERSION	Build version (core number)

15.2.5.1.3 Interrupt register decoder (SWREG1)

15.2.5.1.3.1 Offset

Register	Offset
SWREG1	4h

15.2.5.1.3.2 Diagram

15.2.5.1.3.3 Fields

Field	Function
31-19 —	Reserved.
18 SW_DEC_TIMEOUT	Interrupt status bit decoder timeout. When high the decoder has been idling for too long. HW will self reset. Possible only if timeout interrupt is enabled
17 —	Reserved.
16 SW_DEC_ERROR_INT	Interrupt status bit input stream error. When high an error is found in input data stream decoding. HW will self reset.
15	Reserved.

Table continues on the next page...

Field	Function
—	
14 SW_DEC_BUFF ER_INT	Interrupt status bit input buffer empty. When high input stream buffer is empty but picture is not ready. HW will not self reset.
13 SW_DEC_BUS_ INT	Interrupt status bit bus. Error response from bus. HW will self reset.
12 SW_DEC_RDY_ INT	Interrupt status bit decoder. When this bit is high decoder has decoded a picture. HW will self reset.
11 SW_DEC_ABO RT_INT	Interrupt status bit decoding aborted. When this bit is high decoder has aborted the current picture decoding as SW requested (sw_dec_abort_e). Decoder self reset and sw_dec_abort_e written low
10-9 —	Reserved.
8 SW_DEC_IRQ	Decoder IRQ. When high decoder requests an interrupt. SW will reset this after interrupt is handled.
7-6 —	Reserved.
5 SW_DEC_ABO RT_E	Abort decoding enable. Setting this bit high will cause HW to abort decoding and safely to reset itself down. After abort is complete the corresponding interrupt status is set and this bit is set low as well as the decoder enable.
4 SW_DEC_IRQ_ DIS	Decoder IRQ disable. When high there are no interrupts concerning decoder from HW. Polling must be used to see the interrupt statuses.
3-1 —	Reserved.
0 SW_DEC_E	Decoder enable. Setting this bit high will start the decoding operation. HW will reset this when picture is processed or ASO or stream error is detected or bus error or timeout interrupt is given.

15.2.5.1.4 Data configuration register decoder (SWREG2)

15.2.5.1.4.1 Offset

Register	Offset
SWREG2	8h

15.2.5.1.4.2 Diagram

15.2.5.1.4.3 Fields

Field	Function
31-28 SW_DEC_STRM_SWAP	<p>Byte swap configuration for stream data 4 Bit byte order vector to control byte locations inside HW internal 128 bit data vector. For 64 and 32 bit external bus widths, the data is first gathered to 128 bit width and then bytes swapped accordingly:</p> <p>Bit 0: 8 bit swap Bit 1: 16 bit swap Bit 2: 32 bit swap Bit 3: 64 bit swap</p> <p>'0000' = 0-1-2-3-4-5-6-7-8-9-10-11-12-13-14-15 '0001' = 1-0-3-2-5-4-7-6... Table continues on the next page...

Field	Function
	'1111'=15-14-13-12-11-10-9-8-7-6-5-4-3-2-1-0
27-24 SW_DEC_PIC_SWAP	Byte swap configuration for decoder reference output picture data
23-20 SW_DEC_DIRM_V_SWAP	Byte swap configuration for direct mode MV data (read/write)
19-16 SW_DEC_TAB0_SWAP	Byte swap configuration for VP9 stream propability tables
15-12 SW_DEC_TAB1_SWAP	Byte swap configuration for HEVC scaling lists / VP9 segmentation map read/write
11-8 SW_DEC_TAB2_SWAP	Byte swap configuration for VP9 CTX counter values
7-4 SW_DEC_TAB3_SWAP	Byte swap configuration for tile sizes
3-0 SW_DEC_RSCAN_SWAP	Byte swap for raster scan output picture data

15.2.5.1.5 Decoder control register 0 (SWREG3)

15.2.5.1.5.1 Offset

Register	Offset
SWREG3	Ch

15.2.5.1.5.2 Diagram

15.2.5.1.5.3 Fields

Field	Function
31-27 SW_DEC_MODE	Decoding mode: 00000-01011b - Reserved 01100b - HEVC 01101b - VP9 01110-11111b - Reserved
26-24 —	Reserved.
23-20 SW_DEC_COMP_TABLE_SWAP	Byte swap configuration for compress table data
19-18 —	Reserved.
17 SW_DEC_OUT_EC_BYPASS	Compress bypass

Table continues on the next page...

Field	Function
16 SW_DEC_OUT_RS_E	Raster scan output enable. If high decoder writes the raster scan output if the configuration of Decoder includes PP raster scan output
15 SW_DEC_OUT_DIS	Disable decoder output picture writing 0b - Decoder output picture is written to external memory 1b - Decoder output picture is not written to external memory
14 SW_FILTERING_DIS	De-block filtering disable 0b - Filtering is enabled for current picture 1b - Filtering is disabled for current picture
13 —	Reserved.
12 SW_WRITE_MVS_E	Direct mode motion vector write enable for current picture 0b - Writing disabled for current picture. 1b - The direct mode motion vectors are written to external memory. HEVC/VP9 direct mode motion vectors are written to DPB aside with the corresponding reference picture. Other decoding mode dir mode mvs are written to external memory starting from sw_dir_mv_base.
11 SW_APF_ONE_PID	Prefetch partitions that have the same pic_id together
10-0 —	Reserved.

15.2.5.1.6 Decoder control register 1 (SWREG4)

15.2.5.1.6.1 Offset

Register	Offset
SWREG4	10h

15.2.5.1.6.2 Diagram

15.2.5.1.6.3 Fields

Field	Function
31-19 SW_PIC_WIDT H_IN_CBS	Picture width in min coded blocks (min = 8pix)
18-6 SW_PIC_HEIG HT_IN_CBS	Picture height in min coded blocks (min = 8pix)
5 —	Reserved.
4-0 SW_REF_FRA MES	HEVC: num_ref_frames maximum number of short and long term reference frames in decoded picture buffer

15.2.5.1.7 Decoder control register 2 (SWREG5)

15.2.5.1.7.1 Offset

Register	Offset
SWREG5	14h

15.2.5.1.7.2 Diagram

15.2.5.1.7.3 Fields

Field	Function
31-25 SW_STRM_START_BIT	Exact bit of stream start word where decoding can be started (associates with sw_rlc_vlc_base)
24 SW_SCALING_LIST_E	Scaling matrix enable 0b - Normal transform 1b - Use scaling matrix for transform (read from external memory)
23-19 SW_CH_QP_OFFSET	Chroma Qp filter offset. (For HEVC this offset concerns Cb only)

Table continues on the next page...

VPU G2 Memory Map/Register Definition

Field	Function
18-14 SW_CH_QP_O FFSET2	Chroma Qp filter offset for cr type
13 —	Reserved.
12 SW_SIGN_DATA_HIDE	Flag for stream decoding
11 SW_TEMPORAL_MVP_E	Temporal mvp enable
10-5 SW_MAX_CU_QPD_DEPTH	Max CU qp delta depth
4 SW_CU_QPD_E	CU qp delta enable
3-0 —	Reserved.

15.2.5.1.8 Decoder control register 3 (SWREG6)

15.2.5.1.8.1 Offset

Register	Offset
SWREG6	18h

15.2.5.1.8.2 Diagram

15.2.5.1.8.3 Fields

Field	Function
31-0 SW_STREAM_LEN	Amount of stream data bytes in input buffer. If the given buffer size is not enough for finishing the picture the corresponding interrupt is given and new stream buffer base address and stream buffer size information should be given (associates with sw_rlc_vlc_base). For HEVC the buffer must include at least data for one slice/VP of the picture

15.2.5.1.9 Decoder control register 4 (SWREG7)

15.2.5.1.9.1 Offset

Register	Offset
SWREG7	1Ch

15.2.5.1.9.2 Diagram

15.2.5.1.9.3 Fields

Field	Function
31 SW_CABAC_INIT_PRESENT	CABAC init present enable for stream decoding
30 SW_BLACKWHITTE_E	Sampling 0b - 4:2:0 sampling format 1b - 4:0:0 sampling format (H264 monochroma)
29 —	Reserved.
28 SW_WEIGHT_PRED_E	Weighted prediction enable for P slices
27-26 SW_WEIGHT_BIPR_IDC	Weighted prediction specification 00b - Default weighted prediction is applied to B slices 01b - Explicit weighted prediction shall be applied to B slices 10b - NA 11b - NA
25 SW_FILTER_SLICE_BORDER	Filter enable over slice border
24 SW_FILTER_TILE_BORDER	Filter enable over tile border
23 SW_ASYM_PRED_E	Asymmetric prediction flag for stream decoding
22 SW_SAO_E	Sample Adaptive Offset enable for stream decoding
21 SW_PCM_FILTER_DISABLE	Disable for PCM loop filtering
20 SW_SLICE_CHQP_FLAG	Slice header flag for chroma QP present (if it is included in slice header)
19 SW_DEPEND_SLICE_E	Dependent slice enable
18 SW_FILTER_OVERRIDE_E	Filter override enable
17 SW_STRONG_SMOOTH_E	Strong smoothing enable
16-12	Filter beta offset (declared as div2)

Table continues on the next page...

Field	Function
SW_FILT_OFFS ET_BETA	
11-7 SW_FILT_OFFS ET_TC	Filter tc offset (declared as div2)
6 SW_SLICE_HD R_EXT_E	Slice header extension enable. Reserved for future use
5-3 SW_SLICE_HD R_EBITS	Number of extra slice header bits (if enabled slice header extension)
2-0 —	Reserved.

15.2.5.1.10 Decoder control register 5 (SWREG8)

15.2.5.1.10.1 Offset

Register	Offset
SWREG8	20h

15.2.5.1.10.2 Diagram

15.2.5.1.10.3 Fields

Field	Function
31 SW_CONST_INTRA_E	constrained_intra_pred_flag equal to 1 specifies that intra prediction uses only neighbouring intra macroblocks in prediction. When equal to 0 also neighbouring inter macroblocks are used in intra prediction process.
30 SW_FILT_CTRL_PRE	deblocking_filter_control_present_flag indicates whether extra variables controlling characteristics of the deblocking filter are present in the slice header.
29-28 —	Reserved.
27-17 —	Reserved.
16 SW_IDR_PIC_E	IDR (instantaneous decoding refresh) picture flag.
15-12 SW_PCM_BITDEPTH_Y	Bit depth for PCM Y data
11-8	Bit depth for PCM C data

Table continues on the next page...

Field	Function
SW_PCM_BITDEPTH_C	
7-6 SW_BIT_DEPTH_H_Y_MINUS8	Bit depth of luma samples minus 8
5-4 SW_BIT_DEPTH_H_C_MINUS8	Bit depth of chroma samples minus 8
3 SW_OUTPUT_8_BITS	enable rasterscan output force to 8 bit(only for hevc main10 and vp9 10bit)
2-0 SW_OUTPUT_FORMAT	Raster scan and down scale output data format 000b - Each pixel in 10 bits when luma or chroma pixel bit depth is larger than 8; or 8 bits when both luma and chroma pixel bit depth are 8 bits. (default) 001b - Store in P010 format when luma or chroma pixel bit depth is larger than 8. 010b - A customized format: please refer to register SWREG23[6].

15.2.5.1.11 Decoder control register 6 (SWREG9)

15.2.5.1.11.1 Offset

Register	Offset
SWREG9	24h

15.2.5.1.11.2 Diagram

15.2.5.1.11.3 Fields

Field	Function
31-24 —	Reserved.
23-19 SW_REFIDX1_ACTIVE	Specifies the maximum reference index that can be used while decoding inter predicted macro blocks.
18-14 SW_REFIDX0_ACTIVE	Specifies the maximum reference index that can be used while decoding inter predicted macro blocks. This is same as in previous decoders (width increased with q bit)
13-0 SW_HDR_SKIP_LENGTH	Length of slice header skip length (bytes used by sw)

15.2.5.1.12 Decoder control register 7 (SWREG10)

15.2.5.1.12.1 Offset

Register	Offset
SWREG10	28h

15.2.5.1.12.2 Diagram

15.2.5.1.12.3 Fields

Field	Function
31 SW_START_CODE_E	Bit for indicating stream start code existence 0b - Stream does not contain start codes 1b - Stream contains start codes
30-24 SW_INIT_QP	Initial value for quantization parameter (picture quantizer).
23-19 SW_NUM_TILE_COLS	Number of tile columns in picture
18-14	Number of tile rows in picture

Table continues on the next page...

VPU G2 Memory Map/Register Definition

Field	Function
SW_NUM_TILE_ROWS	
13-2 —	Reserved.
1 SW_TILE_ENABLE	Tile enable
0 SW_ENTR_CO DE_SYNCH_E	Entropy coding synchronization enable (Possible parallel cabac decoding)

15.2.5.1.13 Decoder control register 8 (SWREG11)

15.2.5.1.13.1 Offset

Register	Offset
SWREG11	2Ch

15.2.5.1.13.2 Diagram

15.3 VPU H1 (VPU_H1)

15.3.1 Overview

This block describes the features and functionality of the VPU H1 VP8/H.264/MVC video encoder.

15.3.1.1 Block Diagram

The block diagram of the VPU H1 encoder is shown below.

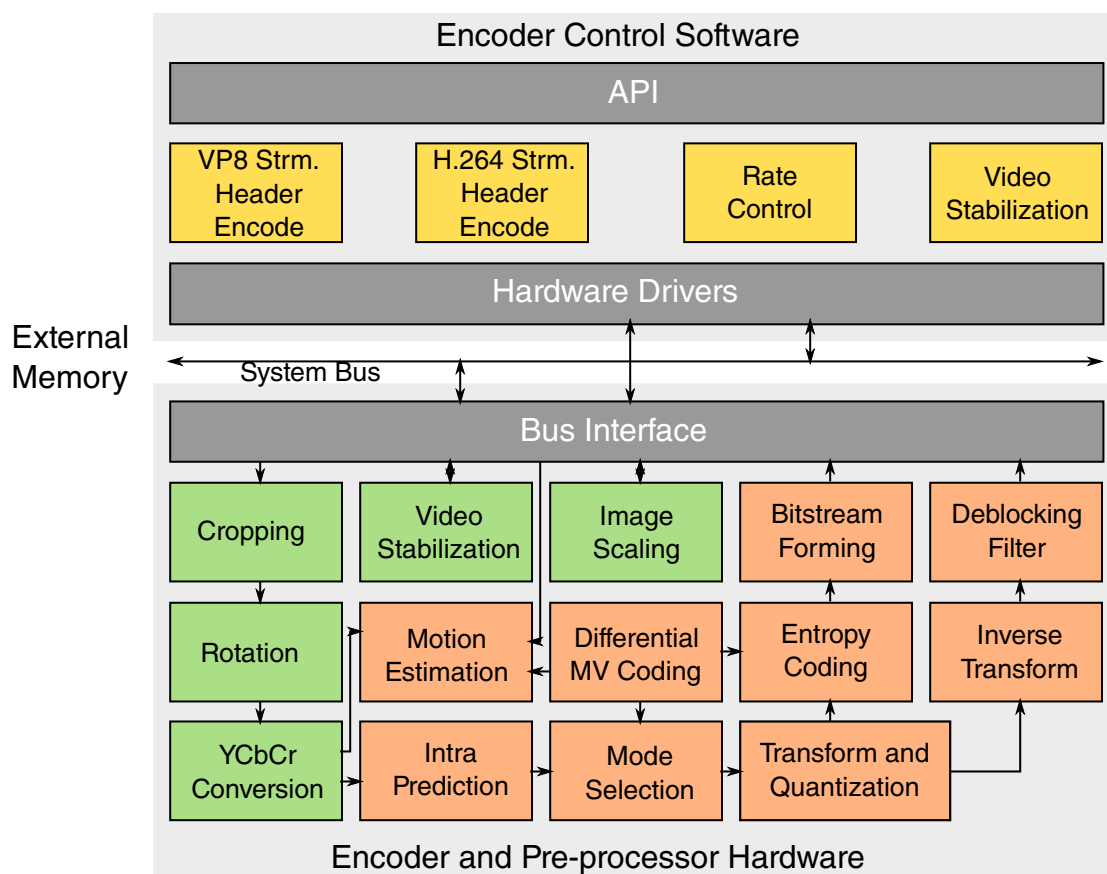

Figure 15-14. VPU H1 Encoder Block Diagram

15.3.1.2 Features

The supported standards, profiles and levels are presented in the table below.

Table 15-5. Supported Standards, Profiles and Levels

Standard	Encoder support
VP8	VP8
H.264 Profile and level	Baseline Profile, levels 1 – 5.1 Main Profile, levels 1 - 5.1 High Profile, levels 1 - 5.1
MVC extension to H.264	Stereo High

The supported VP8 and H.264 video tools are shown in the tables below.

Table 15-6. Supported VP8 Tools

Tool	Encoder support
Frame Types	I, P, Golden and droppable frames
Basic coding tools	14 intra prediction modes 4x4 transform Loop filter: normal, simple and off Error resilience: o Stream mode with no cumulative probability updates
Motion estimation	Configurable search area : - vertical ± 30 pixels, horizontal ± 126 pixels or - vertical ± 14 pixels, horizontal ± 126 pixels Pixel accuracy: $\frac{1}{2}$ or $\frac{1}{4}$ MB and Sub-MB partitions: 16x16, 16x8, 8x16, 8x8 and 4x4 Algorithm: Indexed motion estimation Reconstruction filter: bicubic and bilinear
Number of reference frames	Up to 2
Maximum number of segments	Up to 4 different quantization parameters per frame
Maximum number of residual partitions	5 (control + up to 4 residual partitions)

Table 15-7. Supported H.264 / MVC Tools

Tool	Encoder support
Slices	I and P slices Programmable slice type (mixed I and P slices in one frame)
Fr types	Progressive Interlaced fields
Entropy encoding	CAVLC CABAC Mixed CAVLC (for intra frames) / CABAC (for inter frames)

Table continues on the next page...

Table 15-7. Supported H.264 / MVC Tools (continued)

Tool	Encoder support
Basic	Error resilience: o Constrained intra prediction o Slices, multiple of macroblocks rows Maximum motion vector length: o Vertical +-126 pixels o Horizontal +-30 pixels Motion vector pixel accuracy: o $\frac{1}{4}$ or $\frac{1}{2}$ pixels Macroblock and sub-macroblock partitions: o 16x16, 8x16, 16x8, 8x8, 4x8, 8x4 and 4x4 12 intra prediction modes o 4x4 and 8x8 transforms
Number of reference frames	Up to 2
Maximum number of segments	Up to 4 different quantization parameters per frame
Maximum number of slice groups	1

Table 15-8. VP8 / H.264 / MVC Features

Feature	Encoder support
Input data format	YCbCr formats: o YCbCr 4:2:0 planar o YCbCr 4:2:0 semi-planar o YCrCb 4:2:0 semi-planar o YCbYCr 4:2:2 raster-scan 1) o CbYCrY 4:2:2 raster-scan 1) RGB formats: 1) o RGB444 and BGR444 o RGB555 and BGR555 o RGB565 and BGR565 o RGB888 and BRG888 o RGB101010 and BRG101010
Output data format	VP8: o VP8 bitstream H.264/MVC: o Byte unit stream o NAL unit stream
Supported image size	144 x 96 to 4080 x 4080 Step size 4 pixels
Maximum frame rate	Unlimited by the hardware 30 fps at 1920 x 1080 for VP8 60 fps at 1920 x 1080 for H.264
Bit rate	Minimum: 10kbps Maximum: 40 Mbps at 1080p 60 fps
Motion detection	Encoder outputs the best matching motion vector, the motion estimation quality information (a SAD value) and other coding information for each macroblock
Region-of-interest	Two user definable rectangular areas with separate quantizer setting
Region-of-intra	One user definable rectangular area coded as intra
Cyclic Intra Refresh	Supported

Preprocessing is pipelined with the encoder and it can be used only with the VPU H1 encoder. Preprocessing features are presented in the table below.

Table 15-9. Supported Standards, Profiles and Levels

Feature	Encoder support
RGB to YCbCr 4:2:0 color space conversion	BT.601, BT.709 or user defined coefficients conversion for RGB: <ul style="list-style-type: none"> o RGB444 and BGR444 o RGB555 and BGR555 o RGB565 and BGR565 o RGB888 and BRG888 o RGB101010 and BRG101010
YCbCr 4:2:2 to YCbCr 4:2:0 color space conversion	YCbCr formats: <ul style="list-style-type: none"> o YCbCr 4:2:0 planar o YCbCr 4:2:0 semi-planar o YCrCb 4:2:0 semi-planar o YCbYCr 4:2:2 raster-scan o CbYCrY 4:2:2 raster-scan
Cropping	Video - from 8192 x 8192 to any supported encoding size
Rotation	90 or 270 degrees
Image down-scaling	Proprietary averaging filter Arbitrary, non-integer scaling ratio separately for both dimensions Unlimited down-scaling ratio (e.g. from 1080p to QCIF)

31-0	Base address MSB for reference chroma compression table
BF_0	

15.3.2.1.367 VPU H1 Register 425 (SWREG425)

15.3.2.1.367.1 Offset

Register	Offset
SWREG425	6A4h

15.3.2.1.367.2 Diagram

15.3.2.1.367.3 Fields

Field	Function
31-0 BF_0	Base address MSB for reconstructed luma compression table

15.3.2.1.368 VPU H1 Register 426 (SWREG426)

15.3.2.1.368.1 Offset

Register	Offset
SWREG426	6A8h

15.3.2.1.368.2 Diagram

15.3.2.1.368.3 Fields

Field	Function
31-0 BF_0	Base address for reconstructed chroma compression table

15.3.2.1.369 VPU H1 Register 427 (SWREG427)**15.3.2.1.369.1 Offset**

Register	Offset
SWREG427	6ACh

15.3.2.1.369.2 Diagram**15.3.2.1.369.3 Fields**

Field	Function
31-0 BF_0	Base address MSB for second reference luma compression table

15.3.2.1.370 VPU H1 Register 428 (SWREG428)

15.3.2.1.370.1 Offset

Register	Offset
SWREG428	6B0h

15.3.2.1.370.2 Diagram

15.3.2.1.370.3 Fields

Field	Function
31-0	Base address MSB for second reference chroma compression table
BF_0	

15.3.2.1.371 VPU H1 Register 429 (SWREG429)

15.3.2.1.371.1 Offset

Register	Offset
SWREG429	6B4h

15.3.2.1.371.2 Diagram

15.3.2.1.371.3 Fields

Field	Function
31-0 BF_0	high 32 bits of Base address for output stream data

15.3.2.1.372 VPU H1 Register 430 (SWREG430)

15.3.2.1.372.1 Offset

Register	Offset
SWREG430	6B8h

15.3.2.1.372.2 Diagram

15.3.2.1.372.3 Fields

Field	Function
31-0 BF_0	high 32 bits of Base address for output control data

15.3.2.1.373 VPU H1 Register 431 (SWREG431)

15.3.2.1.373.1 Offset

Register	Offset
SWREG431	6BCh

15.3.2.1.373.2 Diagram

15.3.2.1.373.3 Fields

Field	Function
31-0 BF_0	high 32 bits of Base address for reference luma

15.3.2.1.374 VPU H1 Register 432 (SWREG432)

15.3.2.1.374.1 Offset

Register	Offset
SWREG432	6C0h

15.3.2.1.374.2 Diagram**15.3.2.1.374.3 Fields**

Field	Function
31-0	high 32 bits of Base address for reference chroma
BF_0	

15.3.2.1.375 VPU H1 Register 433 (SWREG433)**15.3.2.1.375.1 Offset**

Register	Offset
SWREG433	6C4h

15.3.2.1.375.2 Diagram

15.3.2.1.375.3 Fields

Field	Function
31-0 BF_0	high 32 bits of Base address for reconstructed luma

15.3.2.1.376 VPU H1 Register 434 (SWREG434)

15.3.2.1.376.1 Offset

Register	Offset
SWREG434	6C8h

15.3.2.1.376.2 Diagram

15.3.2.1.376.3 Fields

Field	Function
31-0 BF_0	high 32 bits of Base address for reconstructed chroma

15.3.2.1.377 VPU H1 Register 435 (SWREG435)**15.3.2.1.377.1 Offset**

Register	Offset
SWREG435	6CCh

15.3.2.1.377.2 Diagram**15.3.2.1.377.3 Fields**

Field	Function
31-0 BF_0	high 32 bits of Base address for input picture luma

15.3.2.1.378 VPU H1 Register 436 (SWREG436)

15.3.2.1.378.1 Offset

Register	Offset
SWREG436	6D0h

15.3.2.1.378.2 Diagram

15.3.2.1.378.3 Fields

Field	Function
31-0	high 32 bits of Base address for input picture cb
BF_0	

15.3.2.1.379 VPU H1 Register 437 (SWREG437)

15.3.2.1.379.1 Offset

Register	Offset
SWREG437	6D4h

15.3.2.1.379.2 Diagram

15.3.2.1.379.3 Fields

Field	Function
31-0 BF_0	high 32 bits of Base address for input picture cr

15.3.2.1.380 VPU H1 Register 438 (SWREG438)

15.3.2.1.380.1 Offset

Register	Offset
SWREG438	6D8h

15.3.2.1.380.2 Diagram

15.3.2.1.380.3 Fields

Field	Function
31-0 BF_0	high 32 bits of Base address for second reference luma

15.3.2.1.381 VPU H1 Register 439 (SWREG439)

15.3.2.1.381.1 Offset

Register	Offset
SWREG439	6DCh

15.3.2.1.381.2 Diagram

15.3.2.1.381.3 Fields

Field	Function
31-0 BF_0	high 32 bits of Base address for second reference chroma

15.3.2.1.382 VPU H1 Register 440 (SWREG440)

15.3.2.1.382.1 Offset

Register	Offset
SWREG440	6E0h

15.3.2.1.382.2 Diagram**15.3.2.1.382.3 Fields**

Field	Function
31-0	high 32 bits of H264 secondary ref pic base
BF_0	

15.3.2.1.383 VPU H1 Register 441 (SWREG441)**15.3.2.1.383.1 Offset**

Register	Offset
SWREG441	6E4h

15.3.2.1.383.2 Diagram

15.3.2.1.383.3 Fields

Field	Function
31-0 BF_0	high 32 bits of H264 secondary ref pic base

15.3.2.1.384 VPU H1 Register 442 (SWREG442)

15.3.2.1.384.1 Offset

Register	Offset
SWREG442	6E8h

15.3.2.1.384.2 Diagram

15.3.2.1.384.3 Fields

Field	Function
31-0 BF_0	high 32 bits of Base address for next pic luminance

15.3.2.1.385 VPU H1 Register 443 (SWREG443)**15.3.2.1.385.1 Offset**

Register	Offset
SWREG443	6ECh

15.3.2.1.385.2 Diagram**15.3.2.1.385.3 Fields**

Field	Function
31-0 BF_0	high 32 bits of Base address for cabac context tables (H264) or probability tables (VP8)

15.3.2.1.386 VPU H1 Register 444 (SWREG444)

15.3.2.1.386.1 Offset

Register	Offset
SWREG444	6F0h

15.3.2.1.386.2 Diagram

15.3.2.1.386.3 Fields

Field	Function
31-0	high 32 bits of Base address for MV output writing
BF_0	

15.3.2.1.387 VPU H1 Register 445 (SWREG445)

15.3.2.1.387.1 Offset

Register	Offset
SWREG445	6F4h

15.3.2.1.387.2 Diagram

15.3.2.1.387.3 Fields

Field	Function
31-0 BF_0	high 32 bits of Base address for VP8 1st DCT partition

15.3.2.1.388 VPU H1 Register 446 (SWREG446)

15.3.2.1.388.1 Offset

Register	Offset
SWREG446	6F8h

15.3.2.1.388.2 Diagram

15.3.2.1.388.3 Fields

Field	Function
31-0 BF_0	high 32 bits of Base address for VP8 2nd DCT partition

15.3.2.1.389 VPU H1 Register 447 (SWREG447)

15.3.2.1.389.1 Offset

Register	Offset
SWREG447	6FCh

15.3.2.1.389.2 Diagram

15.3.2.1.389.3 Fields

Field	Function
31-0 BF_0	high 32 bits of Base address for VP8 counters for probability updates

15.3.2.1.390 VPU H1 Register 448 (SWREG448)

15.3.2.1.390.1 Offset

Register	Offset
SWREG448	700h

15.3.2.1.390.2 Diagram**15.3.2.1.390.3 Fields**

Field	Function
31-0 BF_0	high 32 bits of Base address for VP8 segmentation map. segmentId 2-bits/macroblock

15.3.2.1.391 VPU H1 Register 449 (SWREG449)**15.3.2.1.391.1 Offset**

Register	Offset
SWREG449	704h

15.3.2.1.391.2 Diagram

15.3.2.1.391.3 Fields

Field	Function
31-0 BF_0	high 32 bits of Base address for output of down-scaled encoder image in YUYV 4:2:2 format

15.3.2.1.392 VPU H1 Register 450 (SWREG450)

15.3.2.1.392.1 Offset

Register	Offset
SWREG450	708h

15.3.2.1.392.2 Diagram

15.3.2.1.392.3 Fields

Field	Function
31-0 BF_0	high 32 bits of Base address for VP8 3rd DCT partition

15.3.2.1.393 VPU H1 Register 451 (SWREG451)**15.3.2.1.393.1 Offset**

Register	Offset
SWREG451	70Ch

15.3.2.1.393.2 Diagram**15.3.2.1.393.3 Fields**

Field	Function
31-0 BF_0	high 32 bits of Base address for VP8 4th DCT partition

15.3.2.1.394 VPU H1 Register 452 (SWREG452)

15.3.2.1.394.1 Offset

Register	Offset
SWREG452	710h

15.3.2.1.394.2 Diagram

15.3.2.1.394.3 Fields

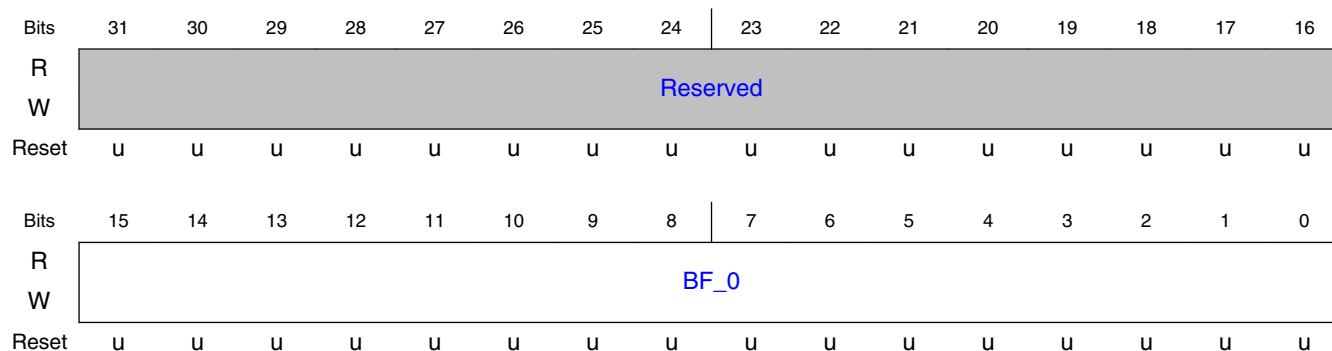

Field	Function
31 BF_31	Enable/disable the de-noise function
30-27 —	Reserved.
26-16 BF_16	Denoise filter strength
15-0 BF_0	Number of Noisy MB

15.3.2.1.395 VPU H1 Register 453 (SWREG453)

15.3.2.1.395.1 Offset

Register	Offset
SWREG453	714h

15.3.2.1.395.2 Diagram

15.3.2.1.395.3 Fields

Field	Function
31-16 —	Reserved.
15-0 BF_0	Max noise level

15.3.2.1.396 VPU H1 Register 454 (SWREG454)

15.3.2.1.396.1 Offset

Register	Offset
SWREG454	718h

15.3.2.1.396.2 Diagram

15.3.2.1.396.3 Fields

Field	Function
31-28 —	Reserved.
27-16 BF_16	Noise level inverted for chroma
15-12 —	Reserved.
11-0 BF_0	Noise level inverted for luma

15.3.2.1.397 VPU H1 Register 455 (SWREG455)

15.3.2.1.397.1 Offset

Register	Offset
SWREG455	71Ch

15.3.2.1.397.2 Diagram

15.3.2.1.397.3 Fields

Field	Function
31-0 BF_0	calculated sigma of coding frame

15.3.2.1.398 VPU H1 Register 456 (SWREG456)

15.3.2.1.398.1 Offset

Register	Offset
SWREG456	720h

15.3.2.1.398.2 Diagram

15.3.2.1.398.3 Fields

Field	Function
31-0	noise sigma for current frame
BF_0	

15.3.2.1.399 VPU H1 Register 457 (SWREG457)

15.3.2.1.399.1 Offset

Register	Offset
SWREG457	724h

15.3.2.1.399.2 Diagram

15.3.2.1.399.3 Fields

Field	Function
31-24 BF_24	Denoise Filter Parameters Set 1, No.3.
23-16 BF_16	Denoise Filter Parameters Set 1, No.2.
15-8 BF_8	Denoise Filter Parameters Set 1, No.1.
7-0 BF_0	Denoise Filter Parameters Set 1, No.0.

15.3.2.1.400 VPU H1 Register 458 (SWREG458)

15.3.2.1.400.1 Offset

Register	Offset
SWREG458	728h

15.3.2.1.400.2 Diagram

15.3.2.1.400.3 Fields

Field	Function
31-24 BF_24	Denoise Filter Parameters Set 1, No.7.
23-16 BF_16	Denoise Filter Parameters Set 1, No.6.
15-8 BF_8	Denoise Filter Parameters Set 1, No.5.
7-0 BF_0	Denoise Filter Parameters Set 1, No.4.

15.3.2.1.401 VPU H1 Register 459 (SWREG459)

15.3.2.1.401.1 Offset

Register	Offset
SWREG459	72Ch

15.3.2.1.401.2 Diagram

15.3.2.1.401.3 Fields

Field	Function
31-24 BF_24	Denoise Filter Parameters Set 1, No.11.
23-16 BF_16	Denoise Filter Parameters Set 1, No.10.
15-8 BF_8	Denoise Filter Parameters Set 1, No.9.
7-0 BF_0	Denoise Filter Parameters Set 1, No.8.

15.3.2.1.402 VPU H1 Register 460 (SWREG460)

15.3.2.1.402.1 Offset

Register	Offset
SWREG460	730h

Chapter 16

Low Speed Communication and Interconnects

16.1 I2C Controller (I2C)

16.1.1 Overview

This chapter describes block-level operation and programming of I2C. The chapter is intended for a block-driver software developer. To understand how the block is integrated at the SoC level, a system software developer should see discussions of the block in the appropriate SoC-level chapter(s).

References: This document assumes an understanding of the following document:

- *The I2C Bus Specification*, Version 2.1, by Philips Semiconductor

The Inter IC (I2C) provides functionality of a standard I2C slave and master. The I2C is designed to be compatible with the standard NXP I2C bus protocol.

NOTE

Four independent I2C channels are available.

I2C is a two-wire, bidirectional serial bus that provides a simple, efficient method of data exchange, minimizing the interconnection between devices. This bus is suitable for applications requiring occasional communications over a short distance between many devices. The flexible I2C standard allows additional devices to be connected to the bus for expansion and system development. See the connection diagram in the figure below.

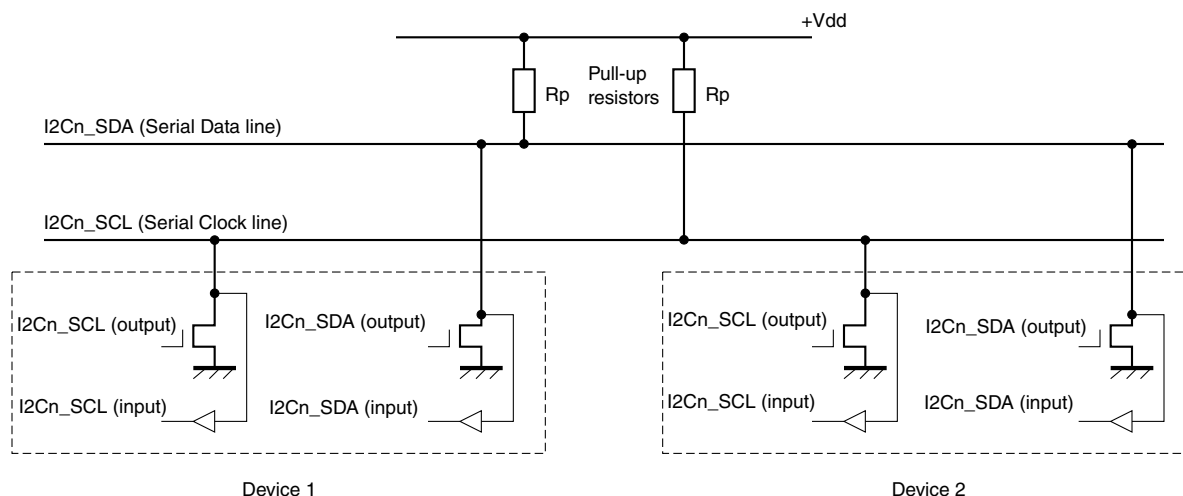

Figure 16-1. Connection of devices to I2C bus

The I2C interface speed is dependent on the I2C bus loading and timing characteristics. For pin requirement details, see *The I2C Bus Specification*. The I2C system is a true multimaster bus including arbitration and collision detection that prevents data corruption if multiple devices attempt to control the bus simultaneously. This feature supports complex applications with multiprocessor control and can be used for rapid testing and alignment of end products through external connections to an assembly-line computer. The figure below shows the block diagram of I2C.

Figure 16-2. I2C block diagram

16.1.1.1 Features

The I2C has the following key features:

- Compatibility with I2C bus standard
- Multimaster operation
- Software programmability for one of 64 different serial clock frequencies
- Software-selectable acknowledge bit
- Interrupt-driven, byte-by-byte data transfer
- Arbitration-lost interrupt with automatic mode switching from master to slave

- Calling address identification interrupt
- Start and stop signal generation/detection
- Repeated Start signal generation
- Acknowledge bit generation/detection
- Bus-busy detection

16.1.1.2 Modes and operations

The I2C operates primarily in two functional modes: Standard mode and Fast mode.

- In Standard mode, I2C supports the data transfer rates up to 100 kbits/s.
- In Fast mode, data transfer rates up to 400 kbits/s can be achieved. Per block operation, there is no special configuration required for Fast or Standard mode. It is the data transfer rate that distinguishes Standard and Fast mode.

16.1.2 Functional description

This section provides a complete functional description of the block.

16.1.2.1 I2C system configuration

After a reset, the I2C defaults to Slave Receive operations. Thus, when not operating as a master or responding to a slave transmit address, the I2C defaults to the Slave Receive state.

For exceptions, see [Initialization sequence](#).

NOTE

The I2C is designed to be compatible with the PhilipsTM I2C bus protocol. For information on system configuration, protocol, and restrictions, see the *I2C Bus Specification*, version 2.1, by Philips Semiconductors. The I2C supports Standard and Fast modes only.

16.1.2.2 Arbitration procedure

If multiple devices simultaneously request the bus, the bus clock is determined by a synchronization procedure in which the low period equals the longest clock-low period among the devices, and the high period equals the shortest. A data arbitration procedure determines the relative priority of competing devices.

A device loses arbitration if it sends logic high while another sends logic low; it immediately switches to Slave Receive mode and stops driving I2Cn_SDA. In this case, the transition from master to Slave mode does not generate a Stop condition. Meanwhile, hardware sets the arbitration lost bit in the I2C Status register (I2C_I2SR[IAL] to indicate loss of arbitration).

16.1.2.3 Clock synchronization

Because wire-AND logic is used, a high-to-low transition on SCL affects devices connected to the bus. Devices start counting their low period when the master drives SCL low. When a device clock goes low, it holds SCL low until the Clock High state is reached. However, the low-to-high change in this device clock may not change the state of SCL if another device clock is still in its low period. Therefore, the device with the longest low period holds the synchronized clock SCL low.

Devices with shorter low periods enter a High Wait state during this time (see [Figure 16-3](#)). When all devices involved have counted off their low periods, the synchronized clock SCL is released and pulled high. There is then no difference between device clocks and the state of SCL, so all of the devices start counting their high periods. The first device to complete its high period pulls SCL low again.

Figure 16-3. Synchronized clock SCL

16.1.2.4 Handshaking

The clock synchronization mechanism can be used as a handshake in data transfers. Slave devices can hold SCL low after completing one byte transfer (9 bits). In such a case, the clock mechanism halts the bus clock and forces the master clock into a Wait state until the slave releases SCL.

16.1.2.5 Clock stretching

Slaves can use the clock synchronization mechanism to slow down the transfer bit rate. After the master has driven SCL low, the slave can drive SCL low for the required period and then release it. If the slave SCL low period is longer than the master SCL low period, the resulting SCL bus signal low period is stretched.

16.1.2.6 Peripheral bus accesses

I2C is a 16-bit block. Only half-word accesses should be performed to the block.

16.1.2.7 Generation of transfer error on IP bus

If an address is received on the peripheral slave bus interface but it is not implemented, an access error is generated.

16.1.2.8 Reset

The I2C can be reset in the following ways:

- Global reset: A hard asynchronous reset of the whole I2C
- Software reset: An internal reset for the whole I2C (except for I2C_IADR and I2C_IFDR registers) initiated by deasserting the I2C_I2CR[IEN] bit

16.1.2.9 Interrupts

There is only one interrupt from the block, which is enabled by setting the I2C_I2CR[IIEN] bit.

The interrupt is generated in any one of the following conditions:

- One byte transfer is completed (the interrupt is set at the falling edge of the ninth clock).
- An address is received that matches its own specific address in Slave Receive mode.
- Arbitration is lost.

16.1.2.10 Byte order

The block only supports the Little-Endian mode.

16.1.3 Initialization

NOTE

Ensure the input select pins for IOMUXC are configured correctly for I2C.

16.1.3.1 Initialization sequence

Before the interface can transfer serial data, registers must be initialized, as listed here.

1. Set the data sampling rate (I2C_IFDR[IC]) to obtain SCL frequency from the system bus clock.
2. Update the address in the (I2C_IADR) to define its slave address (address can range from 0 to 0x7f).
3. Set the I2C enable bit (I2C_I2CR[IEN]) to enable the I2C bus interface system.
4. Modify the bits in the I2C_I2CR to select Master/Slave mode, Transmit/Receive mode, and Interrupt-Enable or not.

16.1.3.2 Generation of Start

After completion of the initialization procedure, serial data can be transmitted by selecting the Master Transmit mode. On a multimaster bus system, the busy bus (I2C_I2SR[IBB]) must be tested to determine whether the serial bus is free. If the bus is free (IBB = 0), the Start signal and the first byte (the slave address) can be sent. The data written to the data register comprises the address of the desired slave and the LSB indicates the transfer direction.

The free time between a Stop and the next Start condition is built into the hardware that generates the Start cycle. Depending on the relative frequencies of the system clock and the SCL period, it may be necessary to wait until the I2C is not busy after writing the calling address to the data register (I2C_I2DR), before proceeding to load data into the data register (I2C_I2DR).

16.1.3.3 Post-transfer software response

Sending or receiving a byte sets the data transferring bit (I2C_I2SR[ICF]), which indicates one byte of communication is finished. Upon completion, the interrupt status (I2C_I2SR[IIF]) is also set. An external interrupt is generated if the interrupt enable (I2C_I2CR[IIEN]) is set. The software must first clear the interrupt status (I2C_I2SR[IIF]) in the interrupt routine.

See the flow chart in [Figure 16-5](#).

The data transferring bit (I2C_I2SR[ICF]) is cleared either by reading from I2C_I2DR in Receive mode or by writing to this register in Transmit mode.

The software can service the I2C I/O in the main program by monitoring the interrupt status (I2C_I2SR[IIF]) if the interrupt enable is deasserted. In this case, the interrupt status should be polled in the data transferring bit (I2C_I2SR[ICF]) because the operation is different when arbitration is lost.

When an interrupt occurs at the end of the address cycle, the master is always in Transmit mode; that is, the address is sent. If Master Receive mode is required, then I2C_I2CR[MTX] should be toggled and a dummy read of the I2C_I2DR register must be executed to trigger receive data.

During Slave-mode address cycles (I2C_I2SR[IAAS] = 1), the slave read/write bit I2C_I2SR[SRW] is read to determine the direction of the next transfer. The transmit/receive bit (I2C_I2CR[MTX]) should also be programmed accordingly. For Slave-mode data cycles (IAAS = 0), SRW is invalid. MTX should be read to determine the current transfer direction.

16.1.3.4 Generation of Stop

A data transfer ends when the master signals a Stop, which can occur after all data is sent.

For a master receiver to terminate a data transfer, it must inform the slave transmitter by not acknowledging the last data byte. This is done by setting the transmit acknowledge bit (I2C_I2CR[TXAK]) before reading the next-to-last byte. Before the last byte is read, a Stop signal must be generated.

16.1.3.5 Generation of Repeated Start

After the data transfer, if the master still requires the bus, it can signal another Start followed by another slave address without signaling a Stop.

16.1.3.6 Slave mode

In the slave interrupt service routine (see [Figure 16-5](#)), the block addressed as slave bit (IAAS) should be tested to check if a calling of its own address has just been received. If IAAS is set, software should set the Transmit/Receive mode select bit (I2C_I2CR[MTX]) according to the I2C_I2SR[SRW]. Writing to the I2C_I2CR clears the IAAS automatically. The only time IAAS is read as set is from the interrupt at the end of the address cycle where an address match occurred; interrupts resulting from subsequent data transfers will have IAAS cleared. A data transfer can now be initiated by writing information to I2C_I2DR for slave transmits, or read from I2C_I2DR in Slave Receive mode. A dummy read of I2C_I2DR in Slave Receive mode releases SCL, allowing the master to send data.

In the slave transmitter routine, the receive acknowledge bit (I2C_I2SR[RXAK]) must be tested before sending the next byte of data. Setting RXAK means an end-of-data signal from the master receiver, after which the software must switch it from Transmit to Receiver mode. Reading the data register (I2C_I2DR) then releases SCL so the master can generate a Stop signal.

16.1.3.7 Arbitration lost

If several devices try to engage the bus at the same time, one becomes master. Hardware immediately switches devices that lose arbitration to Slave Receive mode. Data output to 12Cn_SDA stops, but 12Cn_SCL is still generated until the end of the byte during which arbitration is lost. An interrupt occurs at the falling edge of the ninth clock of this transfer if the arbitration is lost (I2C_I2SR[IAL] = 1), and the Slave mode is selected (I2C_I2CR[MSTA] = 0).

See the flow chart in [Figure 16-5](#).

If a device that is not a master tries to transmit or do a Start, hardware inhibits the transmission, clears MSTA without signaling a Stop, generates an interrupt to the Arm platform, and sets I2C_I2SR[IAL] to indicate a failed attempt to engage the bus. When considering these cases, the slave service routine should first test I2C_I2SR[IAL], and the software should clear it if it is set.

For Multimaster mode, when an I2C is enabled when the bus is busy and asserts Start, the I2C_I2SR[IAL] bit gets set only for 12Cn_SDA=0, 12Cn_SCL=0/1, 12Cn_SDA=1, and 12Cn_SCL=0; but not for 12Cn_SDA=1 and I2Cn_SCL=1, which is the equivalent of Bus Idle state.

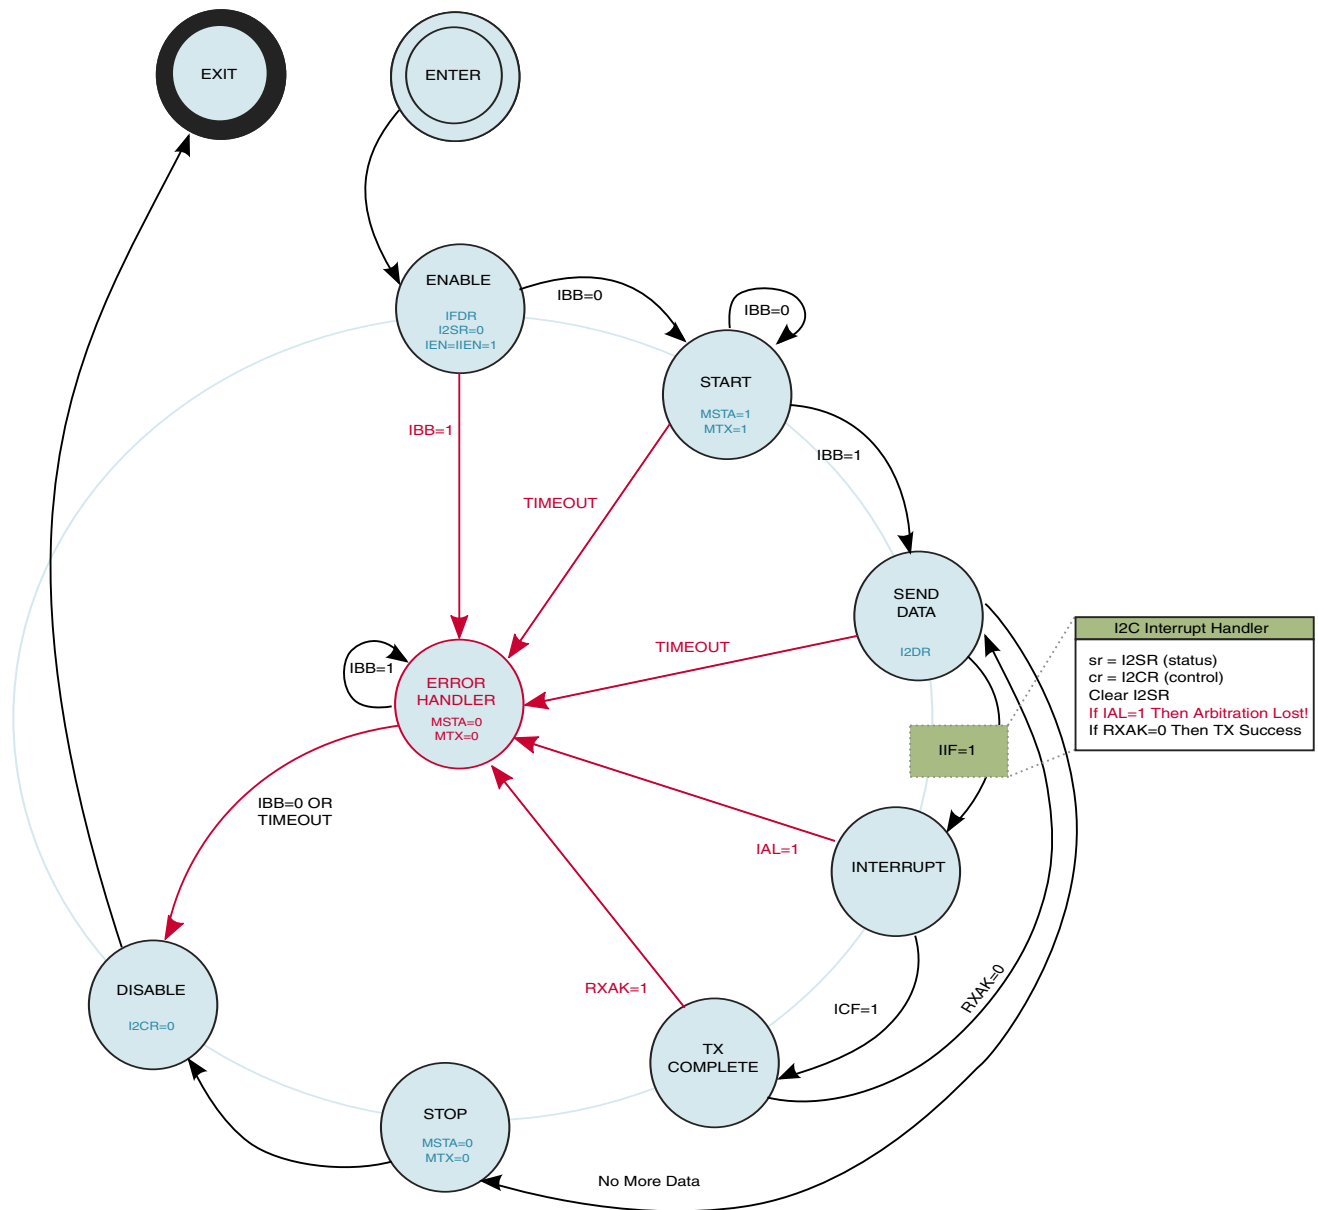

Figure 16-4. I2C Programming state diagram

Figure 16-5. Flowchart of typical I2C interrupt routine

NOTE

For a Repeated Start only, the Stop-generation stage does not occur in Master mode. A loop repeats itself without stopping for the next start.

For Master Receive mode, I2C is programmed as Master Transmit during Address mode and after slave address transfer; the MTX bit should be cleared and a dummy read on the I2C_I2DR register should be performed so I2C can read the next receive data.

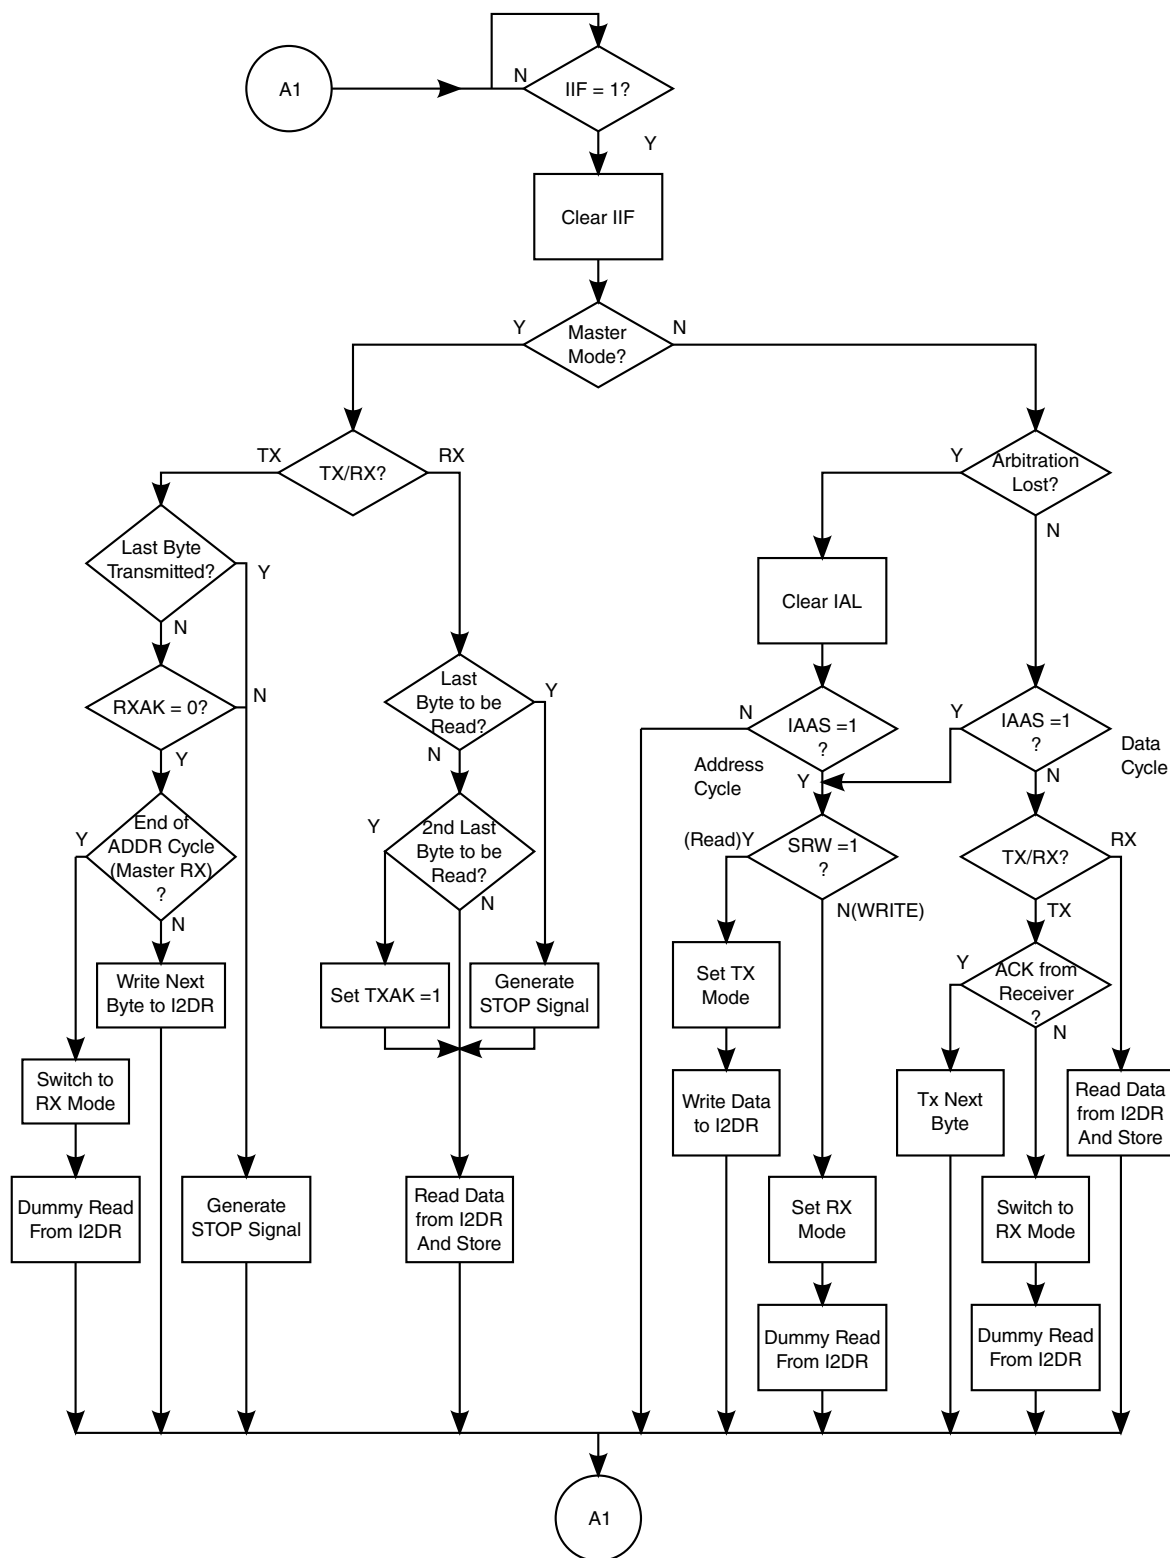

Figure 16-6. Flowchart for typical I2C polling routine

NOTE

The timeout value depends on the bus frequency at which I2C is operating. The minimum timeout for polling the IIF bit at a maximum I2C bus frequency of 400 kHz is $T_{\min} = 25 \mu\text{s}$ ($= 2.5 \times 10 \mu\text{s}$). This value can be calculated for any bus frequency. The formula is $T_{\min} = 10/F_{\text{SCL}}$, where F_{SCL} is the frequency of the I2C clock (SCL).

Figure 16-7. Detailed flowchart of a typical I2C Master Transmit mode, part 1

Figure 16-8. Detailed flowchart of a typical I2C Master Transmit mode, part 2

Figure 16-7 and Figure 16-8 show the Master Transmit mode operation with interrupt subroutine. If an interrupt is generated and the MSTA bit is 0, then bus arbitration is lost and IAL is set. Software can clear the IAL bit and reprogram I2C. If the MSTA bit is 1, then it is a transfer-generated interrupt. In this case, software can check the RXAK bit for a data receive acknowledgement by the slave and, accordingly, decide to do one of the following:

- Generate a STOP
- Generate a REPEATED START by writing to the I2C_I2CR register
- Perform the next data transfer by writing to the I2C_I2DR register

NOTE

The IBB bit is asserted by a Start condition on the bus, and it is deasserted by a Stop condition on the bus. Therefore, if arbitration is lost due to an unexpected Stop condition during transfer, then IBB is cleared. If arbitration is lost due to a data mismatch, then it is not cleared. Software should always clear the IEN bit and then set it if arbitration is lost.

16.1.4 Software restriction

Software should ensure that there is a delay of at least two module clock cycles after it sets the I2C_I2CR[RSTA] bit and before writing to the I2C_I2DR register. The maximum possible clock period of the module clock is 78 ns.

16.1.5 I2C Memory Map/Register Definition

The I2C contains five 16-bit registers.

NOTE

Registers at offsets 0x0002, 0x0006, 0x000A, and 0x000E are reserved for future additions.

I2C memory map

16.1.5.1 I2C Address Register (I2Cx_IADR)

Address: Base address + 0h offset

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	0								ADR							
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

I2Cx_IADR field descriptions

Field	Description
15–8 Reserved	This read-only field is reserved and always has the value 0.
7–1 ADR	Slave address. Contains the specific slave address to be used by the I2C. Slave mode is the default I2C mode for an address match on the bus. NOTE: The I2C_IADR holds the address to which the I2C responds when addressed as a slave. The slave address is not the address sent on the bus during the address transfer. The register is not reset by a software reset.
0 Reserved	This read-only field is reserved and always has the value 0.

16.1.5.2 I2C Frequency Divider Register (I2Cx_IFDR)

The I2C_IFDR provides a programmable prescaler to configure the clock for bit-rate selection. The register does not get reset by a software reset.

The following table describes the divider and register values for the register field "IC."

Table 16-1. I2C_IFDR Register Field Values

IC	Divider		IC	Divider		IC	Divider		IC	Divider
0x00	30		0x10	288		0x20	22		0x30	160
0x01	32		0x11	320		0x21	24		0x31	192

I2Cx_IFDR field descriptions

Field	Description
15–6 Reserved	This read-only field is reserved and always has the value 0.
IC	<p>I2C clock rate. Prescales the clock for bit-rate selection. Due to potentially slow I2Cn_SCL and I2Cn_SDA rise and fall times, bus signals are sampled at the prescaler frequency. The serial bit clock frequency may be lower than IPG_CLK_ROOT divided by the divider shown in the I2C Data I/O Register.</p> <p>NOTE: The IC value should not be changed during the data transfer, however, it can be changed before a Repeat Start or Start programming sequence in I2C. The I2C protocol supports bit rates of up to 400 kbps. The IC bits need to be programmed in accordance with this constraint.</p>

16.1.5.3 I2C Control Register (I2Cx_I2CR)

The I2C_I2CR is used to enable the I2C and the I2C interrupt. It also contains bits that govern operation as a slave or a master.

Address: Base address + 8h offset

Bit	15	14	13	12	11	10	9	8
Read	0							
Write								
Reset	0	0	0	0	0	0	0	0
Bit	7	6	5	4	3	2	1	0

Write						RSTA		
Reset	0	0	0	0	0	0	0	0

I2Cx_I2CR field descriptions

Field	Description
15–8 Reserved	This read-only field is reserved and always has the value 0.
7 IEN	<p>I2C enable. Also controls the software reset of the entire I2C. Resetting the bit generates an internal reset to the block. If the block is enabled in the middle of a byte transfer, Slave mode ignores the current bus transfer and starts operating when the next Start condition is detected. Master mode is not aware that the bus is busy, so initiating a start cycle may corrupt the current bus cycle, ultimately causing either the current master or the I2C to lose arbitration. Subsequently, bus operation returns to normal.</p> <p>0 The block is disabled, but registers can still be accessed. 1 The I2C is enabled. This bit must be set before any other I2C_I2CR bits have an effect.</p>
6 I2EN	<p>I2C interrupt enable.</p> <p>NOTE: If data is written during the Start condition, that is, just after setting the I2C_I2CR[MSTA] and I2C_I2CR[MTX] bits, then the ICF bit is cleared at the falling edge of SCLK after Start. If data is written after the Start condition and falling edge of SCLK, then the ICF bit is cleared as soon as data is written.</p> <p>0 I2C interrupts are disabled, but the status flag I2C_I2SR[IIF] continues to be set when an Interrupt condition occurs. 1 I2C interrupts are enabled. An I2C interrupt occurs if I2C_I2SR[IIF] is also set.</p>
5 MSTA	<p>Master/Slave mode select bit. If the master loses arbitration, MSTA is cleared without generating a Stop signal.</p> <p>NOTE: The module clock should be on for writing to the MSTA bit.</p> <p>NOTE: The MSTA bit is cleared by software to generate a Stop condition; it can also be cleared by hardware when the I2C loses the bus arbitration.</p>

Table continues on the next page...

I2Cx_I2CR field descriptions (continued)

Field	Description
	0 Slave mode. Changing MSTA from 1 to 0 generates a Stop and selects Slave mode. 1 Master mode. Changing MSTA from 0 to 1 signals a Start on the bus and selects Master mode.
4 MTX	Transmit/Receive mode select bit. Selects the direction of master and slave transfers. 0 Receive. When a slave is addressed, the software should set MTX according to the slave read/write bit in the I2C status register (I2C_I2SR[SRW]). 1 Transmit. In Master mode, MTX should be set according to the type of transfer required. Therefore, for address cycles, MTX is always 1.
3 TXAK	Transmit acknowledge enable. Specifies the value driven onto I2Cn_SDA during acknowledge cycles for both master and slave receivers. NOTE: Writing TXAK applies only when the I2C bus is a receiver. 0 An acknowledge signal is sent to the bus at the ninth clock bit after receiving one byte of data. 1 No acknowledge signal response is sent (that is, the acknowledge bit = 1).
2 RSTA	Repeat start. Always reads as 0. Attempting a repeat start without bus mastership causes loss of arbitration. 0 No repeat start 1 Generates a Repeated Start condition
Reserved	This read-only field is reserved and always has the value 0.

16.1.5.4 I2C Status Register (I2Cx_I2SR)

The I2C_I2SR contains bits that indicate transaction direction and status.

Address: Base address + Ch offset

Bit	15	14	13	12	11	10	9	8
Read	0							
Write								
Reset	0	0	0	0	0	0	0	0
Bit	7	6	5	4	3	2	1	0
Read	ICF	IAAS	IBB	IAL	0	SRW	IIF	RXAK
Write								
Reset	1	0	0	0	0	0	0	1

I2Cx_I2SR field descriptions

Field	Description
15–8 Reserved	This read-only field is reserved and always has the value 0.
7 ICF	Data transferring bit. While one byte of data is transferred, ICF is cleared. 0 Transfer is in progress. 1 Transfer is complete. This bit is set by the falling edge of the ninth clock of the last byte transfer.
6 IAAS	I2C addressed as a slave bit. The Arm platform is interrupted if the interrupt enable (I2C_I2CR[IEN]) is set. The Arm platform must check the slave read/write bit (SRW) and set its Transfer/Receive mode accordingly. Writing to I2C_I2CR clears this bit. 0 Not addressed 1 Addressed as a slave. Set when its own address (I2C_IADR) matches the calling address.
5 IBB	I2C bus busy bit. Indicates the status of the bus. NOTE: When I2C is enabled (I2C_I2CR[IEN] = 1), it continuously polls the bus data (SDA) and clock (SCL) signals to determine a Start or Stop condition. 0 Bus is idle. If a Stop signal is detected, IBB is cleared. 1 Bus is busy. When Start is detected, IBB is set.
4 IAL	Arbitration lost. Set by hardware in the following circumstances (IAL must be cleared by software by writing a "0" to it at the start of the interrupt service routine): <ul style="list-style-type: none"> I2Cn_SDA input samples low when the master drives high during an address or data-transmit cycle. I2Cn_SDA input samples low when the master drives high during the acknowledge bit of a data-receive cycle. <p>For the above two cases, the bit is set at the falling edge of the ninth I2Cn_SCL clock during the ACK cycle.</p> <ul style="list-style-type: none"> A Start cycle is attempted when the bus is busy. A Repeated Start cycle is requested in Slave mode. A Stop condition is detected when the master did not request it. <p>NOTE: Software cannot set the bit.</p> 0 No arbitration lost. 1 Arbitration is lost.
3 Reserved	This read-only field is reserved and always has the value 0.
2 SRW	Slave read/write. When the I2C is addressed as a slave, IAAS is set, and the slave read/write bit (SRW) indicates the value of the R/W command bit of the calling address sent from the master. SRW is valid only when a complete transfer has occurred, no other transfers have been initiated, and the I2C is a slave and has an address match. 0 Slave receive, master writing to slave 1 Slave transmit, master reading from slave
1 IIF	I2C interrupt. Must be cleared by the software by writing a "0" to it in the interrupt routine. NOTE: The software cannot set the bit. 0 No I2C interrupt pending. 1 An interrupt is pending.

Table continues on the next page...

I2Cx_I2SR field descriptions (continued)

Field	Description
	<p>This causes a processor interrupt request (if the interrupt enable is asserted [I1EN = 1]). The interrupt is set when one of the following occurs:</p> <ul style="list-style-type: none"> • One byte transfer is completed (the interrupt is set at the falling edge of the ninth clock). • An address is received that matches its own specific address in Slave Receive mode. • Arbitration is lost.
0 RXAK	<p>Received acknowledge. This is the value received from the I2Cn_SDA input for the acknowledge bit during a bus cycle.</p> <p>0 An "acknowledge" signal was received after the completion of an 8-bit data transmission on the bus. 1 A "No acknowledge" signal was detected at the ninth clock.</p>

16.1.5.5 I2C Data I/O Register (I2Cx_I2DR)

In Master Receive mode, reading the data register allows a read to occur and initiates the next byte to be received. In Slave mode, the same function is available after it is addressed.

Address: Base address + 10h offset

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	0								DATA							
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

I2Cx_I2DR field descriptions

Field	Description
15–8 Reserved	This read-only field is reserved and always has the value 0.
DATA	<p>Data Byte. Holds the last data byte received or the next data byte to be transferred. Software writes the next data byte to be transmitted or reads the data byte received.</p> <p>NOTE: The core-written value in I2C_I2DR cannot be read back by the core. Only data written by the I2C bus side can be read.</p>

16.2 Universal Asynchronous Receiver/Transmitter (UART)

16.2.1 Overview

Universal Asynchronous Receiver/Transmitter (UART) provides serial communication capability with external devices through a level converter and an RS-232 cable or through use of external circuitry that converts infrared signals to electrical signals (for reception) or transforms electrical signals to signals that drive an infrared LED (for transmission) to provide low speed IrDA compatibility.

UART supports NRZ encoding format , RS485 compatible 9 bit data format and IrDA-compatible infrared slow data rate (SIR) format.

[Figure 16-9](#) is the UART block diagram.

The "Module Clock" is the UART_CLK which comes from CCM. The "Peripheral Clock" is the IPG_CLK which comes from CCM.

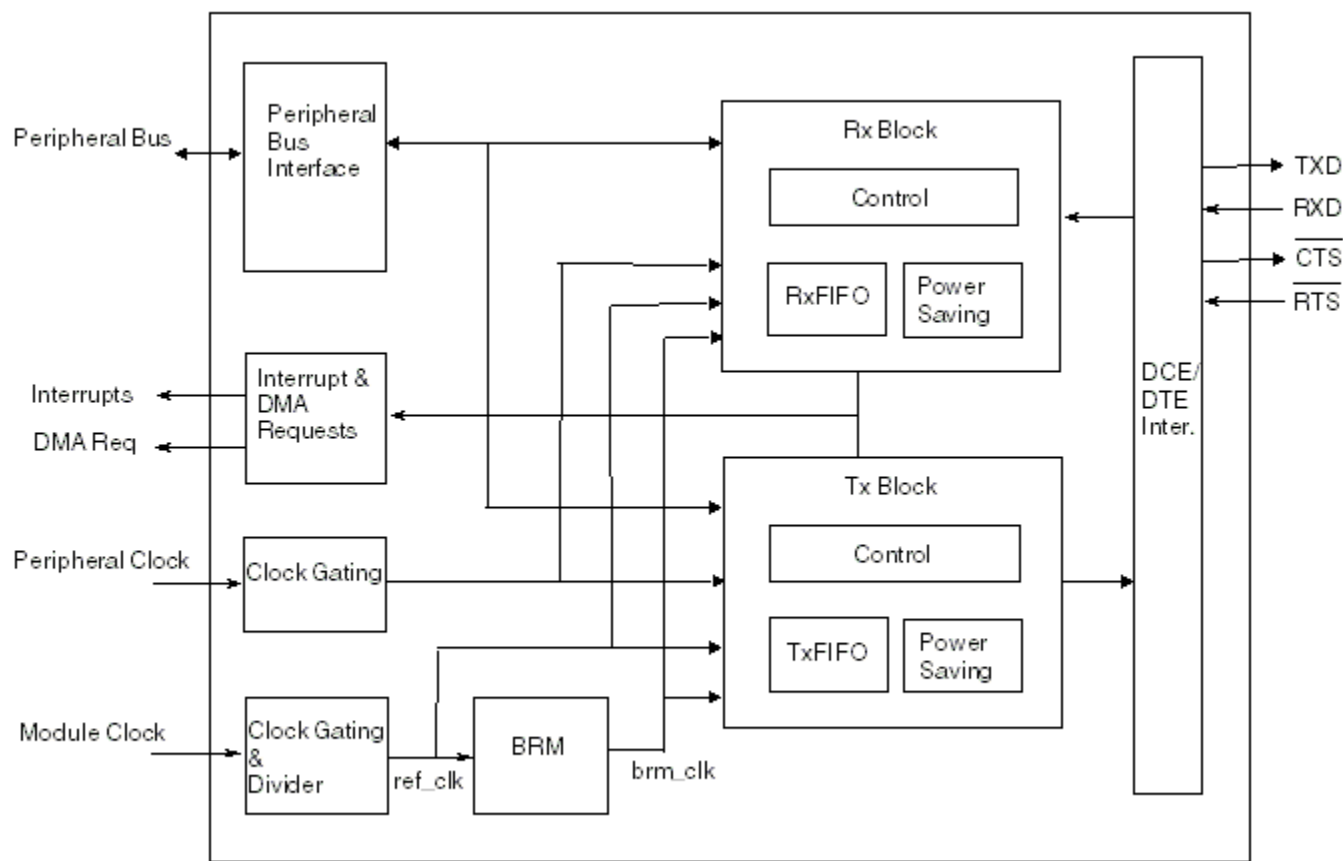

Figure 16-9. UART Block Diagram

16.2.1.1 Features

The UART includes the following features:

- High-speed TIA/EIA-232-F compatible, up to Mbit/s
- Serial IR interface low-speed, IrDA-compatible (up to 115.2 Kbit/s)
- 9-bit or Multidrop mode (RS-485) support (automatic slave address detection)
- 7 or 8 data bits for RS-232 characters, or 9 bit RS-485 format
- 1 or 2 stop bits
- Programmable parity (even, odd, and no parity)
- Hardware flow control support for request to send (RTS_B) and clear to send (CTS_B) signals
- RS-485 driver direction control via CTS_B signal
- Edge-selectable RTS_B and edge-detect interrupts
- Status flags for various flow control and FIFO states
- Voting logic for improved noise immunity (16x oversampling)
- Transmitter FIFO empty interrupt suppression

- UART internal clocks enable/disable
- Auto baud rate detection (up to 115.2 Kbit/s)
- Receiver and transmitter enable/disable for power saving
- RX_DATA input and TX_DATA output can be inverted respectively in RS-232/RS-485 mode
- DCE/DTE capability
- RTS_B, IrDA asynchronous wake (AIRINT), receive asynchronous wake (AWAKE) interrupts wake the processor from STOP mode
- Maskable interrupts
- Two DMA Requests (TxFIFO DMA Request and RxFIFO DMA Request)
- Escape character sequence detection
- Software reset (SRST_B)
- Two independent, 32-entry FIFOs for transmit and receive
- The peripheral clock can be totally asynchronous with the module clock. The module clock determines baud rate. This allows frequency scaling on peripheral clock (such as during DVFS mode) while remaining the module clock frequency and baud rate.

16.2.1.2 Modes of operation

- Serial RS-232NRZ mode
- 9-bit RS-485 mode
- IrDA mode

To set UART in different modes, see the table below.

Table 16-2. UART mode definition

MDEN (UMCR[0])	IREN (UCR1[7])	UART Mode	Description
0	0	RS-232	RXD/TXD data is serial RS-232 NRZ format
0	1	IrDA (Interface)	RXD/TXD data is IrDA-compatible infrared slow data rate (SIR) format
1	0	RS-485	RXD/TXD data is RS485 compatible 9 bit data format
1	1	Undefined	Undefined

16.2.2 Functional Description

This section provides a complete functional description of the block.

16.2.2.1 Interrupts and DMA Requests

See the following table for the lists of all interrupt and DMA signals and associated interrupt and DMA sources of the UART. See register description section for explanation of interrupt/DMA enable and status.

Table 16-3. Interrupts and DMA

Interrupt/DMA Output	Interrupt/DMA Enable	Enable Register Location	Interrupt/DMA Flag	Flag Register Location
<i>interrupt_uart</i>	RRDYEN	UCR1 (bit 9)	RRDY	USR1 (bit 9)

	SADEN	UMCR (bit 3)	SAD	USR1 (bit 3)
<i>dma_req_rx</i>	RXDMAEN	UCR1 (bit 8)	RRDY	USR1 (bit 9)
	ATDMAEN	UCR1 (bit 2)	AGTIM	USR1 (bit 8)
	IDDMAEN	UCR4 (bit 6)	IDLE	USR2 (bit 12)
<i>dma_req_tx</i>	TXDMAEN	UCR1 (bit 3)	TRDY	USR1 (bit 13)

16.2.2.2 Clocks

This section describes clocks and special clocking requirements of the UART.

16.2.2.2.1 Clock requirements

UART module receives 2 clocks, *peripheral_clock* and *module_clock*. The *peripheral_clock* is used as write clock of the TxFIFO, read clock of the Rx FIFO and synchronization of the modem control input pins. It must always be running when UART is enabled. There is an exception in stop mode (see [Clocking in Low-Power Modes](#)).

The *module_clock* is for all the state machines, writing Rx FIFO, reading TxFIFO, etc. It must always be running when UART is sending or receiving characters. This clock is used in order to allow frequency scaling on *peripheral_clock* without changing configuration of baud rate (*module_clock* staying at a fixed frequency).

The constraints on *peripheral_clock* and *module_clock* are as follows:

- *peripheral_clock* and *module_clock* can totally be asynchronous. They can also be synchronous.
- Due to the 16x oversampling of the incoming characters, *module_clock* frequency must always be greater or equal to 16x the maximum baud rate. For example, if max baud rate is 4 Mbit/s, *module_clock* must be greater or equal to $4 \text{ M} \times 16 = 64 \text{ MHz}$.

NOTE

The restriction that *peripheral_clock* frequency must be higher or equal to 16x baud rate has been removed. There is no limitation on *peripheral_clock* frequency to baud rate.

16.2.2.2.2 Maximum Baud Rate

The max baud rate the UART can support is determined by the max frequency of the *module_clock*.

For example, if the SoC can provide the fastest *module_clock* 66.5 MHz, the UART can transmit and receive serial data with the maximum baud rate $66.5\text{M}/16 = 4.15 \text{ Mbit/s}$.

The UART supports serial IR interface low speed. In the low speed IrDA mode, the max baud rate is 115.2 Kbit/s. To support the 115.2 Kbit/s, *module_clock* frequency must be higher or equal to 1.8432 MHz.

16.2.2.2.3 Clocking in Low-Power Modes

The UART supports 2 low-power modes: DOZE and STOP.

In STOP mode (input pin *stop_req* is at '1'), the UART doesn't need any clock. In this mode the UART can wake-up the Arm platform with the asynchronous interrupts (see [Low Power Modes](#)).

- If before entering in STOP mode the software has enabled RTSDEN interrupt, when RTS will change state (put at '0' by external device started to send), the asynchronous interrupt will wake-up the system, *peripheral_clock* and *module_clock* will be provided to the UART before first start bit, so that no data will be lost.
- If RTS doesn't change state (already at '0' before entering in STOP mode), then wake-up interrupt (AWAKE) will be sent at the arrival of first Start bit (on falling edge). In this case, the UART must receive the *peripheral_clock* and *module_clock* during the first half of start bit to correctly receive this character (for example, at 115.2 Kbit/s, UART must receive *peripheral_clock* and *module_clock* at maximum 4.3 microseconds after falling edge of Start bit). If the UART receives *peripheral_clock* and *module_clock* too late, first character will be lost, and so should be dropped. Also, if autobaud detection is enabled, the first character won't be correctly received and another autobaud detection will need to be initiated.

In Doze mode, UART behavior is programmable through DOZE bit (UCR1[1]). If DOZE bit is set to '1', then UART is disabled in Doze mode, and in consequence, UART clocks can be switched-off (after being sure UART is not transmitting nor receiving). On the contrary, if DOZE bit is set to '0', UART is enabled and it must receive *peripheral_clock* and *module_clock*.

16.2.2.3 General UART Definitions

Definitions of terms that occurs the following discussions are given in this section.

- Bit Time-The period of time required to serially transmit or receive 1 bit of data (1 cycle of the baud rate frequency).
- Start bit-The bit time of a logic 0 that indicates the beginning of a data frame. A start bit begins with a 1-to-0 transition, and is preceded by at least 1 bit time of logic 1.
- Stop bit-1 bit time of logic 1 that indicates the end of a data frame.
- BREAK-A frame in which all of the data bits, including the stop bit, are logic 0. This type of frame is usually sent to signal the end of a message or the beginning of a new message.
- Mark - When no data is being sent, the serial port's transmit pin's voltage is 1 and is said to be in a MARK state.

- Space - The serial port can also be forced to keep the transmit pin at a 0 and is said to be the SPACE or BREAK state.
- Frame-A start bit followed by a specified number of data or information bits and terminated by a stop bit. The number of data or information bits depends on the format specified and must be the same for the transmitting device and the receiving device. The most common frame format is 1 start bit followed by 8 data bits (least significant bit first) and terminated by 1 stop bit. An additional stop bit and a parity bit also can be included.
- Framing Error-An error condition that occurs when the stop bit of a received frame is missing, usually when the frame boundaries in the received bit stream are not synchronized with the receiver bit counter. Framing errors can go undetected if a data bit in the expected stop bit time happens to be a logic 1. A framing error is always present on the receiver side when the transmitter is sending BREAKs. However, when the UART is programmed to expect 2 stop bits and only the first stop bit is received, this is not a framing error by definition.
- Parity Error-An error condition that occurs when the calculated parity of the received data bits in a frame does not match the parity bit received on the RX_DATA input. Parity error is calculated only after an entire frame is received.
- Idle-One in NRZ encoding format and selectable polarity in IrDA mode.
- Overrun Error-An error condition that occurs when the latest character received is ignored to prevent overwriting a character already present in the UART receive buffer (RxFIFO). An overrun error indicates that the software reading the buffer (RxFIFO) is not keeping up with the actual reception of characters on the RX_DATA input.

16.2.2.3.1 RTS_B - UART Request To Send

The UART Request To Send input controls the transmitter. The modem or other terminal equipment signals the UART when it is ready to receive by setting '0' on the RTS_B pin.

Normally, the transmitter waits until this signal is active (low) before transmitting a character, however when the Ignore RTS (IRTS) bit is set, the transmitter sends a character as soon as it is ready to transmit. An interrupt (RTSD) can be posted on any transition of this pin and can wake the Arm platform from STOP mode on its assertion. When RTS_B is set to '1' during a transmission, the UART transmitter finishes transmitting the current character and shuts off. The contents of the TxFIFO (characters to be transmitted) remain undisturbed. The operation of this input is the same regardless of whether the UART is in DTE or DCE mode.

16.2.2.3.2 RTS Edge Triggered Interrupt

The input to the RTS_B pin can be programmed to generate an interrupt on a selectable edge.

See the table below for summary of the operation of the RTS edge triggered interrupt (RTSF).

To enable the RTS_B pin to generate an interrupt, set the request to send interrupt enable (RTSEN) bit (UCR2[4]) to 1. Writing 1 to the RTS_B edge triggered interrupt flag (RTSF) bit (USR2[4]) clears the interrupt flag. The interrupt can occur on the rising edge, falling edge, or either edge of the RTS_B input. The request to send edge control (RTEC) field (UCR2[10:9]) programs the edge that generates the interrupt. When RTEC is set to 0x00 and RTSEN = 1, the interrupt occurs on the rising edge (default). When RTEC is set to 0x01 and RTSEN = 1, the interrupt occurs on the falling edge. When RTEC is set to 0x1X and RTSEN = 1, the interrupt occurs on either edge. This is a synchronous interrupt. The RTSF bit is cleared by writing 1 to it. Writing 0 to RTSF has no effect.

Table 16-4. RTS_B Edge Triggered Interrupt Truth Table

RTS_B	RTSEN	RTEC [1]	RTEC [0]	RTSF	Interrupt Occurs On...	interrupt_uart
X	0	X	X	0	Interrupt disabled	1
1->0	1	0	0	0	Rising edge	1
0->1	1	0	0	1	Rising edge	0
1->0	1	0	1	1	Falling edge	0
0->1	1	0	1	0	Falling edge	1
1->0	1	1	X	1	Either edge	0
0->1	1	1	X	1	Either edge	0

There is another RTS_B interrupt that is not programmable. The status bit RTSD asserts the *interrupt_uart* interrupt when the RTS_B delta interrupt enable = 1. This is an asynchronous interrupt. The RTSD bit is cleared by writing 1 to it. Writing 0 to the RTSD bit has no effect.

16.2.2.3.3 CTS_B - Clear To Send

This output pin serves two purposes. Normally, the receiver indicates that it is ready to receive data by asserting this pin (low). When the CTS_B trigger level is programmed to trigger at 32 characters received and the receiver detects the valid start bit of the 33 character, it de-asserts this pin. The operation of this output is the same regardless of whether the UART is in DTE or DCE mode.

16.2.2.3.4 Programmable CTS_B Deassertion

The CTS_B output can also be programmed to deassert when the RxFIFO reaches a certain level. Setting the CTS trigger level (UCR4[15:10]) at any value less than 32 deasserts the CTS_B pin on detection of the valid start bit of the N + 1 character (where N is the trigger level setting). However, the receiver continues to receive characters until the RxFIFO is full.

16.2.2.3.5 TX_DATA - UART Transmit

This is the transmitter serial output. When operating in RS-232/RS-485 mode, NRZ encoded data is transmitted, and the data can be inverted (controlled by INVT (UCR3[1])) before transmitted. When operating in infrared mode, a 3/16 bit-period pulse is output for each 0 bit transmitted, and no pulse is output for each 1 bit transmitted.

For RS-232/RS-485 applications, this pin must be connected to an RS-232/RS-485 transmitter. The operation of this output is the same regardless of whether the UART is in DTE or DCE mode. See [Figure 16-10](#).

16.2.2.3.6 RX_DATA - UART Receive

This is the receiver serial input. When operating in RS-232/RS-485 mode, NRZ encoded data is expected, and the data can be inverted (controlled by INVR (UCR4[9])) before sampled. When operating in infrared mode, a narrow pulse is expected for each 0 bit received and no pulse is expected for each 1 bit received.

External circuitry must convert the IR signal to an electrical signal. RS-232/RS-485 applications require an external RS-232/RS-485 receiver to convert voltage levels. The operation of this input is the same regardless of whether the UART is in DTE or DCE mode. See the figure below.

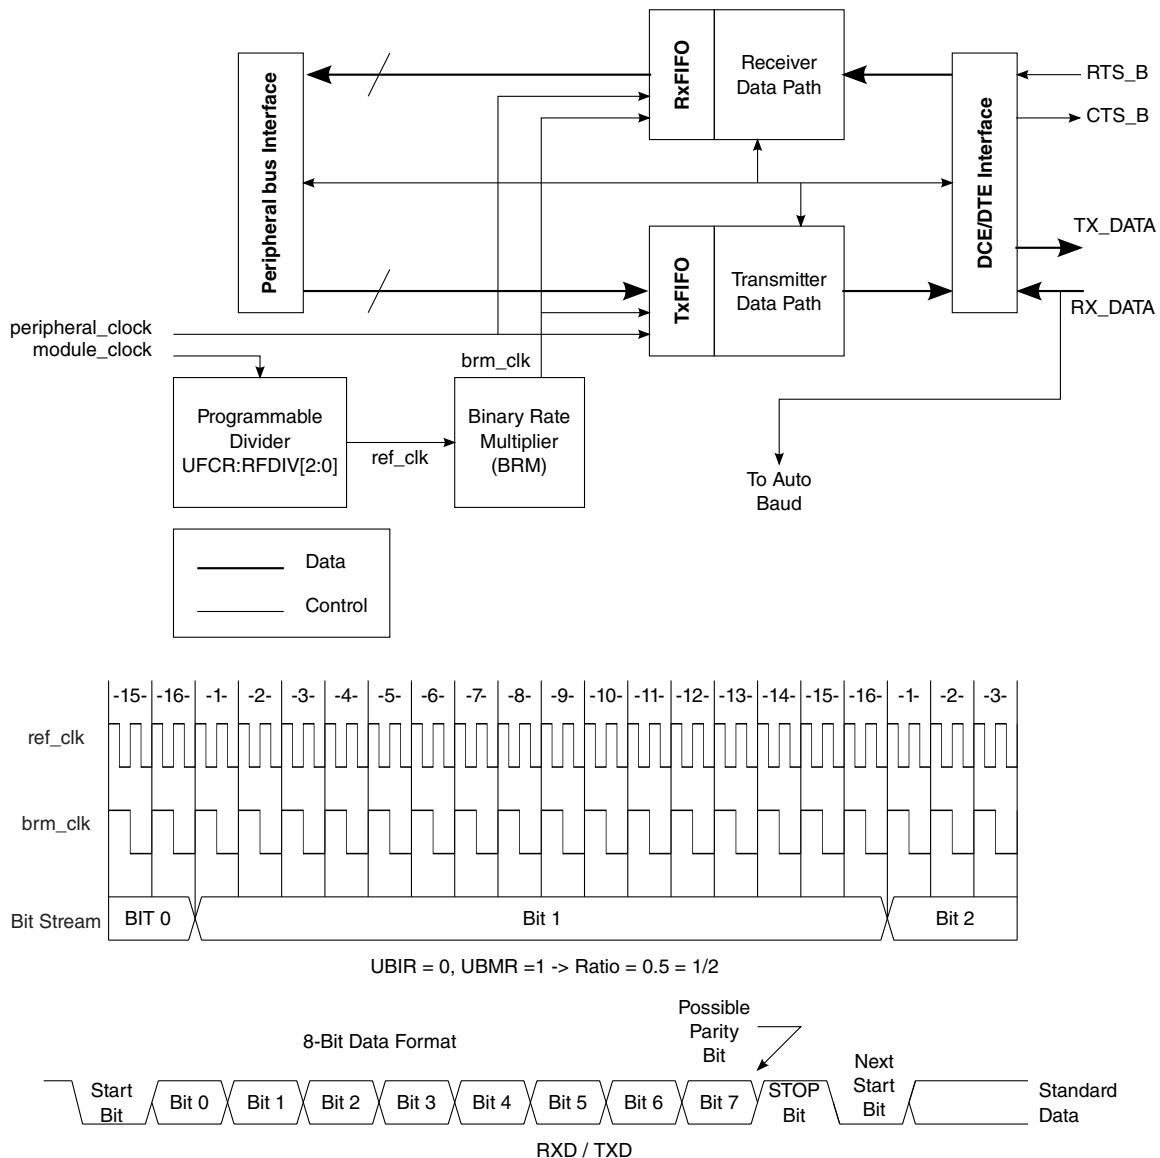

Figure 16-10. UART Simplified Block and Clock Generation Diagrams

16.2.2.4 Transmitter

The transmitter accepts a parallel character from the Arm platform and transmits it serially. The start, stop, and parity (when enabled) bits are added to the character.

When the ignore RTS bit (IRTS) is set, the transmitter sends a character as soon as it is ready to transmit. RTS_B can be used to provide flow-control of the serial data. When RTS_B is set to '1', the transmitter finishes sending the character in progress (if any), stops, and waits for RTS_B to be set to '0' again. Generation of BREAK characters and parity errors (for debugging purposes) is supported. The transmitter operates from the clock provided by the Binary Rate Multiplier(BRM). Normal NRZ encoded data is transmitted when the IR interface is disabled.

The transmitter FIFO (TxFIFO) contains 32 bytes. The data is written to TxFIFO by writing to the UTXD register with the byte data to the [7:0] bits. The data is written consecutively if the TxFIFO is not full. It is read (internally) consecutively if the TxFIFO is not empty. TXFULL bit (UTS[4]) can be used to control whether TxFIFO is full or not. The TxFIFO can be written regardless of the transmitter is disabled or enabled. If the UART is disabled, user can still write data into the TxFIFO correctly. But in this case the write access will yield to a transfer error.

16.2.2.4.1 Transmitter FIFO Empty Interrupt Suppression

The transmitter FIFO empty interrupt suppression logic suppresses the TXFE interrupt between writes to the TxFIFO.

When TxFIFO is empty, the software can either send one or several characters. If the software sends one character, it would write the character into the UTXD register, then that character is immediately transferred to the transmitter shift register, assuming the transmitter is already enabled. Without interrupt suppression logic, the TXFE interrupt flag would be set immediately. But, with this logic, the interrupt flag is set when the last bit of the character has been transmitted, for example, before the transmission of the parity bit (if exists) and the stop bit(s).

So, the suppression logic doesn't immediately send the TXFE interrupt flag. It allows the software to write another character to the TxFIFO before the interrupt flag is asserted.

When the transmitter shift register empties before another character is written to the TxFIFO, the interrupt flag is asserted. Writing data to the TxFIFO would release the interrupt flag. The interrupt flag is asserted on the following conditions:

- System Reset
- UART software reset

- When a single character has been written to Transmitter FIFO and then the Transmitter FIFO and the Transmitter Shift Register become empty until another character is written to the Transmitter FIFO
- The last character in the TxFIFO is transferred to the shift register, when TxFIFO contains two or more characters. See the figure below.

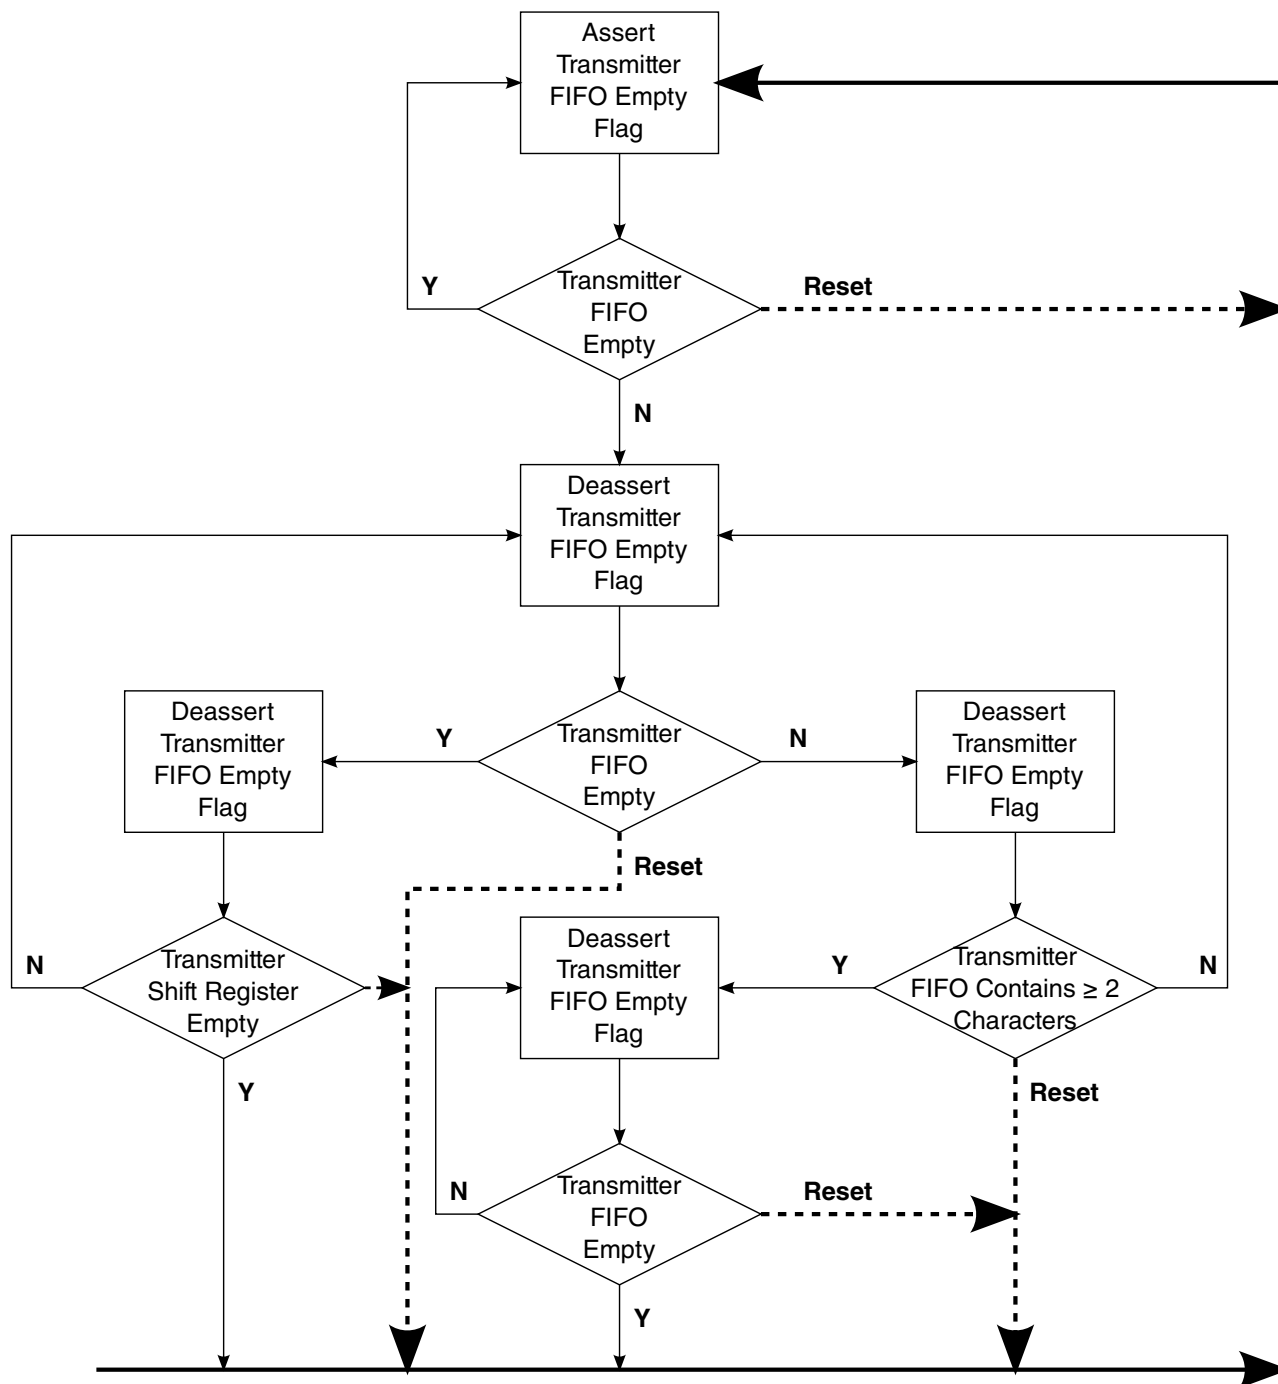

Figure 16-11. Transmitter FIFO Empty Interrupt Suppression Flow Chart

16.2.2.4.2 Transmitting a Break Condition

Asserting SNDBRK bit of the UCR1 Register forces the transmitter to send a break character (continuous zeros). The transmitter will finish sending the character in progress (if any) before sending break until this bit is reset.

The user is responsible to ensure that this bit is high for long enough to generate a valid BREAK. The transmitter samples SNDBRK after every bit is transmitted. Following completion of the BREAK transmission, the UART will transmit two mark bits. The user can continue to fill the FIFO and any character remaining will be transmitted when the break is terminated.

16.2.2.5 Receiver

See the figure below for the receiver flow chart.

The receiver accepts a serial data stream and converts it into parallel characters. When enabled, it searches for a start bit, qualifies it, and samples the following data bits at the bit-center.

Jitter tolerance and noise immunity are provided by sampling at a 16x rate and using voting techniques to clean up the samples. Once the start bit is found, the data bits, parity bit (if enabled), and stop bits (either 1 or 2 depending on user selection) are shifted in. Parity is checked and its status reported in the URXD register when parity is enabled. Frame errors and BREAKs are also checked and reported. When a new character is ready to be read by the Arm platform from the Rx FIFO, the receive data ready (RDR = $USR2[0]$) bit is asserted and an interrupt is posted (if $DREN = UCR4[0] = 1$). If the receiver trigger level is set to 2 ($RXTL[5:0] = UFCR[5:0] = 2$), and 2 chars have been received into Rx FIFO, the receiver ready interrupt flag ($RRDY = USR1[9]$) is asserted and an interrupt is posted if the receiver ready interrupt enable bit is set ($RRDYEN = UCR1[9] = 1$). If the UART Receiver Register (URXD) is read once, and in consequence there is only 1 character in the Rx FIFO, the interrupt generated by the RDR bit is automatically cleared. The RRDY bit is cleared when the data in the Rx FIFO falls below the programmed trigger level.

Normal NRZ encoded data is expected when the IR interface is disabled. The Rx FIFO contains 32 half-word entries. Characters received are written consecutively into this FIFO. If the FIFO is full and a 33rd character is received, this character will be ignored and the $USR2[ORE]$ bit will be set.

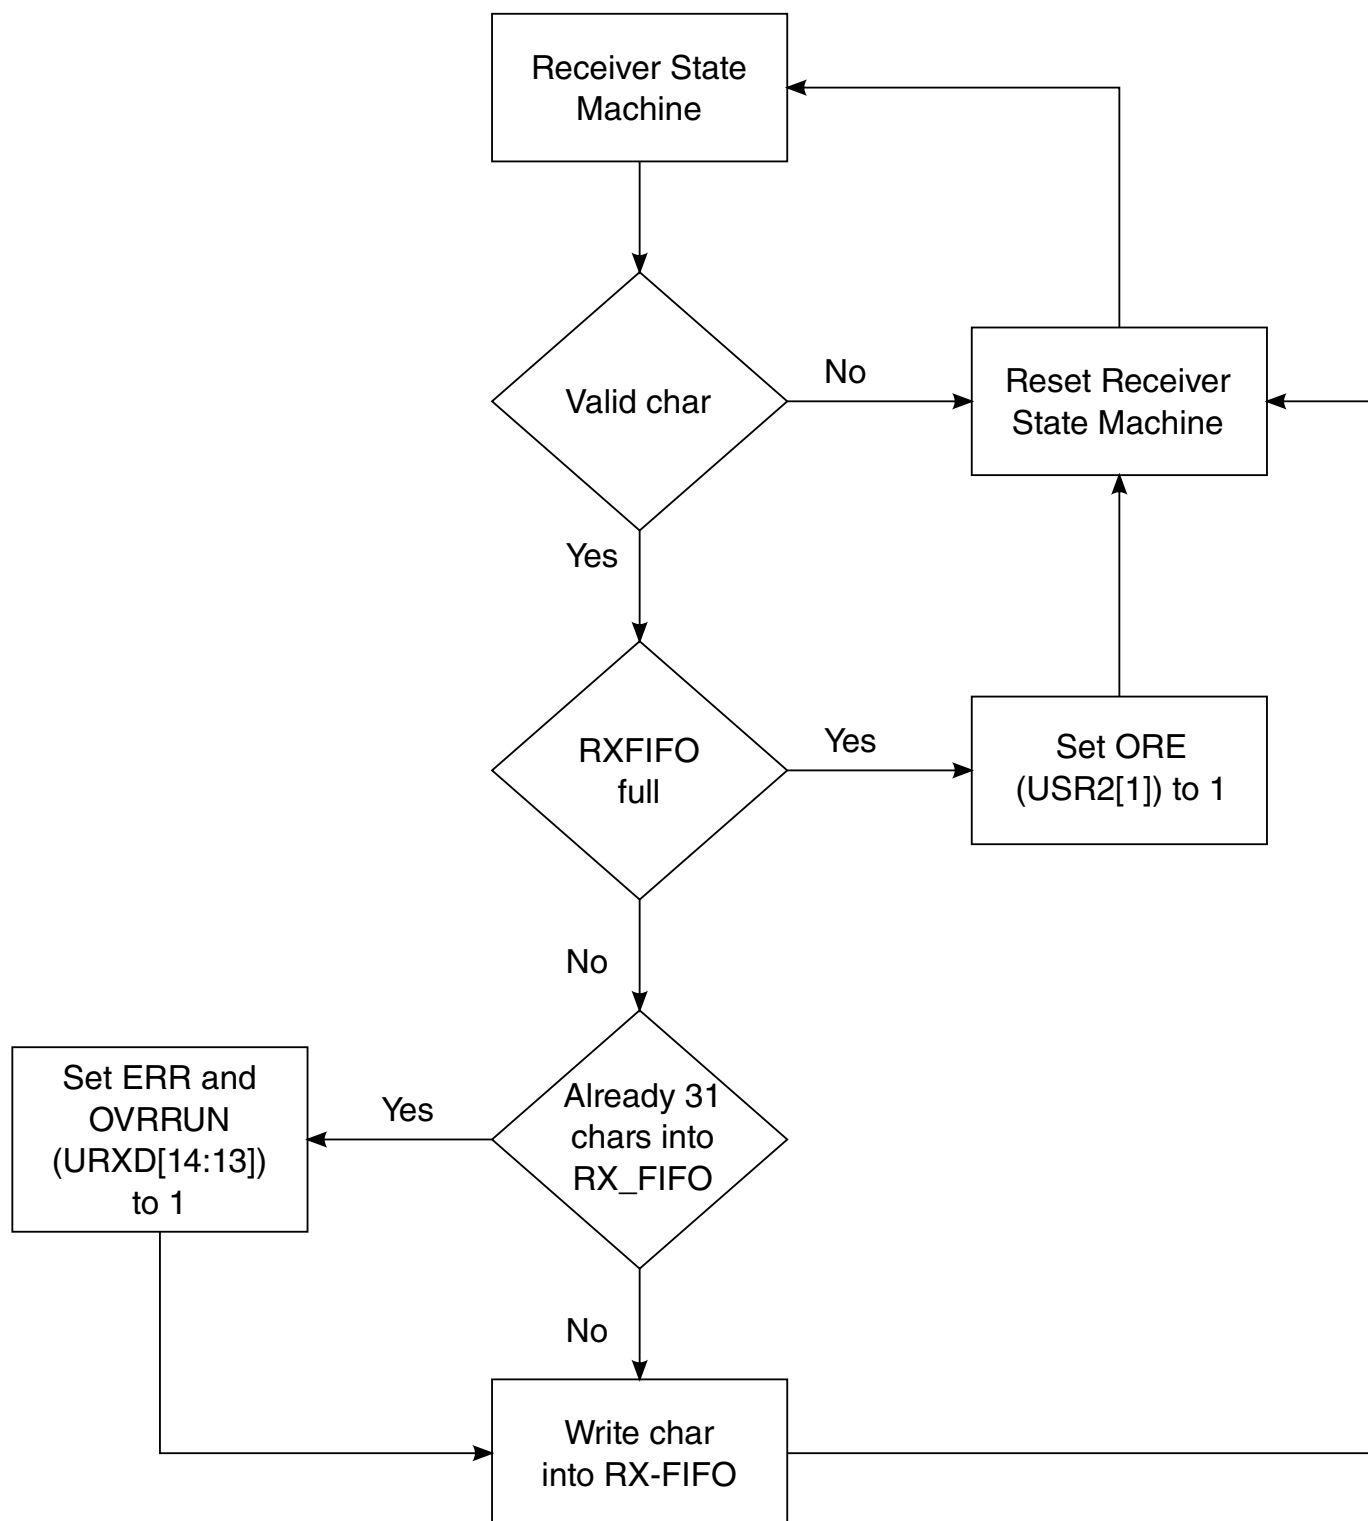

Figure 16-12. Receiver Flow Chart

16.2.2.5.1 Idle Line Detect

The receiver logic block includes the ability to detect an idle line. Idle lines indicate the end or the beginning of a message.

For an idle condition to occur:

- RxFIFO must be empty and
- RX_DATA pin must be idle for more than a configured number of frames (ICD[1:0] = UCR1[11:10]).

When the idle condition detected interrupt enable (IDEN = UCR1[12]) is set and the line is idle for 4 (default), 8, 16, or 32 (maximum) frames, the detection of an idle condition flags an interrupt (see the table below). When an idle condition is detected, the IDLE (USR2[12]) bit is set. Clear the IDLE bit by writing 1 to it. Writing 0 to the IDLE bit has no effect.

Table 16-5. Detection Truth Table

IDEN	ICD [1]	ICD [0]	IDLE	<i>interrupt_uart</i>
0	X	X	0	1
1	0	0	asserted after 4 idle frames	asserted after 4 idle frames
1	0	1	asserted after 8 idle frames	asserted after 8 idle frames
1	1	0	asserted after 16 idle frames	asserted after 16 idle frames
1	1	1	asserted after 32 idle frames	asserted after 32 idle frames
NOTE: This table assumes that no other interrupt is set at the same time this interrupt is set for the <i>interrupt_uart</i> signal. This table shows how this interrupt affects the <i>interrupt_uart</i> signal.				

During a normal message there is no idle time between frames. When all of the information bits in a frame are logic 1s, the start bit ensures that at least one logic 0 bit time occurs for each frame so that the IDLE bit is not asserted.

16.2.2.5.2 Aging Character Detect

The receiver block also includes the possibility to detect when at least one character has been sitting into the RxFIFO for a time corresponding to 8 characters. This aging character capability allows the UART to inform the Arm platform that there is less character into the RxFIFO than the Rx trigger and, no new character has been detected on the RXD line.

The aging capability is a timer which starts to count as soon as the RxFIFO is not empty and its trigger level is not reached (RRDY=0). This counter is reset when either a RxFIFO read is performed or another character starts to present on the RXD line. If none of those two events occurs, the bit AGTIM (USR1[8]) is set when the counter has

measured a time corresponding to 8 characters. AGTIM is cleared by writing a 1 to it. AGTIM can flag an interrupt to Arm platform on *interrupt_uart* if ATEN (UCR2[3]) has been set.

To summarize, AGTIM is set when:

- There is at least one character into RxFIFO.
- No read has occurred on RxFIFO and RXD line has stayed high, for a time corresponding to 8 characters.
- The RxFIFO trigger is not reached (RRDY=0)

16.2.2.5.3 Receiver Wake

The WAKE bit (USR2[7]) is set when the receiver detects a qualified Start bit. For this, two conditions must be fulfilled, firstly a falling edge on RX_DATA line must be detected and secondly the RX_DATA line must stay at low level for more than a half-bit duration.

When the wake interrupt enable WKEN (UCR4[7]) bit is enabled, the receiver flags an interrupt (*interrupt_uart*) if the WAKE status bit is set. The WAKE bit is cleared by writing 1 to it. Writing 0 to the WAKE bit has no effect. The WAKE status bit can be asserted in either serial RS-232 mode or IR mode. The generation of the WAKE interrupt needs the clock *module_clock* .

When the asynchronous wake interrupt (AWAKE) is enabled (AWAKEN = UCR3[4] = 1), and the Arm platform is in STOP mode, and UART clocks have been shut-off, then a falling edge detected on the receive pin (RX_DATA) asserts the AWAKE bit (USR1[4]) and the *interrupt_uart* interrupt to wake the Arm platform from STOP mode. Re-enable UART clocks and clear the AWAKE bit by writing 1 to it. Writing 0 to the AWAKE bit has no effect. When IR interface is enabled (UCR1[7]=1), the AWAKE bit is always not asserted. The generation of the asynchronous AWAKE interrupt does not need any clocks.

In IR mode, if the asynchronous IR WAKE interrupt is enabled (AIRINTEN = UCR3[5] = 1), and if the Arm platform is in STOP mode (UART clocks are off when Arm platform in STOP mode), then the detection of a falling edge on the receive pin (RXD_IR), asserts the AIRINT bit (USR1[5]), and the *interrupt_uart* interrupt. This interrupt wakes the Arm platform from STOP mode. Software re-enables UART clocks and clear the AIRINT bit by writing 1 to it. Writing 0 to the AIRINT bit has no effect. When IR interface is disabled (UCR1[7]=0), the AIRINT bit is always not asserted. The generation of the asynchronous AIRINT interrupt does not need any clocks.

Recommended procedure for programming the asynchronous interrupts is to first clear them by writing 1 to the appropriate bit in the UART Status Register 1 (USR1). Poll or enable the interrupt for the Receiver IDLE Interrupt Flag (RXDS) in the USR1. When asserted, the RXDS bit indicates to the software that the receiver state machine is in the idle state, the next state is idle, and the RX_DATA pin is idle (high). After following this procedure, enable the asynchronous interrupt and enter STOP mode.

16.2.2.5.4 Receiving a BREAK Condition

A BREAK condition is received when the receiver detects all 0s (including a 0 during the bit time of the stop bit) in a frame. The BREAK condition asserts the BRCD bit (USR2[2]) and writes only the first BREAK character to the RxFIFO. Clear the BRCD bit by writing 1 to it. Writing 0 to the BRCD bit has no effect.

Asserting BRCD would generate an interrupt on *interrupt_uart*. The interrupt generation can be masked using the control bit BKEN (UCR4[2]). Receiving a break condition will also effect the following bits in the receiver register URXD:

URXD(11) = BRK. While high this bit indicates that the current char was detected as a break.

URXD(12) = FRMERR. The frame error bit will always be set when BRK is set.

URXD(10) = PRERR. If odd parity was selected the parity error bit will also be set when BRK is set.

URXD(14) = ERR. The error detect bit indicates that the character present in the rx data field has an error status. This can be asserted by a break.

16.2.2.5.5 Vote Logic

The vote logic block provides jitter tolerance and noise immunity by sampling with respect to a 16x clock (*brm_clk*) and using voting techniques to clean up the samples. The voting is implemented by sampling the incoming signal constantly on the rising edge of the *brm_clk*.

See [Figure 16-13](#). The receiver is provided with the majority vote value, which is 2 out of the 3 samples. For examples of the majority vote results of the vote logic, see the following table.

Table 16-6. Majority Vote Results

Samples	Vote
000	0

Table continues on the next page...

Table 16-6. Majority Vote Results (continued)

Samples	Vote
101	1
001	0
111	1

The vote logic captures a sample on every rising edge of *brm_clk*, however the receiver uses 16x oversampling to take its value in the middle of the sample character.

The receiver starts to count when the Start bit is set however it does not capture the contents of the RxFIFO at the time the Start bit is set. The start bit is validated when 0s are received for 7 consecutive 1/16 of bit times following the 1-to-0 transition. Once the counter reaches 0xF, it starts counting on the next bit and captures it in the middle of the sampling frame (see [Table 16-6](#)). All data bits are captured in the same manner. Once the stop bit is detected, the receiver shift register (SIPO_OUT) data is parallel shifted to the RxFIFO.

**Figure 16-13. Majority Vote Results**

A new feature has been recently implemented, it allows to re-synchronize the counter on each edge of RX_DATA line. This is automatic and allows to improve the immunity of UART against signal distortion.

There is a special case when the *brm_clk* frequency is too low and is unable to capture a 0 pulse in IrDA. In this case, the software must set the IRSC (UCR4[5]) bit so that the reference clock (after internal divider) is used for the voting logic. The pulse is validated by counting the length of the pulse.

Refer to [Infrared Interface](#) for more details.

16.2.2.5.6 Baud Rate Automatic Detection Logic

When the baud rate automatic detection logic is enabled, the UART locks onto the incoming baud rate. To enable this feature, set the automatic detection of baud rate bit (ADBR = UCR1[14] = 1) and write 1 to the ADET bit (USR2[15]) to clear it.

When ADET=0 and ADBR =1, the detection starts. Then, once the beginning of start bit (transition from 1-to-0 of RX_DATA) has been detected, UART starts a counter (UBRC) working at reference frequency. Once the end of start bit is detected (transition from 0-to-1 of RX_DATA), the value of UBRC - 1 is directly copied into UBMR register. UBIR register is filled with 0x000F.

So, at the end of start bit, registers gets following values:

```
UBRC = number of reference clock periods (after divider) during Start bit.
UBIR = 0x000F
UBMR = UBRC - 1
```

The updated values of the 3 registers can be read.

See [Table 16-7](#) for list of parameters for baud rate detection and [Figure 16-14](#) for baud rate detection protocol diagram.

If any of the UART BRM registers are simultaneously written by the baud rate automatic detection logic and by the peripheral data bus, the peripheral data bus would have lower priority.

Table 16-7. Baud Rate Automatic Detection

ADBR	ADET	Baud Rate Detection	<i>interrupt_uart</i>
0	X	Manual Configuration	1
1	0	Auto Detection Started	1
1	1	Auto Detection Complete	0
NOTE: This table assumes that no other interrupt is set at the same time this interrupt is set for the <i>interrupt_uart</i> signal.			

Note: LSB Transmitted first.

Figure 16-14. Baud Rate Detection Protocol Diagram

16.2.2.5.6.1 Baud Rate Automatic Detection Protocol

The receiver must receive an ASCII character "A" or "a" to verify proper detection of the incoming baud rate. When an ASCII character "A" (0x41) or "a" (0x61) is received and no error occurs, the Automatic Detect baud rate bit is set (ADET=1) and if the interrupt is enabled (ADEN=UCR1[15]=1), an interrupt *interrupt_uart* is generated.

When an ASCII character "A" or "a" is not received (because of a bit error or the reception of another character), the auto detection sequence restarts and waits for another 1-to-0 transition.

As long as ADET = 0 and ADBR = 1, the UART continues to try to lock onto the incoming baud rate. Once the ASCII character "A" or "a" is detected and the ADET bit is set, the receiver ignores the ADBR bit and continues normal operation with the calculated baud rate.

The UART interrupt is active (*interrupt_uart* = 0) as long as ADET = 1 and ADBR = 1. This can be disabled by clearing the automatic baud rate detection interrupt enable bit (ADEN = 0). Before starting an automatic baud rate detection sequence, set ADET = 0 and ADBR = 1.

The Rx FIFO must contain the ASCII character "A" or "a" following the automatic baud rate detection interrupt.

The 16-bit UART Baud Rate Count Register (UBRC) is reset to 4 and stays at 0xFFFF when an overflow occurs. The UBRC register counts (measures) the duration of start bit. When the start bit is detected and counted, the UART Baud Rate Count Register retains its value until the next automatic baud rate detection sequence is initiated.

The Baud Rate Count Register counts only when auto detection is enabled.

16.2.2.5.6.2 New Baud Rate Determination

In order to fight against the problems caused by the distortion and the noise on the RX_DATA line, the duration of the baud rate measurement has been extended.

Previously, as described above, this determination was based on the measurement of the START bit duration. Now, this measurement is based on the duration of START bit + bit0. Bit0 is the first bit following the START bit. In fact, the counter which is started at the falling edge of START bit is no longer stopped at next rising edge (end of START bit), but it is stopped at the next falling edge (end of bit0). As the character sent is always a "A" (41h) or a "a" (61h), this second falling edge will always be present and it will indicate the end of bit0. Once this counter is stopped, the result is divided by 2 and used by the BRM to determine the incoming baud rate.

NOTE

UBRC register contains the result of this division by two, in consequence it reflects the measurement of the duration of one bit.

16.2.2.5.6.2.1 New Autobaud Counter Stopped bit and Interrupt

A new bit has been added in USR2 register: ACST (USR2[11]). This bit is set immediately after the determination of the baud rate.

So,

- if ADNIMP is not set (default), ACST is set to 1 after the end of bit0,
- If ADNIMP is set to 1, ACST is set to 1 at the end of START bit.

If ACIEN (UCR3[0]) is set to 1, ACST will flag an interrupt on *interrupt_uart* signal. This interrupt informs the Arm platform that the BRM has just been set with the result of the bit length measurement. If needed, the Arm platform can perform a read of UBMR (or UBRC) register and determine by itself the baud rate measured. Then the Arm platform has the possibility to correct the BRM registers with the nearest standardized baud rate.

NOTE

ACST is set only if ADBR is set to 1, for example, the UART is autobauding.

Clear the ACST bit by writing 1 to it. Writing 0 to the ACST bit has no effect.

16.2.2.6 Escape Sequence Detection

An escape sequence typically consists of 3 characters entered in rapid succession (such as +++). Because these are valid characters by themselves, the time between characters determines if it is a valid escape sequence.

Too much time between two of the "+" characters is interpreted as two "+" characters, and not part of an escape sequence.

The software chooses the escape character and writes its value to the UART Escape Character Register (UESC). The software must also enable escape detection feature by setting ESCEN (UCR2[11]) to 1. The hardware compares this value to incoming characters in the RxFIFO. When an escape character is detected, the internal escape timer starts to count. The software specifies a time-out value for the maximum allowable time between 2 successive escape characters (see the table below). The escape timer is programmable in intervals of 2 ms to a maximum interval of 8.192 seconds.

Table 16-8. Escape Timer Scaling

UTIM Register	Maximum Time Between Specified Escape Characters
0x000	2 ms
0x001	4 ms
0x002	6 ms
0x003	8 ms
0x004	10 ms
...	...
0F8	498 ms
0F9	500 ms
...	...
9C3	5 s
...	...
FFD	8.188 s
FFE	8.190 s
FFF	8.192 s
NOTE: To calculate the time interval: $(\text{UTIM_Value} + 1) \times 0.002 = \text{Time_Interval}$ Example: $(09C3 + 1) \times 0.002 = 5 \text{ s.}$	

The escape sequence detection feature is available for all the reference frequencies. Before using Escape Sequence Detection, the user must fill the ONEMS register. This 24-bit register must contain the value of the UART internal frequency divided by 1000. The internal frequency is obtained after the UART internal divider which is applied on *module_clock* clock.

Example I:

- If the input clock *module_clock* frequency is 66.5 MHz.
- And if the input clock *module_clock* is divided by 2 with the internal divider:
UFCR[9:7] = 3'b100

$$\text{ONEMS} = \frac{66.5 \times 10^6}{2 \times 1000} = 33250 = 81\text{E}2\text{h}$$

Figure 16-15. Calculation of Frequency for ONEMS Register

Example II:

- If the input clock *module_clock* frequency is 66.5 MHz.
- And if the input clock *module_clock* is divided by 1 with the internal divider:
UFCR[9:7] = 3'b101

$$\text{ONEMS} = \frac{66.5 \times 10^6}{1000} = 66500 = 103\text{C}4\text{h}$$

Figure 16-16. Calculation of Frequency for ONEMS Register

The escape sequence detection interrupt is asserted when the escape sequence interrupt enable (ESCI) bit is set and an escape sequence is detected (ESCF set). Clear the ESCF bit by writing 1 to it. Writing 0 to the ESCF bit has no effect.

16.2.3 Binary Rate Multiplier (BRM)

The BRM sub-block receives *ref_clk* (*module_clock* clock after divider). From this clock, and with integer and non-integer division, BRM generates a 16x baud rate clock .

The UART transmitter will shift data out based on this 16x baud rate clock. The UART receiver will sample the serial data line based on this 16x baud rate clock. The input and output frequency ratio is programmed in the UART BRM Incremental Register (UBIR) and UART BRM MOD Register (UBMR). The output frequency is divided by the input frequency to produce this ratio. For integer division, set the UBIR = 0x000F and write the divisor to the UBMR register. All values written to these registers must be one less than the actual value to eliminate division by 0 (undefined), and to increase the maximum range of the registers.

Updating the BRM registers requires writing to both registers. The UBIR register must be written before writing to the UBMR register. If only one register is written to by the software, the BRM continues to use the previous values.

The following examples show how to determine what values are to be programmed into UBIR and UBMR for a given reference frequency and desired baud rate. The following equation can be used to help determine these values:

$$\text{BaudRate} = \frac{\text{Ref Freq}}{\left(16 \times \frac{\text{UBMR} + 1}{\text{UBIR} + 1} \right)}$$

Figure 16-17. Frequency and Baud Rate for UBIR and UBMR

With:

Reference Frequency (Hz): UART Reference Frequency (*module_clock* after RFDIV divider)

Baud Rate (bit/s): Desired baud rate.

Integer Division ÷ 21

Reference Frequency = 19.44 MHz

UBIR = 0x000F

UBMR = 0x0014

Baud Rate = 925.7 kbit/s

NOTE

Observe that each value written to the registers is one less than the actual value.

Non-Integer Division

Universal Asynchronous Receiver/Transmitter (UART)

Reference Frequency = 16 MHz
Desired Baud Rate = 920 Kbits/s

$$\frac{UBMR + 1}{UBIR + 1} = \frac{\text{RefFreq}}{16 \times \text{BaudRate}} = \frac{16 \times 10^6}{16 \times 920 \times 10^3} = 1.087$$

Ratio = 1.087 = 1087 / 1000
UBIR = 999 (decimal) = 0x3E7
UBMR = 1086 (decimal) = 0x43E
Non-Integer Division
Reference Frequency = 25 MHz
Desired Baud Rate = 920 kbit/s
Ratio = 1.69837 = 625 / 368
UBIR = 367 (decimal) = 0x16F
UBMR = 624 (decimal) = 0x270

Non-Integer Division

Reference Frequency: 30 MHz
Desired Baud Rate = 115.2 kbit/s
Ratio = 16.276043 = 65153 / 4003
UBIR = 4002 (decimal) = 0x0FA2
UBMR = 65152 (decimal) = 0xFE80

16.2.4 Infrared Interface

16.2.4.1 Generalities-Infrared

The Infrared interface is selected when IREN (UCR1[7]) is set to 1.

The Infrared Interface is compatible with IrDA Serial Infrared Physical Layer Specification. In this specification, a "zero" is represented by a positive pulse, and a "one" is represented by no pulse (line remains low).

In the UART:

In TX: For each "zero" to be transmitted, a narrow positive pulse which is 3/16 of a bit time is generated. For each "one" to be transmitted no pulse is generated (output is low). External circuitry has to be provided to drive an Infrared LED.

In RX: When receiving, a narrow negative pulse is expected for each "zero" transmitted while no pulse is expected for each "one" transmitted (input is high).

NOTE

Rx part of IR block expects to receive an inverted signal compared to IrDA specification. Circuitry external to the IC transforms the Infrared signal to an electrical signal.

The IR interface has an edge triggered interrupt (IRINT). This interrupt validates a zero bit being received. This interrupt is enabled by writing a "one" to ENIRI bit.

The behavior of Infrared Interface is determined by 3 bits INVT (UCR3[1]), INVR (UCR4[9]) and IRSC (UCR4[5]).

16.2.4.2 Inverted Transmission and Reception bits (INVT & INVR)

The values of INVT and INVR depend of the IrDA transceiver connected on the TXD_IR and RXD_IR pins of the UART. If this transceiver is not inverting on both paths Tx and Rx, a Zero is represented by a positive pulse and a One is represented by no pulse (line remains low). In this case, the bit INVT must be set to 0 and the bit INVR must be set to 1 (because Rx IR block expects an inverted signal).

On the contrary user must set INVT=1 and INVR=0 if both paths of the transceiver are inverting, that is, a Zero is represented as a negative pulse and a One is represented by no pulse (line remains high). The transceiver can also be inverting on only one path (Tx or Rx), in this case INVT and INVR must be together equal to 1 or to 0, depending on which path is inverted.

16.2.4.3 InfraRed Special Case (IRSC) Bit

The value to apply to IRSC bit is based on 2 parameters: the baud rate and the Minimum Pulse Duration (MPD) of the transceiver.

According to IrDA Standard Specification, for SIR (Serial IR) baud rates from 2.4 Kbit/s to 115.2 Kbit/s this nominal pulse duration is equal to 3/16 of a bit duration (at the selected baud rate). But, for all the baud rates a Minimum Pulse Duration is also specified. According to IrDA Standard, a Zero is represented by a light pulse, so the IrDA transceiver can't emit a light pulse shorter than the MPD. For SIR, the MPD is constant and equal to 1.41 μ s.

But user must take into account the electrical MPD associated with the transceiver on the receiver path. Typically this value is 2.0 μ s, but for some manufacturers MPD can go down to 1.0 μ s.

In order to understand the meaning of IRSC bit, one must understand how the RX path works in IrDA mode.

When the UART is in IrDA mode, a Zero is not only detected by the state of the RXD_IR line, but also with the duration of the pulse. This pulse duration can be measured with 2 different clocks. In this case, clock is selected with the IRSC bit.

- If IRSC = 0, the clock used is the BRM clock.
- If IRSC = 1, the clock used is the UART internal clock (UART clock after the divider (RFDIV)).

In normal operation, IRSC=0. This means that at any time, the user must ensure that the frequency of BRM_clock is high enough to measure the pulse. The pulse must last at least 2 BRM clock cycles. If this condition is not fulfilled, IRSC must be set to 1.

Let's examine two examples, for a Minimum Pulse Duration equal to the MPD from the IrDA SIR specification (i.e., 1.41 μ s).

1: Calculation of BRM Clock Period (Clock Period < 1.41 μ s)

The user wants to receive IrDA data at 115.2 Kbit/s. The UBIR and UBMR registers are set in order to create the BRM_clock with a frequency of $16 \times \text{baud rate} = 16 \times 115.2\text{K} = 1.843\text{ MHz}$. But at the same time, in order to correctly detect the pulse, the user must be sure that $2 \times \text{BRM_clock period}$ is lower than 1.41 μ s. Let's check:

$\text{BRM_clock period} = 1/1843000 = 542\text{ ns}$

So $2 \times \text{BRM_clock period} = 1.09\text{ }\mu\text{s} < 1.41\text{ }\mu\text{s}$. It is fine.

2: Calculation of BRM Clock Period (Clock Period > 1.41 μ s)

This time the user wants to receive at 19.2 Kbit/s. So, the BRM_clock is set to $16 \times 19200 = 307.2\text{ kHz}$. Let's check if $2 \times \text{BRM_clock period} < 1.41\text{ }\mu\text{s}$:

1. $\text{BRM_clock period} = 1/307200 = 3.25\text{ }\mu\text{s}$

So $2 \times \text{BRM_clock period} = 6.50\text{ }\mu\text{s} >> 1.41\text{ }\mu\text{s}$. It doesn't work.

So, in this case, the BRM clock can't be used to measure the pulse duration and the user must select the UART internal clock by setting IRSC = 1.

NOTE

Like for Escape character detection, when IR Special Case is enabled (IRSC=1), the UART must measure a duration. In order to do that, the user must fill the ONEMS register. Refer to [Escape Sequence Detection](#).

16.2.4.4 IrDA interrupt

Serial infrared mode (SIR) uses an edge triggered interrupt flag IRINT (USR2[8]). When INVR = 0, detection of a falling edge on the RXD pin asserts the IRINT bit. When INVR = 1, detection of a rising edge on the RXD pin asserts the IRINT bit. When IRINT and ENIRI bits are both asserted, the *interrupt_uart* interrupt is asserted. Clear the IRINT bit by writing 1 to it. Writing 0 to the IRINT bit has no effect.

16.2.4.5 Conclusion about IrDA

Before using the UART in IrDA, the baud rate limit must be calculated. This baud rate limit will inform the user if IRSC bit has to be set or not.

Let's determine this limit:

As already described, if IRSC = 0, the following condition must always be fulfilled

$$2 \times \text{BRMClockPeriod} < \text{MinPulseDuration}$$

Figure 16-18. Calculation of Baud Rate

So,

$$\text{BRMClockFrequency} > \frac{2}{\text{MPD}}$$

So, knowing BRM_clock frequency = 16 * Baud Rate, we get:

$$\text{BaudRate} > \frac{1}{8 \times \text{MinPulseDuration}}$$

So, the user needs to set IRSC = 0 when:

- If Minimum Pulse Duration = 2.5 us and Baud Rate > 50 Kbit/s.
- If Minimum Pulse Duration = 2.0 us and Baud Rate > 62.5 Kbit/s.
- If Minimum Pulse Duration = 1.41 us and Baud Rate > 88.6 Kbit/s.

NOTE

For baud rates lower than the limit, IRSC must be set to 1.

16.2.4.6 Programming IrDA Interface

16.2.4.6.1 High Speed

As an example, the following sequence can be used to program the IrDA interface in order to send and receive characters at 115.2 Kbit/s.

Assumptions:

- Input UART clock = 90 MHz
- Internal clock divider = 3 (divide Input UART clock by 3)
- Baud rate = 115.2 Kbit/s
- IrDA transceiver is not inverting on both channels: for Tx and Rx, a Zero is represented by a positive pulse, and a One is represented by no pulse (line stays low).
- Interrupt: Sent to Arm platform when 1 char is received into the Rx FIFO (RDR)

Registers values and Programming orders:

```

UCR1 = 0x0085
UCR1[7] = IREN = 1: Enable IR interface
UCR1[0] = UARTEN = 1: Enable UART
UTS = 0x0000
UFCR = 0x0981
TXTL[5:0] = 0x02: Default value
RFDIV[2:0] = 0x3: Divide Input UART clock by 3 (resulting internal clock is 30 MHz)
RXTL[5:0] = 0x01: Default value
UBIR = 0x0202
UBMR = 0x20BE Baud rate = 115.2 kbit/s with internal clock = 30 MHz
UCR2 = 0x4027
UCR2[14] = IRTS = 1: Ignore level of RTS input signal
UCR2[5] = WS = 1: Characters are 8-bit length
UCR2[2] = TXEN = 1: Enable Rx path
UCR2[1] = RXEN = 1: Enable Tx path
UCR2[0] = SRST_B = 1: No software reset
UCR3 = 0x0000

UCR4 = 0x8201
CTSTL[5:0] = 0x20: Default value
UCR4[9] = INVR = 1: Inverted Infrared Reception (because IrDA transceiver is not inverting)
UCR4[1] = DREN = 1: To enable RDR interrupt (sent when one char is received)

```

The UART is ready to send a character as soon as there is a write into UTXD register. And an interrupt will be sent to Arm platform when a character is received.

16.2.4.6.2 Low Speed

This time, we keep the same assumptions but the speed is now 9.6 Kbit/s. So, this baud rate is below the limit (even with a Min. Pulse Duration of 2.5 us) and thus IRSC must be set to 1.

Assumptions:

- Input UART clock = 90 MHz
- Internal clock divider = 3 (divide Input UART clock by 3)
- Baud rate = 9.6 Kbit/s
- IrDA transceiver is not inverting on both channels: for Tx and Rx, a Zero is represented by a positive pulse, and a One is represented by no pulse (line stays low).
- Interrupt: Sent to Arm platform when 1 char is received into the Rx FIFO (RDR).

Registers values and Programming orders:

```

UCR1 = 0x0085
UCR1[7] = IREN = 1: Enable IR interface
UCR1[0] = UARTEN = 1: Enable UART
UFCR = 0x0981
UFCR[15:10] = TXTL[5:0] = 0x02: Default value
RFDIV[2:0] = 0x3: Divide Input UART clock by 3 (resulting internal clock is 30 MHz)
UFCR[5:0] = RXTL[5:0] = 0x01: Default value
UBIR = 0x00FF
UBMR = 0xC354 Baud rate = 9.6 kbit/s with internal clock = 30 MHz
UCR2 = 0x4027
UCR2[14] = IRTS = 1: Ignore level of RTS input signal
UCR2[5] = WS = 1: Characters are 8-bit length
UCR2[2] = TXEN = 1: Enable Rx path
UCR2[1] = RXEN = 1: Enable Tx path
UCR2[0] = SRST_B = 1: No software reset
UCR3 = 0x0000
UCR3[1] = INVT = 0: Positive pulse represents 0.
UCR4 = 0x8221
UCR4[15:10] = CTSTL[5:0] = 0x20: Default value
UCR4[9] = INVR = 1: Inverted Infrared Reception (because IrDA transceiver is not inverting)
UCR4[5] = IRSC = 1: Because data rate is below the limit and thus the UART internal clock is
used to measure the pulse duration.
UCR4[1] = DREN = 1: To enable RDR interrupt (sent when one char is received)

```

The UART is now ready to send a character as soon as there is a write into UTXD register. An interrupt will be sent to Arm platform when a character is received.

16.2.5 9-bit RS-485 Mode

16.2.5.1 Generalities

The UART provides a 9-bit mode to facilitate multidrop (RS-485) network communication. To enable this mode, set MDEN bit in the UMCR register to 1. When 9-bit RS-485 mode is enabled, UART transmitter can transmit the ninth bit (9th bit) set by TXB8, and UART receiver can differentiate between data frames (9th bit = 0) and address frames (9th bit = 1).

The CTS_B pin can be used to control RS-485 output driver outside the chip.

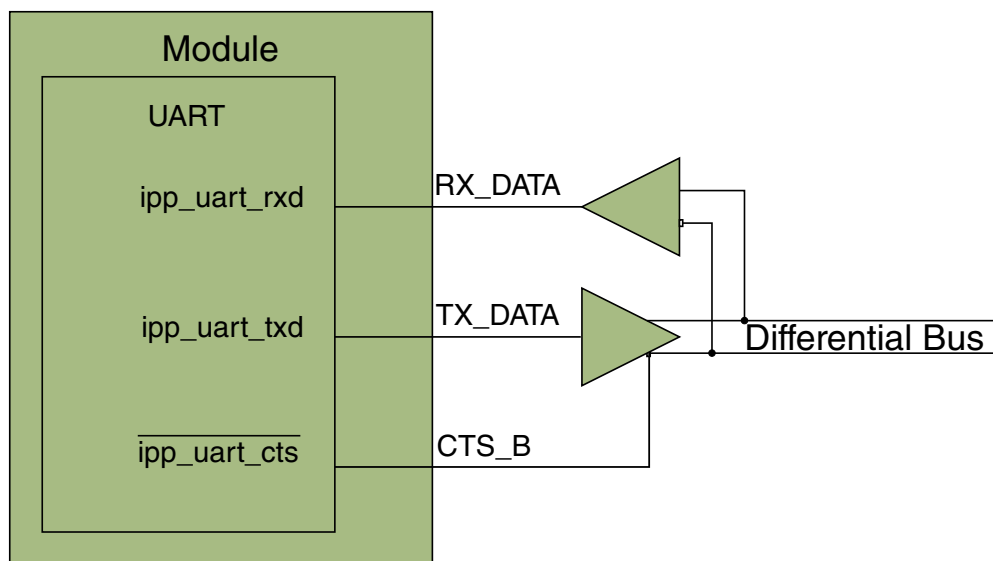

Figure 16-19. RS-485 driver connection (UART in DCE mode)

16.2.5.2 Transmit 9-bit RS-485 frames

To transmit 9-bit RS-485 frames, user need to enable parity (PREN=1) to enable trasmitting the ninth data bit, set 8-bit data word size (WS=1), and write TXB8 (UMCR[2]) as the 9th bit (bit [8]) to be transmitted (write '0' to TXB8 to transmit a data frame, write '1' to transmit a address frame). The other data bit [7:0] is written to TxFIFO by writing to the UTXD same as normal RS-232 operation.

16.2.5.3 Receive 9-bit RS-485 frames

To receive 9-bit RS-485 frames, user need to enable parity (PREN=1) to enable receiving the ninth data bit, set 8-bit data word size (WS=1). The receiver will save the 9-bit data to RxFIFO, and user should read the 9th databit (bit [8]) by reading the PRERR (URXD[10]) bit, and read data bit [7:0] by reading the RX_DATA (URXD[7:0]).

There are two slave address detect modes, normal detect mode and automatic detect mode, and can be selected by SLAM (UMCR[1]).

16.2.5.3.1 RS-485 Slave Address Normal Detect Mode

To enable Normal Detect mode, clear SLAM (UMCR[1] to 0). The receiver ignores all data frames (9th bit = 0) until an address frame is received (9th bit = 1). At that time, the slave address detected (SAD = USR1[3]) bit is asserted and the *interrupt_uart* interrupt is

generated (if SADEN = UMC[3] = 1). The address byte and subsequent bytes are all put into Rx FIFO along with their 9th bit. The UART will also generate DMA request *dma_req_rx* when the Rx FIFO reaches the selected threshold (controlled by RXTL) if receive ready DMA (RXDMAEN = UCR1[8]) request is enabled.

User should read the 9th databit (bit [8]) by reading the PRERR (URXD[10]) bit, and read data bit [7:0] by reading the RX_DATA (URXD[7:0]).

In this mode, once the UART has detected a 9th bit is equal to '1', it will always save the subsequent frames to Rx FIFO. So the software must decide whether the address and data in Rx FIFO are needed or not.

16.2.5.3.2 RS-485 Slave Address Automatic Detect Mode

To enable Automatic Detect Mode, set SLAM (UMCR[1]) to 1. The receiver tries to detect an address byte (frame 9th bit = 1) that matches the programmed SLADDR (UMCR[15:8]) character. If the received byte is a data or an address byte that does not match the programmed SLADDR character, the receiver will discard these data.

Once the UART receives a matching address byte, it will assert the slave address detected (SAD = USR1[3]) bit and the *interrupt_uart* interrupt will be generated (if SADEN = UMC[3] = 1). The address byte and subsequent bytes are all put into Rx FIFO along with their 9th bit. If receive ready DMA (RXDMAEN = UCR1[8]) request is enabled, the UART will also generate DMA request *dma_req_rx* when the Rx FIFO reaches the selected threshold (controlled by RXTL).

If another address byte is received and this address byte does not match SLADDR character, the receiver will discard the address byte and subsequent data byte. If the address byte again matches SLADDR character, the receiver will put this address byte and subsequent data byte in the Rx FIFO along with their 9th bit.

User should read the 9th databit (bit [8]) by reading the PRERR (URXD[10]) bit, and read data bit [7:0] by reading the RX_DATA (URXD[7:0]).

See [Initialization](#) for 9-bit RS-485 programming guide.

16.2.6 Low Power Modes

These modes are controlled by the signals *doze_req* and *stop_req*. The control/status/data registers won't change when getting in/out of low power modes.

Table 16-9. UART Low Power State Operation

	Normal State (<i>doze_req</i> = 1'b0 & <i>stop_req</i> = 1'b0)	Doze State (<i>doze_req</i> = 1'b1)		Stop State (<i>stop_req</i> = 1'b1)
		DOZE bit = 0	DOZE bit = 1	
UART-Clock	ON	ON	ON	OFF
UART Serial / IrDA	ON	ON	OFF	OFF

16.2.6.1 UART Operation in System Doze Mode

While in Doze State (when *doze_req* input pin is set to 1'b1), the UART behavior depends on the DOZE (UCR1[1]) control bit.

While the DOZE bit is negated, the UART serial interface is enabled. While the system is in the Doze State, and the DOZE bit is asserted, the UART is disabled. If the Doze State is entered with the DOZE bit asserted while the UART serial interface was receiving or transmitting data, it will complete the receive/transmit of the current character and signal to the far-end transmitter/receiver to stop sending/receiving.

16.2.6.2 UART Operation in System Stop Mode

The internal baud rate clocks of the transmitter and receiver are gated off if the *stop_req* signal to UART is asserted. Even though the clocks at the input of the UART continue to run during system Stop mode, the UART will not do any transmission or reception.

The following UART interrupts wake the Arm platform processor from STOP mode:

- RTS (RTSD)
- IrDA Asynchronous WAKE (AIRINT)
- Asynchronous WAKE (AWAKE)
- RI (RIDELT in DTE mode only)
- DCD (DCDDELT in DTE mode only)
- DTR (DTRD in DCE mode only)
- DSR (DTRD in DTE mode only)

When an asynchronous WAKE (awake) interrupt exits the Arm platform from STOP mode, make sure that a dummy character is sent first because the first character may not be received correctly.

16.2.6.3 Power Saving Method in UART

The RXEN (UCR2[1]), TXEN (UCR2[2]) and UARTEN (UCR1[0]) bits are set by the user and provide software control of low-power modes.

Setting the UARTEN (UCR1[0]) bit to 0 shuts off the receiver and transmitter logic and the associated clocks.

If the UART is used only in transmit mode, UARTEN and TXEN must be set to 1. If the UART is used only in receive mode, UARTEN and RXEN must be set to 1. Setting TXEN or RXEN to 0 allows to save a lot of power.

16.2.7 UART Operation in System Debug State

The bit UTS [11] controls whether the UART will respond to the input signal *debug_req*, or whether it will continue to run as normal.

If the UART is programmed to respond to *debug_req*:

1. The UART will halt all operations upon detecting the *debug_req* input.
2. A transfer in progress, either to/from a core (using the IP Bus interface) or to/from an external device, will be completed before halting. This means a single byte/word transfer, not an entire FIFO. Reception of any further data from an external device will be disabled.
3. Internal registers will continue to be writable and readable using the IP Bus interface. A read will leave the contents unaffected.
4. The RX FIFO is affected in debug mode in the following way:
 - All writes into the RX FIFO are prevented.
 - The bit RXDBG (UTS[9]) is used to select the readability of the RX FIFO during debug mode:

RXDBG = 0: hold the read pointer at the location it had upon entering debug mode, and URXD register returns only the data value at that location, no matter how many reads attempted.

RXDBG = 1, selectable at any time: Allow to read the characters received in Rx FIFO. It will not be possible to re-read previously read locations, nor will it be possible to readjust the read pointer to the value it had prior to entering debug mode.

16.2.8 Reset

This section describes how to reset the block and explains special requirements related to reset.

16.2.8.1 Hardware reset

All of registers, FIFOs, state machines and sequential elements can be reset to their initial values by hardware reset or power on reset.

16.2.8.2 Software reset

The status registers USR1 and USR2, BRM registers UBIR and UBMIR, TxFIFO and RxFIFO, and transmitter and receiver state machines can be reset by software reset. Internal logic will keep the software reset asserted for about 4 *module_clock* cycles.

Programmer can follow the following software reset sequence:

1. Clear the SRST_B bit (UCR2[0])
2. Wait for software reset complete: poll SOFTRST bit (UTS[0]) until it is 0.
3. Re-program baud rate registers: Re-write UBIR and UBMIR.

16.2.9 Transfer Error

The UART can generate a transfer error on the peripheral bus in the following cases:

- Core is writing into a read-only register.
- Core is accessing (read or write) an unused location within the assigned address space reserved to UART.
- Core is writing into UTXD register with transmit interface disabled (TXEN=0 or UARTEN=0)
- Core is reading URXD register with receive interface disabled (RXEN=0 or UARTEN=0)

16.2.10 Functional Timing

This section includes timing diagrams for functional signaling.

16.2.10.1 IrDA Mode

According to IrDA specification, the low speed (115.2Kbit/s and below) IR frame format is compatible with UART frame.

In this figure, an example data 0x65 is used.

Figure 16-20. Timing diagram of Low Speed IR (≤ 115.2 Kbit/s) Data Line

16.2.11 Initialization

16.2.11.1 Programming the UART in RS-232 mode

As an example, the following sequence can be used to program the UART in order to send and receive characters in RS-232 mode.

Assumptions:

- Input uart clock = 100 MHz
- Baud rate = 921.6 Kbps

- Data bits = 8 bits
- Parity = Even
- Stop bits = 1 bit
- Flow control = Hardware

Main program:

1. UCR1 = 0x0001

Enable the UART.

2. UCR2 = 0x2127

Set hardware flow control, data format and enable transmitter and receiver.

3. UCR3 = 0x0704

Set UCR3[RXDMUXSEL] = 1.

4. UCR4 = 0x7C00

Set CTS trigger level to 31,

5. UFCR = 0x089E

Set internal clock divider = 5 (divide input uart clock by 5). So the reference clock is $100\text{ MHz}/5 = 20\text{ MHz}$.

Set TXTL = 2 and RXTL = 30.

6. UBIR = 0x08FF

7. UBMIR = 0x0C34

In the above two steps, set baud rate to 921.6Kbps based on the 20MHz reference clock.

8. UCR1 = 0x2201

Enable the TRDY and RRDY interrupts.

9. UMCR = 0x0000

UMCR stay at default value 0x0000

Interrupt service routine for the transmitter:

- Write characters into UTXD

The TRDY interrupt will be automatically de-asserted when the data level of the TxFIFO exceeds the TXTL=2. Note: For the first time the interrupt may be de-asserted after 4 characters are written into the TxFIFO because of the shift register.

Interrupt service routine for the receiver:

- Read characters from URXD

The RRDY interrupt will be automatically de-asserted when the data level of the RxFIFO is below the RXTL=30.

16.2.11.2 Programming the UART in 9-bit RS-485 mode

As an example, the following sequence can be used to program the UART in order to send and receive frames in RS-485 mode.

Assumptions:

- Input uart clock = 100 MHz
- Baud rate = 5 Mbps

Main program:

1. UCR1 = 0x0001

Enable the UART.

2. UCR2 = 0x4127

Set software flow control ($\overline{\text{CTS}}$ pin is controlled by UCR2[12]), enable parity(enable 9th bit rxd/txd), 8-bit word size , and enable transmitter and receiver.

3. UCR4 = 0x7C00

Set CTS trigger level to 31,

4. UFCR = 0x0A9E

Set RFDIV = 5 (divide input uart clock by 1), so the reference clock is 100 MHz. Set UART in DCE mode (RS-485 driver connection outside the chip is the same as [Figure 16-19](#))

Set TXTL = 2 and RXTL = 30.

5. UBIR = 0x0003

6. UBMIR = 0x0004

In the above two steps, set baud rate to 5 Mbps based on the 100 MHz reference clock.

7. UCR1 = 0x2001 when UART as a master ,

or UCR1 = 0x0201 (or 0x0101) when UART as a slave.

Enable TRDY interrupt when UART as a master, enable RRDY interrupt or DMA request when UART as a slave.

8. UMCR = 0xA50B

Enable 9-bit RS-485 mode, enable SAD interrupt, set automatic slave address detect mode, set slave address is 0xA5.

Interrupt service routine for the transmitter:

- Transmit data: write its ninth bit (bit[8]) to UMCR[2], write its bit [7:0] into UTXD[7:0]

The TRDY interrupt will be automatically de-asserted when the data level of the TxFIFO exceeds the TXTL=2.

Note: For the first time the interrupt may be de-asserted after 4 characters are written into the TxFIFO because of the shift register.

Interrupt service routine for the receiver:

- Receive data: read its ninth bit (bit[8]) from URXD[10] , read its bit [7:0] from URXD[7:0].

Note: in RS-485 mode, URXD[10] bit is not the parity error, instead it holds the ninth bit (bit[8]) of the received data.

The SAD interrupt can not de-assert automatically, it needs MCU write 1 to USR1[3] to clear it . The RRDY interrupt or DMA request will be automatically de-asserted when the data level of the Rx FIFO is below the RXTL=30.

16.2.13 UART Memory Map/Register Definition

UART supports 8-bit, 16-bit and 32-bit accesses to 32-bit memory-mapped addresses. Any access to unmapped memory location will yield a transfer error.

All registers except the ONEMS described in this section are 16-bit registers. The ONEMS register is a 24-bit register.

- For 32-bit write accesses, the upper two bytes will not be taken into account.
- For 32-bit read accesses the upper two bytes will return 0.

The ONEMS register is expanded from 16 bits to 24 bits in order to support the high frequency of the BRM internal clock *ref_clk* (*module_clock* after divider). The ONEMS register can be accessed as 8 bits, 16 bits or 32 bits.

- For 32-bit write accesses, the most significant byte of the ONEMS will be discarded.
- For 32-bit read accesses, the most significant byte of the ONEMS will be read as 0.

16.2.13.1 UART Receiver Register (UARTx_URXD)

NOTE

The UART will yield a transfer error on the peripheral bus when core is reading URXD register with receive interface disabled (RXEN=0 or UARTEN=0).

Address: Base address + 0h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

UARTx_URXD field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15 CHARRDY	Character Ready. This read-only bit indicates an invalid read when the FIFO becomes empty and software tries to read the same old data. This bit should not be used for polling for data written to the RX FIFO. 0 Character in RX_DATA field and associated flags are invalid. 1 Character in RX_DATA field and associated flags valid and ready for reading.

Table continues on the next page...

UARTx_URXD field descriptions (continued)

Field	Description
14 ERR	<p>Error Detect. Indicates whether the character present in the RX_DATA field has an error (OVRUN, FRMERR, BRK or PRERR) status. The ERR bit is updated and valid for each received character.</p> <p>0 No error status was detected 1 An error status was detected</p>
13 OVRUN	<p>Receiver Overrun. This read-only bit, when HIGH, indicates that the corresponding character was stored in the last position (32nd) of the Rx FIFO. Even if a 33rd character has not been detected, this bit will be set to '1' for the 32nd character.</p> <p>0 No RxFIFO overrun was detected 1 A RxFIFO overrun was detected</p>
12 FRMERR	<p>Frame Error. Indicates whether the current character had a framing error (a missing stop bit) and is possibly corrupted. FRMERR is updated for each character read from the RxFIFO.</p> <p>0 The current character has no framing error 1 The current character has a framing error</p>
11 BRK	<p>BREAK Detect. Indicates whether the current character was detected as a BREAK character. The data bits and the stop bit are all 0. The FRMERR bit is set when BRK is set. When odd parity is selected, PRERR is also set when BRK is set. BRK is valid for each character read from the RxFIFO.</p> <p>0 The current character is not a BREAK character 1 The current character is a BREAK character</p>
10 PRERR	<p>In RS-485 mode, it holds the ninth data bit (bit [8]) of received 9-bit RS-485 data</p> <p>In RS232/IrDA mode, it is the Parity Error flag. Indicates whether the current character was detected with a parity error and is possibly corrupted. PRERR is updated for each character read from the RxFIFO. When parity is disabled, PRERR always reads as 0.</p> <p>0 = No parity error was detected for data in the RX_DATA field 1 = A parity error was detected for data in the RX_DATA field</p>
9–8 -	<p>This field is reserved. Reserved</p>
RX_DATA	<p>Received Data. Holds the received character. In 7-bit mode, the most significant bit (MSB) is forced to 0. In 8-bit mode, all bits are active.</p>

16.2.13.2 UART Transmitter Register (UARTx_UTXD)

NOTE

The UART will yield a transfer error on the peripheral bus when core is writing into UART_URXD register with transmit interface disabled (TXEN=0 or UARTEN=0).

Memory space between UART_URXD and UART_UTXD registers is reserved. Any read or write access to this space will be considered as an invalid access and yield a transfer error.

Address: Base address + 40h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

UARTx_UTXD field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15–8 Reserved	This read-only field is reserved and always has the value 0.
TX_DATA	Transmit Data. Holds the parallel transmit data inputs. In 7-bit mode, D7 is ignored. In 8-bit mode, all bits are used. Data is transmitted least significant bit (LSB) first. A new character is transmitted when the TX_DATA field is written. The TX_DATA field must be written only when the TRDY bit is high to ensure that corrupted data is not sent.

16.2.13.3 UART Control Register 1 (UARTx_UCR1)

Address: Base address + 80h offset

UARTx_UCR1 field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15 ADEN	Automatic Baud Rate Detection Interrupt Enable. Enables/Disables the automatic baud rate detect complete (ADET) bit to generate an interrupt (<i>interrupt_uart</i> = 0). 0 Disable the automatic baud rate detection interrupt 1 Enable the automatic baud rate detection interrupt
14 ADBR	Automatic Detection of Baud Rate. Enables/Disables automatic baud rate detection. When the ADBR bit is set and the ADET bit is cleared, the receiver detects the incoming baud rate automatically. The ADET flag is set when the receiver verifies that the incoming baud rate is detected properly by detecting an ASCII character "A" or "a" (0x41 or 0x61). 0 Disable automatic detection of baud rate 1 Enable automatic detection of baud rate
13 TRDYEN	Transmitter Ready Interrupt Enable. Enables/Disables the transmitter Ready Interrupt (TRDY) when the transmitter has one or more slots available in the TxFIFO. The fill level in the TxFIFO at which an interrupt is generated is controlled by TxTL bits. When TRDYEN is negated, the transmitter ready interrupt is disabled. NOTE: An interrupt will be issued as long as TRDYEN and TRDY are high even if the transmitter is not enabled. In general, user should enable the transmitter before enabling the TRDY interrupt. 0 Disable the transmitter ready interrupt 1 Enable the transmitter ready interrupt
12 IDEN	Idle Condition Detected Interrupt Enable. Enables/Disables the IDLE bit to generate an interrupt (<i>interrupt_uart</i> = 0). 0 Disable the IDLE interrupt 1 Enable the IDLE interrupt

Table continues on the next page...

UARTx_UCR1 field descriptions (continued)

Field	Description
11–10 ICD	Idle Condition Detect. Controls the number of frames RXD is allowed to be idle before an idle condition is reported. 00 Idle for more than 4 frames 01 Idle for more than 8 frames 10 Idle for more than 16 frames 11 Idle for more than 32 frames
9 RRDYEN	Receiver Ready Interrupt Enable. Enables/Disables the RRDY interrupt when the RxFIFO contains data. The fill level in the RxFIFO at which an interrupt is generated is controlled by the RXTL bits. When RRDYEN is negated, the receiver ready interrupt is disabled. 0 Disables the RRDY interrupt 1 Enables the RRDY interrupt
8 RXDMAEN	Receive Ready DMA Enable. Enables/Disables the receive DMA request <i>dma_req_rx</i> when the receiver has data in the RxFIFO. The fill level in the RxFIFO at which a DMA request is generated is controlled by the RXTL bits. When negated, the receive DMA request is disabled. 0 Disable DMA request 1 Enable DMA request
7 IREN	Infrared Interface Enable. Enables/Disables the IR interface. See the IR interface description in Infrared Interface , for more information. Note: MDEN(UMCR[0]) must be cleared to 0 when using IrDA interface. See Table 16-2 0 Disable the IR interface 1 Enable the IR interface
6 TXMPTYEN	Transmitter Empty Interrupt Enable. Enables/Disables the transmitter FIFO empty (TXFE) interrupt. <i>interrupt_uart</i> . When negated, the TXFE interrupt is disabled. NOTE: An interrupt will be issued as long as TXMPTYEN and TXFE are high even if the transmitter is not enabled. In general, user should enable the transmitter before enabling the TXFE interrupt. 0 Disable the transmitter FIFO empty interrupt 1 Enable the transmitter FIFO empty interrupt
5 RTSDEN	RTS Delta Interrupt Enable. Enables/Disables the RTSD interrupt. The current status of the RTS_B pin is read in the RTSS bit. 0 Disable RTSD interrupt 1 Enable RTSD interrupt
4 SNDBRK	Send BREAK. Forces the transmitter to send a BREAK character. The transmitter finishes sending the character in progress (if any) and sends BREAK characters until SNDBRK is reset. Because the transmitter samples SNDBRK after every bit is transmitted, it is important that SNDBRK is asserted high for a sufficient period of time to generate a valid BREAK. After the BREAK transmission completes, the UART transmits 2 mark bits. The user can continue to fill the TxFIFO and any characters remaining are transmitted when the BREAK is terminated. 0 Do not send a BREAK character 1 Send a BREAK character (continuous 0s)
3 TXDMAEN	Transmitter Ready DMA Enable. Enables/Disables the transmit DMA request <i>dma_req_tx</i> when the transmitter has one or more slots available in the TxFIFO. The fill level in the TxFIFO that generates the <i>dma_req_tx</i> is controlled by the TXTL bits.

Table continues on the next page...

UARTx_UCR1 field descriptions (continued)

Field	Description
	<p>NOTE: A DMA request will be issued as long as TXDMAEN and TRDY are high even if the transmitter is not enabled. In general, user should enable the transmitter before enabling the transmit DMA request.</p> <p>0 Disable transmit DMA request 1 Enable transmit DMA request</p>
2 ATDMAEN	<p>Aging DMA Timer Enable. Enables/Disables the receive DMA request <i>dma_req_rx</i> for the aging timer interrupt (triggered with AGTIM flag in USR1[8]).</p> <p>0 Disable AGTIM DMA request 1 Enable AGTIM DMA request</p>
1 DOZE	<p>DOZE. Determines the UART enable condition in the DOZE state. When <i>doze_req</i> input pin is at '1', (the Arm Platform executes a doze instruction and the system is placed in the Doze State), the DOZE bit affects operation of the UART. While in the Doze State, if this bit is asserted, the UART is disabled. See the description in Low Power Modes.</p> <p>0 The UART is enabled when in DOZE state 1 The UART is disabled when in DOZE state</p>
0 UARTEN	<p>UART Enable. Enables/Disables the UART. If UARTEN is negated in the middle of a transmission, the transmitter stops and pulls the TXD line to a logic 1. UARTEN must be set to 1 before any access to UTXD and URXD registers, otherwise a transfer error is returned.</p> <p>This bit can be set to 1 along with other bits in this register. There is no restriction to the sequence of programing this bit and other control registers.</p> <p>0 Disable the UART 1 Enable the UART</p>

16.2.13.4 UART Control Register 2 (UARTx_UCR2)

Address: Base address + 84h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0

R	ESCI	IRTS	CTSC	CTS	ESCN	RTEC	PREN	PRO E	STPB	WS	RTSEN	ATEN	TXEN	RXEN	SRST	
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

UARTx_UCR2 field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15 ESCI	Escape Sequence Interrupt Enable. Enables/Disables the ESCF bit to generate an interrupt. 0 Disable the escape sequence interrupt 1 Enable the escape sequence interrupt
14 IRTS	Ignore RTS Pin. Forces the RTS input signal presented to the transmitter to always be asserted (set to low), effectively ignoring the external pin. When in this mode, the RTS pin serves as a general purpose input. 0 Transmit only when the RTS pin is asserted 1 Ignore the RTS pin
13 CTSC	CTS Pin Control. Controls the operation of the CTS_B module output. When CTSC is asserted, the CTS_B module output is controlled by the receiver. When the RxFIFO is filled to the level of the programmed trigger level and the start bit of the overflowing character (TRIGGER LEVEL + 1) is validated, the CTS_B module output is negated to indicate to the far-end transmitter to stop transmitting. When the trigger level is programmed for less than 32, the receiver continues to receive data until the RxFIFO is full. When the CTSC bit is negated, the CTS_B module output is controlled by the CTS bit. On reset, because CTSC is cleared to 0, the CTS_B pin is controlled by the CTS bit, which again is cleared to 0 on reset. This means that on reset the CTS_B signal is negated. 0 The CTS_B pin is controlled by the CTS bit 1 The CTS_B pin is controlled by the receiver
12 CTS	Clear to Send. Controls the CTS_B pin when the CTSC bit is negated. CTS has no function when CTSC is asserted. 0 The CTS_B pin is high (inactive) 1 The CTS_B pin is low (active)
11 ESCEN	Escape Enable. Enables/Disables the escape sequence detection logic. 0 Disable escape sequence detection 1 Enable escape sequence detection
10–9 RTEC	Request to Send Edge Control. Selects the edge that triggers the RTS interrupt. This has no effect on the RTS delta interrupt. RTEC has an effect only when RTSEN = 1 (see Table 16-4). 00 Trigger interrupt on a rising edge 01 Trigger interrupt on a falling edge 1X Trigger interrupt on any edge
8 PREN	Parity Enable. Enables/Disables the parity generator in the transmitter and parity checker in the receiver. When PREN is asserted, the parity generator and checker are enabled, and disabled when PREN is negated. 0 Disable parity generator and checker 1 Enable parity generator and checker
7 PROE	Parity Odd/Even. Controls the sense of the parity generator and checker. When PROE is high, odd parity is generated and expected. When PROE is low, even parity is generated and expected. PROE has no function if PREN is low. 0 Even parity 1 Odd parity

Table continues on the next page...

UARTx_UCR2 field descriptions (continued)

Field	Description
6 STPB	<p>Stop. Controls the number of stop bits after a character. When STPB is low, 1 stop bit is sent. When STPB is high, 2 stop bits are sent. STPB also affects the receiver.</p> <p>0 The transmitter sends 1 stop bit. The receiver expects 1 or more stop bits. 1 The transmitter sends 2 stop bits. The receiver expects 2 or more stop bits.</p>
5 WS	<p>Word Size. Controls the character length. When WS is high, the transmitter and receiver are in 8-bit mode. When WS is low, they are in 7-bit mode. The transmitter ignores bit 7 and the receiver sets bit 7 to 0. WS can be changed in-between transmission (reception) of characters, however not when a transmission (reception) is in progress, in which case the length of the current character being transmitted (received) is unpredictable.</p> <p>0 7-bit transmit and receive character length (not including START, STOP or PARITY bits) 1 8-bit transmit and receive character length (not including START, STOP or PARITY bits)</p>
4 RTSEN	<p>Request to Send Interrupt Enable. Controls the RTS edge sensitive interrupt. When RTSEN is asserted and the programmed edge is detected on the RTS_B pin (the RTSF bit is asserted), an interrupt will be generated on the <i>interrupt_uart</i> pin. (See Table 16-4.)</p> <p>0 Disable request to send interrupt 1 Enable request to send interrupt</p>
3 ATEN	<p>Aging Timer Enable. This bit is used to enable the aging timer interrupt (triggered with AGTIM)</p> <p>0 AGTIM interrupt disabled 1 AGTIM interrupt enabled</p>
2 TXEN	<p>Transmitter Enable. Enables/Disables the transmitter. When TXEN is negated the transmitter is disabled and idle. When the UARTEN and TXEN bits are set the transmitter is enabled. If TXEN is negated in the middle of a transmission, the UART disables the transmitter immediately, and starts marking 1s. The transmitter FIFO cannot be written when this bit is cleared.</p> <p>0 Disable the transmitter 1 Enable the transmitter</p>
1 RXEN	<p>Receiver Enable. Enables/Disables the receiver. When the receiver is enabled, if the RXD input is already low, the receiver does not recognize BREAK characters, because it requires a valid 1-to-0 transition before it can accept any character.</p> <p>0 Disable the receiver 1 Enable the receiver</p>
0 SRST	<p>Software Reset. Once the software writes 0 to SRST_B, the software reset remains active for 4 <i>module_clock</i> cycles before the hardware deasserts SRST_B. The software can only write 0 to SRST_B. Writing 1 to SRST_B is ignored.</p> <p>0 Reset the transmit and receive state machines, all FIFOs and register USR1, USR2, UBIR, UBMR, UBRC, URXD, UTXD and UTS[6-3]. 1 No reset</p>

16.2.13.5 UART Control Register 3 (UARTx_UCR3)

Address: Base address + 88h offset

UARTx_UCR3 field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15–14 DPEC	This bit is not used in this chip.
13 DTREN	This bit is not used in this chip.
12 PARERREN	Parity Error Interrupt Enable. Enables/Disables the interrupt. When asserted, PARERREN causes the PARITYERR bit to generate an interrupt. 0 Disable the parity error interrupt 1 Enable the parity error interrupt
11 FRAERREN	Frame Error Interrupt Enable. Enables/Disables the interrupt. When asserted, FRAERREN causes the FRAMERR bit to generate an interrupt. 0 Disable the frame error interrupt 1 Enable the frame error interrupt
10 DSR	This bit is not used in this chip.
9 DCD	This bit is not used in this chip.
8 RI	This bit is not used in this chip.
7 ADNIMP	Autobaud Detection Not Improved-. Disables new features of autobaud detection (See Baud Rate Automatic Detection Protocol, for more details). 0 Autobaud detection new features selected 1 Keep old autobaud detection mechanism

Table continues on the next page...

UARTx_UCR3 field descriptions (continued)

Field	Description
6 RXDSEN	Receive Status Interrupt Enable. Controls the receive status interrupt (<i>interrupt_uart</i>). When this bit is enabled and RXDS status bit is set, the interrupt <i>interrupt_uart</i> will be generated. 0 Disable the RXDS interrupt 1 Enable the RXDS interrupt
5 AIRINTEN	Asynchronous IR WAKE Interrupt Enable. Controls the asynchronous IR WAKE interrupt. An interrupt is generated when AIRINTEN is asserted and a pulse is detected on the RXD pin. 0 Disable the AIRINT interrupt 1 Enable the AIRINT interrupt
4 AWAKEN	Asynchronous WAKE Interrupt Enable. Controls the asynchronous WAKE interrupt. An interrupt is generated when AWAKEN is asserted and a falling edge is detected on the RXD pin. 0 Disable the AWAKE interrupt 1 Enable the AWAKE interrupt
3 DTRDEN	This bit is not used in this chip.
2 RXDMUXSEL	RXD Muxed Input Selected. Selects proper input pins for serial and Infrared input signal. NOTE: In this chip, UARTs are used in MUXED mode, so that this bit should always be set.
1 INVT	Invert TXD output in RS-232/RS-485 mode, set TXD active level in IrDA mode. In RS232/RS-485 mode(UMCR[0] = 1), if this bit is set to 1, the TXD output is inverted before transmitted. In IrDA mode , when INVT is cleared, the infrared logic block transmits a positive IR 3/16 pulse for all 0s and 0s are transmitted for 1s. When INVT is set (INVT = 1), the infrared logic block transmits an active low or negative infrared 3/16 pulse for all 0s and 1s are transmitted for 1s. 0 TXD is not inverted 1 TXD is inverted 0 TXD Active low transmission 1 TXD Active high transmission
0 ACIEN	Autobaud Counter Interrupt Enable. This bit is used to enable the autobaud counter stopped interrupt (triggered with ACST (USR2[11]). 0 ACST interrupt disabled 1 ACST interrupt enabled

Table continues on the next page...

UARTx_UCR4 field descriptions (continued)

Field	Description
7 WKEN	WAKE Interrupt Enable. Enables/Disables the WAKE bit to generate an interrupt. The WAKE bit is set at the detection of a start bit by the receiver. 0 Disable the WAKE interrupt 1 Enable the WAKE interrupt
6 IDDMAEN	DMA IDLE Condition Detected Interrupt Enable Enables/Disables the receive DMA request <i>dma_req_rx</i> for the IDLE interrupt (triggered with IDLE flag in USR2[12]). 0 DMA IDLE interrupt disabled 1 DMA IDLE interrupt enabled
5 IRSC	IR Special Case. Selects the clock for the vote logic. When set, IRSC switches the vote logic clock from the sampling clock to the UART reference clock. The IR pulses are counted a predetermined amount of time depending on the reference frequency. See InfraRed Special Case (IRSC) Bit . 0 The vote logic uses the sampling clock (16x baud rate) for normal operation 1 The vote logic uses the UART reference clock
4 LPBYP	Low Power Bypass. Allows to bypass the low power new features in UART. To use during debug phase. 0 Low power features enabled 1 Low power features disabled
3 TCEN	TransmitComplete Interrupt Enable. Enables/Disables the TXDC bit to generate an interrupt (<i>interrupt_uart</i> = 0) NOTE: An interrupt will be issued as long as TCEN and TXDC are high even if the transmitter is not enabled. In general, user should enable the transmitter before enabling the TXDC interrupt. 0 Disable TXDC interrupt 1 Enable TXDC interrupt
2 BKEN	BREAK Condition Detected Interrupt Enable. Enables/Disables the BRCD bit to generate an interrupt. 0 Disable the BRCD interrupt 1 Enable the BRCD interrupt
1 OREN	Receiver Overrun Interrupt Enable. Enables/Disables the ORE bit to generate an interrupt. 0 Disable ORE interrupt 1 Enable ORE interrupt
0 DREN	Receive Data Ready Interrupt Enable. Enables/Disables the RDR bit to generate an interrupt. 0 Disable RDR interrupt 1 Enable RDR interrupt

16.2.13.7 UART FIFO Control Register (UARTx_UFCR)

UARTx_USR1 field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15 PARITYERR	Parity Error Interrupt Flag. Indicates a parity error is detected. PARITYERR is cleared by writing 1 to it. Writing 0 to PARITYERR has no effect. When parity is disabled, PARITYERR always reads 0. At reset, PARITYERR is set to 0. 0 No parity error detected 1 Parity error detected (write 1 to clear)
14 RTSS	RTS_B Pin Status. Indicates the current status of the RTS_B pin. A "snapshot" of RTS_B is taken immediately before RTSS is presented to the data bus. RTSS cannot be cleared because all writes to RTSS are ignored. At reset, RTSS is set to 0.

Table continues on the next page...

UARTx_USR1 field descriptions (continued)

Field	Description
	0 The RTS_B module input is high (inactive) 1 The RTS_B module input is low (active)
13 TRDY	Transmitter Ready Interrupt / DMA Flag. Indicates that the TxFIFO emptied below its target threshold and requires data. TRDY is automatically cleared when the data level in the TxFIFO exceeds the threshold set by TXTL bits. At reset, TRDY is set to 1. 0 The transmitter does not require data 1 The transmitter requires data (interrupt posted)
12 RTSD	RTS Delta. Indicates whether the RTS_B pin changed state. It (RTSD) generates a maskable interrupt. When in STOP mode, RTS assertion sets RTSD and can be used to wake the processor. The current state of the RTS_B pin is available on the RTSS bit. Clear RTSD by writing 1 to it. Writing 0 to RTSD has no effect. At reset, RTSD is set to 0. 0 RTS_B pin did not change state since last cleared 1 RTS_B pin changed state (write 1 to clear)
11 ESCF	Escape Sequence Interrupt Flag. Indicates if an escape sequence was detected. ESCF is asserted when the ESCEN bit is set and an escape sequence is detected in the RxFIFO. Clear ESCF by writing 1 to it. Writing 0 to ESCF has no effect. 0 No escape sequence detected 1 Escape sequence detected (write 1 to clear).
10 FRAMERR	Frame Error Interrupt Flag. Indicates that a frame error is detected. The <i>interrupt_uart</i> interrupt will be generated if a frame error is detected and the interrupt is enabled. Clear FRAMERR by writing 1 to it. Writing 0 to FRAMERR has no effect. 0 No frame error detected 1 Frame error detected (write 1 to clear)
9 RRDY	Receiver Ready Interrupt / DMA Flag. Indicates that the RxFIFO data level is above the threshold set by the RXTL bits. (See the RXTL bits description in UART FIFO Control Register (UART_UFCR) for setting the interrupt threshold.) When asserted, RRDY generates a maskable interrupt or DMA request. RRDY is automatically cleared when data level in the RxFIFO goes below the set threshold level. At reset, RRDY is set to 0. 0 No character ready 1 Character(s) ready (interrupt posted)
8 AGTIM	Ageing Timer Interrupt Flag. Indicates that data in the RxFIFO has been idle for a time of 8 character lengths (where a character length consists of 7 or 8 bits, depending on the setting of the WS bit in UCR2, with the bit time corresponding to the baud rate setting) and FIFO data level is less than RxFIFO threshold level (RXTL in the UFCR). Clear by writing a 1 to it. 0 AGTIM is not active 1 AGTIM is active (write 1 to clear)
7 DTRD	This bit is not used in this chip.
6 RXDS	Receiver IDLE Interrupt Flag. Indicates that the receiver state machine is in an IDLE state, the next state is IDLE, and the receive pin is high. RXDS is automatically cleared when a character is received. RXDS is active only when the receiver is enabled. 0 Receive in progress 1 Receiver is IDLE

Table continues on the next page...

UARTx_USR1 field descriptions (continued)

Field	Description
5 AIRINT	Asynchronous IR WAKE Interrupt Flag. Indicates that the IR WAKE pulse was detected on the RXD pin. Clear AIRINT by writing 1 to it. Writing 0 to AIRINT has no effect. 0 No pulse was detected on the RXD IrDA pin 1 A pulse was detected on the RXD IrDA pin
4 AWAKE	Asynchronous WAKE Interrupt Flag. Indicates that a falling edge was detected on the RXD pin. Clear AWAKE by writing 1 to it. Writing 0 to AWAKE has no effect. 0 No falling edge was detected on the RXD Serial pin 1 A falling edge was detected on the RXD Serial pin
3 SAD	RS-485 Slave Address Detected Interrupt Flag. Indicates if RS-485 Slave Address was detected . SAD was asserted in RS-485 mode when the SADEN bit is set and Slave Address is detected in RxFIFO (in Nomal Address Detect Mode, the 9 th data bit = 1; in Automatic Address Detect Mode, the received charater matches the programmed SLADDR). 0 No slave address detected 1 Slave address detected
-	This field is reserved. Reserved

16.2.13.9 UART Status Register 2 (UARTx_USR2)

Address: Base address + 98h offset

UARTx_USR2 field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15 ADET	Automatic Baud Rate Detect Complete. Indicates that an "A" or "a" was received and that the receiver detected and verified the incoming baud rate. Clear ADET by writing 1 to it. Writing 0 to ADET has no effect. 0 ASCII "A" or "a" was not received 1 ASCII "A" or "a" was received (write 1 to clear)
14 TXFE	Transmit Buffer FIFO Empty. Indicates that the transmit buffer (TxFIFO) is empty. TXFE is cleared automatically when data is written to the TxFIFO. Even though TXFE is high, the transmission might still be in progress. 0 The transmit buffer (TxFIFO) is not empty 1 The transmit buffer (TxFIFO) is empty
13 DTRF	This bit is not used in this chip.

Table continues on the next page...

UARTx_USR2 field descriptions (continued)

Field	Description
12 IDLE	<p>Idle Condition. Indicates that an idle condition has existed for more than a programmed amount frame (see Idle Line Detect). An interrupt can be generated by this IDLE bit if IDEN (UCR1[12]) is enabled. IDLE is cleared by writing 1 to it. Writing 0 to IDLE has no effect.</p> <p>0 No idle condition detected 1 Idle condition detected (write 1 to clear)</p>
11 ACST	<p>Autobaud Counter Stopped. In autobaud detection (ADBR=1), indicates the counter which determines the baud rate was running and is now stopped. This means either START bit is finished (if ADNIMP=1), or Bit 0 is finished (if ADNIMP=0). See New Autobaud Counter Stopped bit and Interrupt, for more details. An interrupt can be flagged on <i>interrupt_uart</i> if ACIEN=1.</p> <p>0 Measurement of bit length not finished (in autobaud) 1 Measurement of bit length finished (in autobaud). (write 1 to clear)</p>
10 RIDELT	This bit is not used in this chip.
9 RIIN	This bit is not used in this chip.
8 IRINT	<p>Serial Infrared Interrupt Flag. When an edge is detected on the RXD pin during SIR Mode, this flag will be asserted. This flag can cause an interrupt which can be masked using the control bit ENIRI: UCR4 [8].</p> <p>0 no edge detected 1 valid edge detected (write 1 to clear)</p>
7 WAKE	<p>Wake. Indicates the start bit is detected. WAKE can generate an interrupt that can be masked using the WKEN bit. Clear WAKE by writing 1 to it. Writing 0 to WAKE has no effect.</p> <p>0 start bit not detected 1 start bit detected (write 1 to clear)</p>
6 DCDDELT	This bit is not used in this chip.
5 DCDIN	This bit is not used in this chip.
4 RTSF	<p>RTS Edge Triggered Interrupt Flag. Indicates if a programmed edge is detected on the RTS_B pin. The RTEC bits select the edge that generates an interrupt (see Table 16-4). RTSF can generate an interrupt that can be masked using the RTSEN bit. Clear RTSF by writing 1 to it. Writing 0 to RTSF has no effect.</p> <p>0 Programmed edge not detected on RTS_B 1 Programmed edge detected on RTS_B (write 1 to clear)</p>
3 TXDC	<p>Transmitter Complete. Indicates that the transmit buffer (TxFIFO) and Shift Register is empty; therefore the transmission is complete. TXDC is cleared automatically when data is written to the TxFIFO.</p> <p>0 Transmit is incomplete 1 Transmit is complete</p>
2 BRCD	<p>BREAK Condition Detected. Indicates that a BREAK condition was detected by the receiver. Clear BRCD by writing 1 to it. Writing 0 to BRCD has no effect.</p> <p>0 No BREAK condition was detected 1 A BREAK condition was detected (write 1 to clear)</p>
1 ORE	<p>Overrun Error. When set to 1, ORE indicates that the receive buffer (Rx FIFO) was full (32 chars inside), and a 33rd character has been fully received. This 33rd character has been discarded. Clear ORE by writing 1 to it. Writing 0 to ORE has no effect.</p>

Table continues on the next page...

UARTx_USR2 field descriptions (continued)

Field	Description
	0 No overrun error 1 Overrun error (write 1 to clear)
0 RDR	Receive Data Ready -Indicates that at least 1 character is received and written to the RxFIFO. If the URXD register is read and there is only 1 character in the RxFIFO, RDR is automatically cleared. 0 No receive data ready 1 Receive data ready

16.2.13.10 UART Escape Character Register (UARTx_UESC)

Address: Base address + 9Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

UARTx_UTIM field descriptions

Field	Description
31–12 Reserved	This read-only field is reserved and always has the value 0.
TIM	UART Escape Timer. Holds the maximum time interval (in ms) allowed between escape characters. The escape timer register is programmable in intervals of 2 ms. See Escape Sequence Detection and Table 16-8 for more information on the UART escape sequence detection. Reset value 0x000 = 2 ms up to 0xFFFF = 8.192 s.

16.2.13.12 UART BRM Incremental Register (UARTx_UBIR)

This register can be written by both software and hardware. When enabling the automatic baud rate detection feature hardware can write 0x000F value into the UBIR after finishing detecting baud rate. Hardware has higher priority when both software and hardware try to write it at the same cycle³.

Please note software reset will reset the register to its reset value.

Address: Base address + A4h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																INC															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

UARTx_UBIR field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
INC	Incremental Numerator. Holds the numerator value minus one of the BRM ratio (see Binary Rate Multiplier (BRM)). The UBIR register MUST be updated before the UBMR register for the baud rate to be updated correctly. If only one register is written to by software, the BRM will ignore this data until the other register is written to by software. Updating this field using byte accesses is not recommended and is undefined.

16.2.13.13 UART BRM Modulator Register (UARTx_UBMR)

This register can be written by both software and hardware. When enabling the automatic baud rate detection feature hardware can write a proper value into the UBMR based on detected baud rate. Hardware has higher priority when both software and hardware try to write it at the same cycle⁴.

Please note software reset will reset the register to its reset value.

Address: Base address + A8h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																MOD															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

3. Note: The write priority in the new design is not same as the original UART. In the original design, software has higher priority than hardware when writing this register at the same time.

4. Note: The write priority in the new design is not same as the original UART. In the original design, software has higher priority than hardware when writing this register at the same time.

UARTx_UBMR field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
MOD	Modulator Denominator. Holds the value of the denominator minus one of the BRM ratio (see Binary Rate Multiplier (BRM)). The UBIR register MUST be updated before the UBMR register for the baud rate to be updated correctly. If only one register is written to by software, the BRM will ignore this data until the other register is written to by software. Updating this register using byte accesses is not recommended and undefined.

16.2.13.14 UART Baud Rate Count Register (UARTx_UBRC)

Address: Base address + ACh offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																BCNT															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0

UARTx_UBRC field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
BCNT	Baud Rate Count Register. This read only register is used to count the start bit of the incoming baud rate (if ADNIMP=1), or start bit + bit0 (if ADNIMP=0). When the measurement is done, the Baud Rate Count Register contains the number of UART internal clock cycles (clock after divider) present in an incoming bit. BCNT retains its value until the next Automatic Baud Rate Detection sequence has been initiated. The 16 bit Baud Rate Count register is reset to 4 and stays at hex FFFF in the case of an overflow.

16.2.13.15 UART One Millisecond Register (UARTx_ONEMS)

NOTE

This register has been expanded from 16 bits to 24 bits. In previous versions, the 16-bit ONEMS can only support the maximum 65.535MHz (0xFFFFx1000) *ref_clk*. To support 4Mbps Bluetooth application with 66.5MHz *module_clock*, the value 0x103C4 (66.5M/1000) should be written into this register. In this case, the 16 bits are not enough to contain the 0x103C4. So this register was expanded to 24 bits to support high frequency of the *ref_clk*.

Address: Base address + B0h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0								ONEMS																							
W

UARTx_ONEMS field descriptions

Field	Description
31–24 Reserved	This read-only field is reserved and always has the value 0.
ONEMS	<p>One Millisecond Register. This 24-bit register must contain the value of the UART internal frequency (<i>ref_clk</i> in Figure 16-9) divided by 1000. The internal frequency is obtained after the UART BRM internal divider ($F(\text{ref_clk}) = F(\text{module_clock}) / \text{RFDIV}$).</p> <p>In fact this register contains the value corresponding to the number of UART BRM internal clock cycles present in one millisecond.</p> <p>The ONEMS (and UTIM) registers value are used in the escape character detection feature (Escape Sequence Detection) to count the number of clock cycles left between two escape characters. The ONEMS register is also used in infrared special case mode (IRSC = UCR4[5] = 1'b1), see InfraRed Special Case (IRSC) Bit.</p>

16.2.13.16 UART Test Register (UARTx_UTS)

Address: Base address + B4h offset

W																
Reset	0	0	0	0	0	0	0	0	0	1	1	0	0	0	0	0

UARTx_UTS field descriptions

Field	Description
31–14 Reserved	This read-only field is reserved and always has the value 0.
13 FRCPERR	Force Parity Error. Forces the transmitter to generate a parity error if parity is enabled. FRCPERR is provided for system debugging. 0 Generate normal parity 1 Generate inverted parity (error)
12 LOOP	Loop TX and RX for Test. Controls loopback for test purposes. When LOOP is high, the receiver input is internally connected to the transmitter and ignores the RXD pin. The transmitter is unaffected by LOOP. If RXDMUXSEL (UCR3[2]) is set to 1, the loopback is applied on serial and IrDA signals. If RXDMUXSEL is set to 0, the loopback is only applied on serial signals. 0 Normal receiver operation 1 Internally connect the transmitter output to the receiver input
11 DBGEN	This bit is not used in this chip. debug_enable_B. This bit controls whether to respond to the <i>debug_req</i> input signal. 0 UART will go into debug mode when <i>debug_req</i> is HIGH 1 UART will not go into debug mode even if <i>debug_req</i> is HIGH
10 LOOPIR	Loop TX and RX for IR Test (LOOPIR). This bit controls loopback from transmitter to receiver in the InfraRed interface. 0 No IR loop 1 Connect IR transmitter to IR receiver
9 RXDBG	This bit is not used in this chip. RX_fifo_debug_mode. This bit controls the operation of the RX fifo read counter when in debug mode. 0 rx fifo read pointer does not increment 1 rx_fifo read pointer increments as normal

Table continues on the next page...

UARTx_UTS field descriptions (continued)

Field	Description
8–7 Reserved	This read-only field is reserved and always has the value 0.
6 TXEMPTY	TxFIFO Empty. Indicates that the TxFIFO is empty. 0 The TxFIFO is not empty 1 The TxFIFO is empty
5 RXEMPTY	RxFIFO Empty. Indicates the RxFIFO is empty. 0 The RxFIFO is not empty 1 The RxFIFO is empty
4 TXFULL	TxFIFO FULL. Indicates the TxFIFO is full. 0 The TxFIFO is not full 1 The TxFIFO is full
3 RXFULL	RxFIFO FULL. Indicates the RxFIFO is full. 0 The RxFIFO is not full 1 The RxFIFO is full
2–1 Reserved	This read-only field is reserved and always has the value 0.
0 SOFTTRST	Software Reset. Indicates the status of the software reset (SRST_B bit of UCR2). 0 Software reset inactive 1 Software reset active

16.2.13.17 UART RS-485 Mode Control Register (UARTx_UMCR)

Address: Base address + B8h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W

R	SLADDR								0				SADEN	TXB8	SLAM	MDEN
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

UARTx_UMCR field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15–8 SLADDR	RS-485 Slave Address Character. Holds the selected slave address character that the receiver will try to detect.
7–4 Reserved	This read-only field is reserved and always has the value 0.
3 SADEN	RS-485 Slave Address Detected Interrupt Enable. 0 Disable RS-485 Slave Address Detected Interrupt 1 Enable RS-485 Slave Address Detected Interrupt
2 TXB8	Transmit RS-485 bit 8 (the ninth bit or 9 th bit). In RS-485 mode, software writes TXB8 bit as the 9 th data bit to be transmitted. 0 0 will be transmitted as the RS485 9 th data bit 1 1 will be transmitted as the RS485 9 th data bit
1 SLAM	RS-485 Slave Address Detect Mode Selection. 0 Select Normal Address Detect mode 1 Select Automatic Address Detect mode
0 MDEN	9-bit data or Multidrop Mode (RS-485) Enable. 0 Normal RS-232 or IrDA mode, see Table 16-2 for detail. 1 Enable RS-485 mode, see Table 16-2 for detail
